(54) Title: COMBINATION HEATSINK AND BATTERY HEATER FOR ELECTRONIC DEVICES

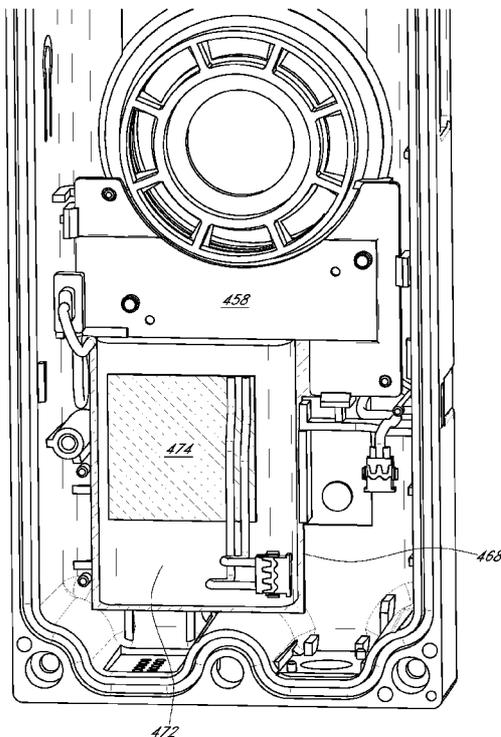

FIG. 17

(57) Abstract: Some embodiments provide a novel method for harnessing the heat generated by one or more components (e.g., a set of IR LEDs) of an A/V recording and communication device in order to manage the temperature of one or more batteries of the A/V recording and communication device. Some aspects of the present embodiments raise the temperature of the battery in a cold weather without requiring any additional electrical power (e.g., without consuming any additional power for heating up the battery). In one aspect of the present embodiments, a thermally conductive sheet is coupled to a printed circuit board to which one or more IR LEDs are coupled. The thermally conductive sheet transfers the waste heat generated by the IR LEDs of the A/V recording and communication device to a rechargeable battery of the device.

COMBINATION HEATSINK AND BATTERY HEATER FOR ELECTRONIC DEVICES

CROSS-REFERENCE TO RELATED APPLICATION

[0001] This application claims priority to provisional application Serial No. 62/319,758, filed on April 7, 2016, the entire contents of which are hereby incorporated by reference.

Technical Field

[0002] The present embodiments relate to electronic devices, such as audio/video (A/V) recording and communication devices that include rechargeable batteries, and techniques for counteracting the negative impact of cold temperatures on such rechargeable batteries.

Background

[0003] Home safety is a concern for many homeowners and renters. Those seeking to protect or monitor their homes often wish to have video and audio communications with visitors, for example, those visiting an external door or entryway. Audio/Video (A/V) recording and communication devices, such as doorbells, provide this functionality, and can also aid in crime detection and prevention. For example, audio and/or video captured by an A/V recording and communication device can be uploaded to the cloud and recorded on a remote server. Subsequent review of the A/V footage can aid law enforcement in capturing perpetrators of home burglaries and other crimes. Further, the presence of one or more A/V recording and communication devices on the exterior of a home, such as a doorbell unit at the entrance to the home, acts as a powerful deterrent against would-be burglars.

[0004] Many A/V recording and communication devices are powered by one or more rechargeable lithium-ion (Li-ion) batteries. Li-ion batteries are also widely used in many different types of electronic devices, such as laptop computers, tablet computers, cellular telephones, etc. While commercial grade Li-ion batteries have many desirable properties, such as high energy density, and relatively small size and weight, they also have drawbacks. One drawback is their performance characteristics at low temperatures, such as below freezing (0° C). For instance, charging at below-freezing temperatures can cause permanent damage to the battery. As described below, the present embodiments are directed to solving this problem.

SUMMARY

[0005] The various embodiments of the present combination heatsink and battery heater for electronic devices have several features, no single one of which is solely responsible for their desirable attributes. Without limiting the scope of the present embodiments as expressed by the claims that follow, their more prominent features now will be discussed briefly. After considering this discussion, and particularly after reading the section entitled "Detailed Description," one will understand how the features of the present embodiments provide the advantages described herein.

[0006] One aspect of the present embodiments includes the realization that battery-powered electronic devices for outdoor applications, such as A/V recording and communication devices, would benefit from an energy efficient technique for counteracting the negative impact of cold temperatures on such rechargeable batteries. Such a technique would be especially advantageous if it did not consume any additional electrical power (e.g., beyond what is already required to power the device). For example, it would be advantageous to leverage the waste heat generated by one or more components of an A/V recording and communication device to provide heat to a battery of the A/V recording and communication device and raise the temperature of the battery when the weather is cold. Such a solution would not only provide an advantageous source of warmth for the battery, but would also provide an advantageous heat sink for the one or more components generating the waste heat. The present embodiments provide these advantages, as described below. The present embodiments are applicable to electronic devices that are primarily powered, or solely powered, by one or more rechargeable batteries. The present embodiments are also applicable to electronic devices that are primarily powered by AC mains and that use one or more rechargeable batteries for supplemental power and/or to power specific components of the device.

[0007] Another aspect of the present embodiments includes the realization that many A/V recording and communication devices include infrared (IR) illumination, such as IR light-emitting diodes (LEDs). IR illuminators enable A/V recording and communication devices to record video footage in low light conditions. For example, high quality "night vision" based on IR illumination and IR sensor technology requires adequate optical power to be provided to illuminate the field of view. Increased optical power allows clearer imaging at greater distance from the camera. Thus, for clear imaging at large distances (e.g. 3 meters or greater) either the

sensitivity of the camera must be increased, or the light output from the IR illuminator must be increased. The latter requires increasing the electrical power, which increases power dissipation of the IR illuminator. But, the IR illuminator is typically only needed at night, and therefore need only be powered at night. As ambient temperatures are typically lowest at night, it is therefore convenient and synergistic to use the heat dissipation of the IR illuminator as a thermal source for warming the rechargeable battery that powers the A/V recording and communication device.

[0008] In a first aspect, a method for managing a temperature of a rechargeable battery of an electronic device, the method comprising thermally coupling a heat-generating component of the electronic device to the rechargeable battery using a thermally conductive sheet, wherein the thermally conductive sheet transfers waste heat generated by the heat-generating component to the rechargeable battery to raise the temperature of the rechargeable battery.

[0009] In an embodiment of the first aspect, the temperature of the rechargeable battery is raised from a first temperature below, or equal to, a threshold temperature to a second temperature above the threshold temperature.

[0010] In another embodiment of the first aspect, the heat-generating component comprises at least one infrared (IR) illuminator coupled to a printed circuit board (PCB).

[0011] In another embodiment of the first aspect, the at least one IR illuminator comprises an IR light-emitting diode (LED).

[0012] In another embodiment of the first aspect, the at least one IR illuminator is coupled to a first surface of the PCB, and a first portion of the thermally conductive sheet is thermally coupled to a second surface of the PCB.

[0013] In another embodiment of the first aspect, a second portion of the thermally conductive sheet is thermally coupled to the rechargeable battery.

[0014] In another embodiment of the first aspect, the first portion of the thermally conductive sheet is also coupled to a heatsink that is also coupled to the second surface of the PCB.

[0015] In another embodiment of the first aspect, the first portion of the thermally conductive sheet is sandwiched between the second surface of the PCB and the heatsink.

[0016] In another embodiment of the first aspect, the thermally conductive sheet comprises one of copper and a copper alloy.

[0017] In another embodiment of the first aspect, the rechargeable battery comprises a lithium-ion battery.

[0018] In another embodiment of the first aspect, .

[0019] In another embodiment of the first aspect, the electronic device comprises an audio/video (A/V) recording and communication device.

[0020] In another embodiment of the first aspect, the A/V recording and communication device comprises one of a doorbell and a security camera.

[0021] In another embodiment of the first aspect, a first portion of the thermally conductive sheet is thermally coupled to the heat-generating component by either proximity or direct contact, and a second portion of the thermally conductive sheet is thermally coupled to the rechargeable battery by either proximity or direct contact.

[0022] In another embodiment of the first aspect, the thermally conductive sheet is coupled to a first surface of the rechargeable battery, and a resistive battery heater is coupled to a second surface of the rechargeable battery.

[0023] In another embodiment of the first aspect, the resistive battery heater and the thermally conductive sheet both provide heat to the rechargeable battery when the temperature of the rechargeable battery is below a threshold temperature.

[0024] In another embodiment of the first aspect, the heat-generating electrical component comprises at least one illuminator coupled to a printed circuit board (PCB), the method further comprising receiving, at a processor of the A/V recording and communication device, a signal indicative of the temperature of the rechargeable battery; determining, by the processor, that the temperature of the rechargeable battery is below a threshold temperature even when the heat is being transferred from the at least one illuminator to the rechargeable battery; and increasing an amount of electrical power provided to the at least one illuminator so that more heat is transferred from the at least one illuminator to the rechargeable battery.

[0025] Another embodiment of the first aspect further increases a time duration of the electrical power delivered to the at least one illuminator to produce more heat to be transferred to the rechargeable battery.

[0026] In another embodiment of the first aspect, the electrical power is provided to the at least one illuminator by an alternating current (AC) power supply.

[0027] In a second aspect, an audio/video (A/V) recording and communication device is provided, the device comprising a camera, a printed circuit board (PCB); one or more infrared (IR) illuminators coupled to a first surface of the PCB and configured to illuminate a field of view of the camera with IR light; a thermally conductive sheet having a first portion coupled to a second surface of the PCB and a second portion extending from the PCB; and a rechargeable battery thermally coupled to the one or more IR illuminators through the thermally conductive sheet such that heat dissipation of the one or more IR illuminators warms the rechargeable battery.

[0028] An embodiment of the second aspect further comprises a heatsink coupled to the second surface of the PCB, wherein the thermally conductive sheet is sandwiched between the PCB and the heatsink.

[0029] In another embodiment of the second aspect, the thermally conductive sheet is thermally coupled to the rechargeable battery by proximity and/or direct contact.

[0030] In another embodiment of the second aspect, the thermally conductive sheet comprises copper or a copper alloy.

[0031] In another embodiment of the second aspect, the one or more IR illuminators comprises at least one IR light-emitting diode (LED).

[0032] In another embodiment of the second aspect, the rechargeable battery comprises a lithium-ion battery.

[0033] Another embodiment of the second aspect further comprises a processor, wherein the processor is configured to monitor the temperature of the rechargeable battery and to control an amount of electrical power and/or a time duration of the electrical power delivered to the set of IR illuminators.

[0034] Another embodiment of the second aspect further comprises a resistive battery heater contacting the rechargeable battery.

[0035] In another embodiment of the second aspect, the resistive battery heater is located on a side of the rechargeable battery opposite the thermally conductive sheet.

[0036] In another embodiment of the second aspect, a surface area of the second portion of the thermally conductive sheet is at least as large as a surface area of the heatsink.

[0037] In another embodiment of the second aspect, the PCB has a metal core.

[0038] In another embodiment of the second aspect, the A/V recording and communication device comprises one of a doorbell and a security camera.

BRIEF DESCRIPTION OF THE DRAWINGS

[0039] The various embodiments of the present combination heatsink and battery heater for electronic devices now will be discussed in detail with an emphasis on highlighting the advantageous features. These embodiments depict the novel and non-obvious combination heatsink and battery heater for electronic devices shown in the accompanying drawings, which are for illustrative purposes only. These drawings include the following figures, in which like numerals indicate like parts:

[0040] Figure 1 is a functional block diagram illustrating an A/V recording and communication doorbell system according to the present embodiments;

[0041] Figure 2 is a flowchart illustrating a process for streaming and storing A/V content from an A/V recording and communication doorbell system according to various aspects of the present disclosure;

[0042] Figure 3 is a functional block diagram illustrating an embodiment of an A/V recording and communication doorbell system according to the present disclosure;

[0043] Figure 4 is a front perspective view of an embodiment of an A/V recording and communication doorbell according to the present disclosure;

[0044] Figure 5 is a rear perspective view of the A/V recording and communication doorbell of Figure 4;

[0045] Figure 6 is a partially exploded front perspective view of the A/V recording and communication doorbell of Figure 4 showing the cover removed;

[0046] Figures 7, 8, and 9 are front perspective views of various internal components of the A/V recording and communication doorbell of Figure 4;

[0047] Figure 7A is a front perspective view of another embodiment of an infrared (IR) light-emitting diode (LED) printed circuit board (PCB) according to various aspects of the present disclosure;

[0048] Figure 10 is a right-side cross-sectional view of the A/V recording and communication doorbell of Figure 4 taken through the line 10-10 in Figure 4;

[0049] Figures 11-13 are rear perspective views of various internal components of the A/V recording and communication doorbell of Figure 4;

[0050] Figure 14 is a front elevation view of an infrared (IR) light-emitting diode (LED) printed circuit board assembly (PCBA) with attached heatsink according to the present embodiments;

[0051] Figure 15 is a front elevation view of the PCBA of Figure 14 with a thermally conductive sheet extending from the PCBA according to the present embodiments;

[0052] Figure 16 is a rear elevation view of the PCBA and thermally conductive sheet of Figure 15 within a housing for an electronic device according to the present embodiments;

[0053] Figure 17 is a rear elevation view of the PCBA and thermally conductive sheet within a housing for an electronic device of Figure 16 with a rechargeable battery overlying the thermally conductive sheet and an electrically powered battery heater overlying the rechargeable battery;

[0054] Figure 18 is a functional block diagram of a client device on which the present embodiments may be implemented according to various aspects of the present disclosure; and

[0055] Figure 19 is a functional block diagram of a general-purpose computing system on which the present embodiments may be implemented according to various aspects of present disclosure.

DETAILED DESCRIPTION

[0056] The following detailed description describes the present embodiments with reference to the drawings. In the drawings, reference numbers label elements of the present embodiments. These reference numbers are reproduced below in connection with the discussion of the corresponding drawing features.

[0057] The embodiments of the present combination heatsink and battery heater for electronic devices are described below with reference to the figures. These figures, and their written descriptions, indicate that certain components of the apparatus are formed integrally, and certain other components are formed as separate pieces. Those of ordinary skill in the art will appreciate that components shown and described herein as being formed integrally may in alternative embodiments be formed as separate pieces. Those of ordinary skill in the art will further appreciate that components shown and described herein as being formed as separate

pieces may in alternative embodiments be formed integrally. Further, as used herein the term integral describes a single unitary piece.

[0058] Some aspects of the present embodiments provide apparatus and methods for harnessing the waste heat generated by one or more components (e.g., a set of IR LEDs) of an A/V recording and communication device (e.g., a doorbell, a security camera, etc.) to manage the temperature of one or more batteries of the A/V recording and communication device. One aspect of the present embodiments advantageously raises the temperature of the battery in cold weather without requiring any additional electrical power (e.g., without consuming any additional power for heating up the battery). In one aspect of the present embodiments, a thermally conductive sheet extends between a printed circuit board to which one or more IR LEDs are coupled and a rechargeable battery of the device. The thermally conductive sheet transfers the waste heat generated by the IR LEDs to the rechargeable battery, thereby simultaneously acting as a heat sink for the IR LEDs and as a source of warmth for the rechargeable battery. In some of the present embodiments, the thermally conductive sheet may also be coupled to a separate heatsink of the IR LEDs. As such, the thermally conductive sheet not only transfers the heat generated by the IR LEDs to the rechargeable battery, but also acts as an additional component that prevents the IR LEDs from overheating.

[0059] Some aspects of the present embodiments measure the temperature of the rechargeable battery and dynamically manage the rechargeable battery's temperature based on the measured temperature. For example, when it is determined that the rechargeable battery would benefit from an application of additional heat, some of the present embodiments provide additional power to one or more components (e.g., one or more IR LEDs) of the A/V recording and communication device so that these components generate more heat for the rechargeable battery. Instead of, or in addition to, providing additional power to the IR LEDs, some of the present embodiments may extend the time during which power is provided to the IR LEDs so that the IR LEDs produce additional heat.

[0060] With reference to Figure 1, the present embodiments include an audio/video (A/V) recording and communication doorbell 100. The A/V recording and communication doorbell 100 is typically located near the entrance to a structure (not shown), such as a dwelling, a business, a storage facility, etc. The A/V recording and communication doorbell 100 includes a camera 102, a microphone 104, and a speaker 106. The camera 102 may comprise, for

example, a high definition (HD) video camera, such as one capable of capturing video images at an image display resolution of 720p or better. While not shown, the A/V recording and communication doorbell 100 may also include other hardware and/or components, such as a housing, one or more motion sensors (and/or other types of sensors), a button, etc. The A/V recording and communication doorbell 100 may further include similar componentry and/or functionality as the wireless communication doorbells described in US Patent Application Publication Nos. 2015/0022620 (Application Serial No. 14/499,828) and 2015/0022618 (Application Serial No. 14/334,922), both of which are incorporated herein by reference in their entireties as if fully set forth.

[0061] With further reference to Figure 1, the A/V recording and communication device 100 communicates with a user's network 110, which may be for example a wired and/or wireless network. If the user's network 110 is wireless, or includes a wireless component, the network 110 may be a Wi-Fi network compatible with the IEEE 802.11 standard and/or other wireless communication standard(s). The user's network 110 is connected to another network 112, which may comprise, for example, the Internet and/or a public switched telephone network (PSTN). As described below, the A/V recording and communication doorbell 100 may communicate with a user's client device 114 via the user's network 110 and the network 112 (Internet/PSTN). The user's client device 114 may comprise, for example, a mobile telephone (may also be referred to as a cellular telephone), such as a smartphone, a personal digital assistant (PDA), or another communication device. The user's client device 114 comprises a display (not shown) and related components capable of displaying streaming and/or recorded video images. The user's client device 114 may also comprise a speaker and related components capable of broadcasting streaming and/or recorded audio, and may also comprise a microphone. The A/V recording and communication doorbell 100 may also communicate with one or more remote storage device(s) 116 (may be referred to interchangeably as "cloud storage device(s)"), one or more servers 118, and/or a backend API (application programming interface) 120 via the user's network 110 and the network 112 (Internet/PSTN). While Figure 1 illustrates the storage device 116, the server 118, and the backend API 120 as components separate from the network 112, it is to be understood that the storage device 116, the server 118, and/or the backend API 120 may be considered to be components of the network 112.

[0062] The network 112 may be any wireless network or any wired network, or a combination thereof, configured to operatively couple the above mentioned modules, devices, and systems as shown in Figure 1. For example, the network 112 may include one or more of the following: a PSTN (public switched telephone network), the Internet, a local intranet, a PAN (Personal Area Network), a LAN (Local Area Network), a WAN (Wide Area Network), a MAN (Metropolitan Area Network), a virtual private network (VPN), a storage area network (SAN), a frame relay connection, an Advanced Intelligent Network (AIN) connection, a synchronous optical network (SONET) connection, a digital T1, T3, E1 or E3 line, a Digital Data Service (DDS) connection, a DSL (Digital Subscriber Line) connection, an Ethernet connection, an ISDN (Integrated Services Digital Network) line, a dial-up port such as a V.90, V.34, or V.34bis analog modem connection, a cable modem, an ATM (Asynchronous Transfer Mode) connection, or an FDDI (Fiber Distributed Data Interface) or CDDI (Copper Distributed Data Interface) connection. Furthermore, communications may also include links to any of a variety of wireless networks, including WAP (Wireless Application Protocol), GPRS (General Packet Radio Service), GSM (Global System for Mobile Communication), CDMA (Code Division Multiple Access), TDMA (Time Division Multiple Access), FDMA (Frequency Division Multiple Access), and/or OFDMA (Orthogonal Frequency Division Multiple Access) cellular phone networks, GPS, CDPD (cellular digital packet data), RIM (Research in Motion, Limited) duplex paging network, Bluetooth radio, or an IEEE 802.11-based radio frequency network. The network can further include or interface with any one or more of the following: RS-232 serial connection, IEEE-1394 (Firewire) connection, Fibre Channel connection, IrDA (infrared) port, SCSI (Small Computer Systems Interface) connection, USB (Universal Serial Bus) connection, or other wired or wireless, digital or analog, interface or connection, mesh or Digi® networking.

[0063] According to one or more aspects of the present embodiments, when a person (may be referred to interchangeably as "visitor") arrives at the A/V recording and communication doorbell 100, the A/V recording and communication doorbell 100 detects the visitor's presence and begins capturing video images within a field of view of the camera 102. The A/V recording and communication doorbell 100 may also capture audio through the microphone 104. The A/V recording and communication doorbell 100 may detect the visitor's presence by detecting motion using the camera 102 and/or a motion sensor, and/or by detecting that the visitor has depressed the button on the A/V recording and communication doorbell 100.

[0064] In response to the detection of the visitor, the A/V recording and communication doorbell 100 sends an alert to the user's client device 114 (Figure 1) via the user's network 110 and the network 112. The A/V recording and communication doorbell 100 also sends streaming video, and may also send streaming audio, to the user's client device 114. If the user answers the alert, two-way audio communication may then occur between the visitor and the user through the A/V recording and communication doorbell 100 and the user's client device 114. The user may view the visitor throughout the duration of the call, but the visitor cannot see the user (unless the A/V recording and communication doorbell 100 includes a display, which it may in some embodiments).

[0065] The video images captured by the camera 102 of the A/V recording and communication doorbell 100 (and the audio captured by the microphone 104) may be uploaded to the cloud and recorded on the remote storage device 116 (Figure 1). In some embodiments, the video and/or audio may be recorded on the remote storage device 116 even if the user chooses to ignore the alert sent to his or her client device 114.

[0066] With further reference to Figure 1, the system may further comprise a backend API 120 including one or more components. A backend API (application programming interface) may comprise, for example, a server (e.g. a real server, or a virtual machine, or a machine running in a cloud infrastructure as a service), or multiple servers networked together, exposing at least one API to client(s) accessing it. These servers may include components such as application servers (e.g. software servers), depending upon what other components are included, such as a caching layer, or database layers, or other components. A backend API may, for example, comprise many such applications, each of which communicate with one another using their public APIs. In some embodiments, the API backend may hold the bulk of the user data and offer the user management capabilities, leaving the clients to have very limited state.

[0067] The backend API 120 illustrated Figure 1 may include one or more APIs. An API is a set of routines, protocols, and tools for building software and applications. An API expresses a software component in terms of its operations, inputs, outputs, and underlying types, defining functionalities that are independent of their respective implementations, which allows definitions and implementations to vary without compromising the interface. Advantageously, an API may provide a programmer with access to an application's functionality without the programmer needing to modify the application itself, or even understand how the application

works. An API may be for a web-based system, an operating system, or a database system, and it provides facilities to develop applications for that system using a given programming language. In addition to accessing databases or computer hardware like hard disk drives or video cards, an API can ease the work of programming GUI components. For example, an API can facilitate integration of new features into existing applications (a so-called "plug-in API"). An API can also assist otherwise distinct applications with sharing data, which can help to integrate and enhance the functionalities of the applications.

[0068] The backend API 120 illustrated in Figure 1 may further include one or more services (also referred to as network services). A network service is an application that provides data storage, manipulation, presentation, communication, and/or other capability. Network services are often implemented using a client-server architecture based on application-layer network protocols. Each service may be provided by a server component running on one or more computers (such as a dedicated server computer offering multiple services) and accessed via a network by client components running on other devices. However, the client and server components can both be run on the same machine. Clients and servers may have a user interface, and sometimes other hardware associated with them.

[0069] Figure 2 is a flowchart illustrating a process for streaming and storing A/V content from an A/V recording and communication doorbell system according to various aspects of the present disclosure. At block B200, the A/V recording and communication doorbell 100 detects the visitor's presence and begins capturing video images within a field of view of the camera 102. The A/V recording and communication doorbell 100 may also capture audio through the microphone 104. As described above, the A/V recording and communication doorbell 100 may detect the visitor's presence by detecting motion using the camera 102 and/or a motion sensor, and/or by detecting that the visitor has depressed the button on the A/V recording and communication doorbell 100.

[0070] At block B202, a communication module of the A/V recording and communication doorbell 100 sends a connection request, via the user's network 110 and the network 112, to a device in the network 112. For example, the network device to which the request is sent may be a server such as the server 118. The server 118 may comprise a computer program and/or a machine that waits for requests from other machines or software (clients) and responds to them. A server typically processes data. One purpose of a server is to share data

and/or hardware and/or software resources among clients. This architecture is called the client-server model. The clients may run on the same computer or may connect to the server over a network. Examples of computing servers include database servers, file servers, mail servers, print servers, web servers, game servers, and application servers. The term server may be construed broadly to include any computerized process that shares a resource to one or more client processes.

[0071] In response to the request, at block B204 the network device may connect the A/V recording and communication doorbell 100 to the user's client device 114 through the user's network 110 and the network 112. At block B206, the A/V recording and communication doorbell 100 may record available audio and/or video data using the camera 102, the microphone 104, and/or any other sensor available. At block B208, the audio and/or video data is transmitted (streamed) from the A/V recording and communication doorbell 100 to the user's client device 114 via the user's network 110 and the network 112. At block B210, the user may receive a notification on his or her client device 114 with a prompt to either accept or deny the call.

[0072] At block B212, the process determines whether the user has accepted or denied the call. If the user denies the notification, then the process advances to block B214, where the audio and/or video data is recorded and stored at a cloud server. The session then ends at block B216 and the connection between the A/V recording and communication doorbell 100 and the user's client device 114 is terminated. If, however, the user accepts the notification, then at block B218 the user communicates with the visitor through the user's client device 114 while audio and/or video data captured by the camera 102, the microphone 104, and/or other sensors is streamed to the user's client device 114. At the end of the call, the user may terminate the connection between the user's client device 114 and the A/V recording and communication doorbell 100 and the session ends at block B216. In some embodiments, the audio and/or video data may be recorded and stored at a cloud server (block B214) even if the user accepts the notification and communicates with the visitor through the user's client device 114.

[0073] Many of today's homes include a wired doorbell system that does not have A/V communication capabilities. Instead, standard wired doorbell systems include a button outside the home next to the front door. The button activates a signaling device (such as a bell or a buzzer) inside the building. Pressing the doorbell button momentarily closes the doorbell circuit, which may be, for example, a single-pole, single-throw (SPST) push button switch. One

terminal of the button is wired to a terminal on a transformer. The transformer steps down the 120-volt or 240-volt household AC electrical power to a lower voltage, typically 16 to 24 volts. Another terminal on the transformer is wired to a terminal on the signaling device. Another terminal on the signaling device is wired to the other terminal on the button. A common signaling device includes two flat metal bar resonators, which are struck by plungers operated by two solenoids. The flat bars are tuned to different notes. When the doorbell button is pressed, the first solenoid's plunger strikes one of the bars, and when the button is released, a spring on the plunger pushes the plunger in an opposite direction, and the momentum of the plunger causes a striking of the other bar having a different acoustic resonance (e.g., thereby create a two-tone sound ("ding-dong")).

[0074] Many current A/V recording and communication doorbell systems (other than the present embodiments) are incompatible with existing wired doorbell systems of the type described in the preceding paragraph. One reason for this incompatibility is that the A/V recording and communication doorbell draws an amount of power from the household AC electrical power supply that is above the threshold necessary for causing the signaling device to sound. The A/V recording and communication doorbell thus causes frequent inadvertent sounding of the signaling device, which is not only bothersome to the home's occupant(s), but also undermines the usefulness of the doorbell. The present embodiments solve this problem by limiting the power consumption of the A/V recording and communication doorbell to an amount that is below the threshold necessary for causing the signaling device to sound. Embodiments of the present A/V recording and communication doorbell can thus be connected to the existing household AC power supply and the existing signaling device without causing inadvertent sounding of the signaling device.

[0075] Several advantages flow from the ability of the present embodiments to be connected to the existing household AC power supply. For example, the camera of the present A/V recording and communication doorbell can be powered on continuously. In a typical battery-powered A/V recording and communication doorbell, the camera is powered on only part of the time so that the battery does not drain too rapidly. The present embodiments, by contrast, do not rely on a battery as a primary (or sole) power supply, and are thus able to keep the camera powered on continuously. Because the camera is able to be powered on continuously, it can always be recording, and recorded footage can be continuously stored in a rolling buffer or

sliding window. In some embodiments, about 10-15 seconds of recorded footage can be continuously stored in the rolling buffer or sliding window. Also because the camera is able to be powered on continuously, it can be used for motion detection, thus eliminating any need for a separate motion detection device, such as a passive infrared sensor (PIR). Eliminating the PIR simplifies the design of the A/V recording and communication doorbell and enables the doorbell to be made more compact. Also because the camera is able to be powered on continuously, it can be used as a light detector for use in controlling the current state of the IR cut filter and turning the IR LED on and off. Using the camera as a light detector eliminates any need for a separate light detector, thereby further simplifying the design of the A/V recording and communication doorbell and enabling the doorbell to be made even more compact.

[0076] Figures 3-13 illustrate one embodiment of a low-power-consumption A/V recording and communication doorbell 130 according to various aspects of the present disclosure. Figure 3 is a functional block diagram illustrating various components of the A/V recording and communication doorbell 130 and their relationships to one another. For example, the A/V recording and communication doorbell 130 includes a pair of terminals 131, 132 configured to be connected to a source of external AC (alternating-current) power, such as a household AC power supply 134 (may also be referred to as AC mains). The AC power 134 may have a voltage in the range of 16-24 VAC, for example. The incoming AC power 134 may be converted to DC (direct-current) by an AC/DC rectifier 136. An output of the AC/DC rectifier 136 may be connected to an input of a DC/DC converter 138, which may step down the voltage from the output of the AC/DC rectifier 136 from 16-24 VDC to a lower voltage of about 5 VDC, for example. In various embodiments, the output of the DC/DC converter 138 may be in a range of from about 2.5 V to about 7.5 V, for example.

[0077] With further reference to Figure 3, the output of the DC/DC converter 138 is connected to a power manager 140, which may comprise an integrated circuit including a processor core, memory, and/or programmable input/output peripherals. In one non-limiting example, the power manager 140 may be an off-the-shelf component, such as the BQ24773 chip manufactured by Texas Instruments. As described in detail below, the power manager 140 controls, among other things, an amount of power (current) drawn from the external power supply 134, as well as an amount of supplemental current drawn from a battery 142, to power the A/V recording and communication doorbell 130. The power manager 140 may, for example,

limit the amount of current drawn from the external power supply 134 so that a threshold current draw is not exceeded. In one non-limiting example, the threshold current, as measured at the output of the DC/DC converter 138, may be equal to 1.4 A. The power manager 140 may also control an amount of current drawn from the external power supply 134 and directed to the battery 142 for recharging of the battery 142. An output of the power manager 140 is connected to a power sequencer 144, which controls a sequence of power delivery to other components of the A/V recording and communication doorbell 130, including a communication module 146, a front button 148, a microphone 150, a speaker driver 151, a speaker 152, an audio CODEC (Coder-DECoder) 153, a camera 154, an infrared (IR) light source 156, an IR cut filter 158, a processor 160 (may also be referred to as a controller 160), a plurality of light indicators 162, and a controller 164 for the light indicators 162. Each of these components is described in detail below. The power sequencer 144 may comprise an integrated circuit including a processor core, memory, and/or programmable input/output peripherals. In one non-limiting example, the power sequencer 144 may be an off-the-shelf component, such as the RT5024 chip manufactured by Richtek.

[0078] With further reference to Figure 3, the A/V recording and communication doorbell 130 further comprises an electronic switch 166 that closes when the front button 148 is depressed. When the electronic switch 166 closes, power from the AC power source 134 is diverted through a signaling device 168 that is external to the A/V recording and communication doorbell 130 to cause the signaling device 168 to emit a sound, as further described below. In one non-limiting example, the electronic switch 166 may be a triac device. The A/V recording and communication doorbell 130 further comprises a reset button 170 configured to initiate a hard reset of the processor 160, as further described below.

[0079] With further reference to Figure 3, the processor 160 may perform data processing and various other functions, as described below. The processor 160 may comprise an integrated circuit including a processor core, memory 172, non-volatile memory 174, and/or programmable input/output peripherals (not shown). The memory 172 may comprise, for example, DDR3 (double data rate type three synchronous dynamic random-access memory). The non-volatile memory 174 may comprise, for example, NAND flash memory. In the embodiment illustrated in Figure 3, the memory 172 and the non-volatile memory 174 are illustrated within the box representing the processor 160. It is to be understood that the

embodiment illustrated in Figure 3 is merely an example, and in some embodiments the memory 172 and/or the non-volatile memory 174 are not necessarily physically incorporated with the processor 160. The memory 172 and/or the non-volatile memory 174, regardless of their physical location, may be shared by one or more other components (in addition to the processor 160) of the present A/V recording and communication doorbell 130.

[0080] The transfer of digital audio between the user and a visitor may be compressed and decompressed using the audio CODEC 153, which is operatively coupled to the processor 160. When the visitor speaks, audio from the visitor is compressed by the audio CODEC 153, digital audio data is sent through the communication module 146 to the network 112 via the user's network 110, routed by the server 118 and delivered to the user's client device 114. When the user speaks, after being transferred through the network 112, the user's network 110, and the communication module 146, the digital audio data is decompressed by the audio CODEC 153 and emitted to the visitor through the speaker 152, which is driven by the speaker driver 151.

[0081] With further reference to Figure 3, some of the present embodiments may include a shunt 176 connected in parallel with the signaling device 168. The shunt 176 facilitates the ability of the A/V recording and communication doorbell 130 to draw power (current) from the AC power source 134 without inadvertently triggering the signaling device 168. The shunt 176, during normal standby operation, presents a relatively low electrical impedance, such as a few ohms, across the terminals of the signaling device 168. Most of the current drawn by the A/V recording and communication doorbell 130, therefore, flows through the shunt 176, and not through the signaling device 168. The shunt 176, however, contains electronic circuitry that switches the shunt 176 between a state of low impedance, such as a few ohms, for example, and a state of high impedance, such as $> 1K$ ohms, for example. When the front button 148 of the A/V recording and communication doorbell 130 is pressed, the electronic switch 166 closes, causing the voltage from the AC power source 134 to be impressed mostly across the shunt 176 and the signaling device 168 in parallel, while a small amount of voltage, such as about IV , is impressed across the electronic switch 166. The circuitry in the shunt 176 senses this voltage, and switches the shunt 176 to the high impedance state, so that power from the AC power source 134 is diverted through the signaling device 168. The diverted AC power 134 is above the threshold necessary to cause the signaling device 168 to emit a sound. Pressing the front button 148 of the doorbell 130 therefore causes the signaling device 168 to "ring," alerting any

person(s) within the structure to which the doorbell 130 is mounted that there is a visitor at the front door (or at another location corresponding to the location of the doorbell 130). In one non-limiting example, the electronic switch 166 may be a triac device. Further details of the shunt 176 are described in Application Serial No. 62/308,746, filed on March 15, 2016 and entitled Low-Power-Consumption Audio/Video Recording and Communication Doorbell, which is incorporated herein by reference in its entirety as if fully set forth.

[0082] With reference to Figures 4-6, the A/V recording and communication doorbell 130 further comprises a housing 178 having an enclosure 180 (Figure 6), a back plate 182 secured to the rear of the enclosure 180, and a shell 184 overlying the enclosure 180. With reference to Figure 6, the shell 184 includes a recess 186 that is sized and shaped to receive the enclosure 180 in a close fitting engagement, such that outer surfaces of the enclosure 180 abut conforming inner surfaces of the shell 184. Exterior dimensions of the enclosure 180 may be closely matched with interior dimensions of the shell 184 such that friction maintains the shell 184 about the enclosure 180. Alternatively, or in addition, the enclosure 180 and/or the shell 184 may include mating features 188, such as one or more tabs, grooves, slots, posts, etc. to assist in maintaining the shell 184 about the enclosure 180. The back plate 182 is sized and shaped such that the edges of the back plate 182 extend outward from the edges of the enclosure 180, thereby creating a lip 190 against which the shell 184 abuts when the shell 184 is mated with the enclosure 180, as shown in Figures 4 and 5. In some embodiments, multiple shells 184 in different colors may be provided so that the end user may customize the appearance of his or her A/V recording and communication doorbell 130. For example, the A/V recording and communication doorbell 130 may be packaged and sold with multiple shells 184 in different colors in the same package.

[0083] With reference to Figure 4, a front surface of the A/V recording and communication doorbell 130 includes the button 148 (may also be referred to as front button 148, Figure 3), which is operatively connected to the processor 160. In a process similar to that described above with reference to Figure 2, when a visitor presses the front button 148, an alert may be sent to the user's client device to notify the user that someone is at his or her front door (or at another location corresponding to the location of the A/V recording and communication doorbell 130). With further reference to Figure 4, the A/V recording and communication doorbell 130 further includes the camera 154, which is operatively connected to the processor

160, and which is located behind a shield 192. As described in detail below, the camera 154 is configured to capture video images from within its field of view. Those video images can be streamed to the user's client device and/or uploaded to a remote network device for later viewing according to a process similar to that described above with reference to Figure 2.

[0084] With reference to Figure 5, a pair of terminal screws 194 extends through the back plate 182. The terminal screws 194 are connected at their inner ends to the terminals 131, 132 (Figure 3) within the A/V recording and communication doorbell 130. The terminal screws 194 are configured to receive electrical wires to connect to the A/V recording and communication doorbell 130, through the terminals 131, 132, to the household AC power supply 134 of the structure on which the A/V recording and communication doorbell 130 is mounted. In the illustrated embodiment, the terminal screws 194 are located within a recessed portion 196 of the rear surface 198 of the back plate 182 so that the terminal screws 194 do not protrude from the outer envelope of the A/V recording and communication doorbell 130. The A/V recording and communication doorbell 130 can thus be mounted to a mounting surface with the rear surface 198 of the back plate 182 abutting the mounting surface. The back plate 182 includes apertures 200 adjacent its upper and lower edges to accommodate mounting hardware, such as screws (not shown), for securing the back plate 182 (and thus the A/V recording and communication doorbell 130) to the mounting surface. With reference to Figure 6, the enclosure 180 includes corresponding apertures 202 adjacent its upper and lower edges that align with the apertures 200 in the back plate 182 to accommodate the mounting hardware. In certain embodiments, the A/V recording and communication doorbell 130 may include a mounting plate or bracket (not shown) to facilitate securing the A/V recording and communication doorbell 130 to the mounting surface.

[0085] With further reference to Figure 6, the shell 184 includes a central opening 204 in a front surface. The central opening 204 is sized and shaped to accommodate the shield 192. In the illustrated embodiment, the shield 192 is substantially rectangular, and includes a central opening 206 through which the front button 148 protrudes. The shield 192 defines a plane parallel to and in front of a front surface 208 of the enclosure 180. When the shell 184 is mated with the enclosure 180, as shown in Figures 4 and 10, the shield 192 resides within the central opening 204 of the shell 184 such that a front surface 210 of the shield 192 is substantially flush

with a front surface 212 of the shell 184 and there is little or no gap (Figure 4) between the outer edges of the shield 192 and the inner edges of the central opening 204 in the shell 184.

[0086] With further reference to Figure 6, the shield 192 includes an upper portion 214 (located above and to the sides of the front button 148) and a lower portion 216 (located below and to the sides of the front button 148). The upper and lower portions 214, 216 of the shield 192 may be separate pieces, and may comprise different materials. The upper portion 214 of the shield 192 may be transparent or translucent so that it does not interfere with the field of view of the camera 154. For example, in certain embodiments the upper portion 214 of the shield 192 may comprise glass or plastic. As described in detail below, the microphone 150, which is operatively connected to the processor 160, is located behind the upper portion 214 of the shield 192. The upper portion 214, therefore, may include an opening 218 that facilitates the passage of sound through the shield 192 so that the microphone 150 is better able to pick up sounds from the area around the A/V recording and communication doorbell 130.

[0087] The lower portion 216 of the shield 192 may comprise a material that is substantially transparent to infrared (IR) light, but partially or mostly opaque with respect to light in the visible spectrum. For example, in certain embodiments the lower portion 216 of the shield 192 may comprise a plastic, such as polycarbonate. The lower portion 216 of the shield 192, therefore, does not interfere with transmission of IR light from the IR light source 156, which is located behind the lower portion 216. As described in detail below, the IR light source 156 and the IR cut filter 158, which are both operatively connected to the processor 160, facilitate "night vision" functionality of the camera 154.

[0088] The upper portion 214 and/or the lower portion 216 of the shield 192 may abut an underlying cover 220 (Figure 10), which may be integral with the enclosure 180 or may be a separate piece. The cover 220, which may be opaque, may include a first opening 222 corresponding to the location of the camera 154, a second opening (not shown) corresponding to the location of the microphone 150 and the opening 218 in the upper portion 214 of the shield 192, and a third opening (not shown) corresponding to the location of the IR light source 156.

[0089] Figures 7-10 illustrate various internal components of the A/V recording and communication doorbell 130. Figures 7-9 are front perspective views of the doorbell 130 with the shell 184 and the enclosure 180 removed, while Figure 10 is a right-side cross-sectional view of the doorbell 130 taken through the line 10-10 in Figure 4. With reference to Figures 7 and 8,

the A/V recording and communication doorbell 130 further comprises a main printed circuit board (PCB) 224 and a front PCB 226. With reference to Figure 8, the front PCB 226 comprises a button actuator 228. With reference to Figures 7, 8, and 10, the front button 148 is located in front of the button actuator 228. The front button 148 includes a stem 230 (Figure 10) that extends into the housing 178 to contact the button actuator 228. When the front button 148 is pressed, the stem 230 depresses the button actuator 228, thereby closing the electronic switch 166 (Figure 8), as described below.

[0090] With reference to Figure 8, the front PCB 226 further comprises the light indicators 162, which may illuminate when the front button 148 of the doorbell 130 is pressed. In the illustrated embodiment, the light indicators 162 comprise light-emitting diodes (LEDs 162) that are surface mounted to the front surface of the front PCB 226 and are arranged in a circle around the button actuator 228. The present embodiments are not limited to the light indicators 162 being LEDs, and in alternative embodiments the light indicators 162 may comprise any other type of light-emitting device. The present embodiments are also not limited by the number of light indicators 162 shown in Figure 8, nor by the pattern in which they are arranged.

[0091] With reference to Figure 7, the doorbell 130 further comprises a light pipe 232. The light pipe 232 is a transparent or translucent ring that encircles the front button 148. With reference to Figure 4, the light pipe 232 resides in an annular space between the front button 148 and the central opening 206 in the shield 192, with a front surface 234 of the light pipe 232 being substantially flush with the front surface 210 of the shield 192. With reference to Figures 7 and 10, a rear portion of light pipe 232 includes a plurality of posts 236 whose positions correspond to the positions of the LEDs 162. When the LEDs 162 are illuminated, light is transmitted through the posts 236 and the body of the light pipe 232 so that the light is visible at the front surface 234 of the light pipe 232. The LEDs 162 and the light pipe 232 thus provide a ring of illumination around the front button 148. The light pipe 232 may comprise a plastic, for example, or any other suitable material capable of transmitting light.

[0092] The LEDs 162 and the light pipe 232 may function as visual indicators for a visitor and/or a user. For example, the LEDs 162 may illuminate upon activation or stay illuminated continuously. In one aspect, the LEDs 162 may change color to indicate that the front button 148 has been pressed. The LEDs 162 may also indicate that the battery 142 needs

recharging, or that the battery 142 is currently being charged, or that charging of the battery 142 has been completed. The LEDs 162 may indicate that a connection to the user's wireless network is good, limited, poor, or not connected. The LEDs 162 may be used to guide the user through setup or installation steps using visual cues, potentially coupled with audio cues emitted from the speaker 152.

[0093] With further reference to Figure 7, the A/V recording and communication doorbell 130 further comprises a rechargeable battery 142. As described in further detail below, the A/V recording and communication doorbell 130 is connected to an external power source 134 (Figure 3), such as AC mains. The A/V recording and communication doorbell 130 is primarily powered by the external power source 134, but may also draw power (current) from the rechargeable battery 142 so as not to exceed a threshold amount of power from the external power source 134, to thereby avoid inadvertently sounding the signaling device 168. With reference to Figure 3, the battery 142 is operatively connected to the power manager 140. As described below, the power manager 140 controls an amount of power (current) drawn from the battery 142 to supplement the current drawn from the external AC power source 134 to power the A/V recording and communication doorbell 130 when supplemental power is needed. The power manager 140 also controls recharging of the battery 142 using current drawn from the external power source 134. The battery 142 may comprise, for example, a lithium-ion battery, or any other type of rechargeable battery.

[0094] With further reference to Figure 7, the A/V recording and communication doorbell 130 further comprises the camera 154. The camera 154 is coupled to a front surface of the front PCB 226, and includes a lens 238 and an imaging processor 240 (Figure 9). The camera lens 238 may be a lens capable of focusing light into the camera 154 so that clear images may be captured. The camera 154 may comprise, for example, a high definition (HD) video camera, such as one capable of capturing video images at an image display resolution of 720p or better. In certain of the present embodiments, the camera 154 may be used to detect motion within its field of view, as described below.

[0095] With further reference to Figure 7, the A/V recording and communication doorbell 130 further comprises an infrared (IR) light source 242. In the illustrated embodiment, the IR light source 242 comprises an IR light-emitting diode (LED) 242 coupled to an IR LED

printed circuit board (PCB) 244. In alternative embodiments, the IR LED 242 may not comprise a separate PCB 244, and may, for example, be coupled to the front PCB 226.

[0096] With reference to Figures 7 and 10, the IR LED PCB 244 is located below the front button 148 (Figure 7) and behind the lower portion 216 of the shield 192 (Figure 10). As described above, the lower portion 216 of the shield 192 is transparent to IR light, but may be opaque with respect to light in the visible spectrum. Figure 7A illustrates an alternative embodiment of the IR LED PCB 244' comprising three IR LEDs 242. In an embodiment including the IR LED PCB 244' of Figure 7A, or including any IR LED PCB having more than one IR LED 242, the size of the third opening in the cover may be increased to accommodate the larger size of the IR LED PCB 244'.

[0097] The IR LED 242 may be triggered to activate when a low level of ambient light is detected. When activated, IR light emitted from the IR LED 242 illuminates the camera 154's field of view. The camera 154, which may be configured to detect IR light, may then capture the IR light emitted by the IR LED 242 as it reflects off objects within the camera 154's field of view, so that the A/V recording and communication doorbell 130 can clearly capture images at night (may be referred to as "night vision").

[0098] With reference to Figure 9, the A/V recording and communication doorbell 130 further comprises an IR cut filter 158. The IR cut filter 158 is a mechanical shutter that can be selectively positioned between the lens 238 and the image sensor of the camera 154. During daylight hours, or whenever there is a sufficient amount of ambient light, the IR cut filter 158 is positioned between the lens 238 and the image sensor to filter out IR light so that it does not distort the colors of images as the human eye sees them. During nighttime hours, or whenever there is little to no ambient light, the IR cut filter 158 is withdrawn from the space between the lens 238 and the image sensor, so that the camera 154 is sensitive to IR light ("night vision"). In some embodiments, the camera 154 acts as a light detector for use in controlling the current state of the IR cut filter 158 and turning the IR LED 242 on and off. Using the camera 154 as a light detector is facilitated in some embodiments by the fact that the A/V recording and communication doorbell 130 is powered by a connection to AC mains, and the camera 154, therefore, is always powered on. In other embodiments, however, the A/V recording and communication doorbell 130 may include a light sensor separate from the camera 154 for use in controlling the IR cut filter 158 and the IR LED 242.

[0099] With reference back to Figure 6, the A/V recording and communication doorbell 130 further comprises a reset button 170. The reset button 170 contacts a reset button actuator 246 (Figure 8) coupled to the front PCB 226. When the reset button 170 is pressed, it may contact the reset button actuator 246, which may trigger the erasing of any data stored at the non-volatile memory 174 and/or at the memory 172 (Figure 3), and/or may trigger a reboot of the processor 160.

[00100] Figures 11-13 further illustrate internal components of the A/V recording and communication doorbell 130. Figures 11-13 are rear perspective views of the doorbell 130 with the back plate 182 and additional components removed. For example, in Figure 11 the back plate 182 is removed, while in Figure 12 the back plate 182 and the main PCB 224 are removed, and in Figure 13 the back plate 182, the main PCB 224, and the front PCB 226 are removed. With reference to Figure 11, several components are coupled to the rear surface of the main PCB 224, including the communication module 146, the processor 160, memory 172, and non-volatile memory 174. The functions of each of these components are described below. With reference to Figure 12, several components are coupled to the rear surface of the front PCB 226, including the power manager 140, the power sequencer 144, the AC/DC rectifier 136, the DC/DC converter 138, and the controller 164 for the light indicators 162. The functions of each of these components are also described below. With reference to Figure 13, several components are visible within the enclosure 180, including the microphone 150, a speaker chamber 248 (in which the speaker 152 is located), and an antenna 250 for the communication module 146. The functions of each of these components are also described below.

[00101] With reference to Figure 7, the antenna 250 is coupled to the front surface of the main PCB 224 and operatively connected to the communication module 146, which is coupled to the rear surface of the main PCB 224 (Figure 11). The microphone 150, which may also be coupled to the front surface of the main PCB 224, is located near the opening 218 (Figure 4) in the upper portion 214 of the shield 192 so that sounds emanating from the area around the A/V recording and communication doorbell 130 can pass through the opening 218 and be detected by the microphone 150. With reference to Figure 13, the speaker chamber 248 is located near the bottom of the enclosure 180. The speaker chamber 248 comprises a hollow enclosure in which the speaker 152 is located. The hollow speaker chamber 248 amplifies the sounds made by the speaker 152 so that they can be better heard by a visitor in the area near the A/V recording and

communication doorbell 130. With reference to Figures 5 and 13, the lower surface 252 of the shell 184 and the lower surface (not shown) of the enclosure 180 may include an acoustical opening 254 through which the sounds made by the speaker 152 can pass so that they can be better heard by a visitor in the area near the A/V recording and communication doorbell 130. In the illustrated embodiment, the acoustical opening 254 is shaped generally as a rectangle having a length extending substantially across the lower surface 252 of the shell 184 (and also the enclosure 180). The illustrated shape is, however, just one example. With reference to Figure 5, the lower surface 252 of the shell 184 may further include an opening 256 for receiving a security screw (not shown). The security screw may extend through the opening 256 and into a similarly located opening in the enclosure 180 to secure the shell 184 to the enclosure 180. If the doorbell 130 is mounted to a mounting bracket (not shown), the security screw may also maintain the doorbell 130 on the mounting bracket.

[00102] With reference to Figure 13, the A/V recording and communication doorbell 130 may further include a battery heater 258. The present A/V recording and communication doorbell 130 is configured for outdoor use, including in cold climates. Cold temperatures, however, can cause negative performance issues for rechargeable batteries, such as reduced energy capacity, increased internal resistance, reduced ability to charge without damage, and reduced ability to supply load current. The battery heater 258 helps to keep the rechargeable battery 142 warm in order to reduce or eliminate the foregoing negative performance issues. In the illustrated embodiment, the battery heater 258 comprises a substantially flat, thin sheet abutting a side surface of the rechargeable battery 142. The battery heater 258 may comprise, for example, an electrically resistive heating element that produces heat when electrical current is passed through it. The battery heater 258 may thus be operatively coupled to the power manager 140 and/or the power sequencer 144 (Figure 12). In some embodiments, the rechargeable battery 142 may include a thermally sensitive resistor ("thermistor," not shown) operatively connected to the processor 160 so that the battery 142's temperature can be monitored and the amount of power supplied to the battery heater 258 can be adaptively controlled to keep the rechargeable battery 142 within a desired temperature range.

[00103] Figure 14 illustrates another embodiment of an infrared (IR) illuminator 450 according to the present embodiments. The IR illuminator 450 is configured for use with the A/V recording and communication doorbell 130 described above. The IR illuminator 450 is not,

however, limited to use with the A/V recording and communication doorbell 130 described above. The IR illuminator 450 is configured for use with any A/V recording and communication device, including other types of A/V recording and communication doorbells and/or security cameras.

[00104] With reference to Figure 14, the IR illuminator 450 includes a plurality of IR light-emitting diodes (LEDs) 452 mounted to a first surface 454 of a printed circuit board assembly (PCBA) 456 with a heatsink 458 coupled to a second surface of the PCBA 456 opposite the first surface 454. The PCBA 456 may comprise, for example, a metal core. The heatsink 458 comprises a metal plate having a larger surface area than the PCBA 456 to enhance heat transfer away from the PCBA 456. Heat generated by the IR LEDs 452 is transferred through the PCBA 456 to the heatsink 458 via conduction due to direct contact between the PCBA 456 and the heatsink 458. Heat is transferred away from the heatsink 458 into the surrounding air via convection and/or into one or more other abutting components via conduction. In the illustrated embodiment, threaded fasteners (e.g. screws) 460 extend through aligned holes in the PCBA 456 and the heatsink 458 to secure the PCBA 456 and the heatsink 458 to one another. Additional heat transfer may occur via conduction from the PCBA 456 through the threaded fasteners 460 to the heatsink 458. In alternative embodiments, however, the threaded fasteners 460 may be omitted, and the PCBA 456 and the heatsink 458 may be secured to one another with adhesive. In the illustrated embodiment, the heatsink 458 includes through holes 462 configured to receive threaded fasteners (not shown) for securing the heatsink 458 to the electronic device in which the PCBA 456 and the heatsink 458 are located. In alternative embodiments, however, the through holes 462 may be omitted, and the heatsink 458 may be secured to the electronic device with adhesive.

[00105] In the illustrated embodiment, three IR LEDs 452 are provided, but in alternative embodiments any number of IR LEDs 452 may be provided, including only one. Embodiments having multiple IR LEDs 452 provide advantages, including increased electrical-to-optical conversion efficiency, and easier thermal management. Under high illumination conditions, however, the multiple IR LEDs 452 dissipate significant power and generate significant heat. It is desirable to maintain safe IR LED junction temperatures for reliable operation and long operating lifetime, because the failure rate of electronic devices including IR LEDs typically doubles for every 10° C rise in junction temperature. Thus, with reference to Figure 15, the

present embodiments further comprise a thermally conductive sheet 464 having a first portion 466 sandwiched between the PCBA 456 and the heatsink 458 and a second portion 468 extending from the PCBA 456 and the heatsink 458. The thermally conductive sheet 464 advantageously increases the effective surface area of the heatsink 458, thereby allowing the IR LEDs 452 to run cooler for the same power input, or run at higher power for any given temperature rise. Heat generated by the IR LEDs 452 is transferred through the PCBA 456 to the thermally conductive sheet 464 via conduction due to direct contact between the PCBA 456 and the thermally conductive sheet 464. Heat is transferred away from the thermally conductive sheet 464 into the surrounding air via convection and/or into one or more other abutting components via conduction. In certain embodiments, as described below, a rechargeable battery may be positioned adjacent the second portion 468 of the thermally conductive sheet 464, and heat may be transferred from the thermally conductive sheet 464 to the battery.

[00106] The thermally conductive sheet 464 preferably comprises a material having high thermal conductivity, such as a metal foil. The metal foil may comprise copper, for example, or an alloy containing a high percentage of copper. The metal foil may directly abut either or both of the PCBA 456 and the heatsink 458. Thermally conductive films, adhesives, and/or thermal grease may be provided at the interface between the thermally conductive sheet 464 and the PCBA 456 and/or at the interface between the thermally conductive sheet 464 and the heatsink 458 to reduce thermal resistance at the interface(s).

[00107] Because the thermally conductive sheet 464 comprises a material having high thermal conductivity, heat from the PCBA 456 is transferred through the thermally conductive sheet 464 to the heatsink 458. However, heat from the PCBA 456 is also transferred via conduction through the first portion 466 of the thermally conductive sheet 464, which is sandwiched between the PCBA 456 and the heatsink 458, to the second portion 468 of the thermally conductive sheet 464. As described above, the second portion 468 of the thermally conductive sheet 464 extends from the PCBA 456 and the heatsink 458 and increases the effective surface area of the heatsink 458. In certain embodiments, the second portion 468 of the thermally conductive sheet 464 may have a surface area at least equal to, if not larger than, the surface area of the heatsink 458. The second portion 468 thus not only greatly increases the effective surface area of the heatsink 458, but also provides a large surface area for heat transfer to another component of an electronic device, such as a rechargeable battery.

[00108] Many electronic devices are powered by lithium-ion (Li-ion) rechargeable batteries. Cold temperatures cause several negative performance issues for Li-ion batteries, such as reduced energy capacity, increased internal resistance, reduced ability to charge without damage, and reduced ability to supply load current. Thus, it would be advantageous to provide an energy efficient technique for warming the rechargeable battery in battery-powered electronic devices, particularly electronic devices for outdoor applications, such as A/V recording and communication devices. The present embodiments provide these advantages by harnessing the heat produced by the IR illuminator 450 to provide heat to the rechargeable battery. Since the IR illuminator 450 produces heat as a by-product of its normal operation, the present embodiments advantageously warm the rechargeable battery without consuming any additional electrical power beyond that already required to power the device. The present embodiments further provide a synergy based on the coincidence between the time of day, e.g. at night, when the IR illuminator 450 is needed to provide illumination in low-light conditions and the time of day when the ambient temperature is typically lower and the battery, therefore, is most likely to need a source of warmth. The present embodiments are applicable to electronic devices that are primarily powered, or solely powered, by one or more rechargeable batteries. The present embodiments are also applicable to electronic devices that are primarily powered by AC mains and that use one or more rechargeable batteries for supplemental power and/or to power specific components of the device.

[00109] With reference to Figure 16, the PCBA 456, the heatsink 458, and the thermally conductive sheet 464 are illustrated within a housing 470 of an electronic device. The electronic device may comprise the video doorbell 130 described above, or any other A/V recording and communication device (e.g., a security camera), or any other electronic device having a PCB and a rechargeable battery. The PCBA 456 and/or the heatsink 458 may be secured to the housing 470 with fasteners, adhesives, or in any other suitable fashion. The second portion 468 of the thermally conductive sheet 464 extends from the PCBA 456 and the heatsink 458 and provides a surface for transferring heat to a rechargeable battery 472, as shown in Figure 17.

[00110] In certain embodiments, such as that shown in Figure 17, the rechargeable battery 472 may be in direct contact with the second portion 468 of the thermally conductive sheet 464 along substantially an entire surface of the rechargeable battery 472 (e.g. the side surface of the rechargeable battery opposite the viewer in Figure 17). This configuration provides a relatively

large interface for conductive heat transfer from the second portion 468 of the thermally conductive sheet 464 to the rechargeable battery 472. Thermally conductive films, adhesives, and/or thermal grease may be provided at the interface between the thermally conductive sheet 464 and the battery 472 to reduce thermal resistance at the interface. In alternative embodiments, the thermally conductive sheet 464 may wrap around one or more additional surfaces of the rechargeable battery 472 to provide an even larger interface for conductive heat transfer from the thermally conductive sheet 464 to the rechargeable battery 472. For example, the thermally conductive sheet 464 may wrap around the entirety of the rechargeable battery 472. In other embodiments, the thermally conductive sheet 464 may contact the rechargeable battery 472 along only a portion of one surface of the rechargeable battery 472, and in still other embodiments the thermally conductive sheet 464 may have no direct contact with the rechargeable battery 472. In such embodiments, heat transfer from the thermally conductive sheet 464 to the rechargeable battery 472 may occur primarily through convection across an intervening fluid medium, such as air.

[00111] The embodiment illustrated in Figure 17 further comprises an electrically powered battery heater 474 abutting a near side of the rechargeable battery 472 (on the side opposite the thermally conductive sheet 464). The present embodiments of the thermally conductive sheet 464 may be used with or without the electrically powered battery heater 474. In embodiments including both the thermally conductive sheet 464 and an electrically powered battery heater 474, the thermally conductive sheet 464 and the electrically powered battery heater 474 may be positioned on opposite sides of the rechargeable battery 472 as shown in Figure 17 and/or on adjacent sides of the rechargeable battery 472. The electrically powered battery heater 474 may comprise, for example, an electrically resistive heater that generates heat when electrical current passes through it.

[00112] In some embodiments, the rechargeable battery 472 may include a thermally sensitive resistor ("thermistor"). Li-ion batteries, for example, typically include a thermistor. In the present embodiments, the thermistor may be operatively connected to the system processor (e.g., the processor 160) so that the battery's temperature can be used as an input into a control process for the IR illuminator 450. For example, ambient cold temperatures typically occur at night, which is also when the IR illuminator 450 is active. In order to adaptively control the amount of heat supplied to the battery 472 through the thermally conductive sheet 464, the

amount of power supplied to the IR LEDs 452 and/or a time duration of the power delivered to the IR illuminator 450 can be controlled (e.g., by the processor 160) based on the measured temperature of the battery 472. For example, when additional heat supplied to the battery 472 would be advantageous, the amount of power supplied to the IR LEDs 452 and/or the time duration of power delivered to the IR LEDs 452 can be increased (e.g., by the processor 160). Increasing the amount and/or duration of power supplied to the IR LEDs 452 provides advantages, including improving the imaging of distant objects under low ambient light conditions. In some embodiments, the thermistor may provide a signal to the system processor (e.g., the processor 160) in the form of a voltage (or any other type of signal), and the system processor interprets the actual temperature of the battery 472 based on the received signal from the thermistor. In alternative embodiments, another type of device (other than a thermistor) may be used to monitor the temperature of the battery 472. For example, in some embodiments, a battery pack includes a fuel gauge IC for measuring and indicating the battery's temperature.

[00113] In some of the present embodiments, when the monitored temperature of the battery 472 falls below a threshold temperature, additional power may be provided to the IR LEDs 452 to raise the temperature of the battery 472 (e.g., to a temperature above the threshold temperature). In some of the present embodiments, the source of power provided to the IR LEDs 452 for generating additional heat may be different from the rechargeable battery 472. In one aspect of the present embodiments, an AC power supply, such as the AC mains 134 (Figure 3), may provide the additional power to the IR LEDs 452.

[00114] As described above, the present embodiments advantageously provide a combined heatsink and battery heater in which a rechargeable battery is thermally coupled to an IR illuminator through a thermally conductive sheet such that heat dissipation of the IR illuminator acts as a thermal source for warming the rechargeable battery. The present embodiments are particularly advantageous for below-freezing or near-freezing ambient conditions, which typically occur at night, which is also the time of day when the IR illuminator is used for "night vision." By using the heat generated by the IR illuminator to warm the rechargeable battery, the present embodiments advantageously provide a battery heater requiring no additional electrical power beyond that needed to power the IR illuminator. The present embodiments further advantageously enable the IR illuminator to run cooler for the given power input (compared to what the operating temperature would be at the given power input in the absence of the present

embodiments), or run at higher power for a given temperature rise, while at the same time providing heat to the battery to improve the battery's performance characteristics. The present embodiments may increase the power input to and/or the illumination provided by the IR illuminator by more than 50%. Some of the present embodiments may increase IR illumination to almost 100% in very cold weather, such as when TA is -20° C. Some of the present embodiments may also increase IR illumination to almost 100% at TA = +50° C.

[00115] Figure 18 is a functional block diagram of a client device 800 on which the present embodiments may be implemented according to various aspects of the present disclosure. The user's client device 114 described with reference to Figure 1 may include some or all of the components and/or functionality of the client device 800. The client device 800 may comprise, for example, a smartphone.

[00116] With reference to Figure 18, the client device 800 includes a processor 802, a memory 804, a user interface 806, a communication module 808, and a dataport 810. These components are communicatively coupled together by an interconnect bus 812. The processor 802 may include any processor used in smartphones and/or portable computing devices, such as an ARM processor (a processor based on the RISC (reduced instruction set computer) architecture developed by Advanced RISC Machines (ARM)). In some embodiments, the processor 802 may include one or more other processors, such as one or more conventional microprocessors, and/or one or more supplementary co-processors, such as math co-processors.

[00117] The memory 804 may include both operating memory, such as random access memory (RAM), as well as data storage, such as read-only memory (ROM), hard drives, flash memory, or any other suitable memory/storage element. The memory 804 may include removable memory elements, such as a CompactFlash card, a MultiMediaCard (MMC), and/or a Secure Digital (SD) card. In some embodiments, the memory 804 may comprise a combination of magnetic, optical, and/or semiconductor memory, and may include, for example, RAM, ROM, flash drive, and/or a hard disk or drive. The processor 802 and the memory 804 each may be, for example, located entirely within a single device, or may be connected to each other by a communication medium, such as a USB port, a serial port cable, a coaxial cable, an Ethernet-type cable, a telephone line, a radio frequency transceiver, or other similar wireless or wired medium or combination of the foregoing. For example, the processor 802 may be connected to the memory 804 via the dataport 810.

[00118] The user interface 806 may include any user interface or presentation elements suitable for a smartphone and/or a portable computing device, such as a keypad, a display screen, a touchscreen, a microphone, and a speaker. The communication module 808 is configured to handle communication links between the client device 800 and other, external devices or receivers, and to route incoming/outgoing data appropriately. For example, inbound data from the dataport 810 may be routed through the communication module 808 before being directed to the processor 802, and outbound data from the processor 802 may be routed through the communication module 808 before being directed to the dataport 810. The communication module 808 may include one or more transceiver modules capable of transmitting and receiving data, and using, for example, one or more protocols and/or technologies, such as GSM, UMTS (3GSM), IS-95 (CDMA one), IS-2000 (CDMA 2000), LTE, FDMA, TDMA, W-CDMA, CDMA, OFDMA, Wi-Fi, WiMAX, or any other protocol and/or technology.

[00119] The dataport 810 may be any type of connector used for physically interfacing with a smartphone and/or a portable computing device, such as a mini-USB port or an IPHONE®/IPOD® 30-pin connector or LIGHTNING® connector. In other embodiments, the dataport 810 may include multiple communication channels for simultaneous communication with, for example, other processors, servers, and/or client terminals.

[00120] The memory 804 may store instructions for communicating with other systems, such as a computer. The memory 804 may store, for example, a program (e.g., computer program code) adapted to direct the processor 802 in accordance with the present embodiments. The instructions also may include program elements, such as an operating system. While execution of sequences of instructions in the program causes the processor 802 to perform the process steps described herein, hard-wired circuitry may be used in place of, or in combination with, software/firmware instructions for implementation of the processes of the present embodiments. Thus, the present embodiments are not limited to any specific combination of hardware and software.

[00121] Figure 19 is a functional block diagram of a general-purpose computing system on which the present embodiments may be implemented according to various aspects of the present disclosure. The computer system 900 may be embodied in at least one of a personal computer (also referred to as a desktop computer) 900A, a portable computer (also referred to as a laptop or notebook computer) 900B, and/or a server 900C. A server is a computer program

and/or a machine that waits for requests from other machines or software (clients) and responds to them. A server typically processes data. The purpose of a server is to share data and/or hardware and/or software resources among clients. This architecture is called the client-server model. The clients may run on the same computer or may connect to the server over a network. Examples of computing servers include database servers, file servers, mail servers, print servers, web servers, game servers, and application servers. The term server may be construed broadly to include any computerized process that shares a resource to one or more client processes.

[00122] The computer system 900 may execute at least some of the operations described above. The computer system 900 may include at least one processor 910, memory 920, at least one storage device 930, and input/output (I/O) devices 940. Some or all of the components 910, 920, 930, 940 may be interconnected via a system bus 950. The processor 910 may be single- or multi-threaded and may have one or more cores. The processor 910 may execute instructions, such as those stored in the memory 920 and/or in the storage device 930. Information may be received and output using one or more I/O devices 940.

[00123] The memory 920 may store information, and may be a computer-readable medium, such as volatile or non-volatile memory. The storage device(s) 930 may provide storage for the system 900, and may be a computer-readable medium. In various aspects, the storage device(s) 930 may be a flash memory device, a hard disk device, an optical disk device, a tape device, or any other type of storage device.

[00124] The I/O devices 940 may provide input/output operations for the system 900. The I/O devices 940 may include a keyboard, a pointing device, and/or a microphone. The I/O devices 940 may further include a display unit for displaying graphical user interfaces, a speaker, and/or a printer. External data may be stored in one or more accessible external databases 960.

[00125] The features of the present embodiments described herein may be implemented in digital electronic circuitry, and/or in computer hardware, firmware, software, and/or in combinations thereof. Features of the present embodiments may be implemented in a computer program product tangibly embodied in an information carrier, such as a machine-readable storage device, and/or in a propagated signal, for execution by a programmable processor. Embodiments of the present method steps may be performed by a programmable processor

executing a program of instructions to perform functions of the described implementations by operating on input data and generating output.

[00126] The features of the present embodiments described herein may be implemented in one or more computer programs that are executable on a programmable system including at least one programmable processor coupled to receive data and/or instructions from, and to transmit data and/or instructions to, a data storage system, at least one input device, and at least one output device. A computer program may include a set of instructions that may be used, directly or indirectly, in a computer to perform a certain activity or bring about a certain result. A computer program may be written in any form of programming language, including compiled or interpreted languages, and it may be deployed in any form, including as a stand-alone program or as a module, component, subroutine, or other unit suitable for use in a computing environment.

[00127] Suitable processors for the execution of a program of instructions may include, for example, both general and special purpose processors, and/or the sole processor or one of multiple processors of any kind of computer. Generally, a processor may receive instructions and/or data from a read only memory (ROM), or a random access memory (RAM), or both. Such a computer may include a processor for executing instructions and one or more memories for storing instructions and/or data.

[00128] Generally, a computer may also include, or be operatively coupled to communicate with, one or more mass storage devices for storing data files. Such devices include magnetic disks, such as internal hard disks and/or removable disks, magneto-optical disks, and/or optical disks. Storage devices suitable for tangibly embodying computer program instructions and/or data may include all forms of non-volatile memory, including for example semiconductor memory devices, such as EPROM, EEPROM, and flash memory devices, magnetic disks such as internal hard disks and removable disks, magneto-optical disks, and CD-ROM and DVD-ROM disks. The processor and the memory may be supplemented by, or incorporated in, one or more ASICs (application-specific integrated circuits).

[00129] To provide for interaction with a user, the features of the present embodiments may be implemented on a computer having a display device, such as an LCD (liquid crystal display) monitor, for displaying information to the user. The computer may further include a keyboard, a pointing device, such as a mouse or a trackball, and/or a touchscreen by which the user may provide input to the computer.

[00130] The features of the present embodiments may be implemented in a computer system that includes a back-end component, such as a data server, and/or that includes a middleware component, such as an application server or an Internet server, and/or that includes a front-end component, such as a client computer having a graphical user interface (GUI) and/or an Internet browser, or any combination of these. The components of the system may be connected by any form or medium of digital data communication, such as a communication network. Examples of communication networks may include, for example, a LAN (local area network), a WAN (wide area network), and/or the computers and networks forming the Internet.

[00131] The computer system may include clients and servers. A client and server may be remote from each other and interact through a network, such as those described herein. The relationship of client and server may arise by virtue of computer programs running on the respective computers and having a client-server relationship to each other.

[00132] The above description presents the best mode contemplated for carrying out the present embodiments, and of the manner and process of practicing them, in such full, clear, concise, and exact terms as to enable any person skilled in the art to which they pertain to practice these embodiments. The present embodiments are, however, susceptible to modifications and alternate constructions from those discussed above that are fully equivalent. Consequently, the present invention is not limited to the particular embodiments disclosed. On the contrary, the present invention covers all modifications and alternate constructions coming within the spirit and scope of the present disclosure. For example, the steps in the processes described herein need not be performed in the same order as they have been presented, and may be performed in any order(s). Further, steps that have been presented as being performed separately may in alternative embodiments be performed concurrently. Likewise, steps that have been presented as being performed concurrently may in alternative embodiments be performed separately.

WHAT IS CLAIMED IS:

1. A method for managing a temperature of a rechargeable battery of an electronic device, the method comprising:
thermally coupling a heat-generating component of the electronic device to the rechargeable battery using a thermally conductive sheet, wherein the thermally conductive sheet transfers waste heat generated by the heat-generating component to the rechargeable battery to raise the temperature of the rechargeable battery.
2. The method of Claim 1, wherein the temperature of the rechargeable battery is raised from a first temperature below, or equal to, a threshold temperature to a second temperature above the threshold temperature.
3. The method of Claim 1, wherein the heat-generating component comprises at least one infrared (IR) illuminator coupled to a printed circuit board (PCB).
4. The method of Claim 3, wherein the at least one IR illuminator comprises an IR light-emitting diode (LED).
5. The method of Claim 3, wherein the at least one IR illuminator is coupled to a first surface of the PCB, and wherein a first portion of the thermally conductive sheet is thermally coupled to a second surface of the PCB.
6. The method of Claim 5, wherein a second portion of the thermally conductive sheet is thermally coupled to the rechargeable battery.
7. The method of Claim 5, wherein the first portion of the thermally conductive sheet is also coupled to a heatsink that is also coupled to the second surface of the PCB.
8. The method of Claim 7, wherein the first portion of the thermally conductive sheet is sandwiched between the second surface of the PCB and the heatsink.
9. The method of Claim 1, wherein the thermally conductive sheet comprises one of copper and a copper alloy.
10. The method of Claim 1, wherein the rechargeable battery comprises a lithium-ion battery.
11. The method of Claim 1, wherein the electronic device comprises an audio/video (A/V) recording and communication device.
12. The method of Claim 11, wherein the A/V recording and communication device comprises one of a doorbell and a security camera.

13. The method of Claim 1, wherein a first portion of the thermally conductive sheet is thermally coupled to the heat-generating component by either proximity or direct contact, and wherein a second portion of the thermally conductive sheet is thermally coupled to the rechargeable battery by either proximity or direct contact.

14. The method of Claim 1, wherein the thermally conductive sheet is coupled to a first surface of the rechargeable battery, and wherein a resistive battery heater is coupled to a second surface of the rechargeable battery.

15. The method of Claim 14, wherein the resistive battery heater and the thermally conductive sheet both provide heat to the rechargeable battery when the temperature of the rechargeable battery is below a threshold temperature.

16. The method of Claim 1, wherein the heat-generating electrical component comprises at least one illuminator coupled to a printed circuit board (PCB), the method further comprising:

receiving, at a processor of the A/V recording and communication device, a signal indicative of the temperature of the rechargeable battery;

determining, by the processor, that the temperature of the rechargeable battery is below a threshold temperature even when the heat is being transferred from the at least one illuminator to the rechargeable battery; and

increasing an amount of electrical power provided to the at least one illuminator so that more heat is transferred from the at least one illuminator to the rechargeable battery.

17. The method of Claim 16, further comprising increasing a time duration of the electrical power delivered to the at least one illuminator to produce more heat to be transferred to the rechargeable battery.

18. The method of Claim 16, wherein the electrical power is provided to the at least one illuminator by an alternating current (AC) power supply.

19. An audio/video (A/V) recording and communication device, comprising:

a camera;

a printed circuit board (PCB);

one or more infrared (IR) illuminators coupled to a first surface of the PCB and configured to illuminate a field of view of the camera with IR light;

a thermally conductive sheet having a first portion coupled to a second surface of the PCB and a second portion extending from the PCB; and

a rechargeable battery thermally coupled to the one or more IR illuminators through the thermally conductive sheet such that heat dissipation of the one or more IR illuminators warms the rechargeable battery.

20. The device of Claim 19, further comprising a heatsink coupled to the second surface of the PCB, wherein the thermally conductive sheet is sandwiched between the PCB and the heatsink.

21. The device of Claim 19, wherein the thermally conductive sheet is thermally coupled to the rechargeable battery by proximity and/or direct contact.

22. The device of Claim 19, wherein the thermally conductive sheet comprises copper or a copper alloy.

23. The device of Claim 19, wherein the one or more IR illuminators comprises at least one IR light-emitting diode (LED).

24. The device of Claim 19, wherein the rechargeable battery comprises a lithium-ion battery.

25. The device of Claim 19, further comprising a processor, wherein the processor is configured to monitor the temperature of the rechargeable battery and to control an amount of electrical power and/or a time duration of the electrical power delivered to the set of IR illuminators.

26. The device of Claim 19, further comprising a resistive battery heater contacting the rechargeable battery.

27. The device of Claim 26, wherein the resistive battery heater is located on a side of the rechargeable battery opposite the thermally conductive sheet.

28. The device of Claim 19, wherein a surface area of the second portion of the thermally conductive sheet is at least as large as a surface area of the heatsink.

29. The device of Claim 19, wherein the PCB has a metal core.

30. The device of Claim 19, wherein the A/V recording and communication device comprises one of a doorbell and a security camera.

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US 17/24448

A. CLASSIFICATION OF SUBJECT MATTER
 IPC(8) - H01 M 10/61 5; H01 M 10/62; H01 M 10/655; H01 M 10/6554; H01 M 10/6571 (201 7.01)
 CPC - H01 M 10/61 5; H01 M 10/62; H01 M 10/655; H01 M 10/6554; H01 M 10/6571

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

See Search History Document

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

See Search History Document

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

See Search History Document

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X --- Y --- A	WO 2015/031061 A1 (GRAFTECH INTERNATIONAL HOLDINGS INC.), 05 March 2015 (05.03.2015) Fig 1, abstract, para [01 1]-[015], [017], [020], [024]	1, 9, 10, 13 ----- 2-4, 11, 12, 14, 15 ----- 5-8, 16-30
Y	US 2012/0107665 A1 (ABE et al.) 03 May 2012 (03.05.2012), Fig 1, abstract, para [0045], [0046]	2, 14, 15
Y --- A	US 2012/0202565 A1 (LAPSTUN et al.) 09 August 2012 (09.08.2012), Fig 3, abstract, para [0036], [0040], [0043], [0044]	3, 4 ----- 5-8, 16-30
Y	US 2006/0209187 A1 (FARNEMAN) 21 September 2006 (21.09.2006), Fig 4, abstract, para [0027], [0028]	11, 12 ----- 16-18

Further documents are listed in the continuation of Box C. See patent family annex.

* Special categories of cited documents:	"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
"A" document defining the general state of the art which is not considered to be of particular relevance	"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
"E" earlier application or patent but published on or after the international filing date	"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	"&" document member of the same patent family
"O" document referring to an oral disclosure, use, exhibition or other means	
"P" document published prior to the international filing date but later than the priority date claimed	

Date of the actual completion of the international search

19 May 2017

Date of mailing of the international search report
