[57] **ABSTRACT**

A phosphate ore flotation process subjects a phosphate ore containing silica and silicates to froth flotation in the

presence of a collector, said collector being a C₃₆ high molecular weight dibasic acid comprising two carboxylic functional groups, recovering the phosphate concentrate from the overflow, and removing the separated silica and silicates in the underflow. The dibasic acids should be used in conjunction with fuel oil, not only to reduce the reagent consumption, but also to increase the grade and recovery of phosphate concentrate.
