Abstract:
The present invention provides an improved process for conversion of feedstock comprising an alkylatable aromatic compound and an alkylating agent to desired alkylation product under at least partial liquid phase conversion conditions in the presence of specific catalyst comprising a porous crystalline material, e.g. a crystalline aluminosilicate, and binder in the ratio of crystal/binder of from about 20/80 to about 60/40. The porous crystalline material of the catalyst may comprise a crystalline molecular sieve having the structure of Beta, an MCM-22 family material, e.g. MCM-49, or a mixture thereof.
IMPROVED LIQUID PHASE ALKYLATION PROCESS

BACKGROUND OF THE INVENTION

[0001] The present invention relates to an improved process for producing alkylaromatics, for example, ethylbenzene, cumene and sec-butylbenzene.

[0002] Of the alkylaromatic compounds advantageously produced by the present improved process, ethylbenzene and cumene, for example, are valuable commodity chemicals which are used industrially for the production of styrene monomer and coproduction of phenol and acetone respectively. In fact, a common route for the production of phenol comprises a process which involves alkylation of benzene with propylene to produce cumene, followed by oxidation of the cumene to the corresponding hydroperoxide, and then cleavage of the hydroperoxide to produce equimolar amounts of phenol and acetone. Ethylbenzene may be produced by a number of different chemical processes. One process which has achieved a significant degree of commercial success is the vapor phase alkylation of benzene with ethylene in the presence of a solid, acidic ZSM-5 zeolite catalyst. Examples of such ethylbenzene production processes are described in U.S. Patents Nos. 3,751,504 (Keown), 4,547,605 (Kresge) and 4,016,218 (Haag).

[0003] Another process which has achieved significant commercial success is the liquid phase process for producing ethylbenzene from benzene and ethylene since it operates at a lower temperature than the vapor phase counterpart and hence tends to result in lower yields of by-products. For example, U.S. Patent No. 4,891,458 (Innes) describes the liquid phase synthesis of ethylbenzene with zeolite beta, whereas U.S. Patent No. 5,334,795 (Chu) describes the use of MCM-22 in the liquid phase synthesis of ethylbenzene. The latter patent teaches use of catalyst comprising MCM-22 crystalline material and binder in the ratio of crystal/binder of from about 1/99 to about 90/10.

[0004] Cumene has for many years been produced commercially by the liquid phase alkylation of benzene with propylene over a Friedel-Craft catalyst, particularly solid phosphoric acid or aluminum chloride. More recently, however, zeolite-based catalyst systems have been found to be more active and selective for propylation of benzene to cumene. For example, U.S. Patent No. 4,992,606 (Kushnerick) describes the use of MCM-22 in the liquid phase alkylation of benzene with propylene.

[0005] Other publications show use of catalysts comprising crystalline zeolites and
binders for conversion of feedstock comprising an alkylatable aromatic compound and an alkylating agent to alkylaromatic conversion product under at least partial liquid phase conversion conditions. These include U.S. 2005/01975 17Al (Cheng) showing use of a catalyst crystal/binder ratio of 65/35 and 100/0; U.S. 2002/0137977A1 (Hendriksen) showing use of a catalyst crystal/binder ratio of 100/0 while noting the perceived negative effect of binders on selectivity; U.S. 2004/013805 IA1 (Shan) showing use of a catalyst comprising a microporous zeolite embedded in a mesoporous support, where the zeolite/support ratio is from less than 1/99 to more than 99/1, preferably from 3/97 to 90/10; WO 2006/002805 (Spano) teaching use of a catalyst crystal/binder ratio of 20/80 to 95/5, exemplifying 55/45; U.S. Patent No. 6,376,730 (Jan) showing use of layered catalyst crystal/binder of 70/30 and 83/17; EP 0847802B1 showing use of a catalyst crystal/binder ratio of from 50/50 to 95/5, preferably from 70/30 to 90/10; and U.S. Patent No. 5,600,050 (Huang) showing use of catalyst comprising 30 to 70 wt. % H-Beta zeolite, 0.5 to 10 wt. % halogen, and the remainder alumina binder.

[0006] Existing alkylation processes for producing alkylaromatic compounds, for example, ethylbenzene and cumene, inherently produce polyalkylated species as well as the desired monoalkylated product. It is therefore normal to transalkylate the polyalkylated species with additional aromatic feed, for example benzene, to produce additional monoalkylated product, for example ethylbenzene or cumene, either by recycling the polyalkylated species to the alkylation reactor or, more frequently, by feeding the polyalkylated species to a separate transalkylation reactor. Examples of catalysts which have been used in the alkylation of aromatic species, such as alkylation of benzene with ethylene or propylene, and in the transalkylation of polyalkylated species, such as polyethylbenzenes and polyisopropylbenzenes, are listed in U.S Patent No. 5,557,024 (Cheng) and include MCM-49, MCM-22, PSH-3, SSZ-25, zeolite X, zeolite Y, zeolite Beta, acid dealuminized mordenite and TEA-mordenite. Transalkylation over a small crystal (<0.5 micron) form of TEA-mordenite is also disclosed in U.S. Patent 6,984,764.

[0007] Where the alkylation step is performed in the liquid phase, it is also desirable to conduct the transalkylation step under liquid phase conditions. However, by operating at relatively low temperatures, liquid phase processes impose increased requirements on the catalyst, particularly in the transalkylation step where the bulky polyalkylated species must be converted to additional monoalkylated product without producing unwanted by-products. This has proven to be a significant problem in the case of cumene production where existing
catalysts have either lacked the desired activity or have resulted in the production of significant quantities of by-products such as ethylbenzene and n-propylbenzene.

Although it is suggested in the art that catalysts for conversion of feedstock comprising an alkylatable aromatic compound and an alkylating agent to alkylaromatic conversion product under at least partial liquid phase conversion conditions are composed of a porous crystalline aluminosilicate and binder in the ratio of crystal/binder of from 1/99, e.g. 5/95, to 100/0, current commercial catalysts, i.e. those found to be commercially useful, for this process are composed of a porous crystalline aluminosilicate and binder in the ratio of crystal/binder of either 65/35 or 80/20. Finding a commercially acceptable catalyst for such processes conducted under at least partial liquid phase conversion conditions which increases monoselectivity, i.e. lower di- or polyalkyl product make, would allow capacity expansion in existing plants and lower capital expense for grassroots plants as a result of lower aromatic compound/alkylating agent ratios. According to the present invention, it has now unexpectedly been found that a liquid phase or partial liquid phase alkylation process for producing alkylaromatics conducted in the presence of a specific catalyst comprising a porous crystalline material, e.g. a crystalline aluminosilicate, ("crystal") and binder in the ratio of crystal/binder of from about 20/80 to about 60/40, yields a unique combination of activity and, importantly, monoselectivity. This is especially the case when the process involves at least partial liquid phase alkylation for manufacture of ethylbenzene or cumene. This obviates or lessens the demand in many instances for the difficult transalkylation reaction for conversion of unwanted bulky polyalkylated species in such a process.

SUMMARY OF THE INVENTION

According to the present invention, there is provided an improved process for conversion of a feedstock comprising an alkylatable aromatic compound and an alkylating agent to desired alkylaromatic conversion product under at least partial liquid phase conversion conditions in the presence of a specific catalyst comprising a porous crystalline material, e.g. a crystalline aluminosilicate, and binder in the ratio of crystal/binder of from about 20/80 to about 60/40. According to one aspect of the invention, there is provided a process for selectively producing a desired monoalkylated aromatic compound comprising the step of contacting an alkylatable aromatic compound with an alkylating agent in the presence of catalyst under at least partial liquid phase conditions, said catalyst comprising a porous crystalline material, e.g. a crystalline aluminosilicate, and binder in the ratio of
crystal/binder of from about 20/80 to about 60/40. Another aspect of the present invention is an improved alkylation process for the selective production of monoalkyl benzene comprising the step of reacting benzene with an alkylation agent under alkylation conditions in the presence of alkylation catalyst which comprises a porous crystalline material, e.g. a crystalline aluminosilicate, and binder in the ratio of crystal/binder of from about 20/80 to about 60/40.

[0010] The catalyst for use in the present process may comprise, for example, a crystalline molecular sieve having the structure of zeolite Beta, or one having an X-ray diffraction pattern including d-spacing maxima at 12.4±0.25, 6.9±0.15, 3.57±0.07 and 3.42±0.07 Angstroms. More particularly, the catalyst for use herein may comprise a crystalline molecular sieve having the structure of Beta, an MCM-22 family material, e.g. MCM-22, or a mixture thereof.

[0011] The catalyst for use in the present invention preferably comprises an MCM-22 family material, such as for example a crystalline silicate having the structure of MCM-22, PSH-3, SSZ-25, ERB-I, ITQ-1, ITQ-2, ITQ-30, MCM-36, MCM-49, MCM-56, UZM-8 and mixtures thereof.

DETAILED DESCRIPTION OF THE INVENTION

[0012] The present invention relates to an improved process for production of monoalkylated aromatic compounds, particularly ethylbenzene, cumene and sec-butylbenzene, by the liquid or partial liquid phase alkylation of an alkylatable aromatic compound, particularly benzene. More particularly, the present process uses a catalyst composition comprising a porous crystalline material, e.g. a crystalline aluminosilicate, and binder in the ratio of crystal/binder of from about 20/80 to about 60/40.

[0013] Methods for producing the catalysts required for use in the present invention comprise those taught in the publications listed below and incorporated herein by reference, modified only by adjusting the compounding or extrusion, for example, of the final catalyst to comprise a crystal/binder ratio of from about 20/80 to about 60/40. This is well within the ability of those skilled in catalyst manufacturing art. For example, U.S. Patent No. 4,954,325 describes crystalline MCM-22 and catalyst comprising same, U.S. Patent No. 5,236,575 describes crystalline MCM-49 and catalyst comprising same, and U.S. Patent No. 5,362,697 describes crystalline MCM-56 and catalyst comprising same. In compounding or extruding the particular crystalline material with binder to form the catalyst required for use herein, care
is taken to do so such that the final catalyst product comprises a crystal/binder ratio of from about 20/80 to about 60/40.

[0014] The term "aromatic" in reference to the alkylatable aromatic compounds which may be useful as feedstock herein is to be understood in accordance with its art-recognized scope. This includes alkyl substituted and unsubstituted mono- and polynuclear compounds. Compounds of an aromatic character that possess a heteroatom are also useful provided they do not act as catalyst poisons under the reaction conditions selected.

[0015] Substituted aromatic compounds that can be alkylated herein must possess at least one hydrogen atom directly bonded to the aromatic nucleus. The aromatic rings can be substituted with one or more alkyl, aryl, alkaryl, alkoxy, aryloxy, cycloalkyl, halide, and/or other groups that do not interfere with the alkylation reaction.

[0016] Suitable aromatic compounds include benzene, naphthalene, anthracene, naphthacene, perylene, coronene, and phenanthrene, with benzene being preferred.

[0017] Generally the alkyl groups that can be present as substituents on the aromatic compound contain from 1 to about 22 carbon atoms and usually from about 1 to 8 carbon atoms, and most usually from about 1 to 4 carbon atoms.

[0018] Suitable alkyl substituted aromatic compounds include toluene, xylene, isopropylbenzene, n-propylbenzene, alpha-methylnaphthalene, ethylbenzene, mesitylene, durene, cymenes, butylbenzene, pseudocumene, o-diethylbenzene, m-diethylbenzene, p-diethylbenzene, isoamylbenzene, isoheptylbenzene, pentaethylbenzene, pentamethylbenzene; 1,2,3,4-tetraethylbenzene; 1,2,3,5-tetramethylbenzene; 1,2,4-triethylbenzene; 1,2,3-trimethylbenzene, m-butyltoluene; p-butyltoluene; 3,5-diethyltoluene; o-ethyltoluene; p-ethyltoluene; m-propyltoluene; 4-ethyl-m-xylene; dimethylnaphthalenes; ethynaphthalene; 2,3-dimethylanthracene; 9-ethylanthracene; 2-methylanthracene; o-methylanthracene; 9,10-dimethylphenanthrene; and 3-methyl-phenanthrene. Higher molecular weight alkyarylatic compounds can also be used as starting materials and include aromatic organics such as are produced by the alkylation of aromatic organics with olefin oligomers. Such products are frequently referred to in the art as alkylate and include hexylbenzene, nonylbenzene, dodecylbenzene, pentadecylbenzene, hexyltoluene, nonyltoluene, dodecyltoluene, pentadecyltoluene, etc. Very often alkylate is obtained as a high boiling fraction in which the alkyl group attached to the aromatic nucleus varies in size from about C₈ to about C₁₅. When cumene or ethylbenzene is the desired product, the present process produces acceptably little by-products such as xylenes. The xylenes made in such instances may be less than about 500
Reformate containing a mixture of benzene, toluene and/or xylene constitutes a particularly useful feed for the alkylation process of this invention.

The alkylation agents that may be useful in the process of this invention generally include any aliphatic or aromatic organic compound having one or more available alkylation aliphatic groups capable of reaction with the alkylatable aromatic compound, preferably with the alkylation group possessing from 1 to 5 carbon atoms. Examples of suitable alkylation agents are olefins such as ethylene, propylene, the butenes, and the pentenes; alcohols (inclusive of monoalcohols, dialcohols, trialcohols, etc.) such as methanol, ethanol, the propanols, the butanols, and the pentanols; aldehydes such as formaldehyde, acetaldehyde, propionaldehyde, butyraldehyde, and n-valeraldehyde; and alkyl halides such as methyl chloride, ethyl chloride, the propyl chlorides, the butyl chlorides, and the pentyl chlorides, and so forth.

Mixtures of light olefins are useful as alkylation agents in the alkylation process of this invention. Accordingly, mixtures of ethylene, propylene, butenes, and/or pentenes which are major constituents of a variety of refinery streams, e.g., fuel gas, gas plant off-gas containing ethylene, propylene, etc., naphtha cracker off-gas containing light olefins, refinery FCC propane/propylene streams, etc., are useful alkylation agents herein. For example, a typical FCC light olefin stream possesses the following composition:

Reaction products that may be obtained from the process of the present invention include ethylbenzene from the reaction of benzene with ethylene, cumene from the reaction of benzene with propylene, ethyltoluene from the reaction of toluene with ethylene, cymenes from the reaction of toluene with propylene, and sec-butylbenzene from the reaction of benzene and n-butene. Particularly preferred process mechanisms of the invention relate to the production of cumene by the alkylation of benzene with propylene, and production of
ethylbenzene by the alkylation of benzene with ethylene.

[0023] The reactants for the present improved process can be in partially or completely liquid phase and can be neat, i.e. free from intentional admixture or dilution with other material, or they can be brought into contact with the catalyst composition with the aid of carrier gases or diluents such as, for example, hydrogen or nitrogen.

[0024] The improved alkylation process of this invention may be conducted such that the reactants, i.e., the alkylatable aromatic compound and the alkylation agent, are brought into contact with the present catalyst in a suitable reaction zone such as, for example, in a flow reactor containing a fixed bed of the catalyst composition, under effective alkylation conditions. Such conditions include a temperature of from about 0°C to about 500°C, preferably from about 10°C to about 260°C, a pressure of from about 0.2 to about 25000 kPa-a, preferably from about 100 to about 5500 kPa-a, a molar ratio of alkylatable aromatic compound to alkylation agent of from about 0.1:1 to about 50:1, preferably from about 0.5:1 to about 10:1, and a feed weight hourly space velocity (WHSV) based on the alkylation agent of from about 0.1 to 500 hr⁻¹, preferably from about 0.5 to about 100 hr⁻¹.

[0025] When benzene is alkylated with ethylene to produce ethylbenzene, the alkylation reaction is preferably carried out in the liquid phase under conditions including a temperature of from about 150°C to about 300°C, more preferably from about 170°C to about 260°C; a pressure up to about 20400 kPa-a, more preferably from about 2000 kPa-a to about 5500 kPa-a; a weight hourly space velocity (WHSV) based on the ethylene alkylation agent of from about 0.1 to about 20 hr⁻¹, more preferably from about 0.5 to about 6 hr⁻¹; and a ratio of benzene to ethylene in the alkylation reactor of from about 0.5:1 to about 30:1 molar, more preferably from about 1:1 to about 10:1 molar.

[0026] When benzene is alkylated with propylene to produce cumene, the reaction may also take place under liquid phase conditions including a temperature of up to about 250°C, preferably up to about 150°C, e.g., from about 10°C to about 125°C; a pressure of about 25000 kPa-a or less, e.g., from about 100 to about 3000 kPa-a; a weight hourly space velocity (WHSV) based on propylene alkylation agent of from about 0.1 hr⁻¹ to about 250 hr⁻¹, preferably from about 1 hr⁻¹ to about 50 hr⁻¹; and a ratio of benzene to propylene in the alkylation reactor of from about 0.5:1 to about 30:1 molar, more preferably from about 1:1 to about 10:1 molar.

[0027] When benzene is alkylated with butenes, e.g. n-butene, to produce butylbenzene, e.g. sec-butylbenzene, the reaction may also take place under liquid phase conditions
including a temperature of up to about 250°C, preferably up to about 150°C, e.g., from about 10°C to about 125°C; a pressure of about 25000 kPa-a or less, e.g., from about 100 to about 3000 kPa-a; a weight hourly space velocity (WHSV) based on butenes alkylating agent of from about 0.1 hr⁻¹ to about 250 hr⁻¹, preferably from about 1 hr⁻¹ to about 50 hr⁻¹; and a ratio of benzene to butenes in the alkylation reactor of from about 0.5:1 to about 30:1 molar, more preferably from about 1:1 to about 10:1 molar.

[0028] The crystal portion of the catalyst for use in the present invention may comprise a crystalline molecular sieve having the structure of zeolite Beta (described in U.S. Patent No. 3,308,069) or an MCM-22 family material. The catalyst must include the crystalline molecular sieve combined in a conventional manner with an oxide binder as hereinafter detailed in the ratio of crystal/binder of from about 20/80 to about 60/40. For certain applications of the catalyst, the average particle size of the crystalline molecular sieve component may be from about 0.05 to about 200 microns, for example, from 20 to about 200 micron.

[0029] The term "MCM-22 family material" (or "material of the MCM-22 family" or "molecular sieve of the MCM-22 family"), as used herein, includes:

(i) molecular sieves made from a common first degree crystalline building block "unit cell having the MWW framework topology". A unit cell is a spatial arrangement of atoms which is tiled in three-dimensional space to describe the crystal as described in the "Atlas of Zeolite Framework Types", Fifth edition, 2001, the entire content of which is incorporated as reference;

(ii) molecular sieves made from a common second degree building block, a 2-dimensional tiling of such MWW framework type unit cells, forming a "monolayer of one unit cell thickness", preferably one c-unit cell thickness;

(iii) molecular sieves made from common second degree building blocks, "layers of one or more than one unit cell thickness", wherein the layer of more than one unit cell thickness is made from stacking, packing, or binding at least two monolayers of one unit cell thick of unit cells having the MWW framework topology. The stacking of such second degree building blocks can be in a regular fashion, an irregular fashion, a random fashion, or any combination thereof; or

(iv) molecular sieves made by any regular or random 2-dimensional or 3-dimensional combination of unit cells having the MWW framework topology.

[0030] The MCM-22 family materials are characterized by having an X-ray diffraction
pattern including d-spacing maxima at 12.4±0.25, 3.57±0.07 and 3.42±0.07 Angstroms (either calcined or as-synthesized). The MCM-22 family materials may also be characterized by having an X-ray diffraction pattern including d-spacing maxima at 12.4±0.25, 6.9±0.15, 3.57±0.07 and 3.42±0.07 Angstroms (either calcined or as-synthesized). The X-ray diffraction data used to characterize the molecular sieve are obtained by standard techniques using the K-alpha doublet of copper as the incident radiation and a diffractometer equipped with a scintillation counter and associated computer as the collection system. Materials belong to the MCM-22 family include MCM-22 (described in U.S. Pat. No. 4,954,325), PSH-3 (described in U.S. Pat. No. 4,439,409), SSZ-25 (described in U.S. Pat. No. 4,826,667), ERB-I (described in European Patent No. 0293032), ITQ-I (described in U.S. Pat. No. 6,077,498), ITQ-2 (described in International Patent Publication No. WO97/17290), ITQ-30 (described in International Patent Publication No. WO200518476), MCM-36 (described in U.S. Pat. No. 5,250,277), MCM-49 (described in U.S. Pat. No. 5,236,575), MCM-56 (described in U.S. Pat. No. 5,362,697), and UZM-8 (described in U.S. Patent No. 6,756,030). The entire contents of the patents are incorporated herein by reference.

[0031] It is to be appreciated the MCM-22 family molecular sieves described above are distinguished from conventional large pore zeolite alkylation catalysts, such as mordenite, in that the MCM-22 materials have 12-ring surface pockets which do not communicate with the 10-ring internal pore system of the molecular sieve.

[0032] The zeolitic materials designated by the IZA-SC as being of the MWW topology are multi-layered materials which have two pore systems arising from the presence of both 10 and 12 membered rings. The Atlas of Zeolite Framework Types classifies five differently named materials as having this same topology: MCM-22, ERB-I, ITQ-I, PSH-3, and SSZ-25.

[0033] The MCM-22 family molecular sieves have been found to be useful in a variety of hydrocarbon conversion processes. Examples of MCM-22 family molecular sieve are MCM-22, MCM-49, MCM-56, ITQ-I, PSH-3, SSZ-25, and ERB-I. Such molecular sieves are useful for alkylation of aromatic compounds. For example, U.S. Patent No. 6,936,744 discloses a process for producing a monoalkylated aromatic compound, particularly cumene, comprising the step of contacting a polyalkylated aromatic compound with an alkylatable aromatic compound under at least partial liquid phase conditions and in the presence of a transalkylation catalyst to produce the monoalkylated aromatic compound, wherein the transalkylation catalyst comprises a mixture of at least two different crystalline molecular
sieves, wherein each of the molecular sieves is selected from zeolite beta, zeolite Y, mordenite and a material having an X-ray diffraction pattern including d-spacing maxima at 12.4±0.25, 6.9±0.15, 3.57±0.07 and 3.42±0.07 Angstroms.

[0034] In the reaction mechanism of the present invention, the alkylation reactor effluent may contain excess aromatic feed, monoalkylated product, polyalkylated products, and various impurities. The aromatic feed is recovered by distillation and recycled to the alkylation reactor. Usually a small bleed is taken from the recycle stream to eliminate unreactive impurities from the loop. The bottoms from the distillation may be further distilled to separate monoalkylated product from polyalkylated products and other heavies.

[0035] The polyalkylated products separated from the alkylation reactor effluent may be reacted with additional aromatic feed in a transalkylation reactor, separate from the alkylation reactor, over a suitable transalkylation catalyst. The transalkylation catalyst may comprise one or a mixture of crystalline molecular sieves having the structure of zeolite Beta, zeolite Y, mordenite or an MCM-22 family material having an X-ray diffraction pattern including d-spacing maxima at 12.4±0.25, 6.9±0.15, 3.57±0.07 and 3.42±0.07 Angstroms.

[0036] The X-ray diffraction data used to characterize said above catalyst structures are obtained by standard techniques using the K-alpha doublet of copper as the incident radiation and a diffractometer equipped with a scintillation counter and associated computer as the collection system. Materials having the above X-ray diffraction lines include, for example, MCM-22 (described in U.S. Patent No. 4,954,325), PSH-3 (described in U.S. Patent No. 4,439,409), SSZ-25 (described in U.S. Patent No. 4,826,667), ERB-I (described in European Patent No. 0293032), ITQ-I (described in U.S. Patent No. 6,077,498), ITQ-2 (described in U.S. Patent No. 6,231,751), ITQ-30 (described in WO 2005-118476), MCM-36 (described in U.S. Patent No. 5,250,277), MCM-49 (described in U.S. Patent No. 5,236,575) and MCM-56 (described in U.S. Patent No. 5,362,697), with MCM-22 being particularly preferred.

[0037] Zeolite Beta is disclosed in U.S. Patent No. 3,308,069. Zeolite Y and mordenite occur naturally but may also be used in one of their synthetic forms, such as Ultrastable Y (USY), which is disclosed in U.S. Patent No. 3,449,070, Rare earth exchanged Y (REY), which is disclosed in U.S. Patent No. 4,415,438, and TEA-mordenite (i.e., synthetic mordenite prepared from a reaction mixture comprising a tetraethylammonium directing agent), which is disclosed in U.S. Patent Nos. 3,766,093 and 3,894,104. However, in the case of TEA-mordenite for use in the transalkylation catalyst, the particular synthesis regimes described in the patents noted lead to the production of a mordenite product composed of
predominantly large crystals with a size greater than 1 micron and typically around 5 to 10 micron. It has been found that controlling the synthesis so that the resultant TEA-mordenite has an average crystal size of less than 0.5 micron results in a transalkylation catalyst with materially enhanced activity for liquid phase aromatics transalkylation.

[0038] The small crystal TEA-mordenite desired for transalkylation can be produced by crystallization from a synthesis mixture having a molar composition within the following ranges:

[0039] The crystallization of small crystal TEA-mordenite from this synthesis mixture is conducted at a temperature of 90 to 200°C, for a time of 6 to 180 hours.

[0040] The catalyst for use in the present invention will include an inorganic oxide material matrix or binder. Such matrix or binder materials include synthetic or naturally occurring substances as well as inorganic materials such as clay, silica and/or metal oxides. The latter may be either naturally occurring or in the form of gelatinous precipitates or gels including mixtures of silica and metal oxides. Naturally occurring clays which can be composited with the inorganic oxide material include those of the montmorillonite and kaolin families, which families include the subbentonites and the kaolins commonly known as Dixie, McNamee, Georgia and Florida clays or others in which the main mineral constituent is halloysite, kaolinite, dickite, nacrite or anauxite. Such clays can be used in the raw state as originally mined or initially subjected to calcination, acid treatment or chemical modification.

[0041] Specific useful catalyst matrix or binder materials employed herein include silica, alumina, zirconia, titania, silica-alumina, silica-magnesia, silica-zirconia, silica-thoria, silica-beryllia, silica-titania as well as ternary compositions such as silica-alumina-thoria, silica-alumina-zirconia, silica-alumina-magnesia and silica-magnesia-zirconia. The matrix can be in the form of a cogel. A mixture of these components could also be used.

[0042] For the improvement of the present invention, relative proportions of the crystalline molecular sieve and binder or matrix may vary narrowly with the ratio of crystal/binder of from about 20/80 to about 60/40.
[0043] The catalyst for use in the present invention, or its crystalline molecular sieve component, may or may not contain added functionalization, such as, for example, a metal of Group VI (e.g. Cr and Mo), Group VII (e.g. Mn and Re) or Group VIII (e.g. Co, Ni, Pd and Pt), or phosphorus.

[0044] Non-limiting examples of the invention involving an improved alkylation mechanism are described with reference to the following experiments. In these experiments, catalyst reactivity was measured by the following procedure.

**Equipment**

A 300ml Parr batch reaction vessel equipped with a stir rod and static catalyst basket was used for the activity and selectivity measurements. The reaction vessel was fitted with two removable vessels for the introduction of benzene and propylene respectively.

**Feed Pretreatment**

**Benzene**

[0045] Benzene was obtained from a commercial source. The benzene was passed through a pretreatment vessel (2L Hoke vessel) containing equal parts (by volume) molecular sieve 13X, molecular sieve 4A, Engelhard F-24 Clay, and Selexsorb CD (in order from inlet to outlet). All feed pretreatment materials were dried in a 260°C oven for 12 hours before using.

**Propylene**

[0046] Propylene was obtained from a commercial specialty gases source and was polymer grade. The propylene was passed through a 300 ml vessel containing pretreatment materials in the following order:

a. 150 ml molecular sieve 5A  
b. 150 ml Selexsorb CD

Both guard-bed materials were dried in a 260°C oven for 12 hours before using.

**Nitrogen**

[0047] Nitrogen was ultra high purity grade and obtained from a commercial specialty gases source. The nitrogen was passed through a 300 ml vessel containing pretreatment materials in the following order:

a. 150 ml molecular sieve 5A  
b. 150 ml Selexsorb CD

Both guard-bed materials were dried in a 260°C oven for 12 hours before using.
Catalyst Preparation and Loading

[0048] A 2 gram sample of catalyst was dried in an oven in air at 260°C for 2 hours. The catalyst was removed from the oven and immediately 1 gram of catalyst was weighed. Quartz chips were used to line the bottom of a basket followed by loading of 0.5 or 1.0 gram of catalyst into the basket on top of the first layer of quartz. Quartz chips were then placed on top of the catalyst. The basket containing the catalyst and quartz chips was placed in an oven at 260°C overnight in air for about 16 hours.

[0049] The reactor and all lines were cleaned with a suitable solvent (such as toluene) before each experiment. The reactor and all lines were dried in air after cleaning to remove all traces of cleaning solvent. The basket containing the catalyst and quartz chips was removed from the oven and immediately placed in the reactor and the reactor was immediately assembled.

Test Sequence

[0050] The reactor temperature was set to 170°C and purged with 100 seem (standard cubic centimeter) of the ultra high purity nitrogen for 2 hours. After nitrogen purged the reactor for 2 hours, the reactor temperature was reduced to 130°C, the nitrogen purge was discontinued and the reactor vent closed. A 156.1 gram quantity of benzene was loaded into a 300 ml transfer vessel, performed in a closed system. The benzene vessel was pressurized to 790 kPa-a (100 psig) with the ultra high purity nitrogen and the benzene was transferred into the reactor. The agitator speed was set to 500 rpm and the reactor was allowed to equilibrate for 1 hour. A 75 ml Hoke transfer vessel was then filled with 28.1 grams of liquid propylene and connected to the reactor vessel, and then connected with 2169 kPa-a (300 psig) ultra high purity nitrogen. After the one-hour benzene stir time had elapsed, the propylene was transferred from the Hoke vessel to the reactor. The 2169 kPa-a (300 psig) nitrogen source was maintained connected to the propylene vessel and open to the reactor during the entire run to maintain constant reaction pressure during the test. Liquid product samples were taken at 30, 60, 120, 150, 180 and 240 minutes after addition of the propylene.

[0051] In the Examples below, selectivity is the ratio of recovered product diisopropylbenzene to recovered product isopropylbenzene (DIPB/IPB) after propylene conversion reached 100%. The activity of some examples is determined by calculating the 2nd order rate constant using mathematical techniques known to those skilled in the art.

Example 1

[0052] Catalyst comprising MCM-49 and alumina binder in the crystal/binder ratio of
80/20 was prepared by extrusion as a 1.27 mm (l/20th inch) quadrulobe extrudates.

[0053] A 0.5 gram quantity of the catalyst of this example was placed in the batch reactor as described in the catalyst reactivity testing procedure above at a 260°C pretreatment temperature and contacted with 3 parts benzene and 1 part propylene on a molar basis at a temperature of 130°C and pressure of 2169 kPa-a (300 psig). Activity determined by calculating the 2nd order rate constant was 199. The selectivity (DIPB/IPB) was 16.4%.

Example 2

[0054] Catalyst comprising MCM-49 and alumina binder in the crystal/binder ratio of 60/40 was also prepared by extrusion as a 1.27 mm (l/20th inch) quadrulobe in the same manner as the catalyst for Example 1.

[0055] A 0.5 gram quantity of the catalyst of this example was placed in the batch reactor as described in the catalyst reactivity testing procedure above at a 260°C pretreatment temperature and contacted with 3 parts benzene and 1 part propylene on a molar basis at a temperature of 130°C and pressure of 2169 kPa-a (300 psig). Activity determined by calculating the 2nd order rate constant was 236. The selectivity (DIPB/IPB) was 14.3%.

[0056] The process of Example 2 showed a 12.8% improvement in DIPB/IPB selectivity and an 18.6% improvement in activity relative to the parent process of Example 1.

Example 3

[0057] Catalyst comprising MCM-49 and alumina binder in the crystal/binder ratio of 40/60 was also prepared by extrusion as a 1.27 mm (l/20th inch) quadrulobe in the same manner as the catalyst for Example 1.

[0058] A 0.5 gram quantity of the catalyst of this example was placed in the batch reactor as described in the catalyst reactivity testing procedure above at a 260°C pretreatment temperature and contacted with 3 parts benzene and 1 part propylene on a molar basis at a temperature of 130°C and pressure of 2169 kPa-a (300 psig). Activity determined by calculating the 2nd order rate constant was 106. The selectivity (DIPB/IPB) was 10.2%.

[0059] The process of Example 3 showed a 37.8% improvement in DIPB/IPB selectivity relative to the parent process of Example 1 while activity remained within 47% of that of the parent process.

Example 4

[0060] Catalyst comprising MCM-49 and alumina binder in the crystal/binder ratio of 20/80 was prepared by extrusion as a 1.27 mm (l/20th inch) quadrulobe extrudate in the same manner as the catalyst for Example 1.
A 0.5 gram quantity of the catalyst of this example was placed in the batch reactor as described in the catalyst reactivity testing procedure above at a 260°C pretreatment temperature and contacted with 3 parts benzene and 1 part propylene on a molar basis at a temperature of 130°C and pressure of 2169 kPa-a (300 psig). Activity determined by calculating the 2nd order rate constant was 185. The selectivity (DIPB/IPB) was 8.6%.

The process of Example 4 showed an improvement in DIPB/IPB selectivity relative to the parent process of Example 1 of 48%, while activity remained within about 1% of that of the parent.

**Example 5**

Catalyst comprising self-bound MCM-22 (therefore a crystal/binder ratio of 100/0) was prepared by extrusion as a 1.59 mm (1/16th inch) cylindrical extrudate.

A 0.5 gram quantity of the catalyst of this example was placed in the batch reactor as described in the catalyst reactivity testing procedure above at a 260°C pretreatment temperature and contacted with 3 parts benzene and 1 part propylene on a molar basis at a temperature of 130°C and pressure of 2169 kPa-a (300 psig). Activity determined by calculating the 2nd order rate constant was 295. The selectivity (DIPB/IPB) was 26.9%.

**Example 6**

Catalyst comprising MCM-22 and alumina binder in the crystal/binder ratio of 80/20 was prepared by extrusion as 1.59 mm (1/16th inch) cylindrical extrudate in the same manner as the catalyst for Example 5.

A 0.5 gram quantity of the catalyst of this example was placed in the batch reactor as described in the catalyst reactivity testing procedure above at a 260°C pretreatment temperature and contacted with 3 parts benzene and 1 part propylene on a molar basis at a temperature of 130°C and pressure of 2169 kPa-a (300 psig). Activity determined by calculating the 2nd order rate constant was 184. The selectivity (DIPB/IPB) was 14.0%.

**Example 7**

Catalyst comprising MCM-22 and alumina binder in the crystal/binder ratio of 65/35 was prepared by extrusion as 1.59 mm (1/16th inch) cylindrical extrudate in the same manner as the catalyst for Example 5.

A 0.5 gram quantity of the catalyst of this example was placed in the batch reactor as described in the catalyst reactivity testing procedure above at a 260°C pretreatment temperature and contacted with 3 parts benzene and 1 part propylene on a molar basis at a
temperature of 130°C and pressure of 2169 kPa-a (300 psig). Activity determined by calculating the 2nd order rate constant was 222. The selectivity (DIPB/IPB) was 13.7%.

**Example 8**

[0069] Catalyst comprising MCM-22 and alumina binder in the crystal/binder ratio of 60/40 is prepared by extrusion as 1.59 mm (1/16th inch) cylindrical extrudate in the same manner as the catalyst for Example 5.

[0070] A 0.5 gram quantity of the catalyst of this example is placed in the batch reactor as described in the catalyst reactivity testing procedure above at a 260°C pretreatment temperature and contacted with 3 parts benzene and 1 part propylene on a molar basis at a temperature of 130°C and pressure of 2169 kPa-a (300 psig). The selectivity (DIPB/IPB) is about 9.5%, an improvement of from about 31% to about 65% over the processes of Examples 5, 6 and 7.

**Example 9**

[0071] Catalyst comprising MCM-22 and alumina binder in the crystal/binder ratio of 40/60 is prepared by extrusion as 1.59 mm (1/16th inch) cylindrical extrudate in the same manner as the catalyst for Example 5.

[0072] A 0.5 gram quantity of the catalyst of this example is placed in the batch reactor as described in the catalyst reactivity testing procedure above at a 260°C pretreatment temperature and contacted with 3 parts benzene and 1 part propylene on a molar basis at a temperature of 130°C and pressure of 2169 kPa-a (300 psig). The selectivity (DIPB/IPB) is about 4.5%, an improvement of from about 67% to about 83% over the processes of Examples 5, 6 and 7.

**Example 10**

[0073] Catalyst comprising MCM-22 and alumina binder in the crystal/binder ratio of 20/80 is prepared by extrusion as 1.59 mm (1/16th inch) cylindrical extrudate in the same manner as the catalyst for Example 5.

[0074] A 0.5 gram quantity of the catalyst of this example is placed in the batch reactor as described in the catalyst reactivity testing procedure above at a 260°C pretreatment temperature and contacted with 3 parts benzene and 1 part propylene on a molar basis at a temperature of 130°C and pressure of 2169 kPa-a (300 psig). The selectivity (DIPB/IPB) is about 0.5%, an improvement of from about 96% to about 98% over the processes of Examples 5, 6 and 7.

[0075] All patents, patent applications, test procedures, priority documents, articles,
publications, manuals, and other documents cited herein are fully incorporated by reference to the extent such disclosure is not inconsistent with this invention and for all jurisdictions in which such incorporation is permitted.

[0076] When numerical lower limits and numerical upper limits are listed herein, ranges from any lower limit to any upper limit are contemplated.

[0077] While the illustrative embodiments of the invention have been described with particularity, it will be understood that various other modifications will be apparent to and may be readily made by those skilled in the art without departing from the spirit and scope of the invention. Accordingly, it is not intended that the scope of the claims appended hereto be limited to the examples and descriptions set forth herein but rather that the claims be construed as encompassing all the features of patentable novelty which reside in the present invention, including all features which would be treated as equivalents thereof by those skilled in the art to which the invention pertains.
CLAIMS:

We Claim:

1. In a process for catalytic conversion of feedstock comprising at least one alkylatable aromatic compound and an alkylation agent to conversion product comprising an alkylaromatic compound which comprises contacting said feedstock in at least partial liquid phase under catalytic conversion conditions including a temperature of from about 0°C to about 500°C, a pressure of from about 20 to about 25000 kPa-a, a molar ratio of alkylatable aromatic compound to alkylation agent of from about 0.1:1 to about 50:1, and a feed weight hourly space velocity (WHSV) based on the alkylation agent of from about 0.1 to about 500 hr⁻¹, with a catalyst composition comprising a porous crystalline material and a binder, the improvement comprising said catalyst composition having a ratio of crystal/binder of from about 20/80 to about 60/40.

2. The process of claim 1 wherein the porous crystalline material is selected from the group consisting of an MCM-22 family material, Beta and mixtures thereof.

3. The process of claim 2 wherein said porous crystalline material is selected from the group consisting of MCM-22, PSH-3, SSZ-25, ERB-I, ITQ-I, ITQ-2, ITQ-30, MCM-36, MCM-49, MCM-56, UZM-8 and mixtures thereof.

4. The process of any preceding claim, wherein said binder of said catalyst composition comprises an inorganic material selected from the group consisting of clay, silica, metal oxide and mixtures thereof.

5. The process of any preceding claim, wherein said feedstock comprises aromatic compounds selected from the group consisting of benzene, cumene, naphthalene, anthracene, naphthacene, perylene, coronene, phenanthrene and mixtures thereof.

6. The process of claim 1 wherein said feedstock comprises reformate.

7. The process of any one of claims 1-4, wherein said feedstock aromatic compound is benzene and said alkylation agent is ethylene, said conversion product comprises
ethylbenzene, and said conversion conditions include a temperature of from about 150°C to about 300°C, a pressure up to about 20400 kPa-a, a weight hourly space velocity (WHSV) based on the ethylene alkylation agent of from about 0.1 to about 20 hr⁻¹, and a ratio of benzene to ethylene in the alkylation reactor of from about 0.5:1 to about 30:1 molar.

8. The process of any one of claims 1-4, wherein said feedstock aromatic compound is benzene and said alkylation agent is propylene, said conversion product comprises cumene, and said conversion conditions include a temperature of up to about 250°C, a pressure of about 25000 kPa-a or less, a weight hourly space velocity (WHSV) based on propylene alkylation agent of from about 0.1 hr⁻¹ to about 250 hr⁻¹, and a ratio of benzene to propylene in the alkylation reactor of from about 0.5:1 to about 30:1 molar.

9. The process of any one of claims 1-4, wherein said feedstock aromatic compound is benzene and said alkylation agent is butenes, said conversion product comprises butylbenzene, and said conversion conditions include a temperature of up to about 250°C, a pressure of about 25000 kPa-a or less, a weight hourly space velocity (WHSV) based on butenes alkylation agent of from about 0.1 hr⁻¹ to about 250 hr⁻¹, and a ratio of benzene to butenes in the alkylation reactor of from about 0.5:1 to about 30:1 molar.
