ABSTRACT
A cell-free system based on the cytosol of normally growing cells, which reproduces measurable aspects of the apoptotic program, is provided. The apoptotic program is initiated by addition of dATP in the specific exemplification of the HeLa 100,000xg supernatant. Fractionation of the cytosol yielded a 15 kDa protein, identified by absorption spectrum and protein sequence as cytochrome c, that is required for in vitro apoptosis. Elimination of cytochrome c from cytosol by immunodepletion or inclusion of sucrose to stabilize mitochondria during cytosol preparation, diminished the apoptotic activity. Addition of exogenous cytochrome c to cytochrome c-depleted extracts restored apoptotic activity. Cells undergoing apoptosis in vivo showed increased release of cytochrome c to their cytosol, suggesting that mitochondria may function in apoptosis by releasing cytochrome c.

REGULATION OF APOPTOSIS AND IN VITRO MODEL FOR STUDIES THEREOF

CROSS REFERENCE TO RELATED APPLICATIONS

ACKNOWLEDGEMENT OF FEDERAL RESEARCH SUPPORT

[0002] Not applicable.

BACKGROUND OF THE INVENTION

[0003] The field of this invention is the area of apoptosis (programmed cell death) and methods for the study of the regulation thereof. Specifically, the present invention provides an in vitro system for the analysis of apoptosis and specific regulators of the apoptotic pathway.

[0008] Triggering of apoptosis by activated CPP32 is part of the highly regulated mechanism for initiation of apoptosis; careful regulation of this pathway is necessary to prevent unwanted cell death. CPP32 is activated by multiple proteolytic cleavages of its 32 kDa precursor form, generating the 17/11 kDa or 20/11 kDa active form [Nicholson et al. (1995) supra; Wang et al. (1995) supra]. CPP32 is activated by cleavage at aspartic acid residues, a hallmark of ICE-like proteases [Thornberry et al. (1992) Nature 356, 768-774], and a cascade of ICE-like proteolytic cleavages leading to apoptosis has been proposed [Tewari et al. (1995) supra; Wang et al. (1996) supra]. Activated CPP32 from HeLa cell extracts cleaves the CPP32 precursor [Wang et al. (1996) supra], indicating that CPP32 can be activated through autocalaysis. Autocatalytic cleavage is probably responsible for active enzyme when the CPP32 precursor is expressed in large quantity in bacteria [Xue and Horvitz (1995) supra]. Recently, another ICE-family protease has been identified that may be responsible for cleaving the CPP32 precursor into the 20/11 kDa active form. This enzyme has been purified from hamster liver extracts and identified as the hamster homolog of Mch2a [Liu et al. (1996) J. Biol. Chem. 271, 13371-13376; Fernandes-Alemni et al. (1995) Cancer Res. 55, 2737-2742]. Autocatalysis and the protease cascade may provide the signal amplification necessary for rapid and irreversible apoptosis, but the intracellular factors that trigger this amplification have yet to be identified.
There have been several previous reports of cell-free apoptosis systems that induce apoptotic changes in the added nuclei [Lazebnik et al. (1993) J. Cell Biol. 123, 7-22; Newmeyer et al. (1994) Cell 79, 355-364; Ecari et al. (1995) EMBO J. 14, 5191-5200]. These systems require cytosol from cells that are already undergoing apoptosis in vivo; thus, they cannot be used to detect triggering factors.

There is a need in the art for in vitro methods for the analysis of compounds and biological factors which trigger or accelerate apoptosis or which interfere with the induction of apoptosis, as well as those which can increase the apoptotic effect of chemotherapeutic agents in cancers, especially those expressing oncogenic bel-2. This need is met by the present invention, which allows the study of apoptosis and regulators thereof in a cell-free system in which the analysis is not complicated by previous induction of the apoptotic pathway in the cells used to prepare the test extracts.

SUMMARY OF THE INVENTION

The present invention provides an in vitro system and methods for the analysis of regulation of apoptosis and for the identification of activators and inhibitors of the apoptotic pathway; the present system is improved over prior art systems for the study of apoptosis in that the prior art systems depended on cell free extracts prepared from organisms in which the apoptosis pathway had already been induced. Thus, the present system and methods permit freedom from the potential interference of apoptosis-inducing factors or other conditions on which prior art systems have relied.

As exemplified herein, the present invention provides an in vitro system for analysis of apoptosis and its regulation, where the test system includes a 100,000g supernatant of HeLa S cells from suspension culture (S-100). In its first aspect, the HeLa S-100, to which challenge compounds are added, is assessed for CPP32 proteolytic activity using radiolabeled poly adenine dephosphoribose polymerase (PARP) and radiolabeled steroid regulatory binding protein 2 (SREBP-2) and sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) and autoradiography. The radiolabeled PARP and SREBP-2 can be prepared by in vitro translation in the presence of 35S-methionine as described in Example 3 herein. In a second aspect, the HeLa S-100, to which challenge compounds are added, is assessed for DNA fragmentation activity, by incubating the treated S-100 with hamster liver cell nuclei and then extracting the genomic DNA and analyzing by agarose gel electrophoresis. The specific proteolytic activity is accelerated by the addition of dATP or dADP (at a concentration from about 0.1 to about 2 mM, preferably about 1 mM). DNA fragmenting activity is similarly dependent on the presence of dATP. It has been demonstrated that cytochrome c is required in the cell-free extract for the dATP-dependent activation of the apoptotic pathway, especially for the activation of the apoptosis marker protease.

The present invention provides a cell-free system which duplicates the features of the apoptotic program, including the activation of CPP32 and DNA fragmentation. Apoptosis in this system is initiated by the presence of soluble cytochrome c and dATP at sufficient concentrations. This system allows the fractionation and purification of the biochemical components that trigger the activation of the apoptotic proteases and DNA fragmentation.

The present invention further provides a method for identifying antagonists of dATP in the cytosol of adenosine deaminase-deficient cells, such as T cells from persons with severe combined immunodeficiency. dATP levels in adenosine deaminase-deficient cells are elevated in comparison to those of normal cells, and without wishing to be bound by any particular theory, this is believed to contribute to the symptoms of the deficiency. Identification of antagonists of the initiation of apoptosis can lead to treatments for the amelioration of the clinical state of deficient individuals.

The present invention also provides methods for identification of compounds which trigger apoptosis even where the bel-2 oncogene protein is present. The bel-2 oncogene is associated with resistance to chemotherapy in human cancer, and compounds which cause CPP32 protease and DNA fragmentation nucleosome-activation in bel-2oncogene extracts can be identified in the cell free assays of the present invention where the S-100 extract is prepared from BCL-2 expressing cells.

Additionally, the present invention allows the identification of compounds which effectively increase the apoptotic response to dATP and/or cytochrome c, including those which increase dATP levels in treated cells and those which promote release of cytochrome c from mitochondrial membranes. Such compounds can be used to increase the effectiveness of chemotherapeutic agents which act by inducing apoptosis.

BRIEF DESCRIPTION OF THE DRAWINGS

FIGS. 1A-1D illustrate dATP-dependent activation of CPP32 and DNA fragmentation in vitro. Aliquots (10 μl) of HeLa cell S-100 (50 μg) were incubated alone (lane 1), in the presence of 1 mM ATP (lane 2), or in the presence of 1 mM dATP (lane 3) at 30°C for 1 h in a final volume of 20 μl of buffer A. FIG. 1A, samples were subjected to SDS-PAGE and transferred to a nitrocellulose filter, probed with a monoclonal anti-CPP32 antibody, and the antigen/antibody complex was visualized by the ECL method. The filter was exposed to Kodak X-OMAT AR X-ray film for 1 min. In FIG. 1B, an aliquot of 10 μl of in vitro translated, 35S-labeled PARP was added to each reaction. After 5 min, the samples were subjected to SDS-PAGE and transferred to a nitrocellulose filter. The filter was exposed to film for 2 h at room temperature. In FIG. 1C, a 5 μl aliquot of in vitro translated, 35S-labeled SREBP-2 was added to each reaction. After incubation at 30°C for 30 min, the samples were subjected to SDS-PAGE, the gel was dried and exposed to film for 2 h at room temperature. In FIG. 1D, a 50 μl aliquot of HeLa cell S-100 (250 μg) was incubated with 6 μl Hamster Liver nuclei in the absence (lane 1), or presence of 1 mM ATP (lane 2) or dATP (lane 3) for 2 h at 37°C in a final volume of 60 μl of buffer A. DNA was isolated as described in the Examples and size-separated by agarose gel electrophoresis (2% agarose), and the DNA was visualized by ethidium bromide staining.

FIGS. 2A-2B illustrate the nucleotide specificity for in vitro activation of CPP32 and DNA fragmentation. FIG. 2A shows the results of incubating a 10 μl aliquot of HeLa S-100 (50 μg) with a 3 μl aliquot of in vitro translated,
**FIG. 3** illustrates fractionation and reconstitution of dATP-dependent activation of CPP32 by phosphocellulose chromatography. HeLa cell S-100 was subjected to phosphocellulose chromatography and the column flow through and bound material was collected as described in the Examples. Aliquots (10 μl) of HeLa S-100 (50 μg) (lanes 1 and 2), phosphocellulose flow through fraction (PC-F) (lanes 3 and 4), phosphocellulose bound fraction (PC-B) (lanes 5 and 6), and the mixture of phosphocellulose flow through and bound material (lanes 7 and 8) were incubated with aliquots of 3 μl in vitro translated, 35S-labeled CPP32 at 30°C for 1 hr in the presence of 1 mM dATP. The samples were subjected to SDS-PAGE, transferred to a nitrocellulose filter, and the filter was exposed to film for 16 hours at room temperature.

**FIG. 4A-4B** show the results of Mono S column purification of Apaf-2. The Apaf-2 activity that bound to the phosphocellulose column was purified through the Mono S column as described in Example 7. **FIG. 4A** shows the results of incubation of 1 μl aliquots of Mono S column fractions with aliquots of 10 μl phosphocellulose flow through fraction and 3 μl of in vitro translated, 35S-labeled CPP32 at 30°C for 1 hr in the presence of 1 mM dATP in a final volume of 20 μl of buffer A. Samples were subjected to SDS-PAGE, transferred to a nitrocellulose filter, and the filter was exposed to film for 16 hours at room temperature. In **FIG. 4B**, aliquots (30 μl) of the Mono-S fractions were subjected to 15% SDS-PAGE and the proteins were visualized by silver staining.

**FIG. 5** shows the absorption spectrum of Apaf-2. An aliquot of 1 ml of Apaf-2 purified through the Mono S column was subjected to absorption spectrum scanning using a CARY 219 spectrophotometer. Absorption spectrum was recorded between 330 nm and 600 nm at a scanning speed of 1 mm/sec.

**FIG. 6** demonstrates that cytochrome c proteins from bovine heart and rat liver have Apaf-2 activity. Aliquots of 0.2 μg of Apaf-2 purified through the Mono S column (lanes 1, 2), cytochrome c from bovine heart (lanes 3, 4), and rat liver (lanes 5, 6) were incubated with aliquots of 10 μl phosphocellulose flowthrough fraction and 3 μl in vitro translated, 35S-labeled CPP32 at 30°C for 1 hr in a final volume of 20 μl buffer A. After 1 hr incubation at 37°C, the mixture was centrifuged and the supernatant was subjected to SDS-PAGE and transferred to a nitrocellulose filter which was then exposed to a film for 16 hr at room temperature.

**FIGS. 7A-7D** demonstrate immunodepletion of cytochrome c from HeLa S-100 and reconstitution of dATP-dependent activation of CPP32. DNA fragmentation and nuclear morphological change using purified cytochrome c. Cytochrome c present in the HeLa cell S-100 was immunodepleted as described in the Example 10. **FIG. 7A**, 10 μl aliquots of HeLa S-100 (50 μg) (lanes 1 and 2), or 10 μl aliquots of HeLa S-100 immunodepleted of cytochrome c (lanes 3 and 4), or 10 μl of HeLa S-100 immunodepleted of cytochrome c supplemented with 0.2 μg Apaf-2 purified through the Mono S column (H) (lanes 5 and 6), bovine heart cytochrome c (B) (lanes 7 and 8), or rat liver cytochrome c (R) (lanes 9 and 10), were incubated with aliquots of 3 μl in vitro translated, 35S-labeled CPP32 in the absence (lanes 1, 3, 5, 7, 9) or presence (lanes 2, 4, 6, 8, 10) of 1 mM dATP at 30°C. After 1 hr incubation at 37°C, 1 μl aliquots of each sample were subjected to SDS-PAGE and transferred to a nitrocellulose filter which was then exposed to a film for 16 hr at room temperature.

**FIG. 8** illustrates dATP and cytochrome c-dependent activation of CPP32 in S-100 cytosol preparations (immunodepleted of cytochrome c) from human embryonic kidney 293 cells and human mononuclear U937 cells. CPP32 activation reactions were carried out as described in **FIG. 7** except 25 μg of S-100 was used in each reaction. 1 mM of dATP was present in lanes 2, 4, 6, 8, 10, and 12. Lanes 1 and 2, S-100 fraction from 293 cells; Lanes 3-4, S-100 fraction from 293 cell immunodepleted of cytochrome c; lanes 5 and 6, S-100 fraction from 293 cells immunodepleted of cytochrome c supplemented with 0.2 μg of Apaf-2 purified through the Mono S column; Lanes 7 and 8, S-100 fraction from U937 cells; Lanes 8-9, S-100 fraction from U937 cells immunodepleted of cytochrome c; lanes 11-12, S-100 fraction from U937 cells immunodepleted of cytochrome c supplemented with 0.2 μg of Apaf-2 purified through Mono S column step.

**FIG. 9** demonstrates reconstitution of dATP-dependent activation of CPP32 with S-cytosol and purified Apaf-2. On day 0, Hela cells were set up at 5×10⁶ cells per 100 mm dish in medium A as described herebelow. On day 2, cells were harvested, collected by centrifugation (1000 g, 10 min, 4°C). After washing once with ice-cold PBS, the cell pellet was suspended in 5 volumes of ice-cold buffer A.
containing 250 mM sucrose. The cells were disrupted by dousing 3 times in a 5 ml Wheaton douncer with a pestle polished with sand paper. After microcentrifugation for 5 min at 4°C, the supernatants were further centrifuged at 10,000g for 30 min in a table top ultracentrifuge (Beckman Instruments, Fullerton, Calif.). The resulting supernatants were designated as S-cytosol. Aliquots of S-cytosol (50 µg) alone (lanes 1 and 2), or supplemented with 0.2 µg Apaf-2 purified through the Mono S column (lanes 3 and 4), were incubated with aliquots of 3 µl in vitro translated, 35S-labeled CPP32 in the absence (lanes 1, 3) or presence (lanes 2, 4) of 1 mM dATP at 30°C for 1 hr in a final reaction volume of 20 µl of buffer A. Samples were subjected to SDS-PAGE and transferred to a nitrocellulose filter which were then exposed to film for 16 hr at room temperature.

[0026] FIGS. 10A-10B shows increased release of cytochrome c to the cytosol upon apoptotic stimulation. HeLa cells were treated as described in FIG. 9. On day 2, staurosporine at a final concentration of 1 µM was added to the medium as indicated. After incubation at 37°C for 6 hr, the cells were harvested and S-cytosols were prepared as described in FIG. 9. In FIG. 10A, a 50 µg aliquot of HeLa cell S-100 as in FIGS. 1–7 (lane 1), or S-cytosol from HeLa cells (lane 2), or S-cytosol from HeLa cells treated with staurosporine for 6 hr. In lane 4, aliquot of 0.2 µg of Apaf-2 purified through Mono S column step. Proteins were separated using 15% SDS-PAGE, transferred to a nitrocellulose filter, and probed with a monoclonal anti-cytochrome c antibody and the antigen/antibody complex was visualized by the ECL method as described herein. Kodak X-OMAT AR X-ray film was exposed for 15 seconds. The arrow denotes the position of cytochrome c; X denotes protein bands cross-reacting with this antibody. In FIG. 10B, aliquots containing 4.5 µg of S-cytosol from HeLa cells (–staurosporine) or HeLa cells treated with 1 µM staurosporine for 6 hr (staurosporine) were incubated with 10 µl aliquots of in vitro translated, 35S-labeled PARP for 30 min at 30°C in a volume of 20 µl of buffer A. Samples were then subjected to 12% SDS-PAGE, transferred to a nitrocellulose filter, and film was exposed for 4 hr at room temperature.

DETAILED DESCRIPTION OF THE INVENTION

[0027] Apoptosis, or cell death, is a natural phenomenon. Modulation of normal apoptosis or activation of the apoptotic pathway in cells in which apoptosis is inhibited due to the expression of oncogenes, for example, can lead to longer and enhanced life and/or improved medical treatment methods, for example, in cancer patients.

[0028] The present invention provides a method for the identification of inducers and/or inhibitors of apoptosis in a cell-free system comprising 100,000 bg supernatant of cell cytosol (S-100) prepared from actively growing cells and containing the inactive CPP32 and nuclear precursors. Desirably, the S-100 is prepared from mammalian cells, for example, HeLa cells. Activation of the apoptosis marker protease CPP32 and the marker nuclease are triggered in this system in the presence of dATP and soluble cytochrome c in a 100,000 bg cytosol supernatant. Modification of the assay preparation conditions allows the identification of compounds, proteins or compositions which can substitute either for the dATP or the soluble cytochrome c or for both. Initiation of the apoptotic pathway is detected by the proteolytic cleavage of SREBPs or PARP by the CPP32 protease which is activated at an early step of the apoptotic pathway. Triggering of the apoptotic pathway can also be detected via the cleavage of the nuclear active CPP32 protease and active apoptotic DNA fragmentation nuclease are marker enzymes of the apoptotic pathway. In this system soluble cytochrome c and dATP trigger activation of the marker enzymes for apoptosis. It is understood that analogs of dATP and dADP function in triggering the apoptotic activation as well.

[0029] Compounds or proteins which inhibit the initiation of the apoptotic pathway are detected by their prevention of the activation of the CPP32 protease or the marker nuclease in the presence of cytochrome c and dATP, conditions which normally activate the pathway.

[0030] Compounds or proteins which counteract the apoptosis-inhibiting activity of the bel-2 gene product (or of other oncogene products) can be identified by their ability to allow the activation of the marker enzymes of the apoptotic pathway even in the presence of dATP and cytochrome c in S-100 extracts of cells expressing bel-2 or similar oncogenes. Compositions identified in the present assay system can be then used to increase the activity of chemotherapeutic agents used in the treatment of cancers and other hyperplastic disorders, especially in cells expressing oncogenic bel-2 or other oncogenes which decrease apoptosis.

[0031] Activation of CPP32 and DNA fragmentation are two well characterized biochemical markers of apoptosis and its initiation. With the goal of producing an in vitro system that duplicates apoptosis, we prepared 100,000 bg cytosolic supernatant (S-100) from suspension cultures of HeLa cells. The activation of CPP32 is the result of cleavage of its 32 kDa precursor into the 20 kDa NH2-terminal fragment and 11 kDa COOH-terminal fragment [Nicholson et al. (1995) supra], thus the activation of CPP32 in the HeLa cell S-100 was monitored by Western blot analysis using a monoclonal antibody against the 20 kDa fragment of CPP32 (FIG. 1A). The enzymatic activity of CPP32 was assayed by measuring the cleavage of two 35S-labeled substrates, PARP (FIG. 1B) and SREBP-2 (FIG. 1C). DNA fragmentation was assayed by incubating the HeLa cell S-100 with nuclei isolated from hamster liver followed by genomic DNA extraction and analysis by agarose gel electrophoresis. We found that deoxyadenosine-5-triphosphate (dATP) markedly accelerated the activation of CPP32 in the HeLa cell S-100. As shown in FIGS. 1A-1B, no activation of CPP32 was observed when the HeLa cell S-100 was incubated in the presence or absence of 1 mM ATP at 30°C for 1 hr (FIG. 1A, lanes 1 and 2). However, in the presence of 1 mM dATP, most of the CPP32 in the HeLa cell S-100 was activated (FIG. 1A, lane 3). The activated extracts readily cleaved PARP into 85 kDa and 24 kDa fragments (FIG. 1B, lane 3) and SREBP-2 into 55 kDa and 70 kDa fragments (FIG. 1C, lane 3). The sizes of the cleaved products of PARP and SREBP-2 were the same as observed in cells undergoing apoptosis [Kaufmann et al. (1993) Cancer Res. 53, 3976-3985; Wang et al. (1996) supra]. It is likely that this cleavage was the result of the activation of CPP32, and related enzymes such as SC2/Mecl3, which are known to cleave PARP and SREBP at these positions [Fernandes-Alemri et al. (1995) Cancer Res. 55, 6045-6052; Pail et al. (1996) Proc. Natl. Acad. Sci. USA 93, 5437-5442]. HeLa cell S-100 extract in the presence of dATP induced DNA fragmentation
when incubated with hamster liver nuclei (FIG. 1D, lane 3). Such fragmentation did not occur with HeLa S-100 in the presence or absence of ATP, confirming the requirement for dATP (FIG. 1D, lanes 1 and 2).

[0032] To test the nucleotide specificity for activation of CPP32 and DNA fragmentation, HeLa cell S-100 was incubated with in vitro translated, 32P-labeled CPP32 in the presence of 1 mM of various nucleotides (FIG. 2A). Cleavage occurred only in the presence of dATP or dADP (FIG. 2A). CTP, dCTP, GTP, dGTP, UTP, dUTP, ADP, AMP, dAMP, adenosine, deoxyadenosine and cAMP did not replace dATP. Identical nucleotide specificity was observed in the DNA fragmentation assay (FIG. 2B).

[0033] To isolate the protein(s) required for the activation of CPP32, HeLa S-1 to 100 was loaded onto a phosphocellulose column, and the flow-through and bound fractions were collected. Neither fraction alone supported dATP-dependent activation of CPP32 (FIG. 3, lanes 3-6). When the flowthrough and bound fractions were mixed, CPP32-activating activity was restored (lanes 7-8). This experiment indicates that there are multiple factors, which can be separated by the phosphocellulose chromatography, contributing to dATP-dependent activation of CPP32. The factor(s) that flow through the phosphocellulose column are designated apoptotic protease activating factor-1 (Apaf-1) and the factor that bound to the column is designated apoptotic protease activating factor-2 (Apaf-2). It is understood that “Apaf-1” may represent more than one protein or it may represent a combination of protein(s) and other factors.

[0034] Apaf-2 activity was assayed by recombining with Apaf-1 after purification by the following steps. First, the Apaf-2 fraction was subjected to 50% ammonium sulfate precipitation. All of the activity remained in the supernatant while most of the protein precipitated (Table I). The supernatant was loaded onto a phenyl-sepharose (hydrophobic interaction) column and the activity was eluted with 1 M ammonium sulfate. The eluate was passed through a gel filtration column; active fractions were subjected to sequential Mono Q (anion exchange) and Mono S (cation exchange) chromatography. The Apaf-2 activity flowed through the Mono Q column, and the flow through was directly loaded onto the Mono S column. Bound Apaf-2 activity was then eluted with a 100-300 mM NaCl linear salt gradient. The fractions from the Mono S column were collected and assayed. As shown in FIG. 4A, the Apaf-2 activity eluted from the Mono S column at approximately 120 mM NaCl (fractions 2-4). The active fractions were analyzed by SDS-PAGE (FIG. 4B). A protein of apparent molecular mass of 15 kDa was co-eluted with the activity. No other proteins were detected by silver staining in the active Apaf-2 fractions.

[0035] Table I summarizes the results of a complete purification of Apaf-2 starting with the S-100 fraction from 20 liters of HeLa cells (348.5 mg protein). The Apaf-2 protein was purified more than 2000-fold with an overall recovery of 152% activity. The >100% recovery indicates the elimination of inhibitory activities during the purification.

[0036] Purified Apaf-2 had a noticeable pink color, and it showed absorbance peaks at 415, 520 and 549 nm, a spectrum shared by reduced cytochrome c [Margoliash and Walasek (1967) Meth. Enzymol. X, 339-348]. Identity of Apaf-2 with cytochrome c was confirmed by comparison of amino acid sequences generated from tryptic peptides isolated from the 15 kDa Apaf-2 with known cytochrome c amino acid sequence information. All those sequences show 100% identity with portions of the reported sequence of human cytochrome c (Table II).

[0037] To confirm that cytochrome c has Apaf-2 activity, purified bovine heart and rat liver cytochrome c (from a commercial source) were tested for Apaf-2 activity. As shown in FIG. 6, cytochrome c from both sources initiated dATP-dependent activation of CPP32 as efficiently as Apaf-2 (lanes 3-6).

[0038] To rule out the possibility that the Apaf-2 activity is due to a minor contaminating protein that co-purified with cytochrome c, an immunodepletion experiment was carried out using a monoclonal antibody against rat cytochrome c. This monoclonal antibody cross-reacts with purified Apaf-2. As shown in FIGS. 7A and 7D, HeLa cell S-100 depleted of cytochrome c using the monoclonal anti-cytochrome c antibody lost the dATP-dependent activation of CPP32 and the ability to induce DNA fragmentation in the added nuclei (FIGS. 7A and 7C, lanes 3 and 4). Adding back either the purified Apaf-2 from HeLa cells or the commercial cytochrome c from bovine heart or rat liver to the immunodepleted extracts restored the dATP-dependent activation of CPP32 and DNA fragmentation (FIGS. 7A and 7C, lanes 5-10). The reconstitution of cytochrome c dependent-activation of CPP32 was evident with the addition of 0.01 μg (33 nM) of purified cytochrome c to the cytochrome c-depleted extracts (FIG. 7B). Addition of 0.3 μg of cytochrome c recovered more than 100% of control activity, indicating that the cytochrome c in the cytosol is not at saturation level (FIG. 7B). The dATP and cytochrome c-dependent activation of CPP32 and DNA fragmentation was accompanied by the morphological change in the co-incubated nuclei that is characteristic of apoptosis (FIG. 7D).

[0039] To investigate whether the dATP and cytochrome c-dependent activation of CPP32 is a general phenomenon, cytosols were prepared from human embryonic kidney 293 cells and human mononuclear leukemia U937 cells. As shown in FIG. 8, S-100 fractions from both cell types contained a dATP-dependent CPP32 activating activity (Lanes 1, 2 and 7, 8). Immunodepletion of cytochrome c from these cytosols resulted in the loss of CPP32 activating activity (lanes 3, 4 and 9, 10) and addition of purified cytochrome c restored the activity (lanes 5, 6 and 11, 12).

[0040] Human cytochrome c is encoded by a single copy nuclear gene [Evans and Scarpulla (1988) Proc. Natl. Acad. Sci. USA 85, 9625-9629] which is translated on cytoplasmic ribosomes as apocytochrome c. The heme group of cytochrome c is attached to apocytochrome c upon its translocation into mitochondria; holocytochrome c is a soluble protein located in the intermembrane space of mitochondria [Gonzales and Neupert (1990) J. Bioenergetics & Biomembranes 22, 753-768]. The presence of cytochrome c in the cytosolic fraction can therefore be the result of ruptured outer mitochondrial membrane by hypotonic shock during its preparation. To test this hypothesis, cytosol from HeLa cells was prepared in the presence of 250 mM sucrose to protect mitochondrial integrity. The cells were broken gently by bouncing in a sand paper polished piston [Hayakawa et al. (1993) Mol. Cell. Biochem. 119, 95-103]. Cytosol prepared this way (designated S-cytosol) contained little cytochrome c as compared to the cytosol used in the previous experiments (FIG. 10A, lanes 1 and 2). As shown in FIG. 9, S-cytosol injected into the dATP-dependent activation of CPP32 (lanes 1 and 2) unless purified cytochrome c was added (lanes 3 and 4).
The requirement for cytochrome c in the apoptotic program in vitro indicates there is increased release of cytochrome c to the cytosol in cells undergoing apoptosis. HeLa cells were treated with staurosporine. Staurosporine is a broad-spectrum inhibitor of protein kinases, and it has been found to be a potent apoptosis inducer in a variety of cell types [Rueggs and Burgess (1989) Trends Pharmacol. Sci. 10, 218-220; Jacobson et al. (1993) Nature 361, 365-36; Wang et al. (1996) supra]. Cytosol was prepared from staurosporine-treated HeLa cells containing markedly elevated cytochrome c as compared to that from non-treated cells (FIG. 1A, lanes 2 and 3). The same phenomenon was also observed in human monoblastic U937 cells. Arabinosylyctosine, etoposide and mitoxantrone HCl also act to initiate apoptosis.

The present invention provides an in vitro system that faithfully duplicates the two best characterized biochemical markers of apoptosis, i.e. DNA fragmentation into nucleosomal fragments and the activation of the ICE-related apoptotic protease CPP32. This in vitro system allowed us to fractionate and begin to isolate the required components. One required protein factor was purified to homogeneity and identified as the human cytochrome c.

The present dATP- and cytochrome c-dependent in vitro apoptosis system represents a general apoptotic program. Identical results were obtained from cytosols of HeLa cells, human embryonic kidney 293 cells, and human monoblastic U937 cells.

There have been several previous reports of cell-free apoptosis systems based on extracts from hormone-treated Xenopus eggs [Newmeyer et al. (1994) supra], double synchronized mitotic chicken hepatoma cells (Lazebnik et al. (1993) supra), or extracts from Fas, UV irradiated and ceramide treated cells [Earni et al. (1995) supra; Martin et al. (1995) supra]. Our system differs from the previously reported systems in that it uses extracts from normally growing cells which have not been induced to undergo apoptosis. This allows apoptosis to be initiated in vitro. Because it uses only soluble components, the system is amenable to fractionation and reconstitution.

In vitro apoptosis in our system was initiated by the addition of dATP. Although the finding that dATP plays a critical role for initiation of apoptosis in vitro was empirical, dATP has long been implicated in cell death. The best known case is the inherited deficiency of adenosine deaminase (ADA), which results in severe combined immunodeficiency (SCID). In ADA patients, there is an abnormal accumulation of dATP up to mM level in their lymphocytes and death of CD8<sup>+</sup> transitional and CD4-CD8 double-positive thymocytes by an apoptosis mechanism [Cohen et al. (1978) Proc. Natl. Acad. Sci. USA 75, 472-476; Goday, A. et al. (1985) Biochem. Pharmac. 34, 3561-3569; Benveniste and Cohen (1995) Proc. Natl. Acad. Sci. USA 92, 8373-8377]. It has also been reported that deoxyadenosine treatment of cultured chick embryonic sympathetic neurons results in the accumulation of dATP and death through apoptosis [Wakade et al. (1995) J. Biol. Chem. 270, 17986-17992]. Neuronal cell death was prevented by an nucleotide kinase inhibitor, suggesting that dATP accumulation was the cause of cell death [Wakade et al. (1995) supra]. Our finding that dATP can initiate the activation of CPP32 and DNA fragmentation provides a mechanistic explanation for the dATP-mediated death activity. dADP can substitute for dATP. In cells treated with an ADA inhibitor, dADP also accumulates, although to a lesser extent than dATP [Goday et al. (1985) supra].

The fractionation of the factors necessary for dATP-dependent activation of CPP32 resulted in the identification of soluble cytochrome c as one of the necessary components for apoptosis in vitro. It is unlikely that cytochrome c mimics the function of another protein, because cytochrome c is the only protein with Apaf-2 activity purified from the S-100 fraction. The requirement for cytochrome c was confirmed by the depletion and reconstitution experiments.

Cytochrome c is an essential component of the mitochondrial respiratory chain. It is a soluble protein which is localized in the intermembrane space and is loosely attached to the surface of the inner mitochondrial membrane [Gonzales and Neupert (1990) supra]. Cytochrome c is translated by cytoplasmic ribosomes and follows a unique pathway into mitochondria which does not require the signal sequence, electro-chemical potential, and general protein translocation machinery [Mayer et al. (1995) J. Biol. Chem. 270, 12390-123971].

Mitochondria have been implicated in apoptosis since the discovery that the bcl-2 family of proteins are located in the outer mitochondrial membrane [Monaghan et al. (1992) supra; Krajewski et al. (1993) supra; de Jong et al. (1994) supra]. In vitro apoptosis in Xenopus egg extracts requires a dense organelle fraction enriched in mitochondria [Newmeyer et al. (1994) supra]. The present inventors have shown that purified mitochondria from hamster heart can supplement cytosol immunodepleted of cytochrome c, or cytochrome c prepared in the presence of sucrose to support CPP32 activating reaction. However, a potential argument against the involvement of mitochondria in apoptosis comes from a report that apoptosis and bcl-2 protection of apoptosis are normal in mitochondria DNA-<sup>-</sup> mice [Jacobsen et al. (1993) supra]. None of the known mitochondrial functions, such as ATP production, electron transfer, oxidative phosphorylation, generation of reactive oxygen species and Ca<sup>2+</sup> uptake, appear to account for its involvement in apoptosis [Jacobson et al. (1993) supra; Hockenbery et al. (1993) Cell 75, 241-251; Newmeyer et al. (1994) supra].

That cytochrome c is a necessary component of cellular apoptotic program indicates that mitochondria are involved in apoptosis by releasing cytochrome c. Because cytochrome c is encoded by a nuclear gene and translocation of apocytochrome c into mitochondria does not require membrane potential and general protein translocation machinery [Evans and Searpula (1988) supra; Mayer et al. (1995) supra], it can be totally functional in apoptosis in cells lacking mitochondrial DNA. Consistent with this model, the cells undergoing apoptosis induced by staurosporine showed increased cytosolic cytochrome c. Release of cytochrome c into the cytosol provides a target for regulation of apoptosis, possibly by the bcl-2 family of proteins.

The biochemical mechanism of cytochrome c function in the activation of CPP32 remains to be determined. The purification and characterization of Apaf-1, which is at least one other component required for the CPP32 activation reaction, will provide further understanding of the early events in apoptosis.

Monoclonal or polyclonal antibodies, preferably monoclonal, specifically reacting with a target protein can be

**EXAMPLES**

Example 1

[0052] General Methods and Materials

[0053] Nucleotide triphosphates were purchased from Pharmacia (Piscataway, N.J.). ADP, GTP, AMP, dAMP, adenosine and deoxyadenosine were from ICN Biomedicals, Inc. (Costa Mesa, Calif.). Pepstatin A, leupeptin, N-acetyl-leucyl-leucyl-norleucine (ALLN) were obtained from Boehringer Mannheim Corporation (Indianapolis, Ind.). Pholivid-methyl-sulfonyl fluoride (PMSF), Imidazole, cAMP, aprotinin, bovine heart cytochrome c and rat liver cytochrome c were purchased from Sigma Chemical Co. (St. Louis, Mo.). 35S-methionine was purchased from Amersham Corporation (Arlington Heights, Ill.). Molecular weight standards for SDS-PAGE and gel filtration chromatography were obtained from Bio-Rad Laboratories (Hercules, Calif.).

[0054] cDNA clones of human SREBP-2 and hamster CPP32 were described in Wang et al. (1995) and protein concentration was determined by the Bradford method [Bradford, M. M. (1976) _Anal. Biochem._ 72, 248-254]. Silver staining was carried out using a Silver Stain Plus kit from Bio-Rad Laboratories (Hercules, Calif.). Plasmids were purified using a Megaprep kit (Qiagen, Chatsworth, Calif.).

Example 2

[0055] Preparation of S-100 Fractions from HeLa Cells, 293 Cells and U937 Cells

[0056] Human HeLa S3 cells were grown as described [Wang et al. (1993) _J. Biol. Chem._ 268, 14497-14504]. The cells (5x10^9/ml) were harvested by centrifugation at 1,800 x g for 10 min at 4°C. After washing once with ice-cold phosphate buffered saline (PBS), the cell pellet was suspended in 5 volumes of ice-cold buffer A [20 mM Hepes-KOH, pH 7.5, 10 mM KCl, 1.5 mM MgCl2, 1 mM sodium EDTA, 1 mM sodium EGTA, 1 mM diithiothreitol (DTT) and 0.1 mM PMSF] supplemented with protease inhibitors (5 μg/ml pepstatin A, 10 μg/ml leupeptin, 2 μg/ml aprotinin, and 25 μg/ml ALLN). After holding on ice for 15 min, the cells were disrupted by douncing 15 times in a 100 ml Kontes douncer with the B pestle (Kontes Glass Co., Vineland, N.J.). The nuclei were centrifuged at 1000 x g for 10 min at 4°C. The supernatant was further centrifuged at 105 x g for 1 hr in a Beckman SW 28 rotor. The resulting supernatant (S-100 fraction) was stored at -80°C and used for the in vitro apoptosis assay and the starting material for the purification of Apaf-2.

[0057] 293 cells were set up at 5x10^5 cells per 100 mm dish in medium A [Dulbecco’s modified Eagle’s medium (DMEM) supplemented with 10% (v/v) heat-inactivated fetal calf serum, 100 μg/ml penicillin and 100 μg/ml streptomycin sulfate]. After incubation for 48 hr at 37°C in a 5% CO2 incubator, the cells were harvested, collected by centrifugation (1000 g, 10 min, 4°C). U937 cells were set up at 5x10^5 cell/ml in medium B [RPMI 1640 medium supplemented with 10% fetal calf serum, 100 μg/ml penicillin and 100 μg/ml streptomycin sulfate]. After incubation for 48 hr in a 5% CO2 incubator, the cells were collected by centrifugation (1000 g, 10 min, 4°C). The cell pellets of 239 cell and U937 cell were washed once with ice-cold PBS and resuspended in 5 volumes of ice-cold buffer A supplemented with protease inhibitors. After holding on ice for 15 min, the cells were broken by passing 15 times through a G22 needle. After centrifugation in a microcentrifuge for 5 min at 4°C, the supernatants were further centrifuged at 105 x g for 30 min in a table top ultracentrifuge (Beckman Instruments, Fullerton, Calif.). The resulting supernatants were used for the in vitro apoptosis assay.

Example 3

[0058] In vitro Translation of CPP32, SREBP, and PARP

[0059] A PCR fragment encoding amino acids 29-277 of hamster CPP32 [Wang et al. (1996) supra] was cloned into NdeI and BamHI sites of PET 15b vector (Novagen, Madison, Wis.). The resulting fusion protein of six histidines with hamster CPP32 (amino acids 29-277) was translated in a TNT 17 transcription/translation kit (Promega, Madison, Wis.) in the presence of 35S-methionine according to the manufacturer’s instructions. The translated protein was passed through a 1 ml nickel affinity column (Qiagen, Chatsworth, Calif.) equilibrated with buffer A. After washing the column with 10 ml of buffer A, the translated CPP32 was eluted with buffer A containing 500 mM imidazole. Human SREBP-2 was translated in a TNT SP6 transcription/translation kit as described [Wang et al. (1995) [Hua et al. (1993) _Proc. Natl. Acad. Sci. USA_ 90, 11603-11607]. Full length human PARP cDNA [Cheney et al. (1987) _Proc. Natl. Acad. Sci. USA_ 84, 8370-8374] was cloned into Smal and EcoRI sites of pBk-CMV vector (Stratagene, La Jolla, Calif.) and translated in a TNT 17 transcription/translation kit (Promega, Madison, Wis.). The translated SREBP-2 and PARP (200 μl each) were purified by passing each translation mixture through a 10-ml Sephadex G-25 gel-filtration column equilibrated with buffer A. The translated proteins contained within the exclusion volume of the column were collected.
Example 4

[0060] Western Blot Analysis

[0061] A monoclonal antibody against human CPP32 was purchased from Transduction Laboratories and a monoclonal antibody against cytochrome c (7H8.2C12) was obtained as described previously [Jemmerson and Johnson (1991) Proc. Natl. Acad. Sci. USA 88, 4428-4432]. Monoclonal antibody specific for cytochrome c is available from Pharmingen. Immoblot analysis was performed with horseadish peroxidase-conjugated anti-mouse immunoglobulin G using the Enhanced Chemiluminescence (ECL) Western Blotting Detection reagents (Amer sham Corporation, Arlington Heights, III.).

Example 5

[0062] Assay for dATP-dependent Activation of CPP32 Protease

[0063] CPP32 was translated and purified as described above. Aliquot of 3 µl of the in vitro translated CPP32 was incubated with the indicated protein fraction, nucleotides, and 1 mM additional MgCl₂ at 30°C. For 1 hour in a final volume of 20 µl of buffer A. At the end of the incubation, 7 µl of 4×SDS sample buffer was added to each reaction. After boiling for 5 min, each sample was subjected to a 15% SDS-polyacrylamide gel electrophoresis (SDS-PAGE). The gel was transferred to a nitrocellulose filter which was subsequently exposed to a Kodak X-OMAT AR X-ray film (Eastman Kodak, Rochester, N.Y.) for 16 hr at room temperature.

Example 6

[0064] Purification of Apaf-2 from HeLa S-100

[0065] All purification steps were carried out at 4°C. All the chromatography steps except the phosphocellulose column were carried out using an automatic fast protein liquid chromatography (FPLC) station (Pharmacia, Piscataway, N.J.).

[0066] 85 ml of HeLa S-100 was applied to a phosphocellulose column (40 ml bed volume) equilibrated with Buffer A. The column was washed with 3 column volumes of buffer A and eluted with 2 column volumes of buffer A containing 0.5 M NaCl. Ammonium sulfate (50%) was added directly to the phosphocellulose 0.5 M elute. After rotating at 4°C for 1 h, the mixture was centrifuged at 15,000 rpm for 15 min in a JA 20 rotor (Beckman Instruments; Fullerton, Calif.). The supernatant was directly applied to a 10 ml phenyl-sepharose column (phenyl-Sepharose, Pharmacia, Piscata way, N.J.) equilibrated with buffer A containing 50% ammonium sulfate. The column was washed with two bed volumes of buffer A containing 50% ammonium sulfate and eluted with buffer A containing 1 M ammonium sulfate. The eluate was loaded onto a Superdex-200 gel filtration column (Pharmacia, Piscataway, N.J.) (300 ml) equilibrated with buffer A and eluted with the same buffer. Fractions of 10 ml were collected and assayed for Apaf-2 activity. The active fractions from the gel filtration column were pooled and loaded onto an anion exchange Mono Q 5/5 column and a cation exchange Mono S 5/5 column connected together. The columns were pre-equilibrated with Buffer A. After loading, the columns were disconnected and the Mono Q column was washed with 5 ml of buffer A containing 0.1 M NaCl and the Apaf-2 activity was eluted from the column with a 20 ml 0-0.3 M linear NaCl gradient. Fractions of 1 ml were collected.

[0067] Preparation of Hamster Liver Nuclei

[0068] Livers from 4 male Golden Syrian hamsters (Sasco) were rinsed with ice-cold phosphate-buffered saline (PBS) and homogenized in 0.25 g/ml of buffer B (10 mM Hepes-KOH, pH 7.6, 2.4 M sucrose, 15 mM KCl, 2 mM sodium EDTA, 0.15 mM spermine, 0.15 mM spermidine, 0.5 mM DTT, 0.5 mM PMSE) by three strokes of a motor-driven homogenizer. The homogenates were centrifuged through a 10-ml cushion of buffer B at 25,000 rpm for 1 h in a SW 28 rotor at 4°C. The nuclei pellet was resuspended in buffer C (10 mM PIPES, pH 7.4, 80 mM KCl, 20 mM NaCl, 5 mM sodium EGTA, 250 mM sucrose, and 1 mM DTT) at 8.5×10⁵ nuclei/ml and stored at −80°C in multiple aliquots.

Example 7

[0069] DNA Fragmentation Assay

[0070] Aliquots of 50 µl HeLa cell S-100 and 6 µl hamster liver nuclei were incubated at 37°C for 2 h with 1 mM additional MgCl₂ in the absence or presence of 1 mM indicated nucleotide. After incubation, an aliquot of 500 µl buffer D (100 mM Tris-HCl, pH 8.5, 5 mM EDTA, 0.2 M NaCl, 0.2% w/v SDS, and 0.2 mg/ml protease K) was added to each reaction and incubated at 37°C overnight. NaCl was then added to a final concentration of 1.5 M, and the nuclear debris was spun down for 15 min in a micro-centrifuge at room temperature. The DNA in the supernatant was precipitated with an equal volume of 100% (v/v) ethanol. The DNA precipitate was washed once with 70% ethanol and resuspended in 40 µl of buffer E containing 10 mM Tris-HCl, pH 7.5, 1 mM sodium EDTA, and 200 µg/ml DNA-ase-free R-Nase A (Worthington Biochemical Corporation, Freehold, N.J.). After incubation at 37°C for 2 h, the DNA was loaded onto 2% agarose gel and electrophoresis was conducted at 50 V for 2 hr in 0.5×TBE buffer (1×TBE buffer contains 90 mM Tris-borate/2 mM EDTA). The gel was stained with 2 µg/ml ethidium bromide for 15 min, destained with water for 1 hr, and the DNA was visualized using UV light.

Example 8

[0071] Immunodepletion of Cytochrome c from HeLa S-100

[0072] An anti-cytochrome c monoclonal antibody (6H2-B4) which recognizes the native form of cytochrome c was described previously [Jemmer son et al. (1991) Eur. J. Immunol. 21, 143-151]. An aliquot of 100 µl (0.7 mg/ml of IgG 2A) of this antibody was incubated with a 1:1 mixture of 50 µl protein A and protein G agarose beads resuspended in 200 µl of PBS (Santa Cruz) at 4°C for 3 h. The beads were collected by centrifugation for 15 min in a microcentrifuge at 4°C. After removal of the supernatant, the beads were washed once with 1 ml of buffer A and incubated with 1.5 ml S-100 fractions for 5 h in a rotator at 4°C. The beads were subsequently pelleted by centrifugation for 15 min in a microcentrifuge at 4°C. The supernatant was used as S-100 immunodepleted of cytochrome c.

[0073] The foregoing examples and disclosure are provided for illustrative purposes, and they are not intended to limit the scope of the invention as provided herein. Any variations in the exemplified compositions and methods which occur to the skilled artisan are intended to fall within the scope of the present invention.
### TABLE I

**Purification of Apaf-2 from HeLa cells**

S-100 was prepared from 20-liters of HeLa cells in spinner culture as described in the Examples. An aliquot of each fraction was dialyzed against buffer A and the Apaf-2 activity was assayed by recombining with

(D) TOPOLOGY: unknown

(ii) MOLECULE TYPE: peptide

(iii) HYPOTHETICAL: NO

(v) FRAGMENT TYPE: internal

(xi) SEQUENCE DESCRIPTION: SEQ ID NO: 4:
Tyr Ile Pro Gly Thr Lys
1  5

(2) INFORMATION FOR SEQ ID NO: 5:

(i) SEQUENCE CHARACTERISTICS:
(A) LENGTH: 13 amino acids
(B) TYPE: amino acid
(C) STRANDEDNESS: single
(D) TOPOLOGY: unknown

(ii) MOLECULE TYPE: peptide

(iii) HYPOTHETICAL: NO
We claim:

1. A method for assaying compositions in vitro for regulation of initiation of apoptosis, said method comprising the steps of:

(a) preparing a 100,000g supernatant extract from cells derived from a multicellular eukaryote, which cells are not physiologically committed to apoptosis;

(b) introducing into an aliquot of the 100,000g supernatant extract of step (a) a composition which can have a negative, positive or no effect on apoptosis to produce an extract assay,

(c) preparing control extract assays comprising, separately, a composition known to inhibit apoptosis, a composition known to induce apoptosis and a composition known to have no effect on apoptosis;

(d) in the alternative, assessing the activation of apoptosis in response to the introduction of the composition by determining an increase in cytosolic cytochrome c, an increase in CPP32 protease activity or increase in ability to fragment genomic DNA in nuclei introduced into the assay mixture as compared to increase in soluble cytochrome c, CPP32 protease activity or ability to fragment genomic DNA as compared to an assay lacking said composition; or assessing inhibition of activation of apoptosis in response to introduction of the composition into an assay mixture in the presence of a composition known to induce the apoptotic pathway in said 100,000g extract by the reduction in soluble cytochrome c, CPP32 protease activity or genomic DNA fragmentation in an assay comprising said composition and a known inducer of the apoptotic
pathway as compared to an assay comprising a known inducer of the apoptotic pathway but lacking said composition; and

comparing soluble cytochrome c, CPP32 protease activity or DNA fragmentation in an extract comprising said composition with soluble cytochrome c, CPP32 protease activity or DNA fragmentation in an extract lacking said composition;

whereby an apoptosis-inhibiting composition is identified by its ability to increase soluble cytochrome c, CPP32 protease activity or DNA fragmentation in the mammalian 100,000g extract of step (a) and whereby an apoptosis-inhibiting composition is identified by its ability to inhibit induction of apoptosis in response to a known inducer of apoptosis in the mammalian 100,000g extract of step (a) or whereby a composition with no effect on the induction of apoptosis is identified as having no effect on soluble cytochrome c, CPP32 protease activity or DNA fragmentation in the presence or absence of a known inducer of apoptosis.

2. The method of claim 1 wherein said cells are mammalian cells.

3. The method of claim 2 wherein cytosolic cytochrome c is detected in an immunological assay for cytochrome c.

4. The method of claim 2 wherein CPP32 protease activity is detected by introducing radiolabeled poly adenosine diphosphate-ribose polymerase (PARP) or one or more radiolabeled sterol regulatory binding proteins (SREBP) into the assay and subsequently detecting fragments of said PARP or SREBP in the assay.

5. The method of claim 4 wherein said SREBP is SREBP-2.

6. The method of claim 4 wherein fragments of PARP or SREBP are detected by sodium dodecyl sulfate-polyacrylamide gel electrophoresis.

7. The method of claim 2 wherein DNA fragmentation is detected by introducing intact mammalian cell nuclei into the extract assays of steps (b) and (c), incubating and subsequently extracting genomic DNA and analyzing size distributions of said genomic DNAs to assess DNA fragmentation.

8. The method of claim 2 wherein the mammalian cells from which the 100,000g extract is made are tumor cells and wherein compositions are tested for their ability to induce apoptosis.

9. The method of claim 8 wherein the tumor cells express a Bcl-2 protein and wherein compositions comprise chemotherapeutic agents tested for the ability to induce apoptosis despite presence of the Bcl-2 protein.

10. The method of claim 2 wherein the extract assays of steps (b) and (c) comprise deoxyadenosine triphosphate and/or deoxyadenosine diphosphate in an amount sufficient to allow the induction of the apoptotic response when assessing the inhibition of activation of apoptosis by the composition.

11. The method of claim 2 wherein said cells are HeLa cells.

12. The method of claim 10 wherein cytosolic cytochrome c is detected in an immunological assay for cytochrome c.

13. The method of claim 10 wherein CPP32 protease activity is detected by introducing radiolabeled poly adenosine diphosphate-ribose polymerase (PARP) or one or more radiolabeled sterol regulatory binding proteins (SREBP) into the assay and subsequently detecting fragments of said PARP or SREBP in the assay.

14. The method of claim 13 wherein said SREBP is SREBP-2.

15. The method of claim 13 wherein fragments of PARP or SREBP are detected by sodium dodecyl sulfate-polyacrylamide gel electrophoresis.

16. The method of claim 10 wherein DNA fragmentation is detected by introducing intact mammalian cell nuclei into the extract assays of steps (b) and (c), incubating and subsequently extracting genomic DNA and analyzing size distributions of said genomic DNAs to assess DNA fragmentation.
