BACKGROUND OF THE INVENTION

A recent approach for thrombosis has involved inhibiting thrombin enzyme activity, and compounds used for this purpose have included heparin, low molecular weight heparin, Hirudin, argatroban, hirulog and the like. All such compounds inhibit the enzyme activity of thrombin, and work by inhibiting fibrin blood clot formation without specifically inhibiting the effect of thrombin on cells. Bleeding tendency is therefore a common side effect encountered in the clinic. The role of thrombin in thrombosis is not limited to its blood clotting activity, as it is believed to also participate in platelet aggregation at sites of vascular injury occurring as a result of the activation of platelet thrombin receptor.

Another approach for thrombosis has been the use of intravenous injection agents such as Abciximab, Eptifibatide and Tirofiban, as GPIb/IIa receptor antagonists. These compounds, while exhibiting powerful anti-thrombotic effects by suppressing platelet aggregation induced by various stimulation such as thrombin, ADP, collagen, PAF or the like, also produce a bleeding tendency as a side effect similarly to thrombin enzyme activity inhibitors. For this reason, no such compounds have yet been marketed, although their development as oral agents continues to progress.

Restenosis is a vascular hyperproliferative response to vascular wall injury induced by invasive treatment such as coronary angioplasty, and this phenomenon may be provoked by the direct or indirect effect of thrombin on cells. Platelets adhere to injured blood vessels, leading to release of growth factors and eliciting proliferation of smooth muscle cells. Smooth muscle cells may also be affected indirectly by the action of thrombin on endothelial cells. Also, platelet adhesion occurs and procoagulant activity increases at sites of vascular injury. Smooth muscle cells can undergo further direct stimulation due to the high local thrombin concentration which is produced at such sites. While recent studies using the powerful thrombin inhibitor Hirudin have suggested that thrombin induces cell proliferation during the process of restenosis, it has not yet been determined whether the thrombin effect is direct or indirect (Sarembock et al., Circulation 1992, 84: 232-243). Despite the implication of the cellular effects of thrombin in a variety of pathological symptoms, no therapeutically active substance is known which specifically blocks such effects.

The thrombin receptor (PAR1) has recently been cloned (Vu et al., Cell, 1991, 64: 1057-1068), opening an important door to development of substances which target cellular thrombin receptors. Detailed examination of the amino acid sequence of this thrombin receptor has revealed a thrombin binding site and hydrolysis site located in the 100 residue amino terminal domain of the receptor. Later research by amino acid mutation in the receptor has established that limited hydrolysis of this portion of the thrombin receptor by thrombin is necessary for receptor activation (Vu et al., Nature, 1991, 353: 674-677). A synthetic peptide corresponding to the amino acid sequence newly generated by hydrolysis of the thrombin receptor (the synthetic peptide is known as “thrombin receptor activating peptide”, or TRAP) can activate receptors which have not been hydrolyzed by thrombin. This suggests that the cleavage of the receptor, the new amino acid sequence generated at the amino terminal (known as the “tethered ligand peptide”) functions as the ligand and interacts with the distal binding site. Further studies of TRAP have confirmed homology of the thrombin receptors present in platelet, endothelial cell, fibroblast and smooth muscle cell (Hung et al, J. Cell. Biol. 1992, 116: 827-832; and Ngaiz, Jaffe, Biochem. Biophys. Res. Commun. 1991, 179: 1656-1661).

Research on the structure activity relationship of TRAP suggests that the pentapeptide Peu-Leu-Leu-Arg-Asn is a weak antagonist for platelet thrombin receptors activated by either thrombin or TRAP (Vassallo et al., J. Biol. Chem., 1992, 267: 6081-6085(1992)). Different approaches to receptor antagonism have also been examined by other groups. One of these approaches has been an attempt to prepare antibodies for the thrombin binding domain of the thrombin receptor. Such antibodies specifically and effectively suppress activation of platelets by thrombin, and act as thrombin receptor antagonists (Hung et al., J. Clin. Invest. 1992, 89: 1350-1353). Another approach has been the development of peptide derivatives from TRAP (Steven M. S., J. Med. Chem. 1996, 39: 4879-4887; William J. H., Bioorg. Med. Chem. Lett. 1998, 8: 1649-1654; and David F. M., Bioorg. Med. Chem. Lett. 1999, 9: 255-260). Yet another approach has been the development of low molecular weight compounds discovered by high throughput screening using various assay systems such as receptor binding (Andrew W. S. et al., Bioorg Med Chem Lett. 1999, 9: 2073-2078; Scherig Plough WO99/26943; and Halord S. et al., ACS meeting in October 2001).

DETAILED DESCRIPTION OF CERTAIN PREFERRED EMBODIMENTS OF THE INVENTION

Compounds having antagonistic action on thrombin receptors are expected to exhibit excellent effects for therapy or prevention of diseases associated with thrombin, and therefore offer promise for effective therapy or prevention of, for example, thrombosis, vascular restenosis, deep venous thrombosis, pulmonary embolism, cerebral infarction, heart diseases, disseminated intravascular coagulation, hypertension, inflammatory diseases, rheumatism, asthma, glomerulonephritis, osteoporosis, neurological diseases, malignant tumors, and the like. It has been highly desired to provide thrombin receptor antagonists which are satisfactory in numerous aspects including pharmacological activity, thrombin receptor specificity, safety, dosage and oral efficacy.

However, the conventional thrombin receptor antagonists have been inadequate in terms of receptor specificity and oral efficacy.

It is therefore an object of the present invention to search for and discover compounds having excellent throm-
bin receptor inhibiting activity and being therefore useful as thrombin receptor antagonists.

[0010] The inventors have completed thorough research in light of such circumstances, leading to the synthesis of novel 2-iminoimidazole derivatives represented by the following general formula (I), the results of which have unexpectedly revealed that these compounds or salts thereof have excellent thrombin receptor-inhibiting activity and are useful as thrombin receptor antagonists, which culminated in the present invention.

Step 2 represents a step of deprotection when R6 of compound (MO-b) is a protecting group for the phenolic hydroxyl group. For example, compound (MO-c) wherein R6 is methoxymethyl may be obtained by treating compound (MO-b) with an acidic mixed solvent such as 5 N hydrochloric acid/aceton or 10% aqueous perchloric acid/tetrahydrofuran.

Step 3 represents a step of introducing a new substituent R7 at the phenolic hydroxyl group of compound (MO-c).

Compound (MO-d) wherein R7 is methyl may be obtained at a high yield by reacting compound (MO-c) with diazomethane in diethyl ether or with trimethylsilyldiazomethane in acetonitrile-diisopropylethylamine-methanol.

Compound (MO-d) wherein X2 in reagent R7-X2 is hydroxyl may be obtained by reacting compound (MO-c) with reagent R7-X2 by the publicly known Mitsunobu reaction in an appropriate solvent such as tetrahydrofuran or toluene.

In Production Process MO, R6 and R7 may sometimes undergo conversion to a structure which is not defined herein by a method easily predictable by a person skilled in the art at an appropriate stage after introduction. Likewise, the —N—Y1-Y2-Y3(—N)— portion obtained by cyclization in Step 1 may sometimes also undergo conversion to a structure which is not defined herein. (Conversion of the —N—Y1-Y2-Y3(—N)— portion is described in some of the following Production Process examples).

Compounds (MO-b), (MO-c) and (MO-d) obtained in this Production Process may be converted to the final target compounds by Production Process A.
Production Process PR is an exemplary synthetic method for pyrrolidine derivatives.

Scheme PR-1 is an exemplary production scheme whereby the —N—Y1-Y2-Y3(—N) portion obtained by cyclization in Step 1 of Production Process MO may undergo additional structural conversion. In the formulas, R1 has the same definition as R1 in Step 1 of Production Process PP. R10 and R11 have the same definitions as R6 and R7 in Production Process MO. Although only methoxymethyl is mentioned as a protecting group for the phenolic hydroxyl group of compounds (PR1-a) and (PR1-b), there is no limitation to methoxymethyl.

Step 1 represents a step of introducing a substituent R10 at the hydroxyl group of compound (PR1-a). The reaction is conducted using reagent R10-X3 in an appropriate alkaline hydrated organic solvent, in the presence of a phase transfer catalyst. Preferably, compound (PR1-b) is obtained by reaction of reagent R10-X3 with compound (PR1-a) in a mixture of 50% aqueous sodium hydroxide and toluene in the presence of tetraalkylammonium bromide. Here, X3 is a leaving group such as halogen or sulfonate.

Step 2 represents a step of treating compound (PR1-b) in the same manner as Step 2 of Production Process MO to yield compound (PR1-c).

Step 3 represents a step of introducing a new substitutent R11 at the phenolic hydroxyl group of compound (PR1-c). Compound (PR1-c) may be treated in the same manner as for introduction of R7 in Step 3 of Production Process MO to yield R11 introduced compound (PR1-d).

Step 4 represents a step of treating compound (PR1-a) in the same manner as Step 2 of Production Process MO to yield compound (PR1-e).

Step 5 represents a step of selectively introducing substitutent R11 only at the phenolic hydroxyl group of compound (PR1-e). Utilizing the difference in reactivity between the two hydroxyl groups of compound (PR1-e), treatment may be carried out in the same manner as for introduction of R7 in Step 3 of Production Process MO to yield R11 introduced compound (PR1-f).

Step 6 represents a step of treating compound (PR1-f) in the same manner as Step 1 of this Scheme PR-1 to yield compound (PR1-d).

Compounds (PR1-b) and (PR1-d) obtained in this Scheme PR-1 may be converted to the final target compounds by Production Process A.
Scheme PR-2 is another exemplary production scheme whereby the \(-N-Y1-Y2-Y3(-N)\) portion obtained by cyclization in Step 1 of Production Process MO may undergo additional structural conversion. In the formulas, R1 has the same definition as R1 in Step 1 of Production Process PP. R15 and R20 have the same definitions as R6 and R7 in Production Process MO.

Step 1 represents a step of replacing the hydroxyl group of compound (PR1-a) with a substituent R14 (F or CN). When R14 is fluoro, compound (PR1-a) may be treated with diethylaminosulfur trifluoride (DAST) in dichloromethane to yield compound (PR2-a: R14=F). When R14 is cyano, the hydroxyl group of compound (PR1-a) may first be converted to a leaving group with an acyl chloride reagent such as methanesulfonyl chloride in an appropriate solvent such as dichloromethane, in the presence of a base such as triethylamine. A hydrogen cyanide salt may then be reacted with this intermediate to introduce a cyano group. Preferably, the intermediate is added to dimethylformamide and reacted with sodium cyanide in the presence of tetraethylammonium iodide to yield compound (PR2-a: R14=CN).

Step 2 represents a step of treating compound (PR2-a) (R14=F or CN) in the same manner as Step 2 of Production Process MO to yield compound (PR2-b) (R14=F or CN).

Step 3 represents a step of introducing substituent R15 at the phenolic hydroxyl group of compound (PR2-b) (R14=F or CN). Compound (PR2-b) may be treated in the same manner as for introduction of R7 in Step 3 of Production Process MO to yield R15 introduced compound (PR2-c) (R14=F or CN).

Step 4 represents a step of converting compound (PR2-c) wherein R14=CN to compound (PR2-d) wherein cyano may be converted to carboxyl by alkali hydrolysis. Preferably, compound (PR2-c) wherein R14=CN may be reacted by heating to reflux in a mixed solvent of aqueous sodium hydroxide and ethanol to yield compound (PR2-d).

Step 5 represents a step of esterifying or amidating the carboxylic acid group of compound (PR2-d) for introduction of a substituent R18 by common methods. The carboxylic acid group of compound (PR2-d) may be converted to an active species by a common method such as an acid mixing method using a chloroformic acid ester or an acid chloride method using oxalyl chloride, and then reacted with an alcohol or amine for conversion to (PR2-e). Alternatively, (PR2-d) may be esterified by reaction with the corresponding alkyl halide reagent in the presence of an appropriate base or by reaction with di-tert-butyl dicarbonate in the presence of dimethylaminopyridine. The synthesis may also be carried out by other suitable known reactions. R18 represents amino or alkoxy.

Step 6 represents a step of subjecting compound (PR2-a: R14=CN) to alkali hydrolysis in the same manner as Step 4 followed by treatment in the same manner as the esterification in Step 5, and then ketal protection of the carbonyl group of the acetophenone. After converting compound (PR2-a: R14=CN) to a carboxylic acid ester, it may be reacted with a ketalizing reagent such as methyl orthoformate under acidic conditions to yield compound (PR2-f). Preferably, the methyl orthoformate is reacted with the carbonyl group in methanol in the presence of an acid catalyst such as camphorsulfonic acid or p-toluenesulfonic acid and Molecular Sieve 3A, to yield compound (PR2-f).

Step 7 represents a step of reducing the ester group of compound (PR2-f) for conversion to a hydroxymethyl group, and then selectively deprotecting only the ketal protection of the carbonyl group of the acetophenone. First, compound (PR2-f) is reacted with an ester-reducing reagent such as lithium aluminum hydride in an appropriate solvent such as tetrahydrofuran or diethyl ether, for conversion to a hydroxymethyl group. Next, under mildly acidic conditions, and preferably under conditions with an acetic acid-tetrahydrofuran-water (4:1:1) mixed acid solvent, the ketal protecting group for the carbonyl group is selectively deprotected while leaving the methoxymethyl group for the phenolic hydroxyl, to yield compound (PR2-g).

Step 8 represents a step of converting the hydroxyl group of compound (PR2-g) to substituent R19 (cyano or various alkoxy).

When R19 is cyano, treatment is carried out in the same manner as for conversion in Step 1 when R14 is cyano, to yield compound (PR2-h) wherein hydroxymethyl of compound (PR2-g) may be converted to cyanoethyl, in which case R19 represents cyano. When R19 is alkoxy, compound (PR2-g) is treated in the same manner as Step 1 of Scheme PR-1 to yield compound (PR2-h) for conversion to alkoxy, in which case R19 has the same definition as OR10 in Scheme PR-1.

Alternatively, when R24 is methoxymethyl or the like, an excess of methoxymethyl chloride may be reacted with compound (PR3-a) in the presence of diisopropylethylamine to yield compounds (PR3-b) and (PR3-c). Compounds (PR3-b) and (PR3-c) may be separated by silica gel column chromatography.

It is then treated with cesium acetate while heating in dimethylsulfoxide to yield a hydroxyl-inverted acetate. This is treated with potassium carbonate in methanol to yield hydroxyl-inverted compound (PR3-e).

Preferably, Compound (PS-a) is reacted with 37% formalin in dichloromethane in the presence of magnesium sulfate to produce an imine, and the reaction mixture is filtered with celite. After adding 2-trimethylsilyloxy-1,3-butadiene and toluene to the filtrate and cooling to −70° C., a 1 M hexane

Test Examples

The biochemical activities of compounds of the invention and salts thereof and their actions and effects as medicines (thrombin receptor binding capacity, and platelet aggregation inhibitory action) were evaluated by the following methods.
Test Example 1

[1074] [Receptor Binding Assay]

[1075] Blood was sampled from a healthy adult who had taken no drugs for one week, and 3.8% citric acid (a ratio of 1:9 with respect to the blood) was added as an anticoagulant. The mixture was then centrifuged at 100 g for 10 minutes at room temperature to yield platelet rich plasma (PRP). The platelet precipitate obtained by centrifuging the PRP was homogenized with a Dounce homogenizer, and then centrifuged at 40,000 g for 60 minutes to yield platelet membrane. The platelet membrane was suspended in a solution prepared by adding DMSO (dimethyl sulfoxide) at 1% concentration to Buffer 1; a 50 mM Tris-HCl buffer containing 10 mM MgCl₂ and 1 mM EGTA (ethylene glycol tetraacetic acid), and the suspension was stored at −80 °C. Bovine albumin and DMSO were added to Buffer 1 at 0.1% and 20%, respectively, to make a preparation solution for the test compound. The test compounds (20 μl) diluted at various concentrations with the preparation solution were added to a 96-well multiscreen plate. Next, 80 μl of 25 mM [3H]Ala-(4-fluoro)Phe-Arg-(cyclohexyl)Ala-(homo)Arg-Tyr-NH₂ (high affinity TRAP) diluted with Buffer 1 was added and thoroughly mixed therewith. After then adding 100 μl of the previously prepared platelet membrane suspension (0.4 mg/ml) and mixing, incubation was performed at 37 °C for 1 hour. The reaction mixture was suction filtered and then rinsed 3 times with 200 μl of Buffer 1. Next, 30 μl of liquid scintillator was added for measurement of the radioactivity of the plate using a Top Counter (Packard), the value of the radioactivity in the presence of the test compound minus non-specific binding portion was divided by the specific binding value (the value of the binding in the absence of the compound minus the non-specific binding portion) to determine the binding ratio, from which the IC₅₀ value was calculated. The non-specific binding was the value obtained with addition of 10 μM of high affinity TRAP. The results are shown in Table 1.

1078 The compounds of the present invention and salts thereof exhibited excellent thrombin receptor binding capacity in Test Example 1, and especially selective binding capacity with PAR1 thrombin receptor. In addition, the compounds of the invention and salts thereof exhibited excellent platelet aggregation inhibitory action in Test Example 2.

INDUSTRIAL APPLICABILITY

[1079] The present invention provides novel 2-iminoimidazole derivatives represented by the formula (I) and salts thereof. The compounds of the invention represented by the formula (I) and salts thereof exhibit excellent thrombin receptor antagonism and especially selective antagonism for PAR1 thrombin receptors. The compounds of the invention and salts thereof can therefore inhibit cellular response to thrombin which includes platelet aggregation, without inhibiting the catalytic activity of thrombin which converts fibrinogen to fibrin, and can also inhibit vascular smooth muscle proliferation occurring as a result of damage to
vascular walls by coronary angioplasty and the like, based on selective inhibition of PAR1.

[1080] Thus the compounds of the invention and salts thereof are useful as thrombin receptor antagonists (especially PAR1 thrombin receptor antagonists), platelet aggregation inhibitors (thrombogenic agents) and smooth muscle cell proliferation inhibitors, while also being useful as therapeutic or prophylactic agents for restenosis during or following angioplasty, unstable angina, stable angina, myocardial infarction, cerebral infarction, peripheral arterial occlusion and the like, as therapeutic or prophylactic agents for venous thromboses such as deep venous thrombosis, pulmonary embolism and cerebral embolism accompanying atrial fibrillation, glomerulonephritis and the like, as anti-inflammatory agents or as anti-restenosis agents.
