Novel positive-working photoresist compositions are disclosed. The monomers of the base resin of the resist contain diamondoid-containing pendant groups higher than adamantane in the polymanthane series; for example, diamantane, triamantane, tetramantane, pentamantane, hexamantane, etc. The diamondoid-containing pendant group may have hydrophilic-enhancing substituents such as a hydroxyl group, and may contain a lactone group. Advantages of the present compositions include enhanced resolution, sensitivity, and adhesion to the substrate.

PHOTORESIST COMPOSITIONS COMPRISING DIAMONDROID DERIVATIVES

REFERENCE TO RELATED APPLICATIONS

[0001] The present application claims the benefit of U.S. Provisional Patent Application No. 60/508,222 filed Oct. 1, 2003. U.S. Provisional Patent Application No. 60/508,222 is hereby incorporated by reference in its entirety.

BACKGROUND OF THE INVENTION

[0002] 1. Field of the Invention

[0003] Embodiments of the present invention are directed in general toward high performance photoresist compositions used in conjunction with excimer laser and electron beam lithography sources. Specifically, the photoresist compositions of the present invention include diamondoid derivatives having polymerizable and hydrophilic-enhancing functionalities. The diamondoids of the present invention include lower diamondoids such as adamantane, diamantane, and triamantane, as well as the diamondoids tetramantane, pentamantanes, and higher compounds.

[0004] 2. State of the Art

[0005] Increasing demands for devices with higher circuit densities have led to the use of shorter wavelength light sources in optical lithography. KrF (krypton fluoride) excimer laser lithography operating at a wavelength of 248 nm has been used for the production of devices having feature sizes ranging from 0.25 to 0.13 microns. Rapid advances in the miniaturization of microelectronic devices, and demands for devices with increasingly greater circuit densities, are requiring the development of new, imageable polymeric photoresist materials to be used with ArF (argon fluoride) excimer laser lithography at 193 nm, and there is a need on the horizon for resist materials which can operate in the extreme ultraviolet and soft x-ray regim. According to *The National Technology Roadmap for Semiconductors*, (Semiconductor Industry Association, San Jose, Calif., 1997), the next most likely candidate is an F₂ source operating at 157 nm.

[0006] Conventional g-line (436 nm) and i-line (365 nm) photoresists are well-balanced in terms of high-resolution, high sensitivity, and good dry etch resistance, but they typically comprise a novolac base resin and a diazonaphthoquinone PAC (photoactive compound), both of which contain a phenolic moiety that absorbs light having wavelengths below about 365 nm. Thus, the phenolic based resists cannot be used in these shorter wavelengths regimes, such as those found in ArF lithography, because they are completely opaque at 193 nm. The incident radiation cannot penetrate through the full thickness of the resist. This is a significant issue at 248 nm (KrF), which is the wavelength used for 0.25 micron and 0.18 micron generation devices.

[0007] Photoresists are materials used to transfer an image onto a substrate. A layer of the photoresist (or "resist") is formed on a substrate, and then exposed through a mask to a source of radiation. The mask has some regions that are opaque, and some regions that are transparent to the radiation. The portions of the photoresist that are exposed to the radiation undergo a chemical transformation such that the pattern of the mask is transferred to the photoresist layer,

which after development provides a relief image that can be used to selectively process the underlying substrate.

[0008] In general, a photoresist composition comprises at least a resin binder and a photoactive agent. The "chemically amplified" resists in use today were developed for the formation of sub-micron images and other high performance applications. They may be either positive or negative acting. In the case of a positive acting resist, the regions that are exposed to the radiation become more soluble in the developer, while those areas that are not exposed remain comparatively less soluble in the developer. Cationic initiators are used to induce cleavage of certain "blocking groups" pendant from the photoresist binder resin, or cleavage of certain groups that comprise a photoresist binder backbone. Upon cleavage of the blocking group through exposure of a layer of photoresist to light, a base soluble functional group is formed, such as a carboxylic acid or an imide, which results in a different solubility in the developer for the exposed and unexposed regions of the resist layer.

[0009] As taught by J. D. Plummer et al., in "Silicon VLSI Technology" (Prentice Hall, Upper Saddle River, N.J., 2000), pp.221-226, deep ultraviolet (DUV) resists in use today are not modified novolac resists. Deep ultraviolet (DUV) photoresist materials in use today are based on chemistry that makes use of a phenomenon called "chemical amplification." Conventional resist materials that were designed to operate at 365 nm and 248 nm achieved quantum efficiencies of about 0.3, meaning that about 30 percent of the incoming photons interacted with the photoactive compound to expose the resist.

[0010] DUV resists, according to Plummer, work on a different principle that is illustrated in FIG. 1. Referring to FIG. 1, incoming photons react with a photo-acid generator (PAG) 101, creating an acid molecule 102. Acid molecules 102 act as catalysts during a subsequent resistant bake to change the properties of the resist in the exposed region. The photo-acid generator 101 initiates a chemical reaction that makes the resist soluble in a developer in a subsequent developing step that occurs after exposure to the radiation. The reactions are catalytic and the acid molecule 102 is regenerated after each chemical reaction and may therefore participate in tens or even hundreds of further reactions. This is what allows the overall quantum efficiency in a chemically amplified resist to be much larger than 1, and is responsible for improving the sensitivity of a chemically amplified resist from the previous values of about 100 mJ cm⁻² for conventional diazonaphthoquinones to the current values of about 20-40 for the new chemically amplified the ultraviolet photoresists.

[0011] The principle of a chemically amplified photoresist is illustrated in FIG. 1. Referring again to FIG. 1, photoresists of the present invention included in general a photo-acid generator 101 and a blocked or protected polymer 103 which is insoluble in the developer because of attached molecules 104 (labeled additionally "INSOL" in FIG. 1). Incident deep ultraviolet photons interact with the photo-acid generator 101 to create an acid molecule 102. The spatial pattern of the acid molecules 102 within the resist create a "stored," or latent image of the mask pattern. After exposure, the substrate undergoing processing is baked at a temperature of about 120 degrees C. in a process called post exposure bake (PEB). The heat from the post exposure bake

provides the energy needed for the reaction between the acid molecules **102** and the insoluble pendant groups **104** where the reaction is to take place. The heat from the post exposure bake provides the energy needed for the reaction between acid molecules **102** and the insoluble pendant groups **104** attached to main polymer chain **103**; the heat from the post exposure bake also provides diffusion mobility for the acid molecules **102** to seek out unreacted pendant groups **104**, the essence of the catalytic nature of this reaction.

[0012] During the post exposure bake, the insoluble pendant groups **104** are either converted to soluble pendant groups **105**, or cleaved from the polymer chain **103**. In either case, the insoluble, blocked polymer is converted to an unblocked polymer as soluble in an aqueous alkaline developer.

[0013] The polymers that comprise the chain **103** may comprise such polymers as polyamides, polyimides, polyesters, and polycarbonates since these are easily processed, mechanically strong, and thermally stable, and thus have become important materials in the microelectronics industry. Introduction of polycyclic hydrocarbon substituents, including alicyclic rings and other caged hydrocarbons, have been shown to impart greater solubility and enhanced rigidity, improving the mechanical and thermal properties of the resulting polymers. Previous studies have involved the introduction of adamantyl groups into 193 nm resists, but to the applicant's knowledge, there have been no previous attempts to incorporate any diamondoid compound higher than adamantane into the base resin structure. These composition may incorporate lower diamondoids such as diamantane and/or triamantane into the resist structure, or they may include diamondoids such as tetramantane and higher.

[0014] In many instances, the use of photoacid generators that produce weaker photoacids and resists compositions that require lower post exposure bake (PEB) temperatures, such as 110° C. or less, would represent a significant advantage. For example, if the desired deprotection chemistry could be carried out with a weaker acid, a wider range of photoacid generators could potentially be employed. Moreover, the industry continually seeks use of lowered post exposure bake temperatures because of uniformity considerations.

[0015] Thus, it would be advantageous to have new photoresist compositions, particularly positive acting photoresist compositions, that may be effectively imaged in the sub-200 nm wavelength region, such as 193 nm and 157 nm. It is also desirable to provide photoresist compositions that employ photoacid generators.

[0016] Adamantane, the smallest member of the family of diamondoid compounds, is a highly condensed, exceptionally stable hydrocarbon compound. Adamantane and a range of adamantyl derivatives have been commercially available for years. This has made adamantane a regular substituent in a wide variety of families of chemical structures when a large, stable, bulky hydrocarbon moiety is desired. Adamantyl groups are found in polymers and are currently employed as constituents of positive photoresist materials.

[0017] Diamantane is also a highly condensed hydrocarbon compound. It is made up of two face-fused adamantane units. It can be synthesized but also occurs naturally in petroleum and can be isolated from various deep well

hydrocarbon streams such as natural gas streams. A number of diamantane derivatives have been reported in the literature including a variety of mono and poly halides, mono- and dihydroxy materials, mono- and dicarboxylic acid derivatives, mono- and dialkynyls, and mono- and diamines. In addition, there are a number of diamantane-containing polymers in the literature but generally these materials appear to link the diamantane into the polymer through two or more links such that the diamantane forms an integral part of the polymer backbone.

[0018] We now desire to provide a family of derivatives of diamantane that can form polymers having pendant diamantyl groups. In addition, these derivative can contain additional functionality to impart desirable properties to the polymers they form.

SUMMARY OF THE INVENTION

[0019] Embodiments of the present invention are directed to positive working photoresist compositions useable at lithography wavelengths less than about 200 nm, such as the 193 nm wavelength from an ArF eximer laser, a 157 nm F₂ light source, or e-beam excitation. The base resins of the present resist compositions contain acid-cleavable, pendant diamondoid groups that are generally higher in the polymantane series than adamantane. The diamondoid pendant groups have substituents that increase the hydrophilic nature of the diamondoids, thereby rendering them more soluble in an alkali developer, and consequently enhancing their ability to resolve fine feature sizes.

[0020] Embodiments of the present invention specifically include polymerizable diamantyl monomers having the formula Pg-D(R)_n, wherein D is a diamantyl nucleus; Pg is a polymerizable group covalently bonded to a carbon of the diamantyl nucleus; n is an integer ranging from 1 to 6, inclusive; at least one of the R's is a hydrophilic-enhancing moiety; and each of the remaining R's is independently selected from the group consisting of hydrogen and a hydrophilic-enhancing moiety. The hydrophilic-enhancing moieties of these diamantyl monomers may be selected from the group consisting of a hydroxyl group —OH, a carboxylic group —COOH, an alkoxy group —OCH₃ or —OC₂H₅, a keto group —C(O)—, and —OC(O)—OCH₃ or —OC(O)—OC₂H₅.

[0021] Other embodiments of the present invention provide for triamantyl monomers having polymerizable groups and hydrophilic-enhancing moieties similar to those for diamantyl monomers discussed above, as well as diamondoid-containing monomers with polymerizable groups and hydrophilic-enhancing moieties, wherein the diamondoid portion of the diamondoid-containing monomer is selected from the group consisting of tetramantane, pentamantane, hexamantane, heptamantane, octamantane, nonamantane, decamantane, and undecamantane.

[0022] Other embodiments of the present invention provide for methods of forming a layer of patterned photoresist on the surface of a substrate, the method comprising the steps of:

[0023] a) depositing on the surface of the substrate a layer comprising the above mentioned diamantyl, triamantyl, and higher diamondoid containing monomers having polymerizable groups and hydrophilic-enhancing moieties,

[0024] b) polymerizing the deposited monomers to yield a polymerized layer comprising a photo-labile polymer on the surface of the substrate; and

[0025] c) exposing selected regions of the polymerized layer to an electromagnetic beam, thereby modifying the photo-labile polymer in those regions exposed to the electromagnetic beam to yield a selectively modified layer.

[0026] In another embodiment, the base resin of the resist may be represented by the general formula:

[0027] wherein R_1 is selected from the group consisting of $-H$ and $-CH_3$;

[0028] R_2 is selected from the group consisting of $-H$, an alkyl group having from 1 to 4 carbon atoms, and an alkoxy group having from 1 to 4 carbon atoms;

[0029] R_3 is $-H$, or a hydrophilic-enhancing moiety selected from the group consisting of a hydroxyl group $-OH$, a keto group, carboxylic acid group $-COOH$, and alkoxy group $-OR_4$, and $-OC(O)OR_4$;

[0030] R_4 is $-CH_3$ or $-C_2H_5$;

[0031] a is 0.25 to 0.75;

[0032] $b+c=1-a$;

[0033] c is greater than zero; and

[0034] P_1 is a non-diamondoid, acid-cleavable pendant group.

[0035] According to other embodiments of the present invention, the diamondoid pendant groups of the base resin may contain lactone groups, and they may be linked to the main polymer chain by more than one ester linking group, thereby providing multiple sites on which the photo-generated acid can react. This has advantages of allowing either weaker acids, lower post exposure bake temperatures, and a greater variety of photo-acid generators from which to choose. The diamondoid pendant groups may contain hetero atoms in addition to the oxygen atom of a lactone group. The hetero atoms may be selected from the group of O, N, B, S, and/or P. Block co-polymers are also contemplated.

BRIEF DESCRIPTION OF THE DRAWINGS

[0036] This invention will be further described with reference being made to the accompanying drawings in which:

[0037] FIG. 1 is a schematic diagram illustrating the manner in which a positive, chemically amplified resist

operates, taken from J. D. Plummer et al., in "Silicon VLSI Technology" (Prentice Hall, Upper Saddle River, N.J., 2000), pp.221-226;

[0038] FIG. 2 illustrates an exemplary photoresist that has been used for KrF (248 nm) lithography, and an exemplary photoresist that has been used for ArF (193 nm);

[0039] FIG. 3 illustrates the relationship of a diamondoid to the diamond crystal lattice, and enumerates by stoichiometric formula many of the diamondoids available;

[0040] FIG. 4 shows an exemplary process flow for isolating diamondoids from petroleum;

[0041] FIG. 5A is a flow chart that illustrates how diamondoids may be derivatized with hydrophilic-enhancing groups and polymerizable groups to form feed monomers, which may then be polymerized to form the base resin of the resist; the base resin is then mixed with a solvent, photoacid generator, and other additives to produce the fully formulated resist;

[0042] FIG. 5B is a schematic showing how chemistry and processing of diamondoids into derivatized diamondoids contribute to photoresist properties;

[0043] FIGS. 6-20 illustrate exemplary pathways for derivatizing diamondoids;

[0044] FIGS. 21A-B illustrate exemplary base resins of the present invention, wherein the base resin contains a diamondoid pendant group higher in the polymantane series than adamantane (although they may contain adamantane as well);

[0045] FIGS. 21C-D illustrate exemplary non-diamondoid, lactone containing pendant groups;

[0046] FIGS. 22A-E gives nomenclature for the present structural formulas, illustrating how the hydrophilic-enhancing and polymerizable substituents on the diamondoids higher than adamantane have a variety of attachment points;

[0047] FIGS. 23A-B illustrate Ohnishi parameter calculations for base resin repeat units having adamantane, diamantane, triamantane, and iso-tetramantane pendant groups, and for the same pendant groups with 1, 2, 3, and 4 hydroxyl groups, respectively;

[0048] FIG. 24A-D shows exemplary diamondoid-containing monomers with multiple acid-labile sites;

[0049] FIGS. 25A-B illustrate exemplary lactone-containing pendant groups, wherein the lactone group may be part of either the diamondoid-containing pendant group, or the non-diamondoid containing pendant group;

[0050] FIG. 26 illustrates an exemplary block co-polymer of the present invention;

[0051] FIG. 27 illustrates a synthetic pathway for producing a polymer containing iso-tetramantane pendant groups;

[0052] FIG. 28 shows the total ion chromatogram (TIC) of the resulting hydroxylation reaction mixture (10-18 min.);

[0053] FIG. 29 shows the TIC of the separated di-hydroxylated diamantane with its corresponding mass spectrum;

[0054] FIG. 30 shows the TIC of the separated tri-hydroxylated diamantane isomers with a mass spectrum of an isomer;

[0055] FIG. 31 shows a process to separate and purify the tri-hydroxylated diamantanes from the hydroxylation reaction mixture: step 1: water extraction; step 2: first flash column chromatography; step 3: second flash column chromatography. In one embodiment of the present invention, step 2 may be eliminated.

[0056] FIG. 32 shows the TIC of the precipitated solids from the hydroxylation reaction, and the mass spectrum at 17.27 minutes identifying the tetra-hydroxylated diamantanes;

[0057] FIG. 33 shows the TIC of the esterification reaction mixtures (A from example 10 and B from example 11) between 13 and 18 minutes; and

[0058] FIG. 34 shows the TIC of the separated mono-hydroxyl diamantane methacrylate isomers with a mass spectrum of one of the isomer.

DETAILED DESCRIPTION OF THE INVENTION

[0059] Embodiments of the present invention include diamondoids as pendant groups of the base resin of a positive photoresist composition. The present disclosure will be organized in the following manner: first, the term diamondoids will be defined, followed by a discussion of isolation methods of diamondoids from petroleum feedstocks, the derivatization of those isolated diamondoids, and then polymerization of the derivatized diamondoids into photoresist base resins.

[0060] Definition of Diamondoids

[0061] The term "diamondoids" refers to substituted and unsubstituted caged compounds of the adamantane series including adamantane, diamantane, triamantane, tetramantane, pentamantane, hexamantane, heptamantane, octamantane, nonamantane, decamantane, undecamantane, and the like, including all isomers and stereoisomers thereof. The compounds have a "diamondoid" topology, which means their carbon atom arrangement is superimposable on a fragment of an FCC diamond lattice. Substituted diamondoids comprise from 1 to 10 and preferably 1 to 4 independently-selected alkyl substituents. Diamondoids include "lower diamondoids" and "diamondoids," as these terms are defined herein, as well as mixtures of any combination of lower and diamondoids.

[0062] The term "lower diamondoids" refers to adamantane, diamantane and triamantane and any and/or all unsubstituted and substituted derivatives of adamantane, diamantane and triamantane. These lower diamondoid components show no isomers or chirality and are readily synthesized, distinguishing them from "diamondoids."

[0063] The term "diamondoids" refers to any and/or all substituted and unsubstituted tetramantane components; to any and/or all substituted and unsubstituted pentamantane components; to any and/or all substituted and unsubstituted hexamantane components; to any and/or all substituted and unsubstituted heptamantane components; to any and/or all substituted and unsubstituted octamantane components; to any and/or all substituted and unsubstituted nonamantane

components; to any and/or all substituted and unsubstituted decamantane components; to any and/or all substituted and unsubstituted undecamantane components; as well as mixtures of the above and isomers and stereoisomers of tetramantane, pentamantane, hexamantane, heptamantane, octamantane, nonamantane, decamantane, and undecamantane.

[0064] Adamantane chemistry has been reviewed by Fort, Jr. et al. in "Adamantane: Consequences of the Diamondoid Structure," *Chem. Rev.* vol. 64, pp. 277-300 (1964). Adamantane is the smallest member of the diamondoid series and may be thought of as a single cage crystalline subunit. Diamantane contains two subunits, triamantane three, tetramantane four, and so on. While there is only one isomeric form of adamantane, diamantane, and triamantane, there are four different isomers of tetramantane (two of which represent an enantiomeric pair), i.e., four different possible ways of arranging the four adamantane subunits. The number of possible isomers increases non-linearly with each higher member of the diamondoid series, pentamantane, hexamantane, heptamantane, octamantane, nonamantane, decamantane, etc.

[0065] Adamantane, which is commercially available, has been studied extensively. The studies have been directed toward a number of areas, such as thermodynamic stability, functionalization, and the properties of adamantane-containing materials. For instance, the following patents discuss materials comprising adamantane subunits: U.S. Pat. No. 3,457,318 teaches the preparation of polymers from alkenyl adamantanes; U.S. Pat. No. 3,832,332 teaches a polyamide polymer forms from alkyladamantane diamine; U.S. Pat. No. 5,017,734 discusses the formation of thermally stable resins from adamantane derivatives; and U.S. Pat. No. 6,235,851 reports the synthesis and polymerization of a variety of adamantane derivatives.

[0066] In contrast, the diamondoids, have received comparatively little attention in the scientific literature. McKervay et al. have reported the synthesis of anti-tetramantane in low yields using a laborious, multistep process in "Synthetic Approaches to Large Diamondoid Hydrocarbons," *Tetrahedron*, vol.36, pp.971-992 (1980). To the inventor's knowledge, this is the only diamondoid that has been synthesized to date. Lin et al. have suggested the existence of, but did not isolate, tetramantane, pentamantane, and hexamantane in deep petroleum reservoirs in light of mass spectroscopic studies, reported in "Natural Occurrence of Tetramantane ($C_{22}H_{28}$), Pentamantane ($C_{26}H_{32}$) and Hexamantane ($C_{30}H_{36}$) in a Deep Petroleum Reservoir," *Fuel*, vol. 74(10), pp. 1512-1521 (1995). The possible presence of tetramantane and pentamantane in pot material after a distillation of a diamondoid-containing feedstock has been discussed by Chen et al. in U.S. Pat. No. 5,414,189.

[0067] The four tetramantane structures are iso-tetramantane [1(2)₃], anti-tetramantane [121] and two enantiomers of skew-tetramantane [123], with the bracketed nomenclature for these diamondoids in accordance with a convention established by Balaban et al. in "Systematic Classification and Nomenclature of Diamond Hydrocarbons-I," *Tetrahedron* vol. 34, pp.3599-3606 (1978). All four tetramantanes have the formula $C_{22}H_{28}$ (molecular weight 292). There are ten possible pentamantanes, nine having the molecular formula $C_{26}H_{32}$ (molecular weight 344) and among these nine, there are three pairs of enantiomers represented generally by

[12(1)3], [1234], [1213] with the nine enantiomeric pentamantanes represented by [12(3)4], [1(2,3)4], [1212]. There also exists a pentamantane [1231] represented by the molecular formula $C_{25}H_{30}$ (molecular weight 330).

[0068] Hexamantanes exist in thirty-nine possible structures with twenty eight having the molecular formula $C_{30}H_{36}$ (molecular weight 396) and of these, six are symmetrical; ten hexamantanes have the molecular formula $C_{29}H_{34}$ (molecular weight 382) and the remaining hexamantane [12312] has the molecular formula $C_{26}H_{30}$ (molecular weight 342).

[0069] Heptamantanes are postulated to exist in 160 possible structures with 85 having the molecular formula $C_{34}H_{40}$ (molecular weight 448) and of these, seven are achiral, having no enantiomers. Of the remaining heptamantanes 67 have the molecular formula $C_{33}H_{38}$ (molecular weight 434), six have the molecular formula $C_{32}H_{36}$ (molecular weight 420) and the remaining two have the molecular formula $C_{30}H_{34}$ (molecular weight 394).

[0070] Octamantanes possess eight of the adamantane subunits and exist with five different molecular weights. Among the octamantanes, 18 have the molecular formula $C_{34}H_{38}$ (molecular weight 446). Octamantanes also have the molecular formula $C_{38}H_{44}$ (molecular weight 500); $C_{37}H_{42}$ (molecular weight 486); $C_{36}H_{40}$ (molecular weight 472), and $C_{33}H_{36}$ (molecular weight 432).

[0071] Nonamantanes exist within six families of different molecular weights having the following molecular formulas: $C_{42}H_{48}$ (molecular weight 552), $C_{41}H_{46}$ (molecular weight 538), $C_{40}H_{44}$ (molecular weight 524), $C_{39}H_{42}$ (molecular weight 498), $C_{37}H_{40}$ (molecular weight 484) and $C_{34}H_{36}$ (molecular weight 444).

[0072] Decamantane exists within families of seven different molecular weights. Among the decamantanes, there is a single decamantane having the molecular formula $C_{35}H_{36}$ (molecular weight 456) which is structurally compact in relation to the other decamantanes. The other decamantane families have the molecular formulas: $C_{46}H_{52}$ (molecular weight 604); $C_{45}H_{50}$ (molecular weight 590); $C_{44}H_{48}$ (molecular weight 576); $C_{42}H_{46}$ (molecular weight 550); $C_{41}H_{44}$ (molecular weight 536); and $C_{38}H_{40}$ (molecular weight 496).

[0073] Undecamantane exists within families of eight different molecular weights. Among the undecamantanes there are two undecamantanes having the molecular formula $C_{39}H_{40}$ (molecular weight 508) which are structurally compact in relation to the other undecamantanes. The other undecamantane families have the molecular formulas $C_{41}H_{42}$ (molecular weight 534); $C_{42}H_{44}$ (molecular weight 548); $C_{43}H_{46}$ (molecular weight 562); $C_{44}H_{48}$ (molecular weight 576); $C_{45}H_{50}$ (molecular weight 590); $C_{46}H_{52}$ (molecular weight 604); $C_{47}H_{54}$ (molecular weight 618); and $C_{48}H_{56}$ (molecular weight 632).

[0074] Isolation of Diamondoids from Petroleum Feedstocks

[0075] Feedstocks that contain recoverable amounts of diamondoids include, for example, natural gas condensates and refinery streams resulting from cracking, distillation, coking processes, and the like. Particularly preferred feedstocks originate from the Nophlet Formation in the Gulf of Mexico and the LeDuc Formation in Canada.

[0076] These feedstocks contain large proportions of lower diamondoids (often as much as about two thirds) and lower but significant amounts of diamondoids (often as much as about 0.3 to 0.5 percent by weight). The processing of such feedstocks to remove non-diamondoids and to separate higher and lower diamondoids (if desired) can be carried out using, by way of example only, size separation techniques such as membranes, molecular sieves, etc., evaporation and thermal separators either under normal or reduced pressures, extractors, electrostatic separators, crystallization, chromatography, well head separators, and the like.

[0077] A preferred separation method typically includes distillation of the feedstock. This can remove low-boiling, non-diamondoid components. It can also remove or separate out lower and diamondoid components having a boiling point less than that of the diamondoid(s) selected for isolation. In either instance, the lower cuts will be enriched in lower diamondoids and low boiling point non-diamondoid materials. Distillation can be operated to provide several cuts in the temperature range of interest to provide the initial isolation of the identified diamondoid. The cuts, which are enriched in diamondoids or the diamondoid of interest, are retained and may require further purification. Other methods for the removal of contaminants and further purification of an enriched diamondoid fraction can additionally include the following nonlimiting examples: size separation techniques, evaporation either under normal or reduced pressure, sublimation, crystallization, chromatography, well head separators, flash distillation, fixed and fluid bed reactors, reduced pressure, and the like.

[0078] The removal of non-diamondoids may also include a pyrolysis step either prior or subsequent to distillation. Pyrolysis is an effective method to remove hydrocarbonaceous, non-diamondoid components from the feedstock. It is effected by heating the feedstock under vacuum conditions, or in an inert atmosphere, to a temperature of at least about 390° C., and most preferably to a temperature in the range of about 410 to 450° C. Pyrolysis is continued for a sufficient length of time, and at a sufficiently high temperature, to thermally degrade at least about 10 percent by weight of the non-diamondoid components that were in the feed material prior to pyrolysis. More preferably at least about 50 percent by weight, and even more preferably at least 90 percent by weight of the non-diamondoids are thermally degraded.

[0079] While pyrolysis is preferred in one embodiment, it is not always necessary to facilitate the recovery, isolation or purification of diamondoids. Other separation methods may allow for the concentration of diamondoids to be sufficiently high given certain feedstocks such that direct purification methods such as chromatography including preparative gas chromatography and high performance liquid chromatography, crystallization, fractional sublimation may be used to isolate diamondoids.

[0080] Even after distillation or pyrolysis/distillation, further purification of the material may be desired to provide selected diamondoids for use in the compositions employed in this invention. Such purification techniques include chromatography, crystallization, thermal diffusion techniques, zone refining, progressive recrystallization, size separation, and the like. For instance, in one process, the recovered

feedstock is subjected to the following additional procedures: 1) gravity column chromatography using silver nitrate impregnated silica gel; 2) two-column preparative capillary gas chromatography to isolate diamondoids; 3) crystallization to provide crystals of the highly concentrated diamondoids.

[0081] An alternative process is to use single or multiple column liquid chromatography, including high performance liquid chromatography, to isolate the diamondoids of interest. As above, multiple columns with different selectivities may be used. Further processing using these methods allow for more refined separations which can lead to a substantially pure component.

[0082] Detailed methods for processing feedstocks to obtain diamondoid compositions are set forth in U.S. Provisional Patent Application No. 60/262,842 filed Jan. 19, 2001; U.S. Provisional Patent Application No. 60/300,148 filed Jun. 21, 2001; and U.S. Provisional Patent Application No. 60/307,063 filed Jul. 20, 2001, incorporated by reference herein in their entirety.

[0083] Derivatization of Diamondoids

[0084] According to the present embodiments, diamondoid pendant groups are derivatized with at least one functional group to allow attachment to the base polymer chain. Preferably these derivatives have the following Formula I:

[0085] wherein D is a diamondoid nucleus; and, R^1 , R^2 , R^3 , R^4 , R^5 and R^6 are each independently selected from a group consisting of hydrogen and covalently bonded functional groups, provided that there is at least one functional group. More preferably the functionalized diamondoids contain either one or two functional groups.

[0086] In one aspect, as described in U.S. Ser. No. 10/046,486, in the functionalized diamondoids represented by Formula I, R^1 , R^2 , R^3 , R^4 , R^5 and R^6 are preferably independently selected from a group of moieties consisting of $-H$, $-F$, $-Cl$, $-Br$, $-I$, $-OH$, $-SH$, $-NH_2$, $-NHCOCH_3$, $-NHCHO$, $-CO_2H$, $-CO_2R'$, $-COC$, $-CHO$, $-CH_2OH$, $=O$, $-NO_2$, $-CH=CH_2$, $-C\equiv CH$ and $-C_6H_5$; where R' is alkyl (preferably ethyl) provided that R^1 , R^2 , R^3 , R^4 , R^5 and R^6 are not all hydrogen. Typically one or two of R^1 - R^6 are nonhydrogen moieties and the remaining R 's are hydrogens.

[0087] Some functionalized diamondoids can be prepared from diamondoid in a single reaction step. These materials are referred to herein as "primary functionalized diamondoids" and include, for example, diamondoids of Formula I wherein the functionalizing groups are halogens, such as -bromos and -chloros, -oxides, -hydroxyls and -nitros as well as other derivatives formed in one reaction from a diamondoid.

[0088] In another aspect, the functionalized diamondoids are materials prepared from a primary functionalized dia-

mondoid by one or more subsequent reaction steps. These materials are sometimes referred to herein as "secondary functionalized diamondoids." It will be appreciated that in some cases one primary functionalized diamondoid may be conveniently formed by conversion of another primary material. For example, a poly-bromo material can be formed either by single step bromination or by several repeated brominations. Similarly, a hydroxyl diamondoid can be formed directly from a diamondoid in one step or can be prepared by reaction of a bromo-diamondoid, a diamondoid-oxide or the like. Notwithstanding this, to avoid confusion, the primary materials will not be included here in the representative secondary materials. They will, however, be depicted in various figures showing reactions for forming primary and secondary materials to depict both routes to them.

[0089] The functionalized groups available for synthesis of secondary functionalized diamondoids can be selected from a wide range of groups including chloro, bromo, hydroxides, etc. Thus, the following types of secondary materials are merely representatives.

[0090] Representative secondary functionalized diamondoid functional groups include fluoro, iodo, thio, sulfonyl halide, sulfonates, alkyl, haloalkyl, alkoxy, haloalkenyl, alkynyl, haloalkynyl, hydroxyalkyl, heteroaryl, alkylthio, alkoxy; aminoalkyl, aminoalkoxy, aryl, heterocycloalkoxy, cycloalkyloxy, aryloxy, and heteroaryloxy.

[0091] Other functional groups that can be present in secondary functionalized diamondoids are represented by the formula $-C(O)Z$ wherein Z is hydrogen, alkyl, halo, haloalkyl, halothio, amino, monosubstituted amino, disubstituted amino, cycloalkyl, aryl, heteroaryl, heterocyclic; by $-CO_2Z$ wherein Z is as defined previously; by $-R^7COZ$ and $-R^7CO_2Z$ wherein R^7 is alkylene, aminoalkylene, or haloalkylene and Z is as defined previously; by $-NH_2$, $-NHR'$, $-NR'R''$, and $-N^+R'R''R'''$ wherein R' , R'' , and R''' are independently alkyl, amino, thio, thioalkyl, heteroalkyl, aryl, or heteroaryl; by $-R^8NHCOR^9$ wherein R^8 is $-CH_2$, $-OCH_2$, $-NHCH_2$, $-CH_2CH_2$, $-OCH_2CH_2$ and R^9 is alkyl, aryl, heteroaryl, aralkyl, or heteroaralkyl; and by $-R^{10}CONHR^{11}$ wherein R^{10} is selected from $-CH_2$, $-OCH_2$, $-NHCH_2$, $-CH_2CH_2$, and $-OCH_2CH_2$, and R^{11} is selected from alkyl, aryl, heteroaryl, aralkyl, and heteroaralkyl.

[0092] In a further aspect, one or more of the functional groups on the functionalized diamondoids may be of the formulae:

[0093] wherein n is 2 or 3; X is $-O-$, $-S-$, or $-C(O)-$; Y is $=O$ or $=S$; and R^{12} , R^{13} , R^{14} , and R^{15} are independently hydrogen, alkyl, heteroalkyl, aryl or heteroaryl; $=N-Z''$, wherein Z'' is hydrogen, amino, hydroxyl, alkyl,

[0094] cyano, cyanoalkyl, cyanoaryl, or cyanoalkylamino.

[0095] In a further embodiment, one or more of the functional groups on the functionalized diamondoid is $\text{---NHR}'$, $\text{---NR}'\text{R}''$, $\text{---N}^+\text{R}'\text{R}''\text{R}'''$, or $\text{---NHQ}''$ wherein R' , R'' , and R''' independently are hydrogen; aryl; heteroaryl with up to 7 ring members; alkyl; alkenyl; or alkynyl, wherein the alkyl, alkenyl and alkynyl residues can be branched, unbranched or cyclized and optionally substituted with halogen, aryl or heteroaryl with up to 7 ring members; or R' and R'' together with the nitrogen atom form a heterocyclic group with up to 7 ring members. Q'' is thio, thioalkyl, amino, monosubstituted amino, disubstituted amino, or trisubstituted amino with an appropriate counterion such as halogen, hydroxide, sulfate, nitrate, phosphate or other anion.

[0096] In still a further embodiment, the functional group on the functionalized diamondoid is ---COOR^{16} wherein R^{16} is alkyl, aryl, or aralkyl; ---COR^{17} , wherein R^{17} is alkyl, aryl, or heteroalkyl, ---NHNHO , $\text{---R}^{18}\text{NHCOR}^{19}$ wherein R^{18} is absent or selected from alkyl, aryl, or aralkyl, R^{19} is hydrogen, alkyl, ---N_2 , aryl, amino, or ---NHR^{20} wherein R^{20} is hydrogen, $\text{---SO}_2\text{-aryl}$, $\text{---SO}_2\text{-alkyl}$, or $\text{---SO}_2\text{-aralkyl}$, ---CONHR^{21} wherein R^{21} is hydrogen, alkyl, and aralkyl; ---CSNHR^{21} wherein R^{21} is as defined above; and $\text{---NR}^{22}\text{---}(\text{CH}_2)_n\text{---NR}^{23}\text{R}^{24}$, wherein R^{22} , R^{23} , R^{24} are independently selected from hydrogen, alkyl, and aryl, and n is from 1 to 20.

[0097] In an additional embodiment, the functional group on the functionalized diamondoid may be ---N=C=S ; ---N=C=O ; ---R---N=C=O ; ---R---N=C=S ; ---N=S=O ; or ---R---N=S=O wherein R is alkyl; ---PH_2 ; ---POX_2 wherein X is halo; ---PO(OH)_2 ; $\text{---OSO}_3\text{H}$; $\text{---SO}_2\text{H}$; ---SOX wherein X is halo; $\text{---SO}_2\text{R}$ wherein R is alkyl; $\text{---SO}_2\text{OR}$ wherein R is alkyl; $\text{---SONR}^{26}\text{R}^{27}$ wherein R^{26} and R^{27} are independently hydrogen or alkyl; ---N_3 ; ---OC(O)Cl ; or ---OC(O)SCL .

[0098] In a further aspect, the functionalizing group may form a covalent bond to two or more diamondoids and thus serves as a linking group between the two or more diamondoids. This provides functionalized diamondoids of Formula II:

[0099] wherein D is a diamondoid nucleus and L is a linking group and n is 1 or more such as 1 to 10 and especially 1 to 4.

[0100] In this embodiment, the linking group L may be ---N=C---N---

[0101] wherein R^{28} , R^{29} , R^{30} , R^{31} , R^{32} , R^{33} are independently hydrogen or alkyl, and n and m are independently from 2 to 20;

[0102] wherein R^{28} , R^{29} , R^{30} , R^{31} , R^{32} , and R^{33} are hydrogen or alkyl; R^{34} , R^{35} , R^{36} , and R^{37} are independently absent or hydrogen or alkyl with the proviso that at least one of R^{34} , R^{35} , R^{36} , and R^{37} is present; and n and m are independently from 2 to 20 or the like. The counterion may any acceptable monovalent anion, for example, halogen, hydroxide, sulfate, nitrate, phosphate, and the like.

[0103] In another aspect, the present invention relates to functionalized diamondoids of Formula III:

[0104] wherein each D is a diamondoid nucleus and R^{38} and R^{39} are substituents on the diamondoid nucleus and are independently hydrogen or a functionalizing group. Preferably the material contains either 1 or 2 functional groups. Preferably R^{38} and R^{39} are halo; cyano; aryl; arylalkoxy; aminoalkyl; or ---COOR^{40} wherein R^{40} is hydrogen or alkyl.

[0105] In an additional aspect, the present invention provides salts, individual isomers, and mixtures of isomers of diamondoid derivatives of Formulae I, II, and III.

[0106] Turning now to the derivatization reaction of diamondoids, there are three different carbons in the diamon-

doids skeleton: quaternary (4° or C-4), tertiary (3° or C-3), and secondary (2° or C-2) carbons. Of those different carbons, quaternary carbons are impossible to perform any kind of reactions on. Chemical reactions can only take place on those tertiary (3° or C-3) and secondary (2° or C-2) carbons in the diamondoid skeletons. It should be mentioned that some of the tertiary or secondary carbons are equivalent. This means that the derivatives substituted at those equivalent tertiary or secondary carbons are identical.

[0107] FIG. 5 shows a flow chart for the strategy of derivatization of diamondoids and FIG. 6 shows some representative primary derivatives of diamondoids and the corresponding reactions. As shown in FIG. 6, there are, in general, three major reactions for the derivatization of diamondoids sorted by mechanism: nucleophilic (S_N1 -type) and electrophilic (S_E2 -type) substitution reactions, and free radical reaction (details for such reactions and their use with adamantane are shown, for instance in, "Recent developments in the adamantane and related polycyclic hydrocarbons" by R. C. Bingham and P. v. R. Schleyer as a chapter of the book entitled "Chemistry of Adamantanes" (Springer-Verlag, Berlin Heidelberg New York, 1971) and in; "Reactions of adamantanes in electrophilic media" by I. K. Moiseev, N. V. Makarova, M. N. Zemtsova published in *Russian Chemical Review*, 68(12), 1001-1020 (1999); "Cage hydrocarbons" edited by George A. Olah (John Wiley & Son, Inc., New York, 1990).

[0108] S_N1 reactions involve the generation of diamondoid carbocations (there are several different ways to generate the diamondoid carbocations, for instance, the carbocation is generated from a parent diamondoid, a hydroxylated diamondoid or a halogenated diamondoid, shown in FIG. 7), which subsequently react with various nucleophiles. Some representative examples are shown in FIG. 8. Such nucleophiles include, for instance, the following: water (providing hydroxylated diamondoids); halide ions (providing halogenated diamondoids); ammonia (providing aminated diamondoids); azide (providing azidylated diamondoids); nitriles (the Ritter reaction, providing aminated diamondoids after hydrolysis); carbon monoxide (the Koch-Haaf reaction, providing carboxylated diamondoids after hydrolysis); olefins (providing alkenylated diamondoids after deprotonation); and aromatic reagents (providing arylated diamondoids after deprotonation). The reaction occurs similarly to those of open chain alkyl systems, such as t-butyl, t-cumyl and cycloalkyl systems. Since tertiary (bridgehead) carbons of diamondoids are considerably more reactive than secondary carbons under S_N1 reaction conditions, substitution at the tertiary carbons is favored.

[0109] S_E2 -type reactions (i.e., electrophile substitution of a C—H bond via a five-coordinate carbocation intermediate) include, for instance, the following reactions: hydrogen-deuterium exchange upon treatment with deuterated superacids (e.g., $DF-SbF_5$ or DSO_3F-SbF_5); nitration upon treatment with nitronium salts, such as $NO_2^+BF_4^-$ or $NO_2^+PF_6^-$ in the presence of superacids (e.g., CF_3SO_3H); halogenation upon, for instance, reaction with $Cl_2+AgSbF_6$; alkylation of the bridgehead carbons under the Friedel-Crafts conditions (i.e., S_E2 -type σ alkylation); carboxylation under the Koch reaction conditions; and, oxygenation under S_E2 -type a hydroxylation conditions (e.g., hydrogen perox-

ide or ozone using superacid catalysis involving $H_3O_2^+$ or HO_3^+ , respectively). Some representative S_E2 -type reactions are shown in FIG. 9.

[0110] Of those S_N1 and S_E2 reactions, S_N1 -type reactions are the most frequently used for the derivatization of diamondoids. However, such reactions produce the derivatives mainly substituted at the tertiary carbons. Substitution at the secondary carbons of diamondoids is not easy in carbonium ion processes since secondary carbons are considerably less reactive than the bridgehead positions (tertiary carbons) in ionic processes. However, reactions at the secondary carbons are achieved by taking advantage of the low selectivity of free radical reactions and the high ratios of 2° (secondary) to 3° (tertiary, bridgehead) hydrogens in diamondoids. Thus, free radical reactions provide a method for the preparation of a greater number of the possible isomers of a given diamondoid than might be available by ionic processes. The complex product mixtures and/or isomers which result, however, are generally difficult to separate. Due to the decreased symmetry of substituted diamondoids, free radical substitution of these substrates may give rise to very complex product mixtures. Therefore, in most cases, practical and useful free radical substitutions of diamondoids can use photochlorination and/or photooxidation under special circumstances which permit a simpler separation of the product mixture. For instance, photochlorination is particularly useful for the synthesis of chlorinated diamondoids at the secondary carbons because chlorinated diamondoids at the secondary carbons are similar in reactivity to those derivatized at the tertiary carbons.

[0111] Photooxidation is another powerful free radical reaction for the synthesis of hydroxylated derivatives at the secondary carbons which are further oxidized to keto derivatives, which can be reduced to alcohols providing unique hydroxylated diamondoid derivatives at the secondary carbons.

[0112] Considering this significant advantage of separating the keto diamondoids, a variety of diamondoid derivatives at the secondary carbons are prepared starting from the keto derivatives (diamondoidones), such as by reducing the keto group by, for instance, $LiAlH_4$, to provide the corresponding hydroxylated derivatives at the secondary carbons and further derivatizations at the secondary carbons starting from those hydroxylated derivatives. Diamondoidones can also undergo acid-catalyzed (HCl-catalyzed) condensation reaction with, for example, excess phenol or aniline in the presence of hydrogen chloride to form 2,2-bis(4-hydroxyphenyl) diamondoids or 2,2-bis(4-aminophenyl) higher diamondoids substituted at the secondary carbons. With the development of separation technology, such as by using up-to-date HPLC technique, we may predict that more free radical reactions might be employed for the synthesis of derivatives of diamondoids.

[0113] Using those three major types of reactions for the derivatization of diamondoids, a number of diamondoid derivatives are prepared. Representative core reactions and the derivatives are presented as following as either very important means to activate the diamondoid nuclei or very important precursors for further derivatizations.

[0114] FIG. 10 shows some representative pathways for the preparation of brominated diamondoid derivatives.

Mono- and multi-brominated diamondoids are some of the most versatile intermediates in the derivative chemistry of diamondoids. These intermediates are used in, for example, the Koch-Haaf, the Ritter, and the Friedel-Crafts alkylation/arylation reactions. Brominated diamondoids are prepared by two different general routes. One involves direct bromination of diamondoids with elemental bromine in the presence or absence of a Lewis acid (e.g. BBr_3 — AlBr_3) catalyst. The other involves the substitution reaction of hydroxylated diamondoids with hydrobromic acid.

[0115] Direct bromination of diamondoids is highly selective resulting in substitution at the bridgehead (tertiary) carbons. By proper choice of catalyst and conditions, one, two, three, four, or more bromines can be introduced sequentially into the molecule, all at bridgehead positions. Without a catalyst, the mono-bromo derivative is the major product with minor amounts of higher bromination products being formed. By use of suitable catalysts, however, di-, tri-, and tetra-, penta-, and higher bromide derivatives of diamondoids are isolated as major products in the bromination (e.g., adding catalyst mixture of boron bromide and aluminum bromide with different molar ratios into the bromine reaction mixture). Typically, tetrabromo or higher bromo derivatives are synthesized at higher temperatures in a sealed tube.

[0116] To prepare bromo derivatives substituted at secondary carbons, for example, the corresponding hydroxylated diamondoids at the secondary carbons is treated under mild conditions with hydrobromic acid. Preferably, diamondoids hydroxylated at secondary carbons are prepared by the reduction of the corresponding keto derivative as described above.

[0117] Bromination reactions of diamondoids are usually worked up by pouring the reaction mixture onto ice or ice water and adding a suitable amount of chloroform or ethyl ether or carbon tetrachloride to the ice mixture. Excess bromine is removed by distillation under vacuum and addition of solid sodium disulfide or sodium hydrogen sulfide. The organic layer is separated and the aqueous layer is extracted by chloroform or ethyl ether or carbon tetrachloride for an additional 2-3 times. The organic layers are then combined and washed with aqueous sodium hydrogen carbonate and water, and finally dried.

[0118] To isolate the brominated derivatives, the solvent is removed under vacuum. Typically, the reaction mixture is purified by subjecting it to column chromatography on either alumina or silica gel using standard elution conditions (e.g., eluting with light petroleum ether, n-hexane, or cyclohexane or their mixtures with ethyl ether). Separation by preparative gas chromatography (GC) or high performance liquid chromatography (HPLC) is used where normal column chromatography is difficult and/or the reaction is performed on extremely small quantities of material.

[0119] Similarly to bromination reactions, diamondoids are chlorinated or photochlorinated to provide a variety of mono-, di-, tri-, or even higher chlorinated derivatives of the diamondoids. **FIG. 11** shows some representative pathways for the synthesis of chlorinated diamondoid derivatives, especially those chlorinated derivatives at the secondary carbons by way of photochlorination.

[0120] **FIG. 12** shows some representative pathways for the synthesis of hydroxylated diamondoids. Direct hydroxy-

lation is also effected on diamondoids upon treatment with N-hydroxyphthalimide and a binary co-catalyst in acetic acid. Hydroxylation is a very important way of activating the diamondoid nuclei for further derivatizations, such as the generation of diamondoid carbocations under acidic conditions, which undergo the $\text{S}_{\text{N}}1$ reaction to provide a variety of diamondoid derivatives. In addition, hydroxylated derivatives are very important nucleophilic agents, by which a variety of diamondoid derivatives are produced. For instance, the hydroxylated derivatives are esterified under standard conditions such as reaction with an activated acid derivative. Alkylation to prepare ethers is performed on the hydroxylated derivatives through nucleophilic substitution on appropriate alkyl halides.

[0121] The above described three core derivatives (hydroxylated diamondoids and halogenated especially brominated and chlorinated diamondoids), in addition to the parent diamondoids or substituted diamondoids directly separated from the feedstocks as described above, are most frequently used for further derivatizations of diamondoids, such as hydroxylated and halogenated derivatives at the tertiary carbons are very important precursors for the generation of higher diamondoid carbocations, which undergo the $\text{S}_{\text{N}}1$ reaction to provide a variety of diamondoid derivatives thanks to the tertiary nature of the bromide or chloride or alcohol and the absence of skeletal rearrangements in the subsequent reactions. Examples are given below.

[0122] **FIG. 13** shows some representative pathways for the synthesis of carboxylated diamondoids, such as the Koch-Haaf reaction, starting from hydroxylated or brominated diamondoids. It should be mentioned that for most cases, using hydroxylated precursors get better yields than using brominated diamondoids. For instance, carboxylated derivatives are obtained from the reaction of hydroxylated derivatives with formic acid after hydrolysis. The carboxylated derivatives are further esterified through activation (e.g., conversion to acid chloride) and subsequent exposure to an appropriate alcohol. Those esters are reduced to provide the corresponding hydroxymethyl diamondoids (diamondoid substituted methyl alcohols, $\text{D-CH}_2\text{OH}$). Amide formation is also performed through activation of the carboxylated derivative and reaction with a suitable amine. Reduction of the diamondoid carboxamide with reducing agents (e.g. lithium aluminum hydride) provides the corresponding aminomethyl diamondoids (diamondoid substituted methylamines, $\text{D-CH}_2\text{NH}_2$).

[0123] **FIG. 14** shows some representative pathways for the synthesis of acylaminated diamondoids, such as the Ritter reaction starting from hydroxylated or brominated diamondoids. Similarly to the Koch-Haaf reaction, using hydroxylated precursors get better yields than using brominated diamondoids in most cases. Acylaminated diamondoids are converted to amino derivatives after alkaline hydrolysis. Amino diamondoids are further converted to, without purification in most cases, amino diamondoid hydrochloride by introducing hydrochloride gas into the aminated derivatives solution. Amino diamondoids are some of very important precursors in the synthesis of medicines. They are also prepared from the reduction of nitrated compounds. **FIG. 15** shows some representative pathways for the synthesis of nitro diamondoid derivatives. Diamondoids are nitrated by concentrated nitric acid in the presence of glacial acetic acid under high temperature and pressure. The

nitrate diamondoids are reduced to provide the corresponding amino derivatives. In turn, for some cases, amino diamondoids are oxidized to the corresponding nitro derivatives if necessary. The amino derivatives are also synthesized from the brominated derivatives by heating them in the presence of formamide and subsequently hydrolyzing the resultant amide.

[0124] Similarly to the hydroxylated compounds, amino higher diamonds are acylated or alkylated. For instance, reaction of an amino diamondoid with an activated acid derivative produces the corresponding amide. Alkylation is typically performed by reacting the amine with a suitable carbonyl containing compound in the presence of a reducing agent (e.g. lithium aluminum hydride). The amino diamondoids undergo condensation reactions with carbamates such as appropriately substituted ethyl N-arylsulfonylcarbamates in hot toluene to provide, for instance, N-arylsulfonyl-N'-diamondoidylureas.

[0125] FIG. 16 presents some representative pathways for the synthesis of alkylated, alkenylated, alkynylated and arylated diamondoids, such as the Friedel-Crafts reaction. Ethenylated diamondoid derivatives are synthesized by reacting a brominated diamondoid with ethylene in the presence of AlBr_3 followed by dehydrogen bromide with potassium hydroxide (or the like). The ethenylated compound is transformed into the corresponding epoxide under standard reaction conditions (e.g., 3-chloroperbenzoic acid). Oxidative cleavage (e.g., ozonolysis) of the ethenylated diamondoid affords the related aldehyde. The ethynylated diamondoid derivatives are obtained by treating a brominated diamondoid with vinyl bromide in the presence of AlBr_3 . The resultant product is dehydrogen bromide using KOH or potassium t-butoxide to provide the desired compound.

[0126] More reactions are illustrative of methods which can be used to functionalize diamondoids. For instance, fluorination of a diamondoid is carried out by reacting the diamondoid with a mixture of poly(hydrogen fluoride) and pyridine (30% Py, 70% HF) in the presence of nitronium tetrafluoroborate. Sulfur tetrafluoride reacts with a diamondoid in the presence of sulfur monochloride to afford a mixture of mono-, di-, tri- and even higher fluorinated diamondoids. Iodo diamondoids are obtained by a substitutive iodination of chloro, bromo or hydroxyl diamondoids.

[0127] Reaction of the brominated derivatives with hydrochloric acid in dimethylformamide (DMF) converts the compounds to the corresponding hydroxylated derivatives. Brominated or iodinated diamondoids are converted to thiolated diamondoids by way of, for instance, reacting with thioacetic acid to form diamondoid thioacetates followed by removal of the acetate group under basic conditions. Brominated diamondoids, e.g. D-Br, is heated under reflux with an excess (10 fold) of hydroxyalkylamine, e.g. $\text{HO}-\text{CH}_2\text{CH}_2-\text{NH}_2$, in the presence of a base, e.g. triethylamine, diamondoidoxyalkylamine, e.g. $\text{D}-\text{O}-\text{CH}_2\text{CH}_2-\text{NH}_2$, is obtained. On acetylation of the amines with acetic anhydride and pyridine, a variety of N-acetyl derivatives are obtained. Direct substitution reaction of brominated diamondoids, e.g. D-Br, with sodium azide in dipolar aprotic solvents, e.g. DMF, to afford the azido diamondoids, e.g. D- N_3 .

[0128] Diamondoid carboxylic acid hydrazides are prepared by conversion of diamondoid carboxylic acid into a

chloroanhydride by thionyl chloride and condensation with isonicotinic or nicotinic acid hydrazide (FIG. 17).

[0129] Diamondoidones or "diamondoid oxides" are synthesized by photooxidation of diamondoids in the presence of peracetic acid followed by treatment with a mixture of chromic acid-sulfuric acid. Diamondoidones are reduced by, for instance, LiAlH_4 , to diamondoidols hydroxylated at the secondary carbons. Diamondoidones also undergo acid-catalyzed (HCl-catalyzed) condensation reaction with, for example, excess phenol or aniline in the presence of hydrogen chloride to form 2,2-bis(4-hydroxyphenyl) diamondoids or 2,2-bis(4-aminophenyl) diamondoids.

[0130] Diamondoidones (e.g. $\text{D}=\text{O}$) are treated with RCN ($\text{R}=\text{hydrogen, alkyl, aryl, etc.}$) and reduced with LiAlH_4 to give the corresponding C-2-aminomethyl-C-2-D-OH, which are heated with COCl_2 or CSCl_2 in toluene to afford the following derivatives shown in formula IV (where $\text{Z}=\text{O}$ or S):

IV

[0131] Diamondoidones react with a suitable primary amine in an appropriate solvent to form the corresponding imines. Hydrogenation of the imines in ethanol using Pd/C as the catalyst at about 50°C . to afford the corresponding secondary amines. Methylation of the secondary amines following general procedures (see, for instance, H. W. Geluk and V. G. Keiser, *Organic Synthesis*, 53:8 (1973)) to give the corresponding tertiary amines. Quaternization of the tertiary amines by, for instance, slowly dropping CH_3I (excess) into an ethanol solution of the amine at around 35°C . to form the corresponding quaternary amines.

[0132] C-2 derivatives of diamondoids, C-2 D-R' ($\text{R}'=\text{alkyl, alkoxy, halo, OH, Ph, COOH, CH}_2\text{COOH, NHCOCH}_3, \text{CF}_3\text{COOH}$) are prepared by nucleophilic substitution of diamondoid-C-2-spiro-C-3-diazirine in solution at $0-80^\circ\text{C}$. in the presence of an acid catalyst.

[0133] N-sulfinyl diamondoids $[\text{D}-(\text{NSO})_n, n=1, 2, 3, 4, \dots]$ are prepared by refluxing the diamondoid-HCl with SOCl_2 in benzene for about half an hour to several hours affording mono-, di-, tri-, or higher N-sulfinyl diamondoid derivatives.

[0134] Treatment of D-Br and/or D-Cl with HCONH_2 (wt. ratio not $>1:2$) at $<195^\circ\text{C}$. followed by hydrolysis of the formylamino diamondoids D-NHCHO with $<20\%$ HCl at $<110^\circ\text{C}$. affords the amino diamondoid hydrochloride D-NH $_2$ HCl.

[0135] Diamondoid dicarboxamides are prepared by the reaction of diamondoid dicarbonyl chloride or diamondoid diacetyl chloride with aminoalkylamines. For instance, $\text{D}-(\text{COCl})_2$ [from SOCl_2 and the corresponding dicarboxylic acid $\text{D}-(\text{COOH})_2$] are treated with $(\text{CH}_3)_2\text{NCH}_2\text{CH}_2\text{CH}_2\text{NH}_2$ in $\text{C}_5\text{H}_5\text{N}-\text{C}_6\text{H}_6$ to give N,N'-bis(dimethylaminopropyl) diamondoid dicarboxamide.

[0136] Aminoethoxyacetyl amino diamondoids are prepared from chloroacetyl amino diamondoids and $\text{HOCH}_2\text{CH}_2\text{NR}'\text{R}''$. Thus, for instance, amino diamondoids, D-NH_2 , and ClCH_2COCl in benzene, is added to $(\text{CH}_3)_2\text{NCH}_2\text{CH}_2\text{ONa}$ in xylene and refluxed for about 10 hours to give aminoethoxyacetyl amino diamondoids ($\text{R}'=\text{R}''=\text{CH}_3$).

[0137] Ritter reaction of C-3 D-OH and HCN gives D-NH_2 ; the preparation of D-NHCHO from diamondoids and HCN; the reaction of diamondoids with nitriles gives D-NHCHO and D-NH_2 ; the preparation of aza diamondoids from nitriles and compounds containing unsaturated OH groups, and SH groups, and so on.

[0138] Hydroxylated diamondoids, e.g. D-OH, react with COCl_2 or CSCl_2 to afford the diamondoidyl oxycarbonyl derivatives, e.g. D-O-C(O)Cl or D-O-C(S)Cl the former being an important blocking group in biochemical syntheses.

[0139] FIG. 18 shows representative reactions starting from D-NH_2 and D-CONH_2 and the corresponding derivatives, wherein D is a diamondoid nucleus.

[0140] FIG. 19 shows representative reactions starting from D-POCl_2 and the corresponding derivatives, wherein D is a diamondoid nucleus.

[0141] FIG. 20 shows representative reactions starting from D-SH or D-SOCl and the corresponding derivatives, wherein D is a diamondoid nucleus.

[0142] Polymerizable Diamantyl, and Triamantyl, and Higher Diamondoid Containing Monomers

[0143] Embodiments of the present invention specifically include polymerizable diamantyl monomers having the formula Pg-D-(R)_n , wherein D is a diamantyl nucleus; Pg is a polymerizable group covalently bonded to a carbon of the diamantyl nucleus; n is an integer ranging from 1 to 6, inclusive; at least one of the R's is a hydrophilic-enhancing moiety; and each of the remaining R's is independently selected from the group consisting of hydrogen and a hydrophilic-enhancing moiety. The hydrophilic-enhancing moieties of these diamantyl monomers may be selected from the group consisting of a hydroxyl group $-\text{OH}$, a carboxylic group $-\text{COOH}$, an alkyl group $-\text{OCH}_3$ or $-\text{OC}_2\text{H}_5$, a keto group $-\text{C(O)-}$, and a group $-\text{OC(O)-OCH}_3$ or $-\text{OC(O)OC}_2\text{H}_5$.

[0144] Other embodiments of the present invention provide for triamantyl monomers having polymerizable groups and hydrophilic-enhancing moieties similar to those for diamantyl monomers discussed above, as well as diamondoid-containing monomers with polymerizable groups and hydrophilic-enhancing moieties, wherein the diamondoid portion of the diamondoid-containing monomer is selected from the group consisting of tetramantane, pentamantane, hexamantane, heptamantane, octamantane, nonamantane, decamantane, and undecamantane.

[0145] In other embodiments of the present invention, the polymerizable groups Pg of the diamantyl, triamantyl, higher diamondoid containing monomers are capable of forming photo-labile polymers. The polymerizable groups may be covalently bonded to either secondary (2°) carbons or tertiary carbons (3° , also called bridgehead carbons) of the diamantyl, triamantyl, or higher diamondoid nucleus.

These polymerizable groups may comprise an unsaturated acid residue bound to the diamantyl, triamantyl, or higher diamondoid nucleus to form an ester, and the unsaturated acid residue may comprise an acrylate or a lower alkyl acrylate. When the unsaturated acid residue is an acrylic acid residue the respective monomer becomes an acrylate monomer. Similarly, when the unsaturated acid residue is an methacrylic acid residue the respective monomer becomes an methacrylate monomer.

[0146] Further embodiments of the present invention provide for methods of forming a layer of patterned photoresist on the surface of a substrate. Such methods comprise the steps of:

[0147] a) forming a polymer from monomers selected from the group consisting of a diamantyl monomer having a polymerizable group and at least one hydrophilic-enhancing group; a triamantyl monomer having a polymerizable group and at least one hydrophilic-enhancing group; and a diamondoid-containing monomer having a polymerizable group and at least one hydrophilic-enhancing group, the diamondoid of the diamondoid-containing monomer selected from the group consisting of tetramantane, pentamantane, hexamantane, heptamantane, octamantane, nonamantane, decamantane, and undecamantane;

[0148] b) depositing the polymer on a surface of the substrate as a polymeric layer, the polymeric layer comprising a photo-labile polymer; and

[0149] c) exposing selected regions of the polymerized layer to an electromagnetic beam, thereby modifying the photo-labile polymer in those regions exposed to the electromagnetic beam to yield a selectively modified layer.

[0150] According to further embodiments, the method described above may include the step of contacting the selectively modified layer with a solvent system to solubilize the modified regions. The electromagnetic beam may comprise radiation having a wavelength less than about 200 nm, and exemplary wavelengths are 193 nm and 157 nm. The electromagnetic beam may also be an e-beam or an x-ray beam.

[0151] As will be explained, one excellent application for these monomers and polymers is as components of photoresists. In this application the monomers and polymers can serve as components of deposited layers. These layers are additional aspects of this invention as are patterned layers and methods of preparing them all of which employ the instant diamantyl and/or triamantyl monomers and polymers.

[0152] Photoresist Base Resins

[0153] Prior art polymers that have been used in positive-acting photoresists have been discussed by K. Nozaki and E. Yano in "High-Performance Resist Materials for ArF Eximer Laser and Electron Beam Lithography," Fujitsu Sci. Tech. J., 38, 1, p. 3-12 (June, 2002). These authors teach that conventionally, polyvinylphenol-based resists were generally used in electron beam lithography, and such resins made use of a variety of protecting groups such as acetals, tert-butoxycarbonyl, and tert-butyl. The disadvantages of

these protecting groups included a poor dry-etch resistance due to the aliphatic structures. To overcome this problem, K. Nozaki and E. Yano suggested the use of acid sensitive and dry etch resistant protective groups. These authors teach that dry etch resistance may be imparted to the resist by incorporating acid cleavable alicyclic substituents into the base polymer.

[0154] K. Nozaki and E. Yano reported on the use of mevalonic lactone methacrylate (MLMA) and 2-methyl-2-adamantane methacrylate (MAdMA) based copolymers. The adamantyl, polycyclic hydrocarbon substituent provided superior sensitivity, resolution, and dry etch resistance, whereas the lactone containing monomer afforded compatibility with conventional developers such as tetramethylammonium hydroxide (TMAH), and adhesion to silicon substrates. The adamantane and lactone substituents were chosen since they can function as acid labile ester groups in the methacrylate polymer. The hydrophilic mevalonic lactone group provided adhesion to the silicon substrate, and was acid cleavable because it contained an acid sensitive β -hydroxyketone structure and a tertiary alcohol. The alicyclic adamantyl substituent provided dry etch resistance, and was also acid cleavable because of a tertiary alcohol. These authors teach that the adamantyl groups have a stronger dissolution inhibition than, for example, a t-butyl pendant group would have, which comes about from its highly hydrophobic nature and bulky structure. Thus, a large polarity change can be obtained with a small amount of deprotection, and therefore a superior contrast between exposed and unexposed regions of the resist may be realized, contributing to enhance resolution.

[0155] Of particular interest is the imaging results obtained by K. Nozaki and E. Yano. A series of five methacrylate polymers were prepared, wherein the ratios of the monomers MLMA/MAdMA ranged from 0/100, 22/78, 51/49, 72/28, and 100/0, respectively. The polymers prepared from the latter two monomer ratios could not be imaged because they were alkali soluble, and it was not possible to resolve any resist patterns. Furthermore, the polymer prepared from the 100/0 ratio was difficult to spin-coat because the photo-acid generator separated out from the resist composition. The polymers prepared from the first two monomer ratios likewise did not image well (or could not be imaged) because the formulated resist patterns peeled off the silicon substrates, suggesting that the rigid adamantyl units imparted a brittleness to the resist. The photoresist composition containing roughly equal amounts of the two monomers was thought to be a promising compromise, and based on their observations, the optimum composition for the base polymer was about MAdMA/MLMA=1/1.

[0156] The photoresist compositions of the present embodiments include acid-cleavable diamondoid blocking groups higher in the homologous series than adamantane. The advantages of including such diamondoids is that an enhanced etch resistance may be imparted to the base resin, thereby improving the resolution of the resist, but the choice of diamondoid higher than adamantane, the amounts in which it is used, and the number of hydrophilic-enhancing groups with which it is derivatized, comprise a part of the subject matter of the present disclosure.

[0157] Co-Polymer Base Resins with Diamondoids Higher than Adamantane

[0158] According to embodiments of the present invention, the base resin of a positive-acting photoresist may be represented by the general formula illustrated in FIGS. 21A-C. The positive-working photoresist composition shown in FIG. 21A comprises a polymeric backbone chain 210, which may include pendant groups 212. The pendant groups 212 may be a non-diamondoid pendant group represented by P_1 , or the pendant groups may be diamondoid-containing such as the adamantane based pendant group 214 or the diamantane based pendant group 216. In this example, the pendant groups 212 are connected to the main backbone chain 210 through ester groups 218, which is the linkage that imparts the acid-cleavable character to the base resin shown in FIG. 21A. Also depicted in FIG. 21A are alkyl groups R_2 that yield a tertiary alcohol when the blocking groups 214 and 216 are cleaved, as well as hydrophilic-enhancing groups R_3 .

[0159] Specifically, in this exemplary base resin, R_1 may be either $-H$ or $-CH_3$, such that the polymeric backbone chain 210 constitutes either an acrylate type polymer, or a methacrylate type polymer, respectively. R_2 in this example may be either $-H$, in which case the diamondoid-containing monomer is not acid cleavable, or an alkyl (such as $-CH_3$) group having from 1 to 4 carbon atoms. In the latter case the diamondoid-containing pendant group is acid cleavable because the capability of forming a carbon-carbon double bond exists. The dissolution ability of the pendant group (i.e., the ability of the pendant group to dissolve in an alkali developer) is enhanced by the fact that a tertiary alcohol is formed when R_2 is an alkyl group or an alkoxy group. R_3 is either $-H$, or a hydrophilic-enhancing moiety that may be either a hydroxyl group $-OH$, a carboxylic group $-COOH$, an alkyl group $-OR_4$, a keto group $-C(O)-$, or $-OC(O)-OR_4$. It will be apparent to those skilled in the art that $-OR_4$ represents the situation when an alcohol group $-OH$ is protected, wherein the protection may be in the form of an alkyl group or an acetate group.

[0160] One feature of the present embodiments that contribute to their novelty is the fact that, unlike the base polymers taught by K. Nozaki and E. Yano, a monomer having a diamondoid pendant group higher than adamantane is included in the base resin. This exemplary monomer that contains a pendant group higher than adamantane is shown in FIG. 21A as diamantane. The advantages of including monomers with diamondoid-containing pendant groups higher than adamantane is that since because there are more carbons present in the sp^3 -hybridized, diamond cubic crystal structure, the blocking group is more resistant to the etching process, and thus, the exposed and unexposed regions of the resist are more delineated. This feature enhances resolution. Furthermore, because the etch resistance has been improved, it may be possible to incorporate less of the diamondoid containing monomer into the base resin, improving the ability of the resist to adhere to the substrate.

[0161] According to embodiments of the present invention, the ratios of the feed monomers for the exemplary base resin depicted in FIG. 21A may be represented by the relationships:

[0162] a is 0.25 to 0.75;

[0163] $b+c=1-a$; and

[0164] c is greater than zero,

[0165] where a, b, and c represent the relative amounts of the non-diamondoid containing monomer, the adamantane-containing monomer, and the diamantane-containing monomer, respectively. It will be understood by those skilled in the art that the formula shown in **FIG. 21A** is schematic only, and that the repeat units represented in quantities a, b, and c may appear in virtually any order in the polymer chain. In other words, the repeat units do not have to follow the pattern a, b, c, a, b, c, and may instead take the form a, a, b, a, c, a, b, b, a, b, c, a, c, b, etc.

[0166] A consequence of including monomers with diamondoid-containing pendant groups higher than adamantane is that the pendant group will be more hydrophobic, and thus it will be more difficult to dissolve the blocking group in the alkali developer. This issue may be addressed, however, by derivatizing the diamantane or higher pendant group with a larger number of hydrophilic-enhancing groups, such as the —OH group R_3 . The number of these that are required is also the subject matter of the present disclosure.

[0167] The diamondoid-containing monomer having a pendant group higher than adamantane is not limited to diamantane, and may in fact comprise triamantane **220**, and diamondoids **222** that are even higher than triamantane in the polymantane hydrocarbon series. This is illustrated in **FIG. 21B**. The term “diamondoid” in **FIG. 21B** is meant to represent any of the diamondoids tetramantane, pentamantane, hexamantane, heptamantane, octamantane, nonamantane, decamantane, and undecamantane. Again, the order of the repeat units in the chain is not limited to that shown in **FIG. 21B**, as this is just a schematic drawing of an exemplary polymer. If the polymer contains either or both diamantane and triamantane, and even diamondoids, the amounts of these repeat units (which may be the same thing as saying the relative amounts of the monomers in the feed, depending on the reactivity of the monomers during the polymerization process), may be represented by c, d, and e, respectively.

[0168] In the exemplary polymer of **FIG. 21A**, P_1 is a non-diamondoid, acid-cleavable pendant group that may be represented by the structures shown in **FIGS. 21C-D**. The value of “n” may be either 0 or 1. If $n=0$, then the non-diamondoid pendant group shown in **FIG. 21C** comprises a five-membered heterocyclic ring with no R_6 or R_7 substituents on the ring. If $n=1$, then the non-diamondoid pendant group shown in **FIG. 21C** comprises a five-membered heterocyclic ring with substituents R_6 or R_7 on the alpha carbon relative to where the ring attaches to the main polymeric backbone. Again, the linkage in this exemplary polymer is an ester linkage, making the polymer an acrylate or methacrylate, but many other types of linkages are possible.

[0169] A six-membered heterocyclic ring for the non-diamondoid, acid-cleavable pendant group P_1 is shown in **FIG. 21D**. In this case, again exemplary, the substituents R_6 or R_7 are always present on the alpha carbon.

[0170] It will be understood by those skilled in the art that the nomenclature used in **FIGS. 21A-B** is meant to represent that there are multiple attachment sites for the exemplary substituent groups R_2 and R_3 onto the carbon framework of the pendant diamondoid group. An example of this concept is illustrated schematically in **FIGS. 22A-E**. An exemplary

diamondoid pendant group tetramantane is shown at **224** in **FIG. 22A**. The tetramantane pendant group **224** is attached to the main polymer chain by ester linkage **226**, as before. The tetramantane molecule is shown as containing substituents R_2 , R_3 , R_4 , and R_5 , and the nomenclature in **FIG. 22A** is meant to indicate that these substituents may be attached at a number of possible sites to the tetramantane carbon framework (secondary and tertiary carbons shown in **FIGS. 22B-E**). It will become apparent to the reader that one of the advantages of including diamondoid-containing pendant groups higher than adamantane are the vast number of possible attachment sites for hydrophilic-enhancing groups, alkyl groups, and polymerizable groups.

[0171] Etch Resistance

[0172] The inclusion of diamondoid-containing monomers higher than adamantane is contemplated to have the advantageous result of imparting enhanced etch resistance to the polymer. As discussed in a reference titled “Lithographic Resists,” by W. D. Hinsberg et al. (IBM Research Division, K-Othmer, Encyclopedia of Chemical Technology), a parameter was devised by Ohnishi et al. to correlate a photoresist’s chemical composition with its ability to withstand an etching environment. The parameter is given by $N/(N_c - N_o)$, where N is the total number of atoms in the polymer repeat unit, including hydrogen atoms, N_c is the number of carbon atoms, and N_o is the number of oxygen atoms.

[0173] The model serves as a fair predictor of etch rates for polymers under conditions where physical ion bombardment is a significant component, as is the case for reactive ion etching. The relation fails for low ion energy plasma conditions, such as those that what occurred in a downstream glow discharge process, where etching mechanisms are primarily chemical in nature. The Ohnishi parameter predicts that polymers having a high content of carbon (e.g., a low Ohnishi number) will exhibit low etch rates. In contrast, incorporation of hydrogen and/or oxygen into the repeat unit structure increases the etch rate, while an increased carbon content reduces the etch rate.

[0174] The Ohnishi numbers for exemplary monomers of the present invention, with adamantane for comparison, are shown with their respective schematic drawings in **FIG. 23A**. Referring to **FIG. 23A**, an adamantane-containing repeat unit has an Ohnishi number of 3.00, while this number decreases for diamantane, triamantane, and tetramantane as follows: 2.75, 2.60, and 2.50. As taught by the present disclosure, however, it is necessary to include hydrophilic-enhancing groups as substituents on the diamondoid pendant groups, and the number of these hydrophilic-enhancing groups that are required will increase as the size of the diamondoid increases.

[0175] It is a surprising result just how many of these hydrophilic-enhancing groups may be tolerated with respect to etch resistance. For example, **FIG. 23B** calculates the Ohnishi number for the same series adamantane, diamantane, triamantane, and tetramantane, only an additional hydroxyl group is added as a substituent each time the size of the diamondoid is increased. Even with this additional “burden” on the etch resistance of the resist, the Ohnishi number still decreases for the series adamantane with one hydroxyl substituent, diamantane with two hydroxyl substituents, triamantane with three hydroxyl substituents, and tetramantane with four hydroxyl substituents (3.36, 3.29, 3.24, and 3.20, respectively).

[0176] Multiple Acid-Labile Sites

[0177] Embodiments of the present invention include the ability of the diamondoid containing pendant group to be cleaved at multiple sites in the link connecting the pendant group to the main polymer chain. This is illustrated schematically in FIGS. 24A-D. Referring to **FIG. 24A**, a polymerizable group **230**, which along with methyl group **232** and ester group **234** defines this exemplary polymer as a methacrylate, is attached through a second ester linkage **236** to diamondoid **238**. The diamondoid **238** has an alkyl substituent **240** attached to the same carbon atom as the ester linkage **236**. For exemplary purposes, a hydroxyl substituent **242** is shown attached to diamondoid **238**, which in this case is a diamantane molecule.

[0178] The purpose of multiple ester linkages **234** and **236** is to provide a multiplicity of locations for the acid generated from the exposure event to cleave pendant diamondoid **238** from the main polymer chain (not shown). The advantages of providing multiple acid cleaving sites is at least twofold: 1) a weaker acid may be used to cleave the diamondoid pendant groups, allowing at the same time for a decreased post exposure bake temperature relative to what otherwise might have been necessary, and 2) a potentially larger variety of photo-acid generators become available. The ability to lower the post exposure bake temperature, to 110° C. or less, for example, is highly desirable in the industry because of uniformity considerations. Multiple acid-cleaving sites are contemplated to be effective for the purposes cited above because the acid-cleaving process is a diffusion driven one, and having more sites available means that the acid molecule does not have to diffuse as far.

[0179] Three more examples of diamondoid-containing monomers with multiple acid-labile sites are shown in **FIGS. 24B, C, and D**, wherein the diamondoid in **FIG. 24B** is a triamantane with a hydroxyl and methyl substituents, and the linking group **244** contains three ester linkages; the tetramantane in **FIG. 24C** has acetate and a carboxylic acid substituent groups (and two ester linkages), and the triamantane in **FIG. 24D** has two hydroxyl substituents (and three ester linkages).

[0180] Lactone-Containing Diamondoid Pendant Groups

[0181] The adhesion enhancing lactone group need not be restricted to the non-diamondoid containing pendant group **P1** of **FIGS. 21A-B**. An exemplary polymer containing lactone groups in both the non-diamondoid and the diamondoid-containing pendant groups is shown in **FIGS. 25A-B**.

[0182] Fully Formulated Resists

[0183] The photoresist composition may further include a solvent such as ethylene dichloride, cyclohexanone, cyclopentanone, 2-heptanone, γ -butyrolactone, methyl ethyl ketone, ethylene glycol monomethyl ether, ethylene glycol monoethyl ether, 2-methoxyethyl acetate, ethylene glycol monoethyl ether acetate, propylene glycol monomethyl ether (PGME), propylene glycol monomethyl ether acetate (PGMEA), ethylene carbonate, toluene, ethyl acetate, butyl acetate, methyl lactate, ethyl lactate, methyl methoxypropionate, ethyl ethoxypropionate, methyl methoxypropionate, ethyl pyruvate, propyl pyruvate, N,N-dimethylformamide, dimethylsulfoxide, N-methylpyrrolidone, and tetrahydrofuran.

[0184] The photoresist compositions of the present embodiments may be developed in an aqueous alkaline solution such as sodium hydroxide, potassium hydroxide, sodium carbonate, sodium silicate, sodium metasilicate, aqueous ammonia, a primary amine, ethylamine, n-propylamine, a secondary amine, diethylamine, di-n-butylamine, a tertiary amine, triethylamine, methyldiethylamine, an alcohol amine, dimethylethanolamine, triethanolamine, a quaternary ammonium salt, tetramethylammonium hydroxide, tetraethylammonium hydroxide, a cyclic amine, pyrrole, and piperidine.

[0185] The photoresist compositions of the present invention further include a photoacid generator selected from the group consisting of an onium salt, a diazonium salt, an ammonium salt, a phosphonium salt, an iodonium salt, a sulfonium salt, a selenonium salt, an arsonium salt, an organic halogeno compound, and an organo-metal/organic halide compound. The photoacid generator may have an o-nitrobenzyl type protecting group, and it may generate a sulfonic acid upon photolysis. Furthermore, the photoresist composition may contain the photo-acid generator in an amount ranging from about 0.01 to 30 weight percent.

[0186] The photoresist composition of the present embodiments may further include an additive selected from the group consisting of a surface active agent, an organic basic compound, an acid decomposable dissolution inhibiting compound, a dye, a plasticizer, a photosensitizer, and a compound promoting solubility in a developing solution, as well as diamondoid derivatives as an additive.

EXAMPLES

[0187] The present invention will be described in detail below in terms of example; however, the present invention is not limited in any way to these examples. The reaction mixture and the products were analyzed and characterized by gas chromatography/mass spectrometry (GC/MS) to confirm the presence of target compounds formed and the purity of the products separated. The GC/MS systems used is an HP 5890 Series II Chromatography connected to an HP 5973 Series MSD (mass selective detector).

Example 1

[0188] 47.1 g of diamantane was dissolved in 375 ml of acetic acid, then 4.1 g of N-hydroxyphthalimide (NHPI), 0.322 g of Co(acac)₂ (cobalt (II) acetylacetonate) were added into the mixture. The mixture was stirred for about 23 hours at around 75° C. in a bubbling oxygen atmosphere. During the reaction, an additional portion of NHPI and Co(acac)₂ were added. After cooling down to room temperature (20° C.) and filtering off the precipitated unreacted diamantane, the orange colored reaction mixture was concentrated under vacuum to give a dark red oily liquid. The dark red oily liquid was dissolved in methylene chloride. The methylene chloride solution of the reaction mixture was first extracted with water for several times. The combined water layers were then extracted with methylene chloride for a few times and finally the combined organic layers were concentrated and subjected to silica gel column chromatography, thus producing di-hydroxylated diamantane with yields of about 30%. The conversion rate of the diamantane was about 64%.

Example 2

[0189] A mixture of 9.42 g of diamantane, 0.82 g of N-hydroxyphthalimide (NHPI), 0.064 g of Co(acac)₂ (cobalt

(II) acetylacetonate) and 75 ml of acetic acid was stirred for about 23 hours at around 75° C. in an oxygen bubbling atmosphere. During the reaction, an additional portion of NHPI and Co(acac)₂ were added. After cooling down to room temperature (20° C.), the reaction mixture was then concentrated and subjected to silica gel column chromatography, thus producing di- and tri-hydroxylated diamantane with yields of about 30% and 20% respectively.

Example 3

[0190] A mixture of 18.84 g of diamantane, 1.64 g of N-hydroxyphthalimide (NHPI), 0.129 g of Co(acac)₂ (cobalt (II) acetylacetonate) and 75 ml of acetic acid was stirred for about 23 hours at around 75° C. in a bubbling oxygen atmosphere. During the reaction, an additional portion of NHPI and Co(acac)₂ were added. The reaction mixture was concentrated and the concentrated reaction mixture was dissolved in methylene chloride. The methylene chloride solution of the reaction mixture was first extracted with water for several times. The combined water layers were then extracted with methylene chloride for a few times and finally the water was evaporated and the residual was subjected to flash silica gel column chromatography, thus producing tri-hydroxylated diamantane with yields of about 20%.

Example 4

[0191] 12.4 g of the crude red oily liquid from water extractions in Example 1 mainly containing tri-hydroxylated diamantane was dissolved in about 200 mL ethyl alcohol. 27 g of activated carbon (60-100 mesh) was added into the ethyl alcohol solution. The mixture was then stirred for about 3.5 hours at room temperature (20° C). After filtration, the colorless solution was concentrated to give a colorless oily liquid.

Example 5

[0192] 600 mL of combined methylene chloride extractions in Example 1 were added 6 g of activated carbon. The mixture was stirred for about 20 hours at room temperature (20° C.). After filtration, a pale yellow solution was obtained and the solvent evaporated to give a pale yellow solids. The crude solids were subjected to silica gel column chromatography, thus producing a colorless solid of di-hydroxylated diamantane.

Example 6

[0193] 5 g of colorful oily liquid from the water extractions in Example 3 was dissolved in 70 mL of ethyl alcohol. Then 10 g of activated carbon was added and the mixture was stirred for about 3.5 hours at room temperature (20° C.). After filtration, the colorless solution was concentrated to an almost colorless oily liquid. The liquid was then dissolved in 2:1 v/v methylene chloride and THF (tetrahydrofuran). The solution was passed on a flash short silica gel column eluting first with 2:1 v/v methylene chloride and THF followed by THF and ethyl alcohol (5:1 v/v). The second fraction was concentrated to give a colorless oily liquid of tri-hydroxylated diamantane. The first fraction was concentrated to mainly give a white solid of di-hydroxylated diamantane.

Example 7

[0194] A portion of the dark red oily liquid in Example 1 was added a large excess amount of methylene chloride to

precipitate a solid. After filtration and decoloring by activated carbon as above, the solids were analyzed by GC/MS to show the presence of tetra-hydroxylated diamantane.

Example 8

[0195] Methacryloyl chloride was added dropwise to a stirred solution of an equimolar amount of di-hydroxylated diamantane, excess triethylamine, and methylene chloride in a dry nitrogen atmosphere at around -30 to 0° C. Then the resulting mixture was further stirred for several hours while maintaining the temperature. The resultant mixture was filtrated, and the filtrate was concentrated under vacuum. The concentrated mixture was washed with water and brine. The water layers were combined and extracted with methylene chloride. The organic layers were combined and dried over anhydrous Na₂SO₄ and concentrated in vacuum. Finally, the concentrate was subjected to silica gel column chromatography, thus producing mono-hydroxyl diamantane methacrylate (yield: 5%). The conversion rate of the di-hydroxylated diamantane was about 10%.

Example 9

[0196] 0.4 g of mono-hydroxylated diamantane was dissolved in 50 mL of methylene chloride. Methacryloyl chloride (0.2 mL) and triethylamine (0.5 mL) were added to the solution at room temperature (20° C.) under dry nitrogen atmosphere. The mixture was stirred at room temperature (20° C.) under dry nitrogen atmosphere for about 2 hours. Then the mixture was cooled down to 0° C. and another amount of methacryloyl chloride (0.15 mL) and 50 mg 4-DMAP (4-dimethylaminopyridine) in 5 mL cold methylene chloride were added into the mixture. The mixture was stirred at 0° C. for 30 minutes and then the cooling bath was removed. The mixture was again stirred at room temperature (20° C.) for 3 days. GC-MS of the reaction mixture showed the formation of diamantane methacrylate.

Example 10

[0197] To a 50 mL of methylene chloride were added the di-hydroxylated diamantane (5.73 mmol) and methacrylic acid (1.1 molar equ.). The mixture was stirred for 15 minutes at 0° C. under dry nitrogen. Dicyclohexyl carbodiimide (DCC, 2.1 molar equ.) and 4-DMAP (0.3 molar equ.) in about 25 mL cold methylene chloride were added, and the mixture was then stirred for 30 minutes at 0° C. under dry nitrogen. The cooling bath was then removed and the solution allowed to warm to room temperature (about 20° C). After being stirred for 50 hours under nitrogen, the reaction mixture was filtered through a fine glass frit to yield a clear filtrate and the insoluble urea byproduct as a fine white-grey solid. The clear filtrate was washed with water (3×50 mL), 5% acetic acid aqueous solution (3×20 mL), and finally again with water (3×30 mL). The organic layer was separated, dried over anhydrous Na₂SO₄, filtered, and the solvent evaporated. The residual was subjected to column chromatography to give mono-hydroxyl diamantane methacrylate (yield: 50%). The conversion rate of the di-hydroxylated diamantane was about 60%.

Example 11

[0198] 5.8 mmol of di-hydroxylated diamantane, 6.4 mmol of triethylamine and 75 mL of methylene chloride were placed in a three necked round-bottom flask. A mixed

solution of 5.5 mmol of methacryloyl chloride and 5 mL methylene chloride was added dropwise over a period of 5 minutes under stirring with the reaction temperature maintained at 0° C., and the mixture was further stirred for 3 hours at 0° C. under nitrogen. The cooling bath was then removed and the mixture was stirred at room temperature (20° C.) for 23 hours. At last the temperature was increased to about 30° C. and the mixture was stirred at the increased temperature for 2 more hours while adding 0.25 mL of the acid chloride and 0.5 mL of triethylamine. An extraction was performed by adding water to the reaction mixture, and the organic layer was separated, washed with water and brine. The water layer was extracted with methylene chloride. The organic layers were combined, dried with anhydrous Na₂SO₄ and concentrated in vacuum. The concentrate was subjected to silica gel column chromatography, thus producing mono-hydroxyl diamantane methacrylate (yield: 40%). The conversion rate of the di-hydroxylated diamantane was about 60%.

[0199] Many modifications of the exemplary embodiments of the invention disclosed above will readily occur to those skilled in the art. Accordingly, the invention is to be construed as including all structure and methods that fall within the scope of the appended claims.

What is claimed is:

1. A polymerizable diamantyl monomer having the formula Pg-D-(R)_n, wherein:

D is a diamantyl nucleus;

Pg is a polymerizable group covalently bonded to a carbon of the diamantyl nucleus;

n is an integer ranging from 1 to 6, inclusive;

at least one of the R's is a hydrophilic-enhancing moiety; and

each of the remaining R's is independently selected from the group consisting of hydrogen and a hydrophilic-enhancing moiety.

2. The diamantyl monomer of claim 1, wherein the hydrophilic-enhancing moiety is selected from the group consisting of a hydroxyl group —OH, a carboxylic group —COOH, an alkyl group —OCH₃ or —OC₂H₅, a keto group —C(O)—, and a group —OC(O)—OCH₃ or —OC(O)—OC₂H₅.

3. The diamantyl monomer of claim 1, wherein the polymerizable group Pg forms a photo-labile polymer.

4. The diamantyl monomer of claim 1, wherein the polymerizable group Pg is covalently bonded to a tertiary (3°), bridgehead carbon of the diamantyl nucleus.

5. The diamantyl monomer of claim 1, wherein the polymerizable group Pg is an unsaturated acid residue bound to the diamantyl nucleus to form an ester.

6. The diamantyl monomer of claim 5, wherein the unsaturated acid residue is an acrylate or a lower alkyl acrylate.

7. The diamantyl monomer of claim 6, wherein the unsaturated acid residue is an acrylic acid residue such that the diamantyl monomer is an acrylate monomer.

8. The diamantyl monomer of claim 6, wherein the unsaturated acid residue is a methacrylic acid residue such that the diamantyl monomer is a methacrylate monomer.

9. A polymerizable triamantyl monomer having the formula Pg-D-(R)_n, wherein:

D is a triamantyl nucleus;

Pg is a polymerizable group covalently bonded to a carbon of the triamantyl nucleus;

n is an integer ranging from 1 through 6, inclusive;

at least one of the R's is a hydrophilic-enhancing moiety; and

each of the remaining R's is independently selected from the group consisting of hydrogen and a hydrophilic-enhancing moiety.

10. The triamantyl monomer of claim 9, wherein the hydrophilic-enhancing moiety is selected from the group consisting of a hydroxyl group —OH, a carboxylic group —COOH, an alkyl group —OCH₃ or —OC₂H₅, a keto group —C(O)—, and a group —OC(O)—OCH₃ or —OC(O)—OC₂H₅.

11. The triamantyl monomer of claim 9, wherein the polymerizable group Pg forms a photo-labile polymer.

12. The triamantyl monomer of claim 9, wherein the polymerizable group Pg is covalently bonded to a tertiary (3°), bridgehead carbon of the triamantyl nucleus.

13. The triamantyl monomer of claim 9, wherein the polymerizable group Pg is an unsaturated acid residue bound to the triamantyl nucleus to form an ester.

14. The triamantyl monomer of claim 13, wherein the unsaturated acid residue is an acrylate or a lower alkyl acrylate.

15. The triamantyl monomer of claim 14, wherein the unsaturated acid residue is an acrylic acid residue such that the triamantyl monomer is an acrylate monomer.

16. The triamantyl monomer of claim 14, wherein the unsaturated acid residue is a methacrylic acid residue such that the triamantyl monomer is a methacrylate monomer.

17. A polymerizable, diamondoid-containing monomer having the formula Pg-D-(R)_n, wherein:

D is a diamondoid nucleus selected from the group consisting of tetramantane, pentamantane, hexamantane, heptamantane, octamantane, nonamantane, decamantane, and undecamantane;

Pg is a polymerizable group covalently bonded to a carbon of the diamondoid nucleus;

n is an integer ranging from 1 through 6, inclusive;

at least one of the R's is a hydrophilic-enhancing moiety; and

each of the remaining R's is independently selected from the group consisting of hydrogen and a hydrophilic-enhancing moiety.

18. The diamondoid-containing monomer of claim 17, wherein the hydrophilic-enhancing moiety is selected from the group consisting of a hydroxyl group —OH, a carboxylic group —COOH, an alkyl group —OCH₃ or —OC₂H₅, a keto group —C(O)—, and a group —OC(O)—OCH₃ or —OC(O)—OC₂H₅.

19. The diamondoid-containing monomer of claim 17, wherein the polymerizable group Pg forms a photo-labile polymer.

20. The diamondoid-containing monomer of claim 17, wherein the polymerizable group Pg is covalently bonded to a tertiary (3°), bridgehead carbon of the diamondoid nucleus.

21. The diamondoid-containing monomer of claim 17, wherein the polymerizable group Pg is an unsaturated acid residue bound to the diamondoid nucleus to form an ester.

22. The diamondoid-containing monomer of claim 21, wherein the unsaturated acid residue is an acrylate or a lower alkyl acrylate.

23. The diamondoid-containing monomer of claim 22, wherein the unsaturated acid residue is an acrylic acid residue such that the diamondoid-containing monomer is an acrylate monomer.

24. The diamondoid-containing monomer of claim 22, wherein the unsaturated acid residue is a methacrylic acid residue such that the diamondoid-containing monomer is a methacrylate monomer.

25. A polymer having recurring units selected from the group consisting of:

- a) a diamantyl monomer having a polymerizable group and at least one hydrophilic-enhancing group;
- b) a triamantyl monomer having a polymerizable group and at least one hydrophilic-enhancing group; and
- c) a diamondoid-containing monomer having a polymerizable group and at least one hydrophilic-enhancing group, the diamondoid of the diamondoid-containing monomer selected from the group consisting of tetramantane, pentamantane, hexamantane, heptamantane, octamantane, nonamantane, decamantane, and undecamantane.

26. A deposited layer comprising the polymer of claim 25.

27. A method of forming a layer of patterned photoresist on the surface of a substrate, the method comprising the steps of:

- a) forming a polymer from monomers selected from the group consisting of a diamantyl monomer having a polymerizable group and at least one hydrophilic-enhancing group; a triamantyl monomer having a polymerizable group and at least one hydrophilic-enhancing group; and a diamondoid-containing monomer having a polymerizable group and at least one hydrophilic-enhancing group, the diamondoid of the diamondoid-containing monomer selected from the group consisting of tetramantane, pentamantane, hexamantane, heptamantane, octamantane, nonamantane, decamantane, and undecamantane;
- b) depositing the polymer on a surface of the substrate as a polymeric layer, the polymeric layer comprising a photo-labile polymer; and
- c) exposing selected regions of the polymeric layer to an electromagnetic beam, thereby modifying the photo-labile polymer in those regions exposed to the electromagnetic beam to yield a selectively modified layer.

28. The method of claim 27, additionally comprising the step of contacting the selectively modified layer with a solvent system to solubilize the modified regions.

29. The method of claim 28, wherein the electromagnetic beam comprises radiation having a wavelength less than about 200 nm.

30. The method of claim 29, wherein the radiation has a wavelength of about 193 nm.

31. The method of claim 29, wherein the radiation has a wavelength of about 157 nm.

32. The method of claim 28, wherein the electromagnetic beam is an e-beam.

33. The method of claim 28 wherein the electromagnetic beam is an x-ray beam.

34. A patterned surface formed the method of claim 27.

35. A method of forming a selected pattern on a surface of a substrate, the method comprising the steps of:

- a) forming a photo-labile polymer on the surface of the substrate, the photo-labile polymer comprising monomers selected from the group consisting of a diamantyl monomer having at least one polymerizable group and at least one hydrophilic-enhancing group; a triamantyl monomer having a polymerizable group and at least one hydrophilic-enhancing group; and a diamondoid-containing monomer having a polymerizable group and at least one hydrophilic-enhancing group, the diamondoid of the diamondoid-containing monomer selected from the group consisting of tetramantane, pentamantane, hexamantane, heptamantane, octamantane, nonamantane, decamantane, and undecamantane; and

- b) exposing selected regions of the layer comprising the photo-labile polymer to an electromagnetic beam, thereby modifying the photo-labile polymer in those regions exposed to the electromagnetic beam to yield a selectively modified layer.

36. The method of claim 35, additionally comprising the step of contacting the selectively modified layer with a solvent system to solubilize the modified regions.

37. The method of claim 36, wherein the solvent system comprises an alkali developer solution.

38. The method of claim 35, wherein the electromagnetic beam comprises radiation having a wavelength less than about 200 nm.

39. The method of claim 38, wherein the radiation has a wavelength of about 193 nm.

40. The method of claim 38, wherein the radiation has a wavelength of about 157 nm.

41. The method of claim 35, wherein the electromagnetic beam is selected from the group consisting of an e-beam and an x-ray beam.

42. A patterned surface formed the method of claim 35.

43. A positive-working photoresist composition comprising a base resin represented by the general formula:

wherein R_1 is selected from the group consisting of $-H$ and $-CH_3$;

R_2 is selected from the group consisting of $-H$, an alkyl group having from 1 to 4 carbon atoms, and an alkoxy group having from 1 to 4 carbon atoms;

R_3 is $-H$, or a hydrophilic-enhancing moiety selected from the group consisting of a hydroxyl group $-OH$, a keto group $=O$, carboxylic acid group $-COOH$, and alkoxy group $-OR_4$, and a lactone group $-OC(O)OR_4$;

R_4 is CH_3 or $-C_2H_5$;

a is 0.25 to 0.75;

$b+c=1-a$;

c is greater than zero; and

P_1 is a non-diamondoid, acid-cleavable pendant group.

44. The photoresist composition of claim 43, wherein b is about 0 and c is about 0.5.

45. The photoresist composition of claim 43, wherein P_1 is a lactone-containing pendant group.

46. The photoresist composition of claim 44, wherein P_1 is selected from the group consisting of:

wherein n is 0 or 1; and

R_4 , R_6 , and R_7 are each individually selected from the group consisting of H , an alkyl group having from 1 to 4 carbon atoms, and an alkoxy group having from 1 to 4 carbon atoms.

47. A positive-working photoresist composition comprising a base resin represented by the general formula:

wherein R_1 is selected from the group consisting of $-H$ and $-CH_3$;

R_2 is selected from the group consisting of $-H$, an alkyl group having from 1 to 4 carbon atoms, and an alkoxy group having from 1 to 4 carbon atoms;

R_3 is $-H$, or a hydrophilic-enhancing moiety selected from the group consisting of a hydroxyl group $-OH$, a keto group $=O$, carboxylic acid group $-COOH$, and alkoxy group $-OR_4$, and a lactone group $-OC(O)OR_4$;

R_4 is $-CH_3$ or $-C_2H_5$;

a is 0.25 to 0.75;

$b+c+d$ is substantially equal to $1-a$; and

P_1 is a non-diamondoid, acid-cleavable pendant group.

48. The photoresist composition of claim 47, wherein c is about 0 to 0.25.

49. The photoresist composition of claim 47, wherein d is about 0 to 0.25.

50. The photoresist composition of claim 47, wherein $c+d$ is about 0 to 0.25.

51. The photoresist composition of claim 47, wherein $3b$ and $2b$ are substantially equal to d .

52. The photoresist composition of claim 43, wherein P_1 is a lactone-containing pendant group.

53. The photoresist composition of claim 44, wherein P_1 is selected from the group consisting of:

wherein n is 0 or 1; and

R_4 , R_6 , and R_7 are each individually selected from the group consisting of H, an alkyl group having from 1 to 4 carbon atoms, and an alkoxy group having from one to 4 carbon atoms.

54. A positive-working photoresist composition comprising a base resin represented by the general formula:

wherein R_1 is selected from the group consisting of —H and —CH_3 ;

R_2 is selected from the group consisting of —H , an alkyl group having from 1 to 4 carbon atoms, and an alkoxy group having from 1 to 4 carbon atoms;

R_3 is —H , or a hydrophilic-enhancing moiety selected from the group consisting of a hydroxyl group —OH , a keto group =O , carboxylic acid group —COOH , and alkoxy group —OR_4 , and a group —OC(O)OR_4 ;

R_4 is —CH_3 or $\text{—C}_2\text{H}_5$;

a is 0.25 to 0.75;

b+c+d+e is substantially equal to 1-a; and

P_1 is a non-diamondoid, acid-cleavable pendant group.

55. The photoresist composition of claim 54, wherein c ranges from about 0 to 0.25.

56. The photoresist composition of claim 54, wherein d ranges from about 0 to 0.25.

57. The photoresist composition of claim 54, wherein e ranges from about 0 to 0.25.

58. The photoresist composition of claim 54, wherein c+d+e ranges from about 0 to 0.25.

59. The photoresist composition of claim 54, wherein b, the amount of the adamantane containing monomer, is about equal to c+d+e, the total amount of the diamantane, triamantane, and diamondoid-containing monomers.

60. The photoresist composition of claim 54, wherein P_1 is a lactone-containing pendant group.

61. The photoresist composition of claim 60, wherein P_1 is selected from the group consisting of:

wherein n is 0 or 1; and

R_4 , R_6 , and R_7 are each individually selected from the group consisting of H, an alkyl group having from 1 to 4 carbon atoms, and an alkoxy group having from one to 4 carbon atoms.

62. A positive-acting photoresist composition comprising a base resin represented by the general formula:

wherein R_1 is selected from the group consisting of $-H$ and $-CH_3$;

R_2 is selected from the group consisting of $-H$, an alkyl group having from 1 to 4 carbon atoms, and an alkoxy group having from 1 to 4 carbon atoms;

R_3 is $-H$, or a hydrophilic-enhancing moiety selected from the group consisting of a hydroxyl group $-OH$, a keto group $=O$, carboxylic acid group $-COOH$, and alkoxy group $-OR_4$, and a group $-OC(O)OR_4$;

R_4 is $-CH_3$ or $-C_2H_5$;

a is 0.25 to 0.75;

$b=1-a$; and

P_1 is a non-diamondoid, acid-cleavable pendant group.

63. The photoresist composition of claim 62, wherein b and c each range from about 0 to 0.5.

64. The photoresist composition of claim 62, wherein b and c are approximately equal to one another.

65. The photoresist composition of claim 62, wherein P_1 is a lactone-containing pendant group.

66. The photoresist composition of claim 62, wherein P_1 is selected from the group consisting of:

wherein n is 0 or 1; and

R_4 , R_6 , and R_7 are each individually selected from the group consisting of H , an alkyl group having from 1 to 4 carbon atoms, and an alkoxy group having from 1 to 4 carbon atoms.

67. A positive-acting photoresist composition comprising a base resin polymerized from any of the following monomers:

-continued

wherein R_1 is selected from the group consisting of $-H$ and $-CH_3$;

R_2 is selected from the group consisting of $-H$, an alkyl group having from 1 to 4 carbon atoms, and an alkoxy group having from 1 to 4 carbon atoms;

R_3 is $-H$, or a hydrophilic-enhancing moiety selected from the group consisting of a hydroxyl group $-OH$, a keto group $=O$, carboxylic acid group $-COOH$, and alkoxy group $-OR_4$, and a group $-OC(O)OR_4$;

R_4 is $-CH_3$ or $-C_2H_5$.

68. The photoresist composition of claim 67, further including a monomer having adamantane as a pendant group.

69. The photoresist composition of claim 67, further including a monomer having a diamondoid pendant group.

70. A positive-acting photoresist composition comprising a base resin having a heterodiamondoid as a pendant group.

71. The photoresist composition of claim 70, wherein the base resin is polymerized from any of the following monomers:

wherein R_1 is selected from the group consisting of $-H$ and $-CH_3$;

R_2 is selected from the group consisting of $-H$, an alkyl group having from 1 to 4 carbon atoms, and an alkoxy group having from 1 to 4 carbon atoms;

R_3 is $-H$, or a hydrophilic-enhancing moiety selected from the group consisting of a hydroxyl group $-OH$, a keto group $=O$, carboxylic acid group $-COOH$, and alkoxy group $-OR_4$, and a group $-OC(O)OR_4$;

R_4 is $-CH_3$ or $-C_2H_5$;

X is selected from the group consisting of oxygen, nitrogen, boron, and sulfur.

72. A positive-acting photoresist composition wherein the base resin comprises

73. The photoresist composition of any of claims 43, 47, 54, 62, 67, or 71, wherein the average Onichi number of any of the diamondoid containing monomers is greater than about 3.

74. The photoresist composition of any of claims 43, 47, 54, 62, 67, or 71, wherein the average value of the solubility parameter of the base resin, in units of $\text{cal}^{0.5}/\text{cm}^{1.5}$, ranges from about 8 to 13.

75. The photoresist composition of any of claims 43, 47, 54, 62, 67, or 71, further including a photoacid generator selected from the group consisting of an onium salt, a diazonium salt, an ammonium salt, a phosphonium salt, an iodonium salt, a sulfonium salt, a selenonium salt, an arsonium salt, an organic halogeno compound, and an organo-metal/organic halide compound.

76. The photoresist composition of claim 75, wherein the photoacid generator has an o-nitorbenzyl type protecting group.

77. The photoresist composition of claim 75, wherein the photoacid generator generates a sulfonic acid upon photolysis.

78. The photoresist composition of claim 75, wherein the amount of the photoacid generator in the composition ranges from about 0.01 to 30 weight percent.

79. The photoresist composition of any of claims 43, 47, 54, 62, 67, or 71, wherein the composition further comprises an additive selected from the group consisting of a surface active agent, an organic basic compound, an acid decomposable dissolution inhibiting compound, a dye, a plasticizer, a photosensitizer, a compound promoting solubility in a developing solution, and additives comprising hydrophilic diamondoid derivatives.

80. The photoresist composition of any of claims 43, 47, 54, 62, 67, or 71, wherein the composition further includes a solvent selected from the group consisting of ethylene dichloride, cyclohexanone, cyclopentanone, 2-heptanone, γ -butyrolactone, methyl ethyl ketone, ethylene glycol monomethyl ether, ethylene glycol monoethyl ether, 2-methoxyethyl acetate, ethylene glycol monoethyl ether acetate, propylene glycol monomethyl ether (PGME), propylene glycol monomethyl ether acetate (PGMEA), ethylene carbonate, toluene, ethyl acetate, butyl acetate, methyl lactate, ethyl lactate, methyl methoxypropionate, ethyl ethoxypropionate, methyl methoxypropionate, ethyl pyruvate, propyl pyruvate, N,N-dimethylformamide, dimethylsulfoxide, N-methylpyrrolidone, and tetrahydrofuran.

81. The photoresist composition of any of claims 43, 47, 54, 62, 67, or 71, wherein the developing solution for the composition includes an aqueous alkaline solution.

82. The photoresist composition of claim 79, wherein the aqueous alkaline solution includes an inorganic alkali such as sodium hydroxide, potassium hydroxide, sodium carbonate, sodium silicate, sodium metasilicate, aqueous ammonia, a primary amine, ethylamine, n-propylamine, a secondary amine, diethylamine, di-n-butylamine, a tertiary amine, triethylamine, methyldiethylamine, an alcohol amine, dimethylethanolamine, triethanolamine, a quaternary ammonium salt, tetramethylammonium hydroxide, tetraethylammonium hydroxide, a cyclic amine, pyrrole, and piperidine.

83. The photoresist composition of any of claims 43, 47, 54, 62, 67, or 71, wherein the base resin comprises a block co-polymer represented by the general formula:

wherein the D repeat units are lactone containing groups.

84. A method of preparing hydroxylated diamantanes selected from the group consisting of di-hydroxylated diamantane, tri-hydroxylated diamantane, tetra-hydroxylated diamantanes, and mixtures thereof, the method comprising the steps of:

- reacting diamantane with N-hydroxyphthalimide (NHPI) and $\text{Co}(\text{acac})_2$ (cobalt (II) acetylacetonate) in a reaction mixture;
- concentrating the reaction mixture to form a concentrated product; and
- recovering hydroxylated diamantanes from the concentrated product.

85. The method of claim 84, further comprising the step of adding additional portions of N-hydroxyphthalimide (NHPI) and $\text{Co}(\text{acac})_2$ (cobalt (II) acetylacetonate) to the reaction mixture during step a).

86. The method of claim 84, further comprising the step of dissolving the concentrated product in a solvent, and then extracting the resulting solution with water to form a water layer and a solvent layer.

87. The method of claim 86, further comprising the step of subjecting the solvent layer to silica gel column chromatography to recover di-hydroxylated diamantanes.

88. The method of claim 86, wherein the solvent is methylene chloride.

89. The method of claim 86, further comprising the steps of dissolving the water layer in ethyl alcohol to form an ethyl alcohol solution, adding activated carbon to the ethyl alcohol solution, and then recovering tri-hydroxylated diamantanes from the activated carbon and ethyl alcohol solution.

90. The method of claim 86, further comprising the steps of:

- dissolving the water layer in ethyl alcohol to form an ethyl alcohol solution;

- b) adding activated carbon to the ethyl alcohol solution of step a);
- c) concentrating the activated carbon and ethyl alcohol solution of step b) to a concentrated product;
- d) dissolving the concentrated product of step c) in methylene chloride and tetrahydrofuran; and
- e) passing the dissolved concentrated product of step d) through a silica gel column to elute a methylene chloride and tetrahydrofuran fraction and a tetrahydrofuran and ethyl alcohol fraction.

91. The method of claim 90, further comprising the step of recovering di-hydroxylated diamantanes from the methylene chloride and tetrahydrofuran fraction.

92. The method of claim 90, further comprising the step of recovering tri-hydroxylated diamantanes from the tetrahydrofuran and ethyl alcohol fraction.

93. The method of claim 84, further comprising the steps of dissolving the concentrated product in a large excess of methylene chloride to precipitate a solid, and then recovering tetra-hydroxylated diamantane the precipitated solid.

94. A method of preparing diamantane methacrylate, the method comprising the step of:

- a) adding methacryloyl chloride to mono-hydroxylated diamantane and triethylamine to form a reaction mixture;

- b) adding an additional amount of methacryloyl chloride and 4-dimethylaminopyridine to the reaction mixture of step a); and

- c) recovering diamantane methacrylate from the reaction mixture of step b).

95. A method of preparing mono-hydroxylated diamantane methacrylate, the method comprising the steps of:

- a) adding methacryloyl chloride to di-hydroxylated diamantane and triethylamine to form a reaction mixture; and

- b) recovering mono-hydroxylated diamantane methacrylate from the reaction mixture of step a).

96. A method of preparing mono-hydroxylated diamantane methacrylate, the method comprising the steps of:

- a) adding methacryloyl chloride to di-hydroxylated diamantane and methacrylic acid to form a reaction mixture;

- b) adding dicyclohexyl carbodiimide and 4-dimethylaminopyridine to the reaction mixture of step a); and

- c) recovering mono-hydroxylated diamantane methacrylate from the reaction mixture of step b).
