METHOD AND APPARATUS FOR MEASURING BLADDER PRESSURE

[0001] The present invention relates to a method and an apparatus for carrying out measurements of bladder pressure in male patients in order to facilitate the diagnosis of urinary tract obstructions and impaired bladder contraction.

[0002] It is known to make continuous bladder pressure measurements in men using invasive techniques which involve the introduction of a catheter through the patient’s urethra and into their bladder. Although this procedure is normally carried out under aseptic conditions, it is common for bacteria from the skin and urethral passage to be introduced into the bladder, which can lead to infection. Moreover, the introduction of a catheter into this area, which is very sensitive, is very uncomfortable for the patient and can sometimes cause bleeding.

[0003] It is also known to use non-invasive techniques to make bladder pressure measurements in an attempt to mitigate the disadvantages of invasive techniques such as those described above. For example, European patent publication number EP1124486 discloses a method and apparatus for carrying out urodynamic investigations using a pneumatic cuff. The cuff is placed around the penis, and after commencement of urine flow through the penis, it is inflated over a period of time in order to occlude the urethra before voiding (that is, emptying of the bladder) is complete. The relationship between urine flow rate and the cuff pressure is used to determine a measurement of the isovolumetric bladder pressure for the patient (i.e. the pressure in the patient’s bladder when the urine flow rate is zero).

[0004] By way of further example, U.S. Pat. No. 5,807,278 discloses a method and apparatus for carrying out non-invasive bladder pressure and urine flow measurements using a pneumatic cuff. The cuff is placed around the penis, and is inflated in order to occlude the urethra and prevent the flow of urine. Upon the urge to void, the cuff is gradually deflated whilst the bladder muscle contracts. When the pressure generated by the bladder is equal to that exerted on the urethra by the cuff, then urine flow is initiated through the urethra. The cuff is then rapidly deflated in order to allow urine to flow freely under the influence of the bladder pressure of the patient, and the bladder pressure is ascertained.

[0005] Despite being a useful means of assessing the health of the urinary tract of the patient, the above disclosed methods and apparatuses can only provide the clinician with a very limited number of samples (for example, one, two or three) during one particular void and as such do not provide the clinician with a continuous measurement of bladder pressures throughout the void.

[0006] An aim of the present invention is to provide a method and apparatus for measuring bladder pressure, which overcomes or at least alleviates the problems associated with known techniques.

[0007] In accordance with a first aspect of the present invention there is provided a method for measuring bladder pressure in a patient, comprising the steps of:

[0008] (i) attaching an inflatable cuff around the penis of the patient;

[0009] (ii) maintaining a flow of urine at a predetermined flow rate for a period of time during voiding of the bladder, by means of deflating or inflating the cuff over said period of time, as required; and

[0010] (iii) measuring the cuff pressures required to maintain said predetermined urine flow rate during said period of time.

[0011] This provides the advantage that the bladder pressure can be measured continuously during the void. It is to be appreciated that the term “continuous” is to be construed as meaning providing bladder pressure which can be sampled at arbitrarily narrow intervals, during a single void of the bladder. Typically, there are around 10 samples of bladder pressure taken per second during a single void.

[0012] Preferably, the step of maintaining said predetermined urine flow rate for said period of time may comprise measuring the actual urine flow rate and inflating or deflating the cuff as required in order that the urine flow rate is substantially equal to said predetermined flow rate.

[0013] Preferably, the actual urine flow rate may be measured by means of creating electrical signals representative of the actual urine flow rate.

[0014] Preferably, the method may further comprise determining bladder pressure measurements during said period of time based upon the measured cuff pressures required to maintain said predetermined urine flow rate during said period of time.

[0015] The method may comprise inflating the cuff in order to occlude the urethra, before commencement of urine flow through the penis and after the cuff has been attached around the penis of the patient, and then deflating the cuff until the urine flow reaches said predetermined urine flow rate.

[0016] In this way, the cuff is pre-inflated. It is to be appreciated that the term “occlude” is to be construed as meaning applying sufficient pressure to the urethra using the cuff to substantially prevent the flow of urine through the penis.

[0017] This provides the advantage that there is no initial surge of urine and as such there is more time available during the void for the clinician to make bladder pressure measurements.

[0018] Alternatively, the method may comprise inflating the cuff after commencement of urine flow through the penis and after the cuff has been attached around the penis of the patient, as required, until the urine flow reaches said predetermined urine flow rate.

[0019] This provides the advantage that the inflation of the cuff can be triggered automatically as soon as the flow of urine is detected. As such, there is no requirement for either the clinician or the patient to make any judgements regarding when the patient feels the urge to void.

[0020] Preferably however, the method may comprise partially inflating the cuff before commencement of urine flow through the penis and after the cuff has been attached around the penis of the patient, and then inflating or deflating the cuff as required, until the urine flow reaches said predetermined flow rate.

[0021] It is to be appreciated that the term “partially inflating the cuff” is to be construed as meaning applying pressure to the penis to an extent that the flow of urine through the penis is not completely prevented. In this way, the patient is able to void past the pressure applied.

[0022] The partial inflation of the cuff before commencement of voiding (in other words, partial pre-inflation) provides the advantage that the “dead time” is reduced. It is to be appreciated that the dead time is the time required to inflate the cuff until it exerts pressure on the penis. For example, in the event that the patient begins to void, and the clinician wishes to inflate the cuff, then it takes a certain amount of time...
for the cuff to inflate from its completely deflated state to the extent required by the clinician. However, if the cuff is partially inflated before commencement of voiding, then it takes less time to inflate the cuff to that extent required by the clinician, thereby increasing the proportion of the void time during which measurements can be made.

[0023] The partial inflation of the cuff before commencement of voiding (in other words, partial pre-inflation) provides the further advantage that the further inflation of the cuff can be triggered automatically as soon as the flow of urine is detected. As such, there is no requirement for either the clinician or the patient to make any judgements regarding when the patient feels the urge to void.

[0024] In accordance with a second aspect of the present invention there is provided an apparatus for measuring bladder pressure in a patient, comprising:

[0025] (i) an inflatable cuff for attachment around the penis of the patient;

[0026] (ii) a pressure generating device for inflating the cuff and deflecting the cuff, as required;

[0027] (iii) a control means for maintaining a flow of urine at a predetermined flow rate for a period of time during voiding of the bladder, by means of deflecting or inflating the cuff over said period of time, as required; and

[0028] (iv) a measuring means for measuring the cuff pressures required to maintain said predetermined urine flow rate during said period of time.

[0029] Preferably, said apparatus further comprises flow measurement means for measuring the actual urine flow rate and inputting the measured flow rate to said control means.

[0030] Preferably, said flow measurement means creates electrical signals representative of the actual urine flow rate.

[0031] Preferably, the apparatus further comprises analysis means for determining bladder pressure measurements during said period of time based upon the measured cuff pressures required to maintain said predetermined urine flow rate during said period of time.

[0032] Preferred embodiments of the present invention will now be described, by way of example only and not in any limiting sense, with reference to the accompanying drawings in which:

[0033] FIG. 1 shows a block diagram of an apparatus in accordance with a first embodiment of the present invention;

[0034] FIG. 2 shows a block diagram of an apparatus in accordance with a second embodiment of the present invention;

[0035] FIG. 3 shows a block diagram of an apparatus in accordance with a third embodiment of the present invention;

[0036] FIGS. 4a to 4f show examples of cuff pressure measurements over time for different patients;

[0037] FIG. 5 shows a flow chart of an embodiment of a method in accordance with the present invention; and

[0038] FIG. 6 is a schematic diagram illustrating the method of selecting the period of time during which the pressure measurements taken by the clinician can be assumed to be an accurate measurement of the bladder pressure of the patient.

[0039] Referring now to FIG. 1, an apparatus for measuring bladder pressure in a patient is represented generally by reference numeral 1.

[0040] The apparatus 1 comprises an inflatable penile cuff 3 which is adapted to be secured around the patient’s penis. The cuff 3 is operatively connected to a pressure control system 5 incorporating a pneumatic pump, which inflates the cuff 3 and deflates the cuff 3 as required, which will be explained in further detail below.

[0041] The apparatus 1 further comprises a pressure measurement device 7 which is operatively connected to the cuff 3 and which directly measures the pressure applied to the penis by the cuff 3. The pressure measurement device 7 is operatively connected to a recording and analysis system 9, which records the cuff pressure measured by the measurement device 7.

[0042] The apparatus 1 further comprises a flow sensor 11, which converts the force applied by the urine collected during voiding into an electrical signal which is then relayed to a flow measurement device 13. In this embodiment, the flow sensor is a load cell, but it is to be appreciated that any other suitable flow sensor could be used, for example a spinning disk. The flow measurement device 13 uses the electrical signal received from the load cell 11 and establishes the flow rate and the volume of urine voided from the patient’s bladder. These measurements of flow rate and voided volume are inputted into the recording and analysis system 9, along with the cuff pressure as previously described.

[0043] The recording and analysis system 9 uses the measurements of flow rate, voided volume and cuff pressure to provide the clinician with a plot of bladder pressure over time, for a particular flow rate.

[0044] In order to maintain the urine flow rate and further, in order to maintain that flow rate at a low level, a feedback mechanism is employed between the flow measurement device 13 and the cuff 3, with the cuff 3 being inflated and deflated as required, in order to maintain the urine flow at a constant low rate. To elaborate, the pressure control system is set to a predetermined flow rate, for example, 2.5 mls⁻¹. This could be achieved either by pre-programming of the pressure control system or by the clinician manually inputting the value of the pre-determined flow rate. As the patient’s bladder voids, the load cell 11 provides the flow measurement device 13 with an electrical signal which provides a measurement of flow rate at a particular point in time. This measured value of the flow rate is inputted into the pressure control system 5, which compares it with the predetermined flow rate. If the measured value of the flow rate is different from the predetermined flow rate, then the pressure control system 5 either inflates or deflates the cuff 3, as required, until the subsequently measured value of the flow rate changes sufficiently so that it is equal to the predetermined flow rate.

[0045] It is however, also to be appreciated that the clinician could instead manually input a predetermined flow rate into the pressure control system 5, as opposed to the pressure control system 5 being pre-programmed with the predetermined flow rate.

[0046] It is also to be appreciated that the predetermined flow rate of 2.5 mls⁻¹ is provided by means of example only, and that any suitable predetermined flow rate (that is, a predetermined flow rate which is lower than the natural urine flow rate of the patient), could alternatively be used.

[0047] Referring now to FIG. 2, an apparatus for measuring bladder pressure in a patient is represented generally by reference numeral 101.

[0048] The apparatus 101 comprises an inflatable penile cuff 103 which is adapted to be secured around the patient’s penis. The cuff 103 is operatively connected to a pressure measurement and control system 106 incorporating a pneumatic pump, which inflates the cuff 103 and deflates the cuff
103 as required, which will be explained in further detail below. The pressure measurement and control system 106 further comprises a pressure measurement device which is operatively connected to the cuff 103 and which directly measures the pressure applied to the penis by the cuff 103. The pressure measurement and control system 106 is operatively connected to a recording and analysis system 109, which records the cuff pressure measured by the pressure measurement and control system 106.

[0049] The apparatus 101 further comprises a flow measurement device 110, which converts the force applied by the urine collected during voiding into an electrical signal and establishes the flow rate of urine voided from the patient’s bladder. These measurements of flow rate are then inputted into the pressure measurement and control system 106, which maintains the flow rate at the predetermined value and further, maintains that flow rate at a low level using a feedback mechanism. To elaborate, the pressure measurement and control system 106 is set with a predetermined flow rate, for example, 2.5 mls⁻¹. As the patient’s bladder voids, the flow measurement device 210 provides a measurement of urine flow rate at a particular point in time. This measured value of the urine flow rate is inputted into the pressure control system 205, which compares it with the inputted predetermined flow rate. If the measured value of the flow rate is different from the predetermined flow rate, then the pressure control system 205 inflates or deflates the cuff 203, as required, until the subsequently measured value of the flow rate changes sufficiently so that it is equal to the predetermined flow rate.

[0054] The recording and analysis system 209 records the measurements of cuff pressure obtained by the pressure measurement device 207 required to maintain the predetermined flow rate, in order to provide the clinician with a plot of bladder pressure over time, for the particular predetermined value of the flow rate.

[0055] It is to be appreciated that an upper limit of cuff pressure may be set, in order to prevent injury to the patient.

**Procedure**

**Example 1 (Pre-Inflation)**

[0056] Referring now to FIG. 5, a flow chart is shown which illustrates this procedural example.

[0057] In the event that a clinician wishes to measure the bladder pressure of a patient, an inflatable cuff is placed around the patient’s penis and is pre-inflated to 200 cmH₂O using a pneumatic pump (Step 1). The patient is asked when he feels that the cuff is physically stopping his flow of urine, that is, he is asked to identify when he thinks he would be voiding were it not for the presence of the cuff. At this point, the bladder is trying to empty and the physical obstruction of the cuff is stopping the flow, and so the apparatus is activated (Step 2). The method of the invention is then performed, the cuff being deflated until a predetermined urine flow rate is detected by the flow measurement device. The pressure applied by the cuff is then modulated by means of deflation or inflation of the cuff as required, in order to maintain the urine flow rate at the predetermined value (Step 3). For example, if the urine flow rate falls below the predetermined value (that is, Qₑ is greater than Qₑ), then the cuff is deflated until the flow rate reaches the predetermined value. Conversely, if the urine flow rate increases above the predetermined value (that is, Qₑ is less than Qₑ), then the cuff is inflated until the flow rate is substantially equal to the predetermined value once more.

[0058] In this way, the flow rate of urine is allowed to continue but at a low, predetermined value (for example 2.5 mls⁻¹), using the cuff as a means of controlling the urine flow rate and a means of ensuring that as long as possible during the voiding of the patient’s bladder, the urine flow rate is maintained at the predetermined value.

**Procedure**

**Example 2 (No Pre-Inflation)**

[0059] In the event that a clinician wishes to measure the bladder pressure of a patient, the inflatable cuff is placed around the patient’s penis. Soon after the patient begins to void, the cuff is inflated using the pneumatic pump until a predetermined urine flow rate is detected by the flow measurement device. The pressure applied by the cuff is then modulated by means of deflation or inflation of the cuff as required, in order to maintain the urine flow rate at the predetermined value. For example, if the urine flow rate falls below the predetermined value, then the cuff is deflated until the flow rate reaches the predetermined value. Conversely, if
the urine flow rate increases above the predetermined value, then the cuff is inflated until the flow rate is substantially equal to the predetermined value once more.

[0060] In this way, the flow rate of urine is allowed to continue but at a low, predetermined value (for example 2.5 mls⁻¹), using the cuff as a means of controlling the urine flow rate and a means of ensuring that for as long as possible during the voiding of the patient’s bladder, the urine flow rate is maintained at the predetermined value.

Procedure

Example 3 (Partial Pre-Inflation)

[0061] In the event that a clinician wishes to measure the bladder pressure of a patient, an inflatable cuff is placed around the patient’s penis and is pre-inflated using a pneumatic pump. In this example, the cuff is only partially inflated, as opposed to being fully inflated in order to completely occlude the urethra, as is the case with Example 1. With this amount of pressure applied, upon feeling the urge to void, the patient can manage to commence voiding, and the apparatus is activated. At this point, the pressure applied by the cuff is modulated by means of deflation or inflation of the cuff as required, until the measured urine flow rate reaches the predetermined value. The urine flow rate is then maintained at the predetermined value. For example, if the urine flow rate falls below the predetermined value, then the cuff is deflated until the flow rate reaches the predetermined value. Conversely, if the urine flow rate increases above the predetermined value then the cuff is inflated until the flow rate is substantially equal to the predetermined value once more.

[0062] In this way, the flow rate of urine is allowed to continue but at a low, predetermined value (for example 2.5 mls⁻¹), using the cuff as a means of controlling the urine flow rate and a means of ensuring that for as long as possible during the voiding of the patient’s bladder, the urine flow rate is maintained at the predetermined value.

[0063] The reason why the urine flow rate is maintained at a low rate in all of these examples is so that the change in the filled volume of the bladder over time is small. A low urine flow rate also ensures that the pressure drop across any resistance to flow between the bladder and the patient’s penis is kept to a minimum. Moreover, in the event that there is a flow of urine, a proportion of the pressure generated by the bladder is used to produce that flow, and the cuff would then measure the residual pressure. If the urine flow is maintained at a low rate then the residual pressure measured would be closer to the bladder pressure. In this way, the applied pressure by the cuff provides a very good approximation of the actual bladder pressure and the pressure changes in the cuff can accurately reflect the pressure changes in the bladder.

[0064] The inventors have shown that the bladder pressures measured using the method of the present invention are very close to those bladder pressures measured simultaneously using invasive but nevertheless very accurate methods such as catheterisation, as shown by the graphs of FIGS. 4a to 4f, which will be discussed below.

[0065] With reference to FIGS. 4a to 4f, each graph provides results for a particular patient, during one particular void. For example, FIG. 4a shows a plot X of the values of applied cuff pressure measured over time using the method of the present invention, whilst maintaining the flow rate at a constant, low predetermined flow rate. FIG. 4a also shows a second plot Y of the values of bladder pressure measured simultaneously over time invasively using a catheterisation method, during the same void in a patient. It can be seen that for a large proportion of the void, that is, at those times when the measured flow rate is substantially the same as the predetermined value of the flow rate, the measured value of applied cuff pressure is the same as the bladder pressure measured invasively using a catheterisation method.

[0066] With reference to FIG. 6, an algorithm was developed, which assesses at which times during one particular void the value of the cuff pressure measured using the method of the present invention is an accurate estimate of the bladder pressure.

[0067] The way in which this is achieved is by continually comparing the measured flow rate to the predetermined value of the flow rate. When the two are substantially equal to each other, or when the measured flow rate is within a certain range either side of the predetermined value of the flow rate (representing flow rate range C on FIG. 6), the measured cuff pressure can be assumed to be an accurate estimate of the bladder pressure. This period of time is represented by the period A in FIG. 6. The algorithm discounts those cuff pressures measured when the measured flow rate is either not substantially equal to the predetermined value of the flow rate or is not within flow rate range C, since the cuff pressures measured at that time will not be an accurate estimate of the bladder pressure. These periods of time are represented by the period B in FIG. 6.

[0068] In this way, the algorithm generates a data set including “good” and “bad” measurements of bladder pressure. The algorithm selects “good” data by comparing the actual measured flow rate with the predetermined value of the flow rate, and if they are substantially equal or within the flow rate range C, then the measured value of the cuff pressure at that point is “good” data and can be assumed to be an accurate estimate of the bladder pressure.

[0069] The present invention, several embodiments of which are described above, can provide information for use by a clinician for investigating and comparing healthy bladders, diagnosing bladder outlet obstruction and impaired bladder contraction in patients.

[0070] It will be appreciated by persons skilled in the art that the above embodiments have been described by way of example only, and not in any limitative sense, and that various alterations and modifications are possible without departing from the scope of the invention as defined by the appended claims.

1. A method for measuring bladder pressure in a patient, comprising the steps of:
   (i) attaching an inflatable cuff around the penis of the patient;
   (ii) maintaining a flow of urine at a predetermined flow rate for a period of time during voiding of the bladder, by means of deflating or inflating the cuff over said period of time, as required; and
   (iii) measuring the cuff pressures required to maintain said predetermined urine flow rate during said period of time.

2. A method for measuring bladder pressure in a patient as claimed in claim 1, wherein the step of maintaining said predetermined urine flow rate for said period of time comprises measuring the actual urine flow rate and inflating or deflating the cuff as required in order that the urine flow rate is substantially equal to said predetermined flow rate.

3. A method for measuring bladder pressure in a patient as claimed in claim 2, wherein the actual urine flow rate is
measured by means of creating electrical signals representative of the actual urine flow rate.

4. A method for measuring bladder pressure in a patient as claimed in claim 1, further comprising determining bladder pressure measurements during said period of time based upon the measured cuff pressures required to maintain said predetermined urine flow rate during said period of time.

5. A method of measuring bladder pressure in a patient as claimed in claim 1, comprising: (i) an inflatable cuff for attachment around the penis of the patient; (ii) a pressure generating device for inflating the cuff and deflating the cuff, as required; (iii) at least one control device for maintaining a flow of urine at a predetermined flow rate for a period of time during voiding of the bladder, by means of deflating or inflating the cuff over said period of time, as required; and (iv) at least one measuring device for measuring the cuff pressures required to maintain said predetermined urine flow rate during said period of time.

6. A method for measuring bladder pressure in a patient as claimed in claim 1, comprising inflating the cuff in order to occlude the urethra, before commencement of urine flow through the penis and after the cuff has been attached around the penis of the patient, and then deflating the cuff until the urine flow reaches said predetermined urine flow rate.

7. A method for measuring bladder pressure in a patient as claimed in claim 1, comprising partially inflating the cuff before commencement of urine flow through the penis and after the cuff has been attached around the penis of the patient, and then inflating or deflating the cuff as required, until the urine flow reaches said predetermined flow rate.

8. An apparatus for measuring bladder pressure in a patient, comprising: (i) an inflatable cuff for attachment around the penis of the patient; (ii) a pressure generating device for inflating the cuff and deflating the cuff, as required; (iii) at least one control device for maintaining a flow of urine at a predetermined flow rate for a period of time during voiding of the bladder, by means of deflating or inflating the cuff over said period of time, as required; and (iv) at least one measuring device for measuring the cuff pressures required to maintain said predetermined urine flow rate during said period of time.

9. An apparatus for measuring bladder pressure in a patient as claimed in claim 8, further comprising at least one flow measurement device for measuring the actual urine flow rate and inputting the measured flow rate to said at least one control device.

10. An apparatus for measuring bladder pressure in a patient as claimed in claim 9, wherein said at least one flow measurement device creates electrical signals representative of the actual urine flow rate.

11. An apparatus for measuring bladder pressure in a patient as claimed in claim 8, further comprising at least one analysis device for determining bladder pressure measurements during said period of time based upon the measured cuff pressures required to maintain said predetermined urine flow rate during said period of time.

12-13. (canceled)
