(54) Title: APPARATUS AND METHOD USING COMPRESSED CODES FOR TELEVISION PROGRAM RECORD SCHEDULING

(57) Abstract

Encoded video recorder/player (44, 370, 964, 991) timer (40) preprogramming information (10) listed in a television calendar (Figure 8) allows a timer preprogramming feature on a video cassette recorder VCR (44, 370, 964, 991) to be programmed using a compressed code of as few as 1 to 8 digits, which are decoded by a decoder (954) built into a television (48, 950) to convert the compressed code into channel, date, time and length information. The compressed code indications associated with each television program can be printed in a television program calendar in advance. The user would use the television remote (956) or controls on the television (48, 950) to enter the code that signifies the program to be recorded. When the codes are entered they are transmitted to the television (48, 950) and then decoded in the television (48, 950) and then the codes themselves and the CDTL information, which is the result of decoding the codes, could be displayed "on screen" so that the user can verify that the proper codes have been entered.

**APPARATUS AND METHOD USING COMPRESSED CODES
FOR TELEVISION PROGRAM RECORD SCHEDULING**

Background Of The Invention

1. Field of the Invention

This invention relates generally to video cassette recorder systems and particularly to the timer preprogramming feature of video cassette recorders (VCRs) and to an apparatus and method for using encoded information to shorten the time required to perform timer preprogramming and an apparatus and method of embedding the decoding of the encoded information in a television receiver, video cassette recorder, cable box and satellite receiver.

2. Prior Art

The video cassette recorder (VCR) has a number of uses, including playing back of tapes filmed by a video camera, playing back of pre-recorded tapes, and recording and playing back of broadcast and cable television programs.

To record a television program in advance of viewing it, a two-step process is often used: (1) obtain the correct channel, date, time and length (CDTL) information from a television program guide, and (2) program this CDTL information into the VCR. Depending on the model, year and type of the VCR, the CDTL information can be programmed in various ways including: (i) pushing an appropriate sequence of keys in the console according to instructions contained in the user's manual, (ii) pushing an appropriate sequence of keys in a remote hand-held control unit according to instructions contained in the user's manual (remote programming), and (iii) executing a series of keystrokes in the remote hand-held control unit in response to a menu

-2-

1 displayed on the television screen (on-screen programming). Other techniques for
timer preprogramming have been suggested including: (iv) reading in certain bar-code
information using a light pen (light pen programming), and (v) entering instructions
5 through a computer or telephone modem. These various methods differ only in the
physical means of specifying the information while the contents, being CDTL and
certain power/clock/timer on-off commands are generally common although the
detailed protocol can vary with different model VCRs. Methods (i) and (ii) described
above can require up to 100 keystrokes, which has inhibited the free use of the timer
10 preprogramming feature of VCRs. To alleviate this, new VCR models have included
an "On-Screen Programming" feature, which permits remote input of CDTL
information in response to a menu displayed on the television screen. Generally on
screen programming of CDTL information requires an average of about 18 keystrokes,
which is less than some of the prior methods but still rather substantial. Some of the
other techniques such as (iv) above, require the use of special equipment such as a bar
15 code reader.

In general the present state of the art suffers from a number of drawbacks. First,
the procedure for setting the VCR to record in advance can be quite complex and
confusing and difficult to learn; in fact, because of this many VCR owners shun using
the timer preprogramming record feature. Second, the transcription of the CDTL
20 information to the VCR is hardly ever error-free; in fact, many users of VCR's timer
preprogramming features express concern over the high incidence of programming
errors. Third, even for experienced users, the process of entering a lengthy sequence
of information on the channel, date, time and length of desired program can become
tedious. Fourth, techniques such as reading in bar-code information or using a
25 computer require special equipment. These drawbacks have created a serious
impedance in the use of a VCR as a recording device for television programs. The
effect is that time shifting of programs has not become as popular as it once was
thought it would be. Accordingly, there is a need in the art for a simpler system for
effecting VCR timer preprogramming which will enable a user to take advantage of the
30 recording feature of a VCR more fully and freely.

Summary of the Invention

A principal object of the invention is to provide an improved system for the
selection and entering of channel, date, time and length (CDTL) information required
35 for timer preprogramming of a VCR which is substantially simpler, faster and less
error-prone than present techniques. Another principal object of the invention is to
provide televisions having an embedded capability for timer programming control.

1 In accordance with the invention, to program the timer preprogramming feature of
a video system, there is an apparatus and method for using encoded video
recorder/player timer preprogramming information. The purpose is to significantly
5 reduce the number of keystrokes required to set up the timer preprogramming feature
on a VCR. In accordance with this invention it is only necessary for the user to enter
a code with 1 to 7 digits or more into the VCR. This can be done either remotely or
locally at the VCR. Built into either the remote controller or the VCR is a decoding
means which automatically converts the code into the proper CDTL programming
10 information and activates the VCR to record a given television program with the
corresponding channel, date, time and length. Generally multiple codes can be entered
at one time for multiple program selections. The code can be printed in a television
program guide in advance and selected for use with a VCR or remote controller with
the decoding means.

15 Another principal object of the invention is to embed the decoding means into
a television. The television would then at the appropriate time distribute the proper
commands to a VCR and a cable box to record the desired program. The user would
use the television remote or controls on the television to enter the code that signifies
the program to be recorded. The same television remote and controls on the television
20 would also be used to perform normal television control functions, such as channel
selection. When the codes are entered they are transmitted to the television and the
decoder in the television, which decodes the codes into CDTL information and then the
codes themselves and the CDTL information could be displayed "on screen" so that the
user can verify that the proper codes have been entered. Then at the appropriate time
25 the television would transmit the proper commands to a VCR and a cable box, if
necessary, to command the recording of the selected program. This control function
can be carried out by using an infrared link by placing infrared transmitters on the
television cabinet, preferably at the corners. The television circuitry would include the
capability of storing or learning the infrared code protocols for the VCR and the cable
box.

30 Another principal object of the invention is to embed the decoding means into
various equipments associated with television, such as a video cassette recorder, cable
box or satellite receiver. In any system the decoding means would only have to be
present in one of the equipments, such as the cable box, which would then at the
appropriate time distribute the proper commands to the other equipments such as a
35 VCR and a satellite receiver to record the desired program. The user would use the
television remote or controls on the equipment with the decoder to enter the code that
signifies the program to be recorded. The same television remote would also be used

1 to perform normal television control functions, such as channel selection. When the
codes are entered they are transmitted to the equipment with the decoder, which
decodes the codes into CDTL information. Then at the appropriate time the equipment
5 with the decoder would transmit the proper commands to a the other equipment such
as a VCR, satellite receiver and a cable box to command the recording of the selected
program. This control function can be carried out by using an infrared link by
coupling infrared transmitters on the equipment with the decoder. The infrared
transmitter can be placed in a infrared dome on the equipment, mounted behind the
10 front panel, attached to a mouse coupled via a cable to the equipment with the decoder
with the mouse placed near the receiver, or attached to a stick on miniature mouse
coupled via a cable to the equipment with the decoder with the miniature mouse
attached to the device with the receiver. The equipment with the decoder would
include the capability of storing or learning the infrared code protocols for the other
equipment, such as a VCR, satellite receiver and a cable box.

15 Other objects and many of the attendant features of this invention will be more
readily appreciated as the same becomes better understood by reference to the
following detailed descriptions and considered in connection with the accompanying
drawings in which like reference symbols designate like parts throughout the figures.

1 **Description of the Preferred Embodiments**

 Referring now to the drawings, and more particularly, to FIG. 1, there is shown an apparatus for using encoded video recorder/player timer preprogramming information 10 according to this invention. The primary components include a remote controller 12 and a video cassette recorder/player with G-code decoder 14, which can be controlled by remote controller 12 via a command signal 16. The remote controller 12 can have a number of keys, which include numerical keys 20, G-code switch 22, function keys 24, program key 26 and power key 27. There are means in the remote controller 12 that interprets each key as it is pressed and sends the proper command signal 16 to the VCR via an infra-red light emitting diode 28. Except for the G-code switch 22 on the remote controller 12 in FIG. 1, the remote controller 12 is essentially the same as any other remote controller in function. The G-code switch 22 is provided just to allow the user to lock the remote controller 12 in the G-code mode while using a G-code, which is the name given to the compressed code which is the encoded CDTL information, to perform timer preprogramming.

 A G-code consists of 1 to 7 digits, although more could be used, and is associated with a particular program. A user would look up the G-code in a program guide and just enter the G-code on the remote controller 12, instead of the present state of the art, which requires that the user enter the actual channel, date, time and length (CDTL) commands.

 In order to understand the advantages of using a G-code, it is helpful to describe the best of the current state of the art, which is "on screen programming" with direct numerical entry. This technique involves about 18 keystrokes and the user has to keep switching his view back and forth between the TV screen and the remote controller while entering the CDTL information. This situation may be akin to a user having to dial an 18 digit telephone number while reading it from a phone book. The number of keys involved and the switching back and forth of the eye tend to induce errors. A typical keying sequence for timer recording using on-screen CDTL programming is as follows:

30

 PROG 2 1 15 07 30 2 08 00 2 04 PROG

35

 The first program (PROG) key 26 enters the programming mode. Then a sequence of numerical keys 20 are pushed. The 2 means it is timer recording rather than time setting. The 1 means the user is now entering the settings for program 1. The 15 is the date. The 07 is starting hour. The 30 is a starting minute. The 2 means pm. The

-9-

1 next sequence 08 00 2 is the stopping time. The 04 is channel number. Finally, the
 PROG is hit again to exit the program mode.

By contrast, this command could have been "coded" and entered in a typical
 G-code sequence as follows: PROG 1138 PROG. To distinguish that the command
 5 is a coded G-code, the G-code switch 22 should be turned to the "ON" position.
 Instead of having a switch, a separate key "G" can be used. The G-code programming
 keystroke sequence would then be: G 1138 PROG.

The use of a G-code does not preclude "on-screen" confirmation of the
 program information that has been entered. When the keystrokes "PROG 1138 PROG"
 10 are entered with the G-code switch in the "ON" position, the G-code would be
 decoded and the television could display the following message:

PROGRAM	DATE	START TIME	STOP TIME	CHANNEL
1138	15	7:30 PM	8:00 PM	4

15

In order for the G-code to be useful it must be decoded and apparatus for that
 purpose must be provided. Referring to FIG. 1, a video cassette recorder/player with
 G-code decoder 14 is provided to be used in conjunction with remote controller 12.
 The command signal 16 sent from the remote controller 12 is sensed by the photodiode
 20 32 and converted to electrical signals by command signal receiver 30. The electrical
 signals are sent to a command controller 36, which interprets the commands and
 determines how to respond to the commands. As shown in FIG. 1, it is also possible
 for the command controller 36 to receive commands from the manual controls 34 that
 are normally built into a VCR. If the command controller 36 determines that a G-code
 25 was received then the G-code will be sent to the G-code decoder 38 for decoding. The
 G-code decoder 38 converts the G-code into CDTL information, which is used by the
 command controller 36 to set the time/channel programming 40. Built into the VCR
 is a clock 42. This is normally provided in a VCR and is used to keep track of the
 date and time. The clock 42 is used primarily by the time/channel programming 40
 30 and the G-code decoder 38 functions. The time/channel programming 40 function is
 set up with CDTL information by the command controller 36. When the proper date
 and time is read from clock 42, then the time/channel programming 40 function turns
 the record/playback 44 function "ON" to record. At the same time the tuner 46 is
 tuned to the proper channel in the television signal 18. Later the user can command
 35 the record/playback 44 function to a playback mode to watch the program via the
 television monitor 48.

1 An alternate way to control the recorder is to have the command controller 36
keep all the CDTL information instead of sending it to the time/channel programming
40. The command controller would also keep track of the time by periodically reading
5 clock 42. The command controller would then send commands to the time/channel
programming 40 to turn on and off the recorder and to tuner 46 to cause it to tune to
the right channel at the right time according to the CDTL information.

 The clock 42 is also an input to G-code decoder 38, which allows the G-code
decoding to be a function of the clock, which lends a measure of security to the
decoding technique and makes it harder to copy. Of course this requires that the
10 encoding technique must also be a function of the clock.

 A possible realization of the command controller 36 and the G-code decoder
38 is shown in FIG. 2. The command controller 36 function can be realized with a
microprocessor 50, a random access memory 52 and a read only memory 54, which
is used for program storage. The input/output 56 function is adapted to receive
15 commands from the command signal receiver 30, the manual controls 34 and the clock
42, and to output signals to a display 35, the clock 42, and the time/channel
programming 40 function. If the microprocessor 50 interprets that a G-code has been
received, then the G-code is sent to microcontroller 60 for decoding. The
microcontroller 60 has an embedded random access memory 62 and an embedded read
20 only memory 64 for program and table storage. The clock 42 can be read by both
microprocessor 50 and microcontroller 60.

 An alternative to having microcontroller 60 perform the G-code decoding is to
build the G-code decoding directly into the program stored in read only memory 54.
This would eliminate the need for microcontroller 60. Of course, other hardware to
25 perform the G-code decoding can also be used. The choice of which implementation
to use is primarily an economic one.

 The blocks in Figs. 1 and 2 are well known in the prior art and are present in the
following patents: Fields, patent no. 4,481,412; Scholz, patent no. 4,519,003; and
Brugliera, patent no. 4,631,601. For example, clock 42 is analogous to element 7 in
30 Scholz and element 17 in Brugliera. Other analogous elements are: command signal
receiver 30 and Scholz 14 and Brugliera 12; tuner 46 and Scholz 6 and Brugliera 10;
time/channel programming 40 and Scholz 8, 11 and Brugliera 16; record & playback
44 and Scholz 1, 2, 4; command controller 36 and Scholz 11, 10 and Brugliera 12;
microprocessor 50 and Fields 27; RAM 52 and Fields 34; ROM 54 and Fields 33;
35 manual controls 34 and Scholz 15, 16; and remote controller 12 and Scholz 26 and
Brugliera 18.

FIG. 3 illustrates an alternate preferred embodiment of this invention. In FIG. 3 a remote controller with embedded G-code decoder 80 is provided. The remote controller with embedded G-code decoder 80 is very similar to remote controller 12, except for the addition of the G-code decoder 82. Note that it is also possible in any remote controller to provide a display 84. The remote controller with embedded G-code decoder 80 would be used in conjunction with a normal video cassette recorder/player 70, which would not be required to have an embedded G-code decoder. The numerals for the subelements of video cassette recorder/player 70 are the same as described above for the video cassette recorder/player with G-code decoder 14 and have the same function, except for the absence of G-code decoder 38. This preferred embodiment has the advantage that it can be used in conjunction with VCRs that are presently being used. These do not have a G-code decoding capability. Replacing their remote controllers with ones that have this capability built-in can vastly improve the capability to do timer preprogramming for a modest cost.

FIG. 4 illustrates a possible realization of the G-code decoder 82 built into the remote controller with embedded G-code decoder 80. A microprocessor 60 can be used as before to decode the G-code, as well as interface with the display 84, a clock 85, the keypad 88 and the light emitting diode 28. Alternately, other hardware implementations can be used to perform the G-code decoding. The clock 85 is provided in the remote controller 80 so that the G-code decoder 82 can be made to have the clock 85 as one of its inputs. This allows the G-code decoding to be a function of the clock 85, which lends a measure of security to the decoding technique and makes it harder to copy.

The remote controller with embedded G-code decoder as described above would send channel, date, time and length information to the video cassette recorder/player 70, which would use the CDTL information for tuning into the correct channel and starting and stopping the recording function. The remote controller may have to be unique for each different video cassette recorder/player, because each brand or model may have different infrared pulses for each type of information sent such as the channel number keys and start record and stop record keys. The particular infrared pulses used for each key type can be called the vocabulary of the particular remote controller. Each model may also have a different protocol or order of keys that need to be pushed to accomplish a function such as timer preprogramming. The protocol or order of keys to accomplish a function can be called sentence structure. If there is a unique remote controller built for each model type, then the proper vocabulary and sentence structure can be built directly into the remote controller.

1 An alternate to having the remote controller with embedded G-code decoder
send channel, date, time and length information to the video cassette recorder/player
70, is to have the remote controller with embedded G-code decoder perform more
5 operations to simplify the interfacing problem with existing video cassette
recorder/players. In particular, if the remote controller not only performs the G-code
decoding to CDTL, but also keeps track of time via clock 85, then it is possible for the
remote controller to send just channel, start record and stop commands to the video
cassette recorder/player. The channel, start and stop are usually basic one or two key
10 commands, which means there is no complicated protocol or sentence structure
involved. Thus, to communicate with a diverse set of video cassette recorder/player
models it is only necessary to have memory within the remote controller, such as ROM
64 of FIG. 4, for storing the protocol for all the models or at least a large subset. The
G-code would be entered on the remote controller as before and decoded into channel,
15 date, time and length information, which would be stored in the remote controller. Via
clock 85, the time would be checked and when the correct time arrives the remote
controller would automatically send out commands to the VCR unit for tuning to the
correct channel and for starting and stopping the recording. It is estimated that only
two (2) bytes per key for about 15 keys need to be stored for the vocabulary for each
20 video cassette recorder/player model. Thus, to cover 50 models would only require
about $30 \times 50 = 1500$ bytes of memory in the remote controller. It would be necessary
to position the remote controller properly with respect to the VCR unit so that the
infrared signals sent by the remote controller are received by the unit.

 Another preferred embodiment is to provide a universal remote controller 90
with an embedded G-code decoder. Universal remote controllers provide the capability
25 to mimic a number of different remote controllers. This reduces the number of remote
controllers that a user needs to have. This is accomplished by having a learn function
key 94 function on the universal remote controller, as shown in FIG. 5. If the learn
function key 94 is pushed in conjunction with another key, the unit will enter into the
learn mode. Incoming infra-red (IR) pulses from the remote controller to be learned
30 are detected by the infra-red photodiode 96, filtered and wave-shaped into recognizable
bit patterns before being recorded by a microcontroller into a battery-backed static
RAM as the particular IR pulse pattern for that particular key. This is done for all the
individual keys.

 An example of more complex learning is the following. If the learn function
35 key 94 in conjunction with the program key 26 are pushed when the G-code switch is
"ON", the unit will recognize that it is about to record the keying sequence of a
predetermined specific example of timer preprogramming of the particular VCR

1 involved. The user will then enter the keying sequence from which the universal remote controller 90 can then deduce and record the protocol of the timer preprogramming sequence. This is necessary because different VCRs may have different timer preprogramming command formats.

5 If keys are pushed without the learn function key 94 involved, the microcontroller should recognize it is now in the execute mode. If the key is one of the direct command keys, the microcontroller will read back from its static RAM the stored pulse sequence and send out command words through the output parallel I/O to pulse the output light emitting diode 28. If the key is the PROG key and the G-code switch is "OFF", then the microcontroller should recognize the following keys up to
10 the next PROG key as a timer preprogramming CDTL command and send it out through the light emitting diode 28. If the G-code switch 22 is set to "ON" and the program key 26 is pushed, the microcontroller should recognize the following keys up to the next PROG key as a G-code command for timer preprogramming. It will
15 decode the G-code into channel, date, start time and length (CDTL) and the microcontroller will then look up in its static RAM "dictionary" the associated infra-red pulse patterns and concatenate them together before sending them off through the output parallel I/O to pulse the light emitting diode 28 to send the whole message in one continuous stream to the VCR.

20 FIG. 4 illustrates a possible realization of the G-code decoder 92 that could be built into the universal remote controller with embedded G-code decoder 90. A microcontroller 60 can be used as before to decode the G-code, as well as for interfacing with the input/output functions including the photodiode 96. Alternately, the G-code decoding can be performed with other hardware implementations.

25 The universal remote controller can also be used in another manner to simplify the interfacing problem with existing video cassette recorder/players. In particular, if the universal remote controller performs not only the G-code decoding to CDTL, but also keeps track of time via clock 85 in FIG. 4, then it is possible for the universal remote controller to send just channel, start record and stop commands to the video
30 cassette recorder/player, which as explained before, are usually basic one key commands, which means there is no complicated protocol or sentence structure involved. Thus, to communicate with a diverse set of video cassette recorder/player models it is only necessary for the universal remote controller to "learn" each key of the remote controller it is replacing. The G-code would be entered on the universal remote controller as before and decoded into channel, date, time and length
35 information, which would be stored in the universal remote controller. Via clock 85, the time would be checked and when the correct time arrives the universal remote

1 controller would automatically send out commands to the VCR unit for tuning to the correct channel and for starting and stopping the recording. It would be necessary to position the universal remote controller properly with respect to the VCR unit so that the signals sent by the universal remote are received by the VCR unit.

5 There are a number of ways that the G-code decoding can be performed. The most obvious way is to just have a large look up table. The G-code would be the index. Unfortunately, this would be very inefficient and result in a very expensive decoder due to the memory involved. The total storage involved is a function of the number of total combinations. If we allow for 128 channels, 31 days in a month, 48
10 on the hour and on the half hour start times in a twenty four hour day, and 16 length selections in half hour increments, then the total number of combinations is $128 \times 31 \times 48 \times 16 = 3,047,424$. This number of combinations can be represented by a 7 digit number. The address to the table would be the 7 digit number. In the worst case, this requires a lookup table that has about 4,000,000 rows by 15 to 16 digital
15 columns, depending on the particular protocol. These digital columns would correspond to the CDTL information required for "on screen programming". Each digit could be represented by a 4 bit binary number. Thus, the total storage number of bits required for the lookup table would be about $4,000,000 \times 16 \times 4 = 256,000,000$. The present state of the art has about 1 million bits per chip. Thus, G-code decoding
20 using a straightforward table lookup would require a prohibitively expensive number of chips.

Fortunately, there are much more clever ways of performing the G-code decoding. FIG. 6 is a flow diagram of a preferred G-code decoding technique. To understand G-code decoding, it is easiest to first explain the G-code encoding
25 technique, for which FIG. 7 is the flow chart. Then the G-code decoding technique, which is the reverse of the G-code encoding will be explained.

The encoding of the G-codes can be done on any computer and is done prior to preparation of any program guide that would include G-codes. For each program that will be printed in the guide, a channel, date, time and length (CDTL) code 144 is
30 entered in step 142. Step 146 separately reads the priority for the channel, date, time and length in the priority vector storage 122, which can be stored in read only memory 64. The priority vector storage 122 contains four tables: a priority vector C table 124, a priority vector D table 126, a priority vector T table 128 and a priority vector L table
35 130.

-15-

1 The channel priority table is ordered so that the most frequently used channels have a low priority number. An example of the data that is in priority vector C table 124 follows.

5 channel 4 7 2 3 5 6 11 13 ...

 priority 0 1 2 3 4 5 6 7 ...

10 Generally the dates of a month all have an equal priority, so the low number days in a month and the low number priorities would correspond in the priority vector D table as in the following example.

 date 1 2 3 4 5 6 7 8 9 10 ...

 priority 0 1 2 3 4 5 6 7 8 9 ...

15 The priority of the start times would be arranged so that prime time would have a low priority number and programs in the dead of the night would have a high priority number. For example, the priority vector T table would contain:

20 time 6:30pm 7:00pm 8:00pm 7:30pm ...

 priority 0 1 2 3 ...

 An example of the data that is in the priority vector L table 130 is the following:

25 length of program (hours) 0.5 1.0 2.0 1.5 3.0 ...

 priority 0 1 2 3 4 ...

30 Suppose the channel date time length (CDTL) 144 data is 5 10 19.00 1.5, which means channel 5, 10th day of the month, 7:00 PM, and 1.5 hours in length, then for the above example the C_p, D_p, T_p, L_p data 148, which are the result of looking up the priorities for channel, date, time and length in priority tables 124, 126, 128 and 130 of FIG. 7, would be 4 9 1 3. Step 150 converts C_p, D_p, T_p, L_p data to binary numbers. The number of binary bits in each conversion is determined by the number of combinations involved. Seven bits for C_p , which can be denoted as $C_7 C_6 C_5 C_4 C_3 C_2 C_1$, would provide for 128 channels. Five bits for D_p , which can be denoted as $D_5 D_4 D_3 D_2 D_1$, would provide for 31 days in a month. Six bits for T_p , which can be

35

-16-

1 denoted as $T_6 T_5 T_4 T_3 T_2 T_1$, would provide for 48 start times on each half hour of a
 twenty four hour day. Four bits for length, which can be denoted as $L_4 L_3 L_2 L_1$,
 would provide for a program length of up to 8 hours in half hour steps. Together there
 5 are $7+5+6+4 = 22$ bits of information, which correspond to $2^{22} = 4,194,304$
 combinations.

The next step is to use bit hierarchy key 120, which can be stored in read only
 memory 64 to reorder the 22 bits. The bit hierarchy key 120 can be any ordering of
 the 22 bits. For example, the bit hierarchy key might be:

10 $L_8 C_3 \dots T_2 C_2 T_1 C_1 L_1 D_5 D_4 D_3 D_2 D_1$
 $22 \ 21 \dots 10 \ 9 \ 8 \ 7 \ 6 \ 5 \ 4 \ 3 \ 2 \ 1$

15 Ideally the bit hierarchy key is ordered so that programs most likely to be the
 subject of timer preprogramming would have a low value binary number, which would
 eliminate keystrokes for timer preprogramming the most popular programs. Since all
 the date information has equal priority, then the $D_5 D_4 D_3 D_2 D_1$ bits are first. Next
 $T_1 C_1 L_1$ are used, because for whatever date it is necessary to have a time channel and
 length and $T_1 C_1 L_1$ are the most probable in each case due to the ordering of the
 20 priority vectors in priority vector storage 122. The next bit in the hierarchy key is
 determined by the differential probabilities of the various combinations. One must
 know the probabilities of all the channels, times and lengths for this calculation to be
 performed.

For example, the probability for channels may be:

25

channel	4	7	2	3	5	6	11	13	...
priority	0	1	2	3	4	5	6	7	...
probability(%)	5	4.3	4	3	2.9	2.1	2	1.8	...

The probabilities for times might be:

30

time	6:30pm	7:00pm	8:00pm	7:30pm	...
priority	0	1	2	3	...
probability(%)	8	7.8	6	5	...

35

-17-

1 And, the probabilities for lengths might be:

	length of program (hours)	0.5	1.0	2.0	1.5	3.0	...
	priority	0	1	2	3	4	...
5	probability(%)	50	20	15	5	4	...

10 The probabilities associated with each channel, time and length, as illustrated above, are used to determine the proper ordering. Since the priority vector tables are already ordered by the most popular channel, time, and length, the order in which to select between the various binary bits for one table, for example selecting between the $C_7 C_6 C_5 C_4 C_3 C_2 C_1$ bits, is already known. The C_1 bit would be selected first because as the lowest order binary bit it would select between the first two entries in the channel priority table. Then the C_2 bit would be selected and so on. Similarly, the T_1 and L_1 bits would be used before any of the other time and length bits. A combination of the C_1, T_1, L_1 and $D_5 D_4 D_3 D_2 D_1$ bits should be used first, so that all the information is available for a channel, date, time and length. The $D_5 D_4 D_3 D_2 D_1$ bits are all used because the date bits all have equal priority and all are needed to specify a date even if some of the bits are binary zero.

15 At this point the bit hierarchy key could be:

20 $T_1 C_1 L_1 D_5 D_4 D_3 D_2 D_1$

25 The first channel binary bit C_1 by itself can only select between $2^1 = 2$ channels, and the first two channels have a probability percent of 5 and 4.3, respectively. So the differential probability of C_1 is 9.3. Similarly, the differential probability of T_1 is $8 + 7.8 = 15.8$, and the differential probability of L_1 is $50 + 20 = 70$. If the rules for ordering the bit hierarchy key are strictly followed, then the first 8 bits of the bit hierarchy key should be ordered as:

30 $C_1 T_1 L_1 D_5 D_4 D_3 D_2 D_1,$

35 because L_1 has the highest differential priority so it should be next most significant bit after D_5 , followed by T_1 as the next most significant bit, and then C_1 as the next most significant bit. Notice that the bit hierarchy key starts with the least significant bit D_1 , and then is filled in with the highest differential probability bits. This is for the purpose of constructing the most compact codes for popular programs.

1 The question at this point in the encoding process is what should the next most
 significant bit in the hierarchy key be: T_2 , C_2 , or L_2 . This is again determined by the
 differential probabilities, which can be calculated from the above tables for each bit.
 Since we are dealing with binary bits, the C_2 in combination with C_1 selects between
 5 $2^2 = 4$ channels or 2 more channels over C_1 alone. The differential probability for C_2
 is then the additional probabilities of these two additional channels and for the example
 this is: $4 + 3 = 7$. In a similar manner C_3 in combination with C_1 and C_2 selects
 between $2^3 = 8$ channels or $4 = 2^{(3-1)}$ more channels over the combination of C_1 and
 C_2 . So the differential probability of C_3 is the additional probabilities of these four
 10 additional channels and for the example this is: $2.9 + 2.1 + 2 + 1.8 = 8.8$. In a
 similar manner, the differential probabilities of T_2 and L_2 can be calculated to be $6 +$
 $5 = 11$ and $15 + 5 = 20$, respectively. Once all the differential probabilities are
 calculated, the next step is determining which combinations of bits are more probable.

Now for the above example, which combination is more probable: T_2 with C_1
 15 L_1 , or C_2 with $T_1 L_1$, or L_2 with $T_1 C_1$. This will determine the next bit in the key.
 So, which is greater: $11 \times 9.3 \times 70 = 7161$; $7 \times 15.8 \times 70 = 7742$; or $20 \times 15.8 \times 9.3 = 2938.8$?
 In this case the combination with the greatest probability is $7 \times 15.8 \times 70 = 7742$, which
 corresponds to C_2 with $T_1 L_1$. So, C_2 is selected as the next bit in the bit hierarchy
 key.

20 The next bit is selected in the same way. Which combination is more
 probable: C_3 with $T_1 L_1$, or T_2 with C_1 or C_2 and L_1 , or L_2 with C_1 or C_2 and T_1 .
 For the example shown, which has the greatest probability: $8.8 \times 15.8 \times 70 = 9732.8$;
 $11 \times (9.3 + 7) \times 70 = 12551$; or $20 \times (9.3 + 7) \times 15.8 = 5150.8$? In this case the combination
 with the greatest probability is $11 \times (9.3 + 7) \times 70 = 12551$, which corresponds T_2 with C_1
 25 or C_2 and L_1 . So, T_2 is selected as the next bit in the bit hierarchy key. This
 procedure is repeated for all the differential probabilities until the entire key is found.

Alternately, the bit hierarchy key can be just some arbitrary sequence of the
 bits. It is also possible to make the priority vectors interdependent, such as making the
 30 length priority vector dependent on different groups of channels. Another technique
 is to make the bit hierarchy key 120 and the priority vector tables 122, a function of
 clock 42, as shown in FIG. 7. This makes it very difficult for the key and therefore
 the coding technique to be duplicated or copied.

For example it is possible to scramble the date bits in the bit hierarchy key 120
 35 as a function of the clock. Changing the order of the bits as a function of the clock
 would not change the effectiveness of the bit hierarchy key in reducing the number of
 binary bits for the most popular programs, because the date bits all are of equal

-19-

1 priority. This could be as simple as switching the D_1 and D_5 bits periodically, such as every day or week. Thus the bit hierarchy key 120 would switch between

3
5
... $C_1 T_1 L_1 D_5 D_4 D_3 D_2 D_1$ and
... $C_1 T_1 L_1 D_1 D_4 D_3 D_2 D_5$.

Clearly other permutations of the bit hierarchy key as a function of the clock are possible.

10 The priority vector tables could also be scrambled as a function of the clock. For example, the first two channels in the priority channel table could just be swapped periodically. If this technique is followed, then the C_p of 148 in FIG. 7 would change as a function of the clock 42. For example,

15

channel	4	7	2	3	5	6	11	13	...
priority	0	1	2	3	4	5	6	7	...

would change periodically to:

20

channel	7	4	2	3	5	6	11	13	...
priority	0	1	2	3	4	5	6	7	...

25 This would be a fairly subtle security technique, because a decoder that was otherwise correct would only fail if those first two channels were being used. Other clock dependencies are also possible to provide security for the coding technique.

30 However it is derived, the bit hierarchy key 120 is determined and stored. In step 154 the binary bits of C_p, D_p, T_p, L_p are rearranged according to the bit hierarchy key 120 to create one 22 bit binary number. Then the resulting 22 bit binary number is converted to decimal in the convert binary number to decimal G-code step 156. The result is G-code 158.

If the priority vector and the bit hierarchy key are well matched to the viewing habits of the general population, then it is expected that the more popular programs would require no more than 3 or 4 digits for the G-code.

35 Now that the encoding technique has been explained the decoding technique is just reversing the coding technique. This is done according to the flow chart of FIG. 6. This is the preferred G-code decoding that can be built into G-code decoder 38 in VCR 14 or the remote controller G-code decoders 82 and 92 in FIGs. 3 and 5.

1 The first step 102 is to enter G-code 104. Next the G-code 104 is converted
to a 22 bit binary number in step 106. Then the bits are reordered in step 108
according to the bit hierarchy key 120 to obtain the reordered bits 110. Then the bits
are grouped together and converted to decimal form in step 112. As this point we
5 obtain C_p, D_p, T_p, L_p data 114, which are the indices to the priority vector tables. For
the above example, we would have at this step the vector 4 9 1 3. This C_p, D_p, T_p, L_p
data 114 is then used in step 116 to lookup channel, date, time, and length in priority
vector storage 122. The CDTL 118 for the example above is 5 10 19.00 1.5, which
means channel 5, 10th day of the month, 7:00 PM, and 1.5 hours in length.

10 If the coding technique is a function of the clock then it is also necessary to
make the decoding technique a function of the clock. It is possible to make the bit
hierarchy key 120 and the priority vector tables 122, a function of clock 42, as shown
in FIG. 6. This again makes it very difficult for the key and therefore the coding
technique to be duplicated or copied. It is also possible to have the decoding and
15 encoding techniques dependent on any other predetermined or preprogrammable
algorithm.

 Although the above G-code encoding and decoding technique is a preferred
embodiment, it should be understood that there are many ways to perform the intent
of the invention which is to reduce the number of keystrokes required for timer
20 preprogramming. To accomplish this goal there are many ways to perform the G-code
encoding and decoding. There are also many ways to make the encoding and decoding
technique more secure besides just making the encoding and decoding a function of the
clock. This security can be the result of any predetermined or preprogrammed
algorithm.

25 It is possible in the G-code coding and decoding techniques to use mixed radix
number systems instead of binary numbers. For example, suppose that there are only
35 channels, which would require 6 binary bits to be represented; however, 6 binary
bits can represent 64 channels, because $2^6 = 64$. The result is that in a binary number
system there are 29 unnecessary positions. This can have the effect of possibly making
30 a particular G-code longer than it really needs to be. A mixed radix number system
can avoid this result. For example, for the case of 35 channels, a mixed radix number
system with the factors of 7^1 and 5^0 can represent 35 combinations without any empty
space in the code. The allowed numbers for the 7^1 factor are 0, 1, 2, 3, and 4. The
allowed numbers for the 5^0 factor are 0, 1, 2, 3, 4, 5, and 6. For example, digital 0
35 is represented in the mixed radix number system as 00. The digital number 34 is
represented in the mixed radix number system as 46, because $4*7^1 + 6*5^0 = 34$. The
major advantage of a mixed radix number system is in prioritizing the hierarchy key.

1 If the first 5 channels have about equal priority and the next 30 are also about equal,
then the mixed radix number system allows the two tiers to be accurately represented.
This is not to say that a mixed radix number system is necessarily preferable. Binary
5 numbers are easier to represent in a computer and use of a fixed radix number system
such as binary numbers allows a pyramid of prioritization to be easily represented in
the hierarchy key.

Another feature that is desirable in all of the embodiments is the capability to
key in the G-code once for a program and then have the resulting CDTL information
used daily or weekly. Ordinarily the CDTL information is discarded once it is used.
10 In the case of daily or weekly recording of the same program, the CDTL information
is stored and used until it is cancelled. The desire to repeat the program daily or
weekly can be performed by having a "WEEKLY" or "DAILY" button on the remote
controller or built into the VCR manual controls. Another way is to use one key, such
as the PROG key and push it multiple times within a certain period of time such as
15 twice to specify daily or thrice to specify weekly. For example, if the G-code switch
is "ON" and the G-code for the desired program is 99 then daily recording of the
program can be selected by the following keystrokes:

"PROG 99 DAILY PROG"

or by:

20 "PROG 99 PROG PROG".

The G-code 99 would be converted to CDTL information, which would be stored and
used daily in this case. The recording would begin on the date specified and continue
daily after that using the same channel time and length information. A slight twist is
that daily recording could be automatically suspended during the weekends, because
25 most daily programs are different on Saturday and Sunday.

Once a daily or weekly program is set up, then it can be used indefinitely.
If it is desired to cancel a program and if there is a "CANCEL" button on the remote
controller or manual control for the VCR, then one way to cancel a program (whether
it is a normal CDTL, daily or weekly entry) is to key in the following:

30 "PROG xx CANCEL", where xx is the G-code.

Again as before there are alternate ways of accomplishing this.

If "on screen programming" is available, then the programs that have been
selected for timer preprogramming could be reviewed on the screen. The daily and
weekly programs would have an indication of their type. Also the G-codes could be
35 displayed along with the corresponding CDTL information. This would make it quite
easy to review the current "menu" and either add more programs or cancel programs
as desired.

1 A television calendar 200 according to this invention is illustrated in FIG. 8.
As shown, the television calendar has multiple day of year sections 202, multiple day
sections 204, multiple time of day sections 206, channel identifiers 208, and descriptive
5 program identifiers 210, including the name of the program, arranged in a manner that
is common in television guide publications. Arranged in relation to each channel
identifier is a compressed code indication 212 or G-code containing the channel, date,
time and length information for that entry in the television calendar. FIG. 8 shows
how easy it is to perform timer programming. All one needs to do is find the program
one wants to watch and enter the compressed code shown in the compressed code
10 indication. This is in contrast to having to deal with all the channel, date, time and
length entries separately. At least the channel, date and time are explicitly stated in the
television guide. The length is usually only available by searching the guide to find
the time of day section 206 where a new program begins and then performing some
arithmetic to find the length of the program. Using the compressed G-code avoids all
15 these complications.

For cable television programs, there is an additional issue that needs to be
addressed for the compressed G-code to be useful. In a normal television guide,
CDTL information is available for all the normal broadcast channels in the form of
numbers including the channel numbers, such as channel 4 or 7. However, for cable
20 channels like HBO, ESPN etc., only the names of the channels are provided in most
television listings. The reason for this is that in some metropolitan areas, such as Los
Angeles, there may be only one (1) edition of television guide, but there may be quite
a few cable carriers, each of which may assign HBO or ESPN to different cable
channel numbers. In order for a compressed code such as the G-code to be applicable
25 to the cable channels as published by a wide area television guide publication, the
following approach can be used.

First, all the cable channels would be permanently assigned a unique number,
which would be valid across the nation. For example, we could assign ESPN to cable
channel 1, HBO as cable channel 2, SHO as cable channel 3, etc. This assignment
30 would be published by the television guide publications.

The video cassette recorder apparatus, such as the remote controller, the VCR
unit or both, could then be provided with two (2) extra modes: "set" and "cable
channel". One way of providing the user interface to these modes would be to provide
two (2) extra buttons: one called SET and one called CABLE CHANNEL. The
35 buttons could be located on the video cassette recorder unit itself or located on a
remote controller, as shown in FIGs 1, 3 and 5, where SET is element 168 and
CABLE CHANNEL is element 170. Of course, other user interfaces are possible.

-23-

Next, the television viewer would have to go through a one-time "setting" procedure of his VCR for all the cable channels that he would likely watch. This "setting" procedure would relate each of the assigned numbers for each cable channel to the channel number of the local cable carrier. For example, suppose that the local cable carrier uses channel 6 for ESPN, then cable channel number 1 could be assigned to ESPN, as shown in the following table.

	<u>Cable Channel</u>	<u>Assigned</u>	<u>Channel Number in</u>
	<u>Name</u>	<u>Cable Chan. No.</u>	<u>the local cable carrier</u>
10	ESPN	1	6
	HBO	2	24
	SHO	3	23
	.	.	.
	.	.	.
15	.	.	.
	DIS	8	25

The user could perform the "setting" procedure by pushing the buttons on his remote controller as follows:

20

SET 06 CABLE CHANNEL 1 PROGRAM
 SET 24 CABLE CHANNEL 2 PROGRAM
 SET 23 CABLE CHANNEL 3 PROGRAM
 SET 25 CABLE CHANNEL 8 PROGRAM

25

The "setting" procedure would create a cable channel address table 162, which would be loaded into RAM 52 of command controller 36. For the above example, the cable channel address table 162 would have the following information.

30

CABLE CHANNEL ADDRESS TABLE 162

35

1	6
2	24
3	23
.	.
.	.
.	.
8	25

-24-

1 After the "setting" procedure is performed, the TV viewer can now select cable
channels for viewing by the old way: e.g. pushing the key pad buttons 24 will select
HBO. He can also do it the new way: e.g. by pushing CABLE CHANNEL 2, which
5 will also select HBO. The advantage of the new way is that the television guide will
publish [C2] next to the program description, so the viewer will just look up the
assigned channel number identifier instead of having to remember that HBO is local
cable channel 24. When the CABLE CHANNEL button is pushed, command
controller 36 knows that it will look up the local cable channel number in cable channel
10 address table 162 to tune the VCR to the correct channel.

10 For timer preprogramming and for using the compressed G-code, a way to
differentiate between broadcast and cable channels is to add an eighth channel bit,
which would be set to 0 for normal broadcast channels and 1 for cable channels such
as HBO. This eighth channel bit could be one of the low order bits such as the third
15 bit C_3 out of the eight channel bits, so that the number of bits to specify popular
channels is minimized, whether they be normal broadcast or cable channels. For a
normal broadcast channel, the 7 other bits can be decoded according to priority vector
C table 124. For a cable channel, the 7 other bits can be decoded according to a
separate cable channel priority vector table 160, which could be stored in ROM 54 of
20 microcontroller 36. The cable channel priority vector table can be set ahead of time
for the entire country or at least for an area covered by a particular wide area television
guide publication.

A television guide that carries the compressed code known as the G-code will
now print the cable channel information as follows:

6:30 pm
25 [C2] HBO xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx (4679)
xxxxxxxx (program description) xxxxxxxx
xx

30 The [C2] in front of HBO reminds the viewer that he needs only to push CABLE
CHANNEL 2 to select HBO. The (4679) is the G-code indication for this particular
program.

35 FIG. 8 shows a section of a television guide. The cable channels all have an
assigned cable channel number 188 in front of the cable channel mnemonic. Other
than that the cable channel information is arranged the same as the broadcast channels
with a compressed G-code 212 associated with the channel.

For timer preprogramming, the viewer need only enter the number 4679
according to the unit's G-code entry procedure, e.g. PROG 4679 PROG. The G-code

1 decoder unit will decode this G-code into "cable channel 2" and will also signal the
command controller 36 with a cable channel signal 164, as shown in FIGs. 1 and 2,
because the extra channel bit will be "1" which distinguishes that the G-code is for a
cable channel; then, since the association of "cable channel 2" with channel 24 has
5 been established earlier in the "setting" procedure, the command controller, if it has
received a cable channel signal, will immediately look up 2 in the cable channel
address table 162 to translate it to cable channel 24, which will be used as the
recording channel at the appropriate time. By associating the G-code with the assigned
cable channel number rather than the local cable channel number, the G-code for that
10 program will be valid in the whole local area, which may have many different cable
carriers each of which may have different local cable channel numbers.

To include the cable channel compressed G-code feature, the decoding and
encoding algorithms are as shown in FIGs 9 and 10, respectively. The encoding
should be explained first before the decoding. The primary change in FIG. 10 from
15 FIG. 7 is that a cable channel priority vector table 160 has been added and is used in
look up priority step 180 if a cable channel is being encoded. Also if a cable channel
is being encoded then the cable channel bit is added in the correct bit position in the
convert $C_p D_p T_p L_p$ to binary numbers step 182. This could be bit C_3 , as discussed
before. The bit hierarchy key could be determined as before to compress the number
20 of bits in the most popular programs; however, it needs to be 23 bits long to
accommodate the cable channel bit. The maximum compressed G-code length could
still be 7 digits, because $2^{23} = 8,388,608$.

The decoding is shown in FIG. 9 and is just the reverse of the encoding
process. After step 108, test cable channel bit 174 is added and effectively tests the
25 cable channel bit to determine if it is a "1". If so then the command controller 36 is
signaled via cable channel signal 164 of FIGs. 1 and 2 that the CDTL 118 that will be
sent to it from G-code decoder 38 is for a cable channel. Then the command controller
knows to look up the local cable carrier channel number based on the assigned cable
channel number. In step 176 of FIG. 9, the priority vector tables including the cable
30 channel priority vector table 160 are used to look up the CDTL 118 information.

An alternate to having the command controller receive a cable channel signal
164 is for the G-code decoder to perform all of the decoding including the conversion
from assigned cable channel number to local cable carrier number. This would be the
case for the remote controller implementation of FIG. 3. FIG. 11 shows the
35 implementation of the entire decode algorithm if this step is included. All that needs
to be added is convert assigned channel to local cable carrier channel step 166, which

1 performs a lookup in cable channel address table 162, if the cable channel bit indicates that a cable channel is involved. Step 166 effectively replaces step 174 in FIG. 9.

Another issue that needs addressing is the number of programs that can be preprogrammed. Since the G-code greatly simplifies the process of entering programs, it is likely that the user will quickly learn and want to enter a large number of programs; however, some existing VCRs can only store up to four (4) programs, while some can store as many as eight. Thus, the user may get easily frustrated by the programming limitations of the VCR.

One approach to this problem, is to perform the compressed G-code decoding in the remote controller and provide enough memory there to store a large number of programs, e.g. 20 or 40. The remote controller would have the capability of transferring periodically several of these stored programs at a time to the VCR main unit. To provide this capability, extra memory called stack memory 76 is required inside the remote unit, as shown in FIG. 12, which other than that is identical to FIG. 4. Stack memory 76 can be implemented with a random access memory, which may in fact reside in the microcontroller itself, such as RAM 62.

The stack memory 76 is where new entry, insertion & deletion of timer preprogramming information is carried out. It is also where editing takes place. The top memory locations of the stack, for example the first 4 locations, correspond exactly to the available timer preprogramming memory in the VCR main unit. Whenever the top of the stack memory is changed, the new information will be sent over to the VCR main unit to update it.

FIG. 13 shows the sequence of events when the user enters a G-code program on the keypad of the remote controller. For illustration purposes, suppose the VCR main unit can only handle four (4) programs. Suppose also that the stack memory capacity is 20 timer preprograms. Referring to the flow chart in FIG.13, when the user enters a G-code in step 230, the microcontroller 60 first decodes it into the CDTL information in step 234 and displays it on the display unit with the additional word "entered" also displayed. The microcontroller then enters the decoded program into the stack memory in step 236.

If this is the first program entered, it is placed at the top location of the stack memory. If there are already programs in the stack memory, the newly entered program will first be provisionally placed at the bottom of the stack memory. The stack memory will then be sorted into the correct temporal order in step 240, so that the earliest program in time will appear in the top location and the last program in time will be at the bottom. Notice that the nature of the temporally sorted stack memory

-27-

1 is such that if stack memory location n is altered, then all the locations below it will be altered.

For example, suppose the stack memory has six (6) entries already temporally ordered, and a new entry is entered whose temporal ordering places it in location 3 (1 being the top location). If this entry is placed into location 3, information which was in location 3, 4, 5, 6 will be shifted to locations 4, 5, 6, and 7. Locations 1 and 2 will remain unchanged.

The microcontroller 60, after doing the temporal ordering, checks in step 242 whether the first n entries have changed from before, where for the current example n equals 4. In this case, since a new program has been entered into location 3, what used to be in location 3 now moves to location 4. Since the VCR's main unit program menu of 4 entries should correspond exactly to location 1 through 4 of the stack memory, entries 3 and 4 on the VCR main unit must now be revised. The microcontroller therefore sends out the new entries 3 & 4 to the main unit, in step 244 of FIG. 13. If the newly entered program, after temporal ordering, gets entered into location 5, then entries 1 through 4 have not changed from before and the microcontroller will not send any message to the VCR main unit and the microcontroller will just resume monitoring the clock 85 and the keyboard 88 as per step 246. It is assumed that when the user enters the G-code in step 230, the remote controller is pointed at the VCR main unit. The other steps of FIG. 13 happen so fast that the changes are sent in step 244 while the remote controller is still being pointed at the VCR main unit.

If the user decides to delete a program in step 232, the deletion is first carried out in the stack memory. If the first 4 entries are affected, the microcontroller will send the revised information over to the VCR main unit. If the first 4 entries are not affected, then again the remote controller unit will not send anything. The deletion will only change the lower part of the stack (lower meaning location 5 to 20). This new information will be sent over to the VCR main unit at the appropriate time.

In the meantime, the VCR main unit will be carrying out its timer programming function, completing its timing preprogramming entries one by one. By the time all 4 recording entries have been completed, the stack in the remote must send some new entries over to "replenish" the VCR main unit (if the stack has more than 4 entries).

The real time clock 85 in the remote controller unit is monitored by the microcontroller to determine when the programs in the main unit have been used up. Referring to the flow chart in FIG. 14, the microcontroller periodically checks the clock and the times for the programs at the top of the stack in step 250 (say the first

1 4 entries), which are identical to the VCR's main unit's menu. If on one of the
periodic checks, it is determined that the recording of the main unit's menu is
complete, then if there are more entries in the stack, which is tested in step 252, the
5 display unit will be set to a blinking mode or display a blinking message in step 258
to alert the user to send more programs. Next time the user picks up the remote unit,
the blinking will remind him that the VCR main unit's program menu has been
completed and it is time to replenish the VCR main unit with program entries stored
in the remote. The user simply picks up the remote and points it towards the VCR
10 main unit and presses "ENTER". This will "pop" the top of the stack memory in step
260, i.e. pop all the entries in the stack up by four locations. The microcontroller will
then send the new "top of the stack" (i.e. top 4 entries) over to the VCR main unit in
step 262. This process will repeat until the whole stack has been emptied.

Another preferred embodiment of an apparatus for using compressed codes for
recorder preprogramming is the instant programmer 300 of FIG. 15. The instant
15 programmer 300 has number keys 302, which are numbered 0 through 9, a CANCEL
key 304, a REVIEW key 306, a WEEKLY key 308, a ONCE key 310 and a DAILY
(M-F) key 312, which are used to program the instant programmer 300. A lid
normally covers other keys, which are used to setup the instant programmer 300.
When lid 314 is lifted, the following keys are revealed: SAVE key 316, ENTER key
20 318, CLOCK key 320, CH key 322, ADD TIME key 324, VCR key 326, CABLE key
328, and TEST key 330. Other features of instant programmer 300 shown on FIG.
15 are: liquid crystal display 350 and red warning light emitting diode 332. The front
elevation view FIG. 16 of instant programmer 300 shows front infrared (IR) diode 340
mounted on the front side 338. By placing instant programmer 300 in front of the
25 equipment to be programmed such as video cassette recorder 370, cable box 372, and
television 374, as shown in FIG. 19, the front infrared (IR) diode 340 can transmit
signals to control program recording. An IR transparent cover 336 covers additional
IR transmission diodes, which are explained below.

FIG. 18 shows a detail of the liquid crystal display 350. Certain text 354 is
30 at various times visible on the display and there is an entry area 356. Time bars 352
are displayed at the bottom of the display and their function is described below.

A companion element to the instant programmer 300 is the mounting stand
360, shown in FIG. 17, which is designed to hold instant programmer 300 between left
raised side 362 and right raised side 364. The instant programmer 300 is slid between
35 left raised side 362 and right raised side 364 until coming to a stop at front alignment
flange 365, which is at the front of mounting stand 360 and connected across left raised
side 362 and right raised side 364, as shown in FIG. 17A. Together elements 362, 364

1 and 365 provide alignment for instant programmer 300 so that IR transparent cover 336
and the IR diodes 342, 344, 346 and 348, shown in FIG. 17 are properly aligned for
transmission, when the instant programmer is used as shown in FIG. 20. The
5 mounting stand 360 has an alignment flange 366, which has the purpose of aligning the
back edge of mounting stand 360, which is defined as the edge along which alignment
flange 366 is located, along the front side of a cable box or VCR, or similar unit as
shown in FIG. 20. When aligned as shown in FIG. 20, the mounting stand 360 aligns
the instant programmer 300 so that the left IR diode 342, down IR diode 344, two back
10 IR diodes 346 and right IR diode 348, as shown in FIG. 17, are in position to transmit
signals to video cassette recorder 370 and cable box 372, as necessary. If the VCR
and/or cable box functions are located within the television 374 itself, then the instant
programmer 300 could be positioned to transmit to the television 374, either in the
manner of FIG. 19 or by placing the mounting stand on top of the television in the
manner of FIG. 20.

15 By using mounting stand 360, the user only need to align the mounting stand
360, and the instant programmer 300 once with the equipment to be programmed rather
than having the user remember to keep the instant programmer 300 in the correct
location to transmit via front infrared (IR) diode 340, as shown in FIG. 19. Current
experience with various remote controllers shows that it is difficult at best to keep a
20 remote controller in a fixed location, for example, on a coffee table. The mounting
stand 360 solves this problem by locating the instant programmer 300 with the
equipment to be controlled. The left IR diode 342, down IR diode 344, two back IR
diodes 346 and right IR diode 348 are positioned to transmit to the left, downward,
backward, and to the right. The downward transmitter assumes that mounting stand
25 360 will be placed on top of the unit to be programmed. The left and right
transmission allows units to the left or right to be programmed. The backward
transmission back IR diodes 346 are provided so that signals can bounce off walls and
other objects in the room. The front IR diode 340, the left IR diode 342, the right IR
diode 348 and the down IR diode 344 are implemented with 25 degree emitting angle
30 diodes. Two back IR diodes are provided for greater energy in that direction and are
implemented with 5 degree emitting angle diodes, which focus the energy and provide
for greater reflection of the IR energy off of walls or objects in the room.

35 Most VCR's and cable boxes can be controlled by an infrared remote
controller; however, different VCR's and cable boxes have different IR codes.
Although there are literally hundreds of different models of VCR's and cable boxes,
there are fortunately only tens of sets of IR codes. Each set may have a few tens of
"words" that represent the different keys required, e.g. "power", "record", "channel

1 up", "channel down", "stop", "0", "1", "2" etc. For the purpose of controlling the
VCR and cable box to do recording, only the following "words" are required: "0",
"1", "2", "3", "4", "5", "6", "7", "8", "9", "power", "record", "stop". The IR codes
5 for these words for all the sets are stored in the memory of the instant programmer
300, which is located in microcomputer 380 of FIGs. 21 and 22. During setup of the
instant programmer 300, the user interactively inputs to the instant programmer 300
the type and model of his VCR and cable box. The correct set of IR codes will be
recalled from memory during the actual control process. In the case where the user
only has a VCR, the infrared (IR) codes for that particular VCR will be recalled to
10 control the VCR. In the case where the user has a VCR and a cable box, the IR codes
"power", "record", "stop" will be recalled from the set that corresponds to the VCR
whereas the IR codes for "0" through "9" will be recalled from the set that corresponds
to the cable box. The reason is that in this case, the cable box controls the channel
switching. Hence the channel switching signals "0" through "9" must be sent to the
15 cable box instead of the VCR.

Initially, the user performs a setup sequence. First, the user looks up the
number corresponding to the model/brand of VCR to be programmed in a table, which
lists the VCR brand name and a two digit code. Then with the VCR tuned to Channel
3 or Channel 4, whichever is normally used, the user turns the VCR "OFF". Then the
20 user presses the VCR key 326. When the display shows VCR, the user presses the
two-digit code looked up in the VCR model/brand table (for example 01 for RCA).
The user points the instant programmer 300 at the VCR and then presses ENTER key
318. The red warning light emitting diode 332 will flash while it is sending a test
signal to the VCR. If the VCR turned "ON" and changed to Channel 09, the user
25 presses the SAVE key 316 and proceeds to the set clock step. If the VCR did not turn
"ON" or turned "ON" but did not change to Channel 09 the user presses ENTER key
318 again and waits until red warning light emitting diode 332 stops flashing. The
instant programmer 300 sends the next possible VCR code, while the red warning light
emitting diode 332 is flashing. If the VCR turns "ON" and changed to Channel 09 the
30 user presses SAVE key 316, otherwise the user presses ENTER key 318 again until
the VCR code is found that works for the VCR. The display shows "END" if all
possible VCR codes for that brand are tried. If so, the user presses VCR key 326 code
00 and then ENTER key 318 to try all possible codes, for all brands, one at a time.

Once the proper VCR code has been found and saved, the next setup step is
35 to set the clock on instant programmer 300. First, the user presses the CLOCK key
320. When the display shows: "YR:", the user presses the year (for example 90), then
presses ENTER key 318. Then the display shows "MO:", and the user presses the

1 month (for example 07 is July), and then presses ENTER key 318. This is repeated
for "DA:" date (for example 01 for the 1st), "Hr:" hour (for example 02 for 2
o'clock), "Mn:" minute (for example 05 for 5 minutes), and "AM/PM:" 1 for AM or
2 for PM. After this sequence, the display will show "SAVE" for a few seconds and
5 then the display will show the current time and date that have been entered. It is no
longer necessary for the user to set the clock on his/her VCR.

Next, if the instant programmer 300 is also to be used as a cable box
controller, then the setup steps are as follows. First, the number corresponding to the
model/brand of cable box (converter) to be controlled is looked up in a cable box
10 model brand table, that lists cable box brands and corresponding two digit codes. The
VCR is tuned to Channel 03 or 04 and turned "OFF". Then the cable box is tuned to
Channel 02 or 03, whichever is normal, and left "ON". Then the CABLE key 328 is
pressed. When the display shows: "CA B-:" the user enters the two digit code looked
up in cable box model brand table, points the instant programmer 300 at the cable box
15 (converter) and presses ENTER key 318. The red warning light emitting diode 332
will flash while it is sending a test signal to the cable box. If the cable box changed
to Channel 09: then the user presses SAVE key 316; however, if the cable box did not
change to Channel 09 the user presses ENTER key 318 again and waits until red
warning light emitting diode 332 stops flashing, while the next possible code is sent.
20 This is repeated until the cable box changes to Channel 09 and when it does the user
presses SAVE key 316. If the display shows "END" then the user has tried all
possible cable box codes for that brand. If so, the user presses cable code 00 and then
ENTER key 318 to try all possible brand's codes, one at a time.

For some people (probably because they have cable or satellite), the channels
25 listed in their television guide or calendar are different from the channels on their
television or cable. If they are different, the user proceeds as follows. First, the user
presses the CH key 322. The display will look like this: "Guide CH TV CH". Then
the user presses the channel printed in the television guide or calendar (for example,
press 02 for channel 2), and then the user presses the channel number that the printed
30 channel is received on through his/her local cable company. Then the user presses
ENTER key 318. This is repeated for each channel listing that is on a different channel
than the printed channel. When this procedure is finished the user presses SAVE key
316.

Typically the television guide or calendar in the area will have a chart
35 indicating the channel number that has been assigned to each Cable and broadcast
channel, for example: HBO, CNN, ABC, CBS, NBC, etc. This chart would
correspond, for example, to the left two columns of FIG. 28. For example, suppose

-32-

1 the television guide or calendar has assigned channel 14 to HBO but the user's cable
company delivers HBO on channel 18. Since the channel numbers are different, the
user needs to use the CH key 322. The user will press the CH button (the two blank
spaces under the display "Guide CH" will flash). The user then presses 14. (now the
5 two blank spaces under the display "TV CH" will flash). The user then presses 18 and
then ENTER key 318. This is repeated for each channel that is different. When
finished, the user presses SAVE key 316.

After the channel settings have been saved, the user may review the settings
by pressing CH key 322 and then REVIEW key 306. By repeated pressing of the
10 REVIEW key 306 each of the set channels will scroll onto the display, one at a time.

Then the user can test to make sure that the location of the instant programmer
300 is a good one. First, the user makes sure that the VCR is turned "OFF" but
plugged in and makes sure that the cable box (if there is one) is left "ON". Then the
user can press the TEST key 330. If there is only a VCR, then if the VCR turned
15 "ON", changed to channel 09 and started recording, and then turned "OFF", then the
VCR controller is located in a good place.

If there is also a cable box, then if the VCR turned "ON", the cable box turned
to channel 09 and the VCR started recording, and then the VCR stopped and turned
"OFF", then the instant programmer 300 is located in a good place.

20 To operate the instant programmer 300, the VCR should be left OFF and the
cable box ON. The user looks up in the television guide the compressed code for the
program, which he/she wishes to record. The compressed code 212 is listed in the
television guide, as shown in FIG. 8. The television guide/calendar that would be used
with this embodiment would have the same elements as shown on FIG. 8 except that
25 element 188 of FIG. 8 is not required. The compressed code 212 for the program
selected by the user is entered into the instant programmer 300 by using the number
keys 302 and then the user selects how often to record the program. The user presses
the ONCE key 310 to record the program once at the scheduled time, or the user
presses the WEEKLY key 308 to record the program every week at the same scheduled
30 time until cancelled or the user presses the DAILY (M-F) key 312 to record the
program each day Monday through Friday at the same scheduled time until cancelled.
This is most useful for programs such as soapbox operas that air daily, but not on the
weekend. To confirm the entry, the instant programmer 300 will immediately decode
the compressed code and display the date, channel and start time of the program
35 entered by the user. The length of the entered program is also displayed by time bars
352 that run across the bottom of the display. Each bar represents one hour (or less)
of program.

-33-

1 Then the user just needs to leave the instant programmer 300 near the VCR and
cable box so that commands can be transmitted, and at the right time, the instant
programmer 300 will turn "ON" the VCR, change to the correct channel and record
the program and then turn the VCR "OFF". The user must just make sure to insert
5 a blank tape.

The REVIEW key 306 allows the user to step through the entered programs.
These are displayed in chronological order, by date and time. Each time the REVIEW
key 306 is pressed, the next program is displayed, until "END" is displayed, when all
the entered programs have been displayed. If the REVIEW key 306 is pressed again
10 the display will return to the current date and time.

If the user wishes to cancel a program, then the user presses REVIEW key 306
until the program to cancel is displayed, then the user presses CANCEL key 304. The
display will say "CANCELLED". Also, any time the user presses a wrong number,
pressing the CANCEL key 304 will allow the user to start over.

15 Certain television programs, such as live sports, may run over the scheduled
time slot. To ensure that the entire program is recorded, the user may press the ADD
TIME key 324 to increase the recording length, even while the program is being
recorded. The user presses the REVIEW key 306 to display the program, then presses
ADD TIME key 324. Each time ADD TIME key 324 is pressed, 15 minutes is added
20 to the recording length.

When the current time and date is displayed, the amount of blank tape needed
for the next 24 hours is also displayed by the time bars 352 that run across the bottom
of the display. Each bar represents one hour (or less) of tape. The user should check
this before leaving the VCR unattended to ensure that there is enough blank tape.

25 Each time a program code is entered, the instant programmer 300 automatically
checks through all the entries to ensure that there is no overlap in time between the
program entries. If the user attempts to enter a program that overlaps in time with a
program previously entered, then the message "CLASH" appears. Then, as
summarized by step 432 of FIG. 23, the user has the following options: 1) if the user
30 wishes to leave the program previously entered and forget about the new one, the user
does nothing and after a short time delay, the display will return to show the current
time and date; 2) if the user wishes the program which starts first to be recorded to its
end, and then to record the remainder of the second program, then the user presses
ONCE key 310, DAILY (M-F) key 312, or WEEKLY key 308 again (whichever one
35 the user pushed to enter the code). If the programs have the same starting time, then
the program most recently entered will be recorded first. If on being notified of the
"CLASH", the user decides the new program is more important than the previously

1 entered program, then the user can cancel the previously entered program and then re-enter the new one.

5 In some locations, such as in some parts of Colorado, the cable system airs some channels three (3) hours later/earlier than the times listed in the local television guide. This is due to time differences depending on whether the channel is received on a east or west satellite feed. For the user to record the program 3 hours later than the time listed in the television guide the procedure is as follows. First the user enters the code for the program and then presses SAVE key 316 (for +) and then presses ONCE key 310, DAILY (M-F) key 312, or WEEKLY key 308, as desired. For the user to record the program 3 hours earlier than the time listed in the television guide the procedure is as follows. First the user enters the code for the program and then presses ENTER key 318 (for -) and then presses ONCE key 310, DAILY (M-F) key 312, or WEEKLY key 308, as desired. The instant programmer 300 will display the time that the program will be recorded, not the time shown in the television guide.

15 There are certain display messages to make the instant programmer 300 more user friendly. The display "LO BATT" indicates that the batteries need replacement. "Err: ENTRY" indicates an invalid entry during set up. "Err: CODE" indicates that the program code number entered is not a valid number. If this is displayed the user should check the television guide and reenter the number. "Err: DATE" indicates the user may have: tried to select a daily recording (Monday to Friday) for a Saturday or Sunday program; tried to select weekly or daily recording for a show more than 7 days ahead, because the instant programmer 300 only allows the weekly or daily recording option to be used for the current weeks' programs (± 7 days); or tried to enter a program that has already ended. "FULL" indicates that the stack storage of the programs to be recorded, which is implemented in random access memory (RAM) inside the instant programmer 300 has been filled. The user could then cancel one or more programs before entering new programs. "EMPTY" indicates there are no programs entered to be recorded. The number of programs to be recorded that can be stored in the instant programmer 300 varies depending on the density of RAM available and can vary from 10 to more.

30 FIG. 21 is a schematic of the circuitry needed to implement the instant programmer 300. The circuitry consists of microcomputer 380, oscillator 382, liquid crystal display 384, key pad 386, five way IR transmitters 390 and red warning light emitting diode 332. The microcomputer 380 consists of a CPU, ROM, RAM, I/O ports, timers, counters and clock. The ROM is used for program storage and the RAM is used among other purposes for stack storage of the programs to be recorded. The liquid crystal display 384 is display 350 of FIGs. 15 and 18. The key pad 386

-35-

1 implements all the previously discussed keys. The five way IR transmitters 390
consists of front infrared (IR) diode 340, left IR diode 342, down IR diode 344, two
back IR diodes 346 and right IR diode 348. FIG. 22 shows the detailed schematic of
the instant programmer 300 circuitry and previously identified elements are identified
5 by the same numbers. The microcomputer can be implemented with a NEC uPD7530x
part, which can interface directly with the display, the keypad, the light emitting diodes
and the oscillator. The 25 degree IR diodes can be implemented with NEC 313AC
parts and the 5 degree IR diodes can be implement with Litton 2871C IR diodes.

The flow charts for the program that is stored in the read only memory (ROM)
10 of the microcomputer 380 that executes program entry, review and program
cancellation, and record execution are illustrated in FIGs. 23, 24, and 25, respectively.
The FIG. 23 for program entry, which process was described above, consists of the
following steps: display current date, time and time bars step 402, which is the
quiescent state of instant programmer 300; scan keyboard to determine if numeric
15 decimal compressed code entered step 404; display code as it is entered step 406; user
checks if correct code entered step 408 and user presses CANCEL key 304 step 428;
user advances or retards start time by three hours by pressing SAVE key 316 or
ENTER key 318 step 410; user presses ONCE key 310, WEEKLY key 308 or DAILY
key 312 key step 412; microcomputer decodes compressed code into CDTL step 414;
20 test if conflict with stored programs step 416, if so, display "CLASH" message step
420, user presses ONCE key 310, WEEKLY key 308 or DAILY key 312 step 422,
then accommodate conflicting entries step 432, as described above in the discussion of
the "CLASH" options, and entry not saved step 424; set display as date, channel, start
time and duration (time bars) for ONCE, or DA, channel, start time and duration for
25 DAILY, or day of week, channel, start time and duration for WEEKLY step 418; user
presses ADD TIME key 324, which adds 15 minutes to record time step 426; user
checks display step 430; enter program on stack in chronological order step 434
wherein the stack is a portion of the RAM of microcontroller 380; and calculate length
of tape required and update time bars step 436.

30 The FIG. 24 flow chart for review and cancellation, which process was
described above, consists of the following steps: display current date, time and time
bars step 402; REVIEW key 306 pressed step 442; test if stack empty step 444, display
"EMPTY" step 446, and return to current date and time display step 448; display top
stack entry step 450; user presses ADD TIME key 324 step 452 and update time bars
35 step 460; user presses REVIEW key 306 step 454 and scroll stack up one entry step
462; user presses CANCEL key 304 step 456 and display "CANCELLED" and cancel
program step 464; and user does nothing step 458 and wait 30 seconds step 466,

1 wherein the 30 second timeout can be implemented in the timers of microcomputer 380.

5 The FIG. 25 flow chart for record execution, which is the process of automatically recording a program and which was described above, consists of the following steps: compare start time of top program in stack memory with current time step 472; test if three minutes before start time of program step 474; start red warning LED 332 blinking for 30 seconds step 476; display channel, start time and blinking "START" message step 478, is correct start time reached step 480 and send power ON signal to VCR and display "REC" message step 482; test if a cable box is input to VCR step 484, send channel switching signals to VCR step 486 and send channel switching signals to cable box step 488; send record signals to VCR step 490; compare stop time with current time step 492, test if stop time reached step 494 and display "END" message step 496; send stop signals to VCR step 498; send power OFF signal to VCR step 500; and pop program stack step 502.

15 FIG. 26 is a flow chart of the method for encoding channel, date, time and length (CDTL) into decimal compressed code 510. This process is done "offline" and can be implemented on a general purpose computer and is done to obtain the compressed codes 212 that are included in the program guide or calendar of FIG. 8. The first step in the encoding method is the enter channel, date, time and length (CDTL) step 512 wherein for a particular program the channel, date, start time and length CDTL 514 of the program are entered. The next step is the lookup assigned channel number step 516, which substitutes an assigned channel number 522 for each channel 518. Often, for example for network broadcast channels, such as channel 2, the assigned channel number is the same; however, for a cable channel such as HBO a channel number is assigned and is looked up in a cable assigned channel table 520, which would essentially be the same as the first two columns of the table of FIG. 28. Next, the lookup priority of channel, date and time/length in priority vector tables step 524 performs a lookup in priority vector channel (C) table 526, priority vector date (D) table 528 and priority vector time/length (TL) table 530 using the indices of channel, date and time/length, respectively, to produce the vector C_p , D_p , TL_p 532. The use of a combined time/length (TL) table to set priorities recognizes that there is a direct relationship between these combinations and the popularity of a program. For example, at 6:30 PM, a short program is more likely to be popular than a 2 hour program, because it may be the dinner hour.

35

1 The channel priority table is ordered so that the most frequently used channels
have a low priority number. An example of the data that is in the priority vector C
table 526 follows.

5

channel	4	7	2	3	5	6	11	13	...
priority	0	1	2	3	4	5	6	7	...

10 Generally the dates of a month all have an equal priority or equal usage, so the
low number days in a month and the low number priorities would correspond in the
priority vector D table 528 as in the following example.

date	1	2	3	4	5	6	7	8	9	10	...
priority	0	1	2	3	4	5	6	7	8	9	...

15 The priority of the start times and length of the programs could be arranged
in a matrix that would assign a priority to each combination of start times and program
lengths so that more popular combinations of start time and length would have a low
priority number and less popular combinations would have a high priority number.
For example, a partial priority vector T/L table 530 might appear as follows.

		Priority TL Table				
	TIME	6:30pm	7:00pm	7:30pm	8:00pm	...
	Length (hrs)					
25	.5	8	4	7	10	
	1.0	12	15	13	18	
	1.5	20	19	17	30	

30 Suppose the channel, date, time and length (CDTL) 514 data is channel 5,
February 10, 1990, 7:00PM and 1.5 hours in length, then the C_p, D_p, TL_p data 532 for
the above example would be 4 9 19. The next step is the convert C_p, D_p, TL_p to
binary numbers and concatenate them into one binary number step 534, resulting in the
data word $...TL_2TL_1...C_2C_1...D_2D_1$ 536. For the example given above, converting the
 $...TL_2TL_1...C_2C_1...D_2D_1$ 536 word to binary would yield the three binary numbers:
...0010011, ...0100, ...01001. The number of binary bits to use in each conversion
35 is determined by the number of combinations involved. This could vary depending on
the implementation; however one preferred embodiment would use eight bits for C_p ,
denoted as $C_8 C_7 C_6 C_5 C_4 C_3 C_2 C_1$, which would provide for 256 channels, five bits

-38-

1 for D_p , which can be denoted as $D_5 D_4 D_3 D_2 D_1$, would provide for 31 days in a
 month, and fourteen bits for TL_p , denoted as $TL_{14} \dots TL_3 TL_2 TL_1$, which would
 provide for start times spaced every 5 minutes over 24 hours and program lengths in
 increments of 5 minute lengths for programs up to 3 hours in length and program
 5 length in increments of 15 minute lengths for programs from 3 to 8 hours in length.
 This requires about $288 \times (36 + 20) = 16,128$ combinations, which are provided by the
 $2^{14} = 16,384$ binary combinations. Altogether there are $8 + 5 + 14 = 27$ bits of
 information $TL_{14} \dots TL_2 TL_1 C_8 \dots C_2 C_1 D_5 \dots D_2 D_1$. For the above example padding each
 number with zeros and then concatenating them would yield the 27 bit binary number:
 10 00000000100110000010001001.

The next step is to use bit hierarchy key 540, which can be stored in read only
 memory 64 to perform the reorder bits of binary number according to bit hierarchy key
 step 538. As described previously, a bit hierarchy key 540 can be any ordering of the
 $\dots TL_2 TL_1 \dots C_2 C_1 \dots D_2 D_1$ 536 bits and in general will be selected so that programs most
 15 likely to be the subject of timer preprogramming would have a low value compressed
 code 212, which would minimize keystrokes. The ordering of the bit hierarchy key
 can be determined by the differential probabilities of the various bit combinations as
 previously discussed. The details of deriving a bit hierarchy key 540 were described
 relative to bit hierarchy key 120 and the same method can be used for bit hierarchy key
 20 540. For example, the bit hierarchy key might be:

TL_8	C_3	...	TL_{10}	C_2	TL_1	C_1	L_1	D_5	D_4	D_3	D_2	D_1
27	26	...	10	9	8	7	6	5	4	3	2	1

25 The next step is the combine groups of bits and convert each group into
 decimal numbers and concatenate into one decimal number step 542. For example,
 after reordering according to the bit hierarchy key, the code may be
 000000001010010000010001001, which could be grouped as
 00000000101001000,0010001001. If these groups of binary bits are converted to
 30 decimal as 328,137 and concatenated into one decimal number, then the resulting
 decimal number is 328137. The last encoding step is the permute decimal number step
 546, which permutes the decimal number according to permutation function 544 that
 is dependent on the date 548 and in particular the month and year and provides a
 security feature for the codes. After the permute decimal number step 546, the decimal
 35 compressed code $G_8 \dots G_2 G_1$ 550 may, for example, be 238731. These encoded codes

1 are then included in a program guide or calendar as in the compressed code indication
212 of FIG. 8.

5 FIG. 27 is a flow chart of the method for decoding a decimal compressed code
into channel, date, time and length 560, which is step 414 of FIG. 23. Once the
decimal compressed code $G_8 \dots G_2 G_1$ 564 is entered in step 562, it is necessary to invert
the permutation function of steps 544 and 546 of FIG. 26. The first step is the extract
day code step 566, which extracts the day code for the program in the decimal
compressed code and passes the day code to step 568, which also receives the current
10 day 574 from the clock 576, which is implemented by microcomputer 380 in FIGs. 21
and 22. The clock 576 also sends the current month and year to the permutation
function 570, which is dependent on the month and year. Then step 568 performs the
function: if day code is same or greater than current day from clock, then use
permutation function for month/year on clock, otherwise use permutation function for
15 next month after the month on the clock and use next year if the month on the clock
is December. In other words, since there is provision for preprogramming recording
for one month or 31 days ahead, if the day for the program is equal to or greater than
the current day of the month, then it refers to a day in the present month; otherwise,
if the day for the program is less than the current day of the month, it must refer to
a program in the next month. The extract day code step 566, which must be
20 performed before the invert permutation of decimal compressed code step 580, is
accomplished by *a priori* knowledge of how the permute decimal number step 546 of
FIG. 26 is performed relative to the day code information.

The selected permutation method 578 is used in the invert permutation of
decimal compressed code step 580. For the example given above, the output of step
25 580 would be: 328137. The next step is the convert groups of decimal numbers into
groups of binary numbers and concatenate binary groups into one binary number step
584, which is the inverse of step 542 of FIG. 26 and for the above example would
result in the binary code: 000000001010010000010001001. Then the bit hierarchy
key 588 is used in the reorder bits of binary number according to bit hierarchy key
30 586, which inverts step 538 of FIG. 26 to obtain 000000000100110000010001001 for
the above example, which is $\dots TL_2 TL_1 \dots C_2 C_1 \dots D_2 D_1$ 582 corresponding to 536 of
FIG. 26. The next step is to group bits to form three binary numbers TL_b , C_b , D_b and
convert to decimal numbers step 590 resulting in C_p , D_p , TL_p 592, which for the
example above would be: 4, 9, 19, and which are priority vectors for channel, day
35 and time/length, which in turn are used to lookup channel, day, time and length 604
in priority vector channel (C) table 598, priority vector date (D) table 600, and priority
vector time/length (TL) table 602, respectively.

1 The lookup local channel number step 606 looks up the local channel 612 given
the assigned channel number 608, in the assigned/local channel table 610, which is
5 setup by the user via the CH key 322, as explained above. An example of the
assigned/local channel table 610 is the right two columns of the assigned/local channel
table 620 of FIG. 28. The correspondence between the assigned channel numbers,
such as 624 and 628, and the local channel numbers, such as 626 and 630 is
10 established during setup by the user. For the example, FIG. 28 shows an exact
correspondence between the assigned channel number 5 and the local channel number
5. The last step is the append month and year to day to form date step 614. The
correct month and year are obtained from step 568 and are again dependent on whether
the day code is equal to or greater than the day from the clock or less than the day
from the clock. If the day code is equal to or greater than the day from the clock, the
month and year as shown on the clock are used, otherwise the next month is used and
the next year is used if the clock month is December. The result is the channel, date,
15 time and length (CDTL) 618, which for the above example would be channel 5,
February 10, 1990, 7:00PM and 1.5 hours in length.

Another preferred embodiment is to embed the decoding means into a television
receiver with G-code decoder 950, as shown in FIG. 29, which is a block diagram of
20 a system including a television receiver having a G-code decoder. The user would use
the television remote controller 956 or controls on the television receiver to enter the
code that signifies the program to be recorded. The same television remote and
controls on the television would also be used to perform normal television control
functions, such as channel selection. When a G-code is entered, the television remote
would send the G-code to the television with G-code decoder 950 via infrared
25 transmitter 958. An infrared receiver 960 on the television receiver 950 would receive
the transmission and send the code to the G-code decoder 954, which would decode the
code into CDTL and use this information along with a clock, which would also be
embedded in the television receiver 950, to send the proper commands to the VCR 964
and cable box 966 at the appropriate time so that the selected program will be recorded
30 at the proper time. The transmission from the television 950 would be via infrared
transmitters 962, which can be placed at strategic points on the television cabinet, such
as at the corners. The transmission is then received by the VCR 964 via infrared
receiver 968 and the cable box 966 via infrared receiver 969.

FIG. 30 is a schematic of a television receiver having a G-code decoder. The
35 television receiver with G-code decoder 950 would receive signals from the television
remote controller 956 via infrared receiver 960, which would send the signals to either
command controller 974 or directly to G-code decoder 954. The command controller

1 974 may be present in the television receiver to control other items in the television,
including "on screen" functions such as displaying the channel number when the
channel is changed. The G-code decoder 954 would decode a sent G-code and using
the date and time from clock 976 would send the proper commands to the VCR 964
5 and cable box 966 via infrared transmitters 962. The G-codes and other commands
could also be sent to the command controller via manual control 975. When the G-
code is decoded, then the G-code and the decoded CDTL information could be
displayed "on screen" as shown in on screen display 978 on television display/monitor
952. The "on screen" display is not necessary and any format is optional.

10 FIG. 31 is a schematic showing apparatus for a G-code decoder in a television
receiver having G-code decoding. The circuitry is very similar to that described in
FIGs. 21 and 22; however, there are interfaces to an infrared receiver 960 and
command controller 974 rather than LCD 384 and Key Pad 386. The key elements are
15 microcontroller 980 and oscillator 982. The interface to command controller 974 is
one preferred embodiment; another embodiment could have direct interfaces between
the manual control 975, the infrared receiver 960, the television display/monitor 952
and the G-code decoder 954 without going through the intermediary command
controller 974. The television circuitry would include the capability of storing or
20 learning the infrared code protocols for the VCR and the cable box. The warning light
emitting diode 984 would be mounted on the cabinet of the television to warn that
recording was about to begin in order to alert the user to have the VCR ready with tape
to record.

25 With the "on screen" display on television display/monitor 952, the operation
of the television receiver with G-code decoder 950 can be essentially identical to that
described in FIGs. 23, 24 and 25 for program entry, program review and program
cancellation, and execution of recorder preprogramming using compressed codes,
respectively. Every that was displayed on LCD 384 would instead be displayed on the
television monitor 952. The only difference would be that "on screen" would only
30 perform step 402 (display current date, time and time bars) when the user put television
remote controller 956 into a mode for G-code entry and transmission, program review
or program cancellation. The method of encoding program channel, date, time and
length information into decimal compressed codes of FIG. 26, the method of decoding
decimal compressed codes into program channel, date, time and length information of
FIG. 27, and the method of assigning channel numbers to local channel numbers as
35 illustrated in FIG. 28 would stay the same.

Another preferred embodiment of the invention is to embed the decoding means
into various equipments associated with television, such as a video cassette recorder,

1 cable box or satellite receiver. In any system the decoding means would only have to
be present in one of the equipments, such as the cable box, which would then at the
appropriate time distribute the proper commands to the other equipments such as a
VCR and a satellite receiver to record the desired program.

5 FIG. 32 is a block diagram of a system including a television having a G-code
decoder 950, a VCR 964, a cable box 966 and a satellite receiver 986. This system
would work identically to the system shown in FIG. 29, except that a satellite receiver
is included, which could receive commands via infrared receiver 988 from infrared
transmitters 962 mounted on television receiver with G-code decoder 950. The
10 commands received by the satellite receiver could include on/off commands and
channel select commands. The satellite receiver 986 could feed a television signal to
VCR 964, which would record the program and/or relay it to television
display/monitor 952.

FIG. 33 is a block diagram of a system including a VCR having a G-code
15 decoder 991, a television 952, a cable box 966 and a satellite receiver 986. The user
would use the television remote controller 956 or controls on the VCR 991 to enter the
code that signifies the program to be recorded. When a G-code is entered, the
television remote would send the G-code to VCR 991 with G-code decoder 992 via
infrared transmitter 958. An infrared receiver 990 on the VCR 991 would receive the
20 transmission and send the code to the G-code decoder 992, which would decode the
code into CDTL and use this information along with a clock, which would also be
embedded in the VCR 991, to send the proper commands to the cable box 966 and the
satellite receiver 986 at the appropriate time so that the selected program will be
recorded at the proper time. The transmission from the VCR 991 would be via
25 infrared transmitters 994, which can be placed at strategic points on the VCR. The
transmission is then received by the cable box 966 via infrared receiver 969 and the
satellite receiver 986 via infrared receiver 988.

Another preferred embodiment of the transmission method and apparatus
between equipments is shown in FIG. 36, which is a perspective view showing a cable
30 box 372 placed on top of a VCR 370 having an infrared transmitter 1008 behind the
front panel 1009 which communicates to the cable box infrared receiver 1010 via
reflection from surrounding reflecting surfaces such as walls.

Another preferred embodiment of the transmission method and apparatus
between equipments is shown in FIG. 37, which is a perspective view showing a cable
35 box 372 placed on top of a VCR 370 having an infrared transmitter 1014 inside a
infrared dome 1012 on the top of the VCR which communicates to the cable box

1 infrared receiver 1010 via direct communication or reflection depending on placement
of the infrared receiver 1010 relative to infrared dome 1012.

Another preferred embodiment of the transmission method and apparatus
between equipments is shown in FIG. 38, which is a perspective view of a VCR 370
5 having an infrared transmitter 1022 inside a mouse 1020 coupled via a cable 1018,
which is plugged via plug 1017 into receptacle 1016 on the VCR. The mouse 1020
is placed near the cable box infrared receiver 1010. This embodiment is most useful
when the cable box is separated from the VCR by walls of a cabinet, for example, that
would prevent either direct or reflective infrared transmission.

10 Another preferred embodiment of the transmission method and apparatus
between equipments is shown in FIG. 39, which is a perspective view of a VCR 370
having an infrared transmitter 1026 inside a stick on miniature mouse 1024 coupled via
a cable 1018, which is plugged via plug 1017 into receptacle 1016 on the VCR. The
stick on miniature mouse 1024 is stuck onto the cable box very near the infrared
15 receiver 1010. This embodiment is also most useful when the cable box is separated
from the VCR by walls of a cabinet, for example, that would prevent either direct or
reflective infrared transmission.

The transmission methods and apparatus of FIGs. 36, 37, 38 and 39 could also
be used with the system of FIG. 32 to transmit information from television receiver
20 with G-code decoder 950 to VCR 964, cable box 966 and satellite receiver 986.

FIG. 34 is a block diagram of a system including a cable box having a G-code
decoder 997, a television 952, a VCR 964, and a satellite receiver 986. The user
would use the television remote controller 956 or controls on the cable box 997 to
enter the code that signifies the program to be recorded. When a G-code is entered,
25 the television remote would send the G-code to cable box 997 with G-code decoder 998
via infrared transmitter 958. An infrared receiver 996 on the cable box 997 would
receive the transmission and send the code to the G-code decoder 998, which would
decode the code into CDTL and use this information along with a clock, which would
also be embedded in the cable box 997, to send the proper commands to the VCR 964
30 and the satellite receiver 986 at the appropriate time so that the selected program will
be recorded at the proper time. The transmission from the cable box 997 would be via
infrared transmitters 1000, which can be placed at strategic points on the cable box.
The transmission is then received by the VCR 964 via infrared receiver 968 and the
satellite receiver 986 via infrared receiver 988. The transmission methods and
35 apparatus of FIGs. 36, 37, 38 and 39 could also be used with the system of FIG. 34
to transmit information from cable box 997 to VCR 964 and satellite receiver 986.

1 FIG. 35 is a block diagram of a system including a satellite receiver 1005
having a G-code decoder, a television 952, a VCR 964, and a cable box 966. The user
would use the television remote controller 956 or controls on the satellite receiver 1005
5 to enter the code that signifies the program to be recorded. When a G-code is entered,
the television remote would send the G-code to satellite receiver 1005 with G-code
decoder 1004 via infrared transmitter 958. An infrared receiver 1002 on the satellite
receiver 1005 would receive the transmission and send the code to the G-code decoder
1004, which would decode the code into CDTL and use this information along with a
10 clock, which would also be embedded in the satellite receiver 1005, to send the proper
commands to the VCR 964 and the cable box 966 at the appropriate time so that the
selected program will be recorded at the proper time. The transmission from the
satellite receiver 1005 would be via infrared transmitters 1006, which can be placed
at strategic points on the satellite receiver. The transmission is then received by the
VCR 964 via infrared receiver 968 and the cable box 966 via infrared receiver 969.
15 The transmission methods and apparatus of FIGs. 36, 37, 38 and 39 could also be
used with the system of FIG. 35 to transmit information from satellite receiver 1005
to VCR 964 and cable box 966.

 It is thought that the apparatus and method using compressed codes for
television program record scheduling of the present invention and many of its attendant
20 advantages will be understood from the foregoing description and it will be apparent
that various changes may be made in the form, construction and arrangement of the
parts thereof without departing from the spirit and scope of the invention or sacrificing
all of its material advantages, the form hereinbefore described being merely a preferred
or exemplary embodiment thereof.

25

30

35

-45-

1 WE CLAIM:

- 5 1. An apparatus for using compressed codes for recorder preprogramming that comprises:
- 10 a television receiver;
means for recording;
means for channel selection; and
means for entering into said television receiver compressed codes each having at least one digit and each representative of, and compressed in length from, the combination of channel, time-of-day, date and length commands for a program;
- 15 the television receiver comprising:
means for decoding each compressed code into channel, date, time and length commands;
means for storing said channel, date, time-of-day and length commands;
- 20 a clock with an output as a function of time;
means for reordering said channel, time-of-day, date and length commands in said means for storing into temporal order;
means for comparing said date and time-of-day commands of the temporally earliest in time program entry in said means for storing to the output of the clock for a predetermined relation;
- 25 means for transmitting record on commands to said means for recording after the predetermined relationship is found to exist;
means for transmitting said channel commands to said means for channel selection after the predetermined relationship is found to exist;
- 30 means for measuring length of time from transmitting a record on command; and
wherein said means for transmitting transmits record off commands to said means for recording when the measured length of time of recording has a predetermined compared relation with said length command.

35 2. The apparatus of claim 1 wherein said means for entering comprises a television remote controller.

3. The apparatus of claim 1 wherein said means for entering comprises controls coupled to said television receiver.

-46-

1 4. The apparatus of claim 1 wherein said means for channel selection comprises a cable box.

5 5. The apparatus of claim 1 wherein said means for channel selection comprises a satellite receiver.

6. The apparatus of claim 1 wherein said means for channel selection comprises a video cassette recorder.

10 7. The apparatus of claim 1 wherein said means for transmitting comprises at least one infrared transmitter.

15 8. The apparatus of claim 7 that further comprises:
a plurality of infrared transmitters positioned on said television receiver to transmit simultaneously in a plurality of directions.

9. The apparatus of claim 7 wherein said infrared transmitter is enclosed in a dome mounted on said television receiver.

20 10. The apparatus of claim 7 further comprising a mouse wherein said infrared transmitter is enclosed in said mouse and wherein said mouse is attached via a cable to said television receiver and wherein said mouse is placed near said means for recording.

25 11. The apparatus of claim 7 further comprising a mouse wherein said infrared transmitter is enclosed in said mouse and wherein said mouse is attached via a cable to said television receiver and wherein said mouse is placed near said means for channel selection.

30 12. The apparatus of claim 7 further comprising a miniature mouse wherein said infrared transmitter is enclosed in said miniature mouse and wherein said miniature mouse is attached via a cable to said television receiver and wherein said miniature mouse is placed near said means for recording.

35

-47-

1 13. The apparatus of claim 7 further comprising a miniature mouse wherein
said infrared transmitter is enclosed in said miniature mouse and wherein said miniature
mouse is attached via a cable to said television receiver and wherein said miniature
mouse is placed near said means for channel selection.

5

14. An apparatus for using compressed codes for recorder preprogramming
that comprises:

a video cassette recorder;

a means for channel selection; and

10

means for entering into said video cassette recorder compressed codes
each having at least one digit and each representative of, and compressed in length
from, the combination of channel, time-of-day, date and length commands for a
program;

the video cassette recorder comprising:

15

means for decoding each compressed code into channel, date, time
and length commands;

means for storing said channel, date, time-of-day and length
commands;

a clock with an output as a function of time;

20

means for reordering said channel, time-of-day, date and length
commands in said means for storing into temporal order;

means for comparing said date and time-of-day commands of the
temporally earliest in time program entry in said means for storing to the output of the
clock for a predetermined relation;

25

wherein a record on command is given to said video cassette
recorder after the predetermined relationship is found to exist;

means for transmitting said channel commands to said means for
channel selection after the predetermined relationship is found to exist;

means for measuring length of time from transmitting a record on
command; and

30

wherein said video cassette recorder is given a record off
command when the measured length of time of recording has a predetermined
compared relation with said length command.

35

15. The apparatus of claim 14 wherein said means for entering comprises a
television remote controller.

-48-

1 16. The apparatus of claim 14 wherein said means for entering comprises controls coupled to said video cassette recorder.

5 17. The apparatus of claim 14 wherein said means for channel selection comprises a cable box.

 18. The apparatus of claim 14 wherein said means for channel selection comprises a satellite receiver.

10 19. The apparatus of claim 14 wherein said means for transmitting comprises at least one infrared transmitter.

 20. The apparatus of claim 19 that further comprises:
 a plurality of infrared transmitters positioned on said video cassette
15 recorder to transmit simultaneously in a plurality of directions.

 21. The apparatus of claim 19 wherein said infrared transmitter is enclosed in a dome mounted on said video cassette recorder.

20 22. The apparatus of claim 19 further comprising a mouse wherein said infrared transmitter is enclosed in said mouse and wherein said mouse is attached via a cable to said video cassette recorder and wherein said mouse is placed near said means for channel selection.

25 23. The apparatus of claim 19 further comprising a miniature mouse wherein said infrared transmitter is enclosed in said miniature mouse and wherein said miniature mouse is attached via a cable to said video cassette recorder and wherein said miniature mouse is placed near said means for channel selection.

30 24. An apparatus for using compressed codes for recorder preprogramming that comprises:

 a cable box;
 means for recording;
 means for channel selection; and

35 means for entering into said cable box compressed codes each having at least one digit and each representative of, and compressed in length from, the combination of channel, time-of-day, date and length commands for a program;

-49-

1 the cable box comprising:
 means for decoding each compressed code into channel, date, time
 and length commands;
 means for storing said channel, date, time-of-day and length
5 commands;
 a clock with an output as a function of time;
 means for reordering said channel, time-of-day, date and length
 commands in said means for storing into temporal order;
 means for comparing said date and time-of-day commands of the
10 temporally earliest in time program entry in said means for storing to the output of the
 clock for a predetermined relation;
 means for transmitting record on commands to said means for
 recording after the predetermined relationship is found to exist;
 means for transmitting said channel commands to said means for
15 channel selection after the predetermined relationship is found to exist;
 means for measuring length of time from transmitting a record on
 command; and
 wherein said means for transmitting transmits record off commands
 to said means for recording when the measured length of time of recording has a
20 predetermined compared relation with said length command.

25 25. The apparatus of claim 24 wherein said means for entering comprises a
 television remote controller.

26 26. The apparatus of claim 24 wherein said means for entering comprises
 controls coupled to said cable box.

27 27. The apparatus of claim 24 wherein said means for channel selection
30 comprises a satellite receiver.

28 28. The apparatus of claim 24 wherein said means for channel selection
 comprises a cable box.

29 29. The apparatus of claim 24 wherein said means for channel selection
35 comprises a video cassette recorder.

-50-

1 30. The apparatus of claim 24 wherein said means for transmitting comprises
at least one infrared transmitter.

5 31. The apparatus of claim 30 that further comprises:
a plurality of infrared transmitters positioned on said cable box to
transmit simultaneously in a plurality of directions.

10 32. The apparatus of claim 30 wherein said infrared transmitter is enclosed in
a dome mounted on said cable box.

15 33. The apparatus of claim 30 further comprising a mouse wherein said
infrared transmitter is enclosed in said mouse and wherein said mouse is attached via
a cable to said cable box and wherein said mouse is placed near said means for
recording.

20 34. The apparatus of claim 30 further comprising a mouse wherein said
infrared transmitter is enclosed in said mouse and wherein said mouse is attached via
a cable to said cable box and wherein said mouse is placed near said means for channel
selection.

25 35. The apparatus of claim 30 further comprising a miniature mouse wherein
said infrared transmitter is enclosed in said miniature mouse and wherein said miniature
mouse is attached via a cable to said cable box and wherein said miniature mouse is
placed near said means for recording.

30 36. The apparatus of claim 30 further comprising a miniature mouse wherein
said infrared transmitter is enclosed in said miniature mouse and wherein said miniature
mouse is attached via a cable to said cable box and wherein said miniature mouse is
placed near said means for channel selection.

35 37. An apparatus for using compressed codes for recorder preprogramming
that comprises:
a satellite receiver;
means for recording;
means for channel selection; and

-51-

1 means for entering into said satellite receiver compressed codes each having at least one digit and each representative of, and compressed in length from, the combination of channel, time-of-day, date and length commands for a program;

the satellite receiver comprising:

5 means for decoding each compressed code into channel, date, time and length commands;

means for storing said channel, date, time-of-day and length commands;

a clock with an output as a function of time;

10 means for reordering said channel, time-of-day, date and length commands in said means for storing into temporal order;

means for comparing said date and time-of-day commands of the temporally earliest in time program entry in said means for storing to the output of the clock for a predetermined relation;

15 means for transmitting record on commands to said means for recording after the predetermined relationship is found to exist;

means for transmitting said channel commands to said means for channel selection after the predetermined relationship is found to exist;

20 means for measuring length of time from transmitting a record on command; and

wherein said means for transmitting transmits record off commands to said means for recording when the measured length of time of recording has a predetermined compared relation with said length command.

25 38. The apparatus of claim 37 wherein said means for entering comprises a television remote controller.

39. The apparatus of claim 37 wherein said means for entering comprises controls coupled to said satellite receiver.

30 40. The apparatus of claim 37 wherein said means for channel selection comprises a cable box.

35 41. The apparatus of claim 37 wherein said means for channel selection comprises a satellite receiver.

-52-

1 42. The apparatus of claim 37 wherein said means for channel selection comprises a video cassette recorder.

5 43. The apparatus of claim 37 wherein said means for transmitting comprises at least one infrared transmitter.

 44. The apparatus of claim 43 that further comprises:
 a plurality of infrared transmitters positioned on said satellite receiver to transmit simultaneously in a plurality of directions.

10 45. The apparatus of claim 43 wherein said infrared transmitter is enclosed in a dome mounted on said satellite receiver.

15 46. The apparatus of claim 43 further comprising a mouse wherein said infrared transmitter is enclosed in said mouse and wherein said mouse is attached via a cable to said satellite receiver and wherein said mouse is placed near said means for recording.

20 47. The apparatus of claim 43 further comprising a mouse wherein said infrared transmitter is enclosed in said mouse and wherein said mouse is attached via a cable to said satellite receiver and wherein said mouse is placed near said means for channel selection.

25 48. The apparatus of claim 43 further comprising a miniature mouse wherein said infrared transmitter is enclosed in said miniature mouse and wherein said miniature mouse is attached via a cable to said satellite receiver and wherein said miniature mouse is placed near said means for recording.

30 49. The apparatus of claim 43 further comprising a miniature mouse wherein said infrared transmitter is enclosed in said miniature mouse and wherein said miniature mouse is attached via a cable to said satellite receiver and wherein said miniature mouse is placed near said means for channel selection.

35 50. A method of permitting programs to be preprogrammed for recording by a recorder for time shifted viewing comprising:

 providing a television receiver having a means for transmitting signals and a clock with an output as a function of time;

-53-

1 entering into said television receiver compressed codes each having at
least one digit and each representative of, and compressed in length from, the
combination of channel, time-of-day, date and length commands for a program;
 decoding each compressed code to obtain channel, time-of-day, date and
5 length commands;
 providing a memory;
 storing each said channel, time-of-day, date and length commands into
said memory;
 reordering said channel, time-of-day, date and length commands in said
10 memory into temporal order;
 comparing the date and time-of-day commands of the temporally earliest
in time entry in said memory to the output of the clock for a predetermined relation;
 transmitting channel and record on commands from said television
receiver after the predetermined relationship is found to exist;
15 selecting the channel;
 recording the program;
 measuring length of time from transmitting record on command; and
 transmitting record off commands from said television receiver when the
measured length of time has a predetermined compared relation with said length
20 command.

51. A method of permitting programs to be preprogrammed for recording by
a recorder for time shifted viewing comprising:
25 providing a video cassette recorder having a means for transmitting
signals and a clock with an output as a function of time;
 entering into said video cassette recorder compressed codes each having
at least one digit and each representative of, and compressed in length from, the
combination of channel, time-of-day, date and length commands for a program;
 decoding each compressed code to obtain channel, time-of-day, date and
30 length commands;
 providing a memory;
 storing each said channel, time-of-day, date and length commands into
said memory;
 reordering said channel, time-of-day, date and length commands in said
35 memory into temporal order;
 comparing the date and time-of-day commands of the temporally earliest
in time entry in said memory to the output of the clock for a predetermined relation;

-54-

1 transmitting channel commands from said video cassette recorder after
the predetermined relationship is found to exist;
 selecting the channel;
 recording the program when predetermined relation is found to exist;
5 measuring length of time from start of recording; and
 stopping recording when the measured length of time has a
predetermined compared relation with said length command.

10 52. A method of permitting programs to be preprogrammed for recording by
a recorder for time shifted viewing comprising:
 providing a cable box having a means for transmitting signals and a clock
with an output as a function of time;
 entering into said cable box compressed codes each having at least one
digit and each representative of, and compressed in length from, the combination of
15 channel, time-of-day, date and length commands for a program;
 decoding each compressed code to obtain channel, time-of-day, date and
length commands;
 providing a memory;
 storing each said channel, time-of-day, date and length commands into
20 said memory;
 reordering said channel, time-of-day, date and length commands in said
memory into temporal order;
 comparing the date and time-of-day commands of the temporally earliest
in time entry in said memory to the output of the clock for a predetermined relation;
25 transmitting channel and record on commands from said cable box after
the predetermined relationship is found to exist;
 selecting the channel;
 recording the program;
 measuring length of time from transmitting record on command; and
30 transmitting record off commands from said cable box when the
measured length of time has a predetermined compared relation with said length
command.

35 53. A method of permitting programs to be preprogrammed for recording by
a recorder for time shifted viewing comprising:
 providing a satellite receiver having a means for transmitting signals and
a clock with an output as a function of time;

-55-

1 entering into said satellite receiver compressed codes each having at least
one digit and each representative of, and compressed in length from, the combination
of channel, time-of-day, date and length commands for a program;
3 decoding each compressed code to obtain channel, time-of-day, date and
5 length commands;
 providing a memory;
 storing each said channel, time-of-day, date and length commands into
said memory;
 reordering said channel, time-of-day, date and length commands in said
10 memory into temporal order;
 comparing the date and time-of-day commands of the temporally earliest
in time entry in said memory to the output of the clock for a predetermined relation;
 transmitting channel and record on commands from said satellite receiver
after the predetermined relationship is found to exist;
15 selecting the channel;
 recording the program;
 measuring length of time from transmitting record on command; and
 transmitting record off commands from said satellite receiver when the
measured length of time has a predetermined compared relation with said length
20 command.

54. The method of claim 50, 51, 52 or 53 wherein the step of selecting and
recording are performed by a video cassette recorder.

25 55. The method of claim 50, 51, 52 or 53 wherein the step of selecting is
performed by a cable box.

56. The method of claim 50, 51, 52 or 53 wherein the step of selecting is
performed by a satellite receiver.
30

57. The method of claim 50, 51, 52 or 53 wherein the step of transmitting is
performed by at least one infrared transmitter transmitting in multiple directions.

58. The method of claim 50, 51, 52 or 53 wherein the step of transmitting is
performed by an infrared transmitter attached to a cable.
35

-56-

1 59. The method of claim 50, 51, 52 or 53 wherein the step of entering is performed by a television remote.

5 60. The method of claim 50, 51, 52 or 53 wherein the step of decoding each compressed code to obtain channel, time-of-day, date and length commands comprises the steps of:

 permuting said compressed code to obtain a permuted compressed code;
 converting groups of digits of said permuted compressed code to groups of binary digits; and

10 concatenating said groups of binary digits into one binary number;
 reordering the bits in said binary number to obtain a reordered binary compressed code;

 grouping said reordered binary compressed code into channel, date, time and length priority numbers; and

15 deriving said channel, day, time-of-day and length commands from said channel, date, time and length priority numbers.

 61. The method of claim 60 wherein the step of permuting said compressed code further comprises:

20 permuting said compressed code as function of the output of a clock.

 62. The method of claim 60 further comprising the step of:

 extracting a day code from said compressed code; and

25 wherein said day code is used in performing said step of permuting said compressed code.

INTERNATIONAL SEARCH REPORT

 International application No.
PCT/US92/08272

A. CLASSIFICATION OF SUBJECT MATTER

IPC(5) :H04N 5/76

US CL :358/335, 191.1, 194.1; 360/33.1; 455/151.2, 181.1, 186.1

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 358/335, 191.1, 194.1; 360/33.1; 455/151.2, 181.1, 186.1; 358/192.1, 193.1; 359/146; 455/151.4, 154.1, 170.1, 171.1, 185.1

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	US, A, 4,334,242 (MANGOLD) 08 June 1982. See figure 1 and its description.	1-62
Y	US, A, 4,337,480 (BOURASSIN ET AL.) 29 June 1982. See figures 1, 2 and 3 and col. 4 in particular; entire document relevant.	1-62
Y	US, A, 4,706,121 (YOUNG) 10 November 1987. See figures 4,4b, 6, cols. 3-5.	1-62
Y,P	US, A, 5,068,734 (BEERY) 26 November 1991. See cols. 1-3, col. 13, lines 1-6.	1-62
Y	GB, A, 2,034,995 (WRIGHT) 11 June 1980. See the entire document.	1-62

Further documents are listed in the continuation of Box C.

See patent family annex.

* Special categories of cited documents:	"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
"A" document defining the general state of the art which is not considered to be part of particular relevance	"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
"E" earlier document published on or after the international filing date	"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	"&" document member of the same patent family
"O" document referring to an oral disclosure, use, exhibition or other means	
"P" document published prior to the international filing date but later than the priority date claimed
