(54) Title: DROPLET-BASED MULTIWELL OPERATIONS

(57) Abstract: The present invention relates to droplet-based multiwell operations. One aspect of the present invention relates to droplet-based protein crystallization including embodiments related to a screening chip, an optimization chip, and a method of testing conditions for growing a crystal. Another aspect of the present invention relates to a droplet-based multiwell plate including embodiments related to a substrate including one or more input ports, a regular array of processing wells, and a network of droplet transport pathways that provide direct or indirect droplet transport from each of the input ports to each of the one or more processing wells. Yet another aspect of the present invention relates to a droplet-microactuator stamping platform including embodiments related to a stamping device comprising a droplet microactuator and a system regarding the same.

WO 2007/123908 A2

DROPLET-BASED MULTIWELL OPERATIONS

1 Grant Information

5 The work leading to this invention was supported at least in part by NIH Grant Nos. 1 R43 GM072155-01 and 2 R44 GM072155-02. The United States Government may have certain rights in the invention described herein.

2 Related Applications

10 This application is related to and incorporates by reference related provisional U.S. Patent Application Nos. 60/745,049, entitled "Apparatus and Methods for Droplet-Based Protein Crystallization," filed on April 18, 2006; 60/745,054, entitled "Droplet-Based Multi-Well Plate," filed on April 18, 2006; and 60/806,400, entitled "Droplet-Microactuator Stamping Platform," filed on June 30, 2006.

3 Field of the Invention

15 The invention broadly relates to a multiwell chip or droplet microactuator with built-in electronic pumping to perform various fluid-handling operations. The invention relates to a screening chip for varying protein crystallization conditions. The invention also relates to an optimization chip which can be used to set up multiple conditions around a screening condition to identify optimal conditions for crystallization. The invention also relates to a method of using the screening chip to increase screening throughput using low protein volumes at low cost and to a method of using the optimization chip to rapidly and effectively identify optimal crystallization conditions. The invention also relates to the integration of screening and optimization capabilities into a single technology platform.

25 Additionally, the invention relates to a droplet processor platform for high throughput applications in fields such as chemistry and biology. The invention provides integrated fluid handling capability, such as in a planar multiwell plate format, which obviates the need for bulky, slow and expensive robotics to perform high throughput experimentation. The invention also relates to systems which incorporate the chip and to methods of making and using the chips and systems of the invention.

Furthermore, the invention relates to devices, systems and methods for stamping samples on a substrate, e.g., for MALDI-TOF analysis.

4 Background of the Invention

4.1 Protein Crystallization Approaches

5 Protein expression and purification is an expensive process, and it is sometimes difficult to express proteins in large quantities. A large amount of expensive protein is required to establish conditions for crystallization. Consequently, there is a need to reduce the amount of protein required for crystallization screening and to do it more efficiently and at lower cost.

10 4.1.1 Protein Crystal Synthesis

Proteins play a key role in all biological processes. The specific biological function of a protein is determined by the three-dimensional (3D) arrangement of the constituent amino acids. Understanding a protein's 3D structure plays an important role in protein engineering, bioseparations, rational drug design, controlled drug delivery, and the design
15 of novel enzyme substrates, activators, and inhibitors. Protein crystallization is a multi-parametric process that involves the steps of nucleation and growth, during which molecules are brought into a thermodynamically unstable and a supersaturated state.

4.1.2 Miniaturization and Automation of Protein Crystallization Setup

Many proteins of interest are unfortunately available only in limited supply. Efforts are
20 ongoing to reduce the consumption of proteins by miniaturizing the crystallization setup. Despite efforts to reduce the protein volumes, these processes still consume significant amount of protein and are still labor-intensive.

Existing semi-automatic systems do not encompass ideal high-throughput configurations. They require user intervention for multiple tray processing and have other material
25 processing issues. As most of the work performed with these systems is not on a large scale, automation of storage and handling of plates was not addressed in these systems. Even though these industrial systems are capable of setting up thousands of crystallization

screens a day, they are prohibitively expensive for academic research labs. There remains a need in the art for a system that provides the high-throughput automation functionality of an industrial system at an affordable cost for small laboratories or individual investigators.

5 **4.1.3 Lab-on-a-Chip Technologies**

Microfluidic systems can be broadly categorized into continuous-flow and discrete-flow based systems. As the name suggests, continuous-flow systems rely on continuous flow of liquids in channels whereas discrete-flow systems utilize droplets of liquid within channels or in an architecture without channels. A common limitation that continuous
10 flow systems face is that liquid transport is physically confined to fixed channels. The transport mechanisms used are usually pressure-driven by external pumps or electrokinetically-driven by high-voltages. These approaches involve complex channeling and require large supporting instruments in the form of external valves or power supplies. These restrictions make it difficult to achieve high degrees of functional
15 integration and control in conventional continuous-flow systems.

4.2 Multi-Well Plates

Microfluidic technologies are attracting attention in pharmaceutical research, as miniaturization of assay volume and improvement of automation, throughput and precision become more critical in drug discovery research. Examples of recent
20 microfluidic technologies and products include the Topaz™ system for protein crystallization from Fluidigm Corporation (San Francisco, CA), the LabChip® system from Caliper Life Sciences (Hopkinton, MA), and the LabCD™ system from Tecan Systems Inc. (San Jose, CA), both for ADME. These systems perform certain assays using small volumes of liquid. However, none of them even remotely approaches the
25 flexibility of conventional robotic systems. This inadequacy results from inherent technical limitations associated with the way in which fluid handling is implemented in these devices.

Most existing technologies are based on a continuous-flow approach. Liquid is pumped (generally unidirectionally) through a network of microchannels using external pumps,
30 valves, high-voltage supplies or centrifugal force. The primary disadvantage of all of

these continuous-flow microfluidic devices is their architectural and operational rigidity. Most are optimized for a particular assay, providing little or no flexibility to make changes in reaction protocols. The required continuity of fluid in these devices also makes independent operation of different areas of the chip an inherently difficult proposition. Consequently, these technologies are non-modular and difficult to scale.

There is a need in the art for a microfluidic platform that avoids the use of a continuous-flow approach. There is a need for a system that affords flexibility and programmability that is comparable to robotic systems. Further, there is a need for a system that is capable of working with droplets as small as a few nanoliters in volume and avoids the requirements for a network of microchannels, external pumps, valves, high-voltage supplies and/or centrifugal force. Further, there is a need for a system that is scalable, permitting hundreds or even hundreds of thousands of droplets of liquid to be processed in parallel. Finally, there is a need for a system that is both compact and inexpensive to manufacture.

4.3 Protein Stamping Platforms

Mass spectroscopy (MS) is increasingly becoming the method of choice for protein analysis in biological samples. Among the various MS methods, MALDI-TOF (Matrix Assisted Laser Desorption-Ionization Time of Flight) is the most commonly used due to its simplicity, high sensitivity and resolution. A typical MALDI-MS protocol for protein identification involves sample preparation, stamping onto a MALDI target and analysis on a MALDI-TOF mass spectrometer. Sample preparation steps (such as digestion and concentration) are usually done in the well-plate format and last for several hours at the least. The stamping is accomplished using complex robotic systems which are huge, expensive and immobile. Required sample volumes are also very high, which is a concern for proteins available in very small quantities. Existing microfluidic devices are based on continuous flow in fixed microchannels, offering very little flexibility in terms of scalability and reconfigurability. As such, a need exists for a droplet microactuation stamping platform designed to solve the deficiencies found in the prior art.

5 Brief Description of the Invention

One aspect of the present invention relates to droplet-based protein crystallization. According to one embodiment of this aspect, a screening chip is provided and comprises: (a) a port for introduction of one or more crystallization reagents and/or one or more protein solutions; (b) a substrate comprising: (i) an array of two or more mixing wells; and (ii) electric field mediated microfluidics for moving droplets comprising the crystallization reagents and protein solutions into the mixing wells. According to another embodiment of this aspect, an optimization chip is provided and comprises: (a) a port for introduction of one or more crystallization reagents and/or one or more protein solutions; and (b) a substrate comprising: (i) one or more reagent wells in fluid connection with a port; (ii) one or more sample wells in fluid connection with a port; (iii) two or more mixing wells; and (iv) microfluidics for moving: (1) droplets comprising the crystallization reagents from the reagent wells into the mixing wells; and (2) droplets comprising the protein solutions into the mixing wells. According to yet another embodiment of this aspect, a method of testing conditions for growing a crystal is provided and comprises: (a) providing the screening chip as described above; (b) providing droplets in the crystal comprising a variety of potential conditions and the target molecule; and (c) observing the droplets to identify crystal growth.

Another aspect of the present invention relates to a droplet-based multiwell plate. According to one embodiment of this aspect, a substrate is provided and comprises: (a) one or more input ports for introduction of one or more reagents and/or samples; (b) a regular array of processing wells; and (c) a network of droplet transport pathways comprising pathways that provide direct or indirect droplet transport from each of the input ports to each of the one or more processing wells.

Yet another aspect of the present invention relates to a droplet-microactuator stamping platform. According to one embodiment of this aspect, a stamping device comprising a droplet microactuator is provided and comprises: (a) a first plate comprising a path or network of control electrodes for transporting droplets on a surface thereof; (b) a second plate mounted in a substantially parallel orientation with respect to the first plate creating an interior volume between the plates, the second plate comprising one or more stamping ports for transporting some portion or all of a droplet from the interior volume to an exterior location; (c) a port for introducing fluid into the interior volume between the plates; and (d) a path or network of reference electrodes corresponding to the path or

network of control electrodes. According to another embodiment of this aspect, a system is provided and comprises: (a) the stamping device as described above; (b) a computer processor electronically coupled to the stamping device and programmed to effect control of droplet operations on the stamping device; (c) one or more input devices electronically coupled to the computer processor; and (d) one or more output devices electronically coupled to the computer processor.

6 Definitions

As used herein, the following terms have the meanings indicated.

“Activate” with reference to one or more electrodes means effecting a change in the electrical state of the one or more electrodes which results in a droplet operation.

“Analyte,” means a target substance for detection which may be present in a sample. Illustrative examples include antigenic substances, haptens, antibodies, proteins, peptides, amino acids, nucleotides, nucleic acids, drugs, ions, salts, small molecules, and cells.

“Bead,” with respect to beads on a droplet microactuator, means any bead or particle capable of interacting with a droplet on or in proximity with a droplet microactuator. Beads may be any of a wide variety of shapes, such as spherical, generally spherical, egg shaped, disc shaped, cubical and other three dimensional shapes. The bead may, for example, be capable of being transported in a droplet on a droplet microactuator; configured with respect to a droplet microactuator in a manner which permits a droplet on the droplet microactuator to be brought into contact with the bead, on the droplet microactuator and/or off the droplet microactuator. Beads may be manufactured using a wide variety of materials, including for example, resins, and polymers. The beads may be any suitable size, including for example, microbeads, microparticles, nanobeads and nanoparticles. In some cases, beads are magnetically responsive; in other cases beads are not significantly magnetically responsive. For magnetically responsive beads, the magnetically responsive material may constitute substantially all of a bead or only one component of a bead. The remainder of the bead may include, among other things, polymeric material, coatings, and moieties which permit attachment of an assay reagent. Examples of suitable magnetically responsive beads are described in U.S. Patent Publication No. 2005-0260686, “Multiplex flow assays preferably with magnetic particles

as solid phase,” published on November 24, 2005, the entire disclosure of which is incorporated herein by reference for its teaching concerning magnetically responsive materials and beads.

5 “Communicate” (e.g., a first component “communicates with” or “is in communication with” a second component) is used herein to indicate a structural, functional, mechanical, optical, electrical, or fluidic relationship, or any combination thereof, between two or more components or elements. As such, the fact that one component is said to communicate with a second component is not intended to exclude the possibility that additional components may be present between and/or operatively associated or engaged
10 with, the first and second components.

“Chip” refers to any substrate including not only silicon or semiconductors but glass, printed circuit boards, plastics or any other substrate on which the droplets are manipulated.

15 “Droplet” means a volume of liquid on a droplet microactuator which is at least partially bounded by filler fluid. For example, a droplet may be completely surrounded by filler fluid or may be bounded by filler fluid and one or more surfaces of the droplet microactuator. Droplets may take a wide variety of shapes; nonlimiting examples include generally disc shaped, slug shaped, truncated sphere, ellipsoid, spherical, partially compressed sphere, hemispherical, ovoid, cylindrical, and various shapes formed during
20 droplet operations, such as merging or splitting or formed as a result of contact of such shapes with one or more surfaces of a droplet microactuator.

“Droplet operation” means any manipulation of a droplet on a droplet microactuator. A droplet operation may, for example, include: loading a droplet into the droplet microactuator; dispensing one or more droplets from a source droplet; splitting, separating or dividing a droplet into two or more droplets; transporting a droplet from one
25 location to another in any direction; merging or combining two or more droplets into a single droplet; diluting a droplet; mixing a droplet; agitating a droplet; deforming a droplet; retaining a droplet in position; incubating a droplet; heating a droplet; vaporizing a droplet; cooling a droplet; disposing of a droplet; transporting a droplet out of a droplet microactuator; other droplet operations described herein; and/or any combination of the
30 foregoing. The terms “merge,” “merging,” “combine,” “combining” and the like are used

to describe the creation of one droplet from two or more droplets. It should be understood that when such a term is used in reference to two or more droplets, any combination of droplet operations sufficient to result in the combination of the two or more droplets into one droplet may be used. For example, “merging droplet A with droplet B,” can be achieved by transporting droplet A into contact with a stationary droplet B, transporting droplet B into contact with a stationary droplet A, or transporting droplets A and B into contact with each other. The terms “splitting,” “separating” and “dividing” are not intended to imply any particular outcome with respect to size of the resulting droplets (i.e., the size of the resulting droplets can be the same or different) or number of resulting droplets (the number of resulting droplets may be 2, 3, 4, 5 or more). The term “mixing” refers to droplet operations which result in more homogenous distribution of one or more components within a droplet. Examples of “loading” droplet operations include microdialysis loading, pressure assisted loading, robotic loading, passive loading, and pipette loading.

“Electronically coupled” is used herein to indicate an electrical or data relationship between two or more components or elements. As such, the fact that a first component is said to be electronically coupled to a second component is not intended to exclude the possibility that additional components may be present between, and/or operatively associated or engaged with, the first and second components. Further, electrically coupled components may in some embodiments include wireless intervening components.

“Input device” is used broadly to include all possible types of devices and ways to input information into a computer system or onto a network. Examples include stylus-based devices, pen-based devices, keyboard devices, keypad devices, touchpad devices, touch screen devices, joystick devices, trackball devices, mouse devices, bar-code reader devices, magnetic strip reader devices, infrared devices, speech recognition technologies.

“Output device” is used broadly to include all possible types of devices and ways to output information or data from a computer system to a user or to another system. Examples include visual displays, LEDs, printers, speakers, modems and wireless transceivers.

“Protocol” means a series of steps that includes, but is not limited to, droplet operations on one or more droplet microactuators.

“Surface” with reference to immobilization of a molecule, such as an antibody or in analyte, on the surface, means any surface on which the molecule can be immobilized while retaining the capability to interact with droplets on a droplet microactuator. For example, the surface may be a surface on the droplet microactuator, such as a surface on the top plate or bottom plate of the droplet microactuator; a surface extending from the top plate or bottom plate of the droplet microactuator; a surface on a physical object positioned on the droplet microactuator in a manner which permits it to interact with droplets on the droplet microactuator; and/or a bead positioned on the droplet microactuator, e.g., in a droplet and/or in a droplet microactuator but exterior to the droplet.

The terms “top” and “bottom” are used throughout the description with reference to the top and bottom substrates of the droplet microactuator for convenience only, since the droplet microactuator is functional regardless of its position in space.

When a given component such as a layer, region or substrate is referred to herein as being disposed or formed “on” another component, that given component can be directly on the other component or, alternatively, intervening components (for example, one or more coatings, layers, interlayers, electrodes or contacts) can also be present. It will be further understood that the terms “disposed on” and “formed on” are used interchangeably to describe how a given component is positioned or situated in relation to another component. Hence, the terms “disposed on” and “formed on” are not intended to introduce any limitations relating to particular methods of material transport, deposition, or fabrication.

When a liquid in any form (e.g., a droplet or a continuous body, whether moving or stationary) is described as being “on”, “at”, or “over” an electrode, array, matrix or surface, such liquid could be either in direct contact with the electrode/array/matrix/surface, or could be in contact with one or more layers or films that are interposed between the liquid and the electrode/array/matrix/surface.

When a droplet is described as being “on” or “loaded on” a droplet microactuator, it should be understood that the droplet is arranged on the droplet microactuator in a manner which facilitates using the droplet microactuator to conduct droplet operations on the droplet, the droplet is arranged on the droplet microactuator in a manner which facilitates

sensing of a property of or a signal from the droplet, and/or the droplet has been subjected to a droplet operation on the droplet microactuator.

8 Detailed Description of the Invention

15 The present invention relates to droplet-based protein crystallization involving a screening chip for varying protein crystallization conditions and an optimization chip which can be used to set up multiple conditions around a screening condition to identify optimal conditions for crystallization. The present invention also relates to a droplet-based multiwell plate involving integrated fluid handling capability, such as in a planar multiwell plate format. The present invention further relates to a droplet-microactuator stamping platform involving devices, systems and methods for stamping samples on a substrate. Further details of these aspects, as well as droplet microactuator architecture and operations, systems, kits, and other aspects of the present invention follows hereinbelow.

20

8.1 Droplet-Based Protein Crystallization Overview

25 One aspect of the present invention provides a chip for identification of crystallization conditions for target molecules, such as proteins and peptides (for convenience, both are

referred to herein as "proteins"). The chip is also useful for determining crystallization conditions for small molecules, such as small drug molecules. The chips of the invention dramatically reduce the precious protein sample requirements for crystallization screening. Small sample volumes enable rapid synthesis due to shortened crystallization times and also exploration of a larger crystallization parameter space. Miniaturization, automation, and integration provide for simpler and more reproducible experiments, while eliminating tedious tasks and errors. Time spent by researchers in setting up screening conditions is dramatically reduced, enabling much higher throughput as compared to conventional methods.

In some embodiments, the system provides separate screening and optimization chips or separate screening and optimization regions on a single chip. The screening chip or region may, for example, be used to provide a loading and packaging scheme to pre-fill coarse grid reagents in all the on-chip wells or reservoirs. The optimization chip or region may, for example, be used to provide a loading and packaging scheme which automatically constitutes a fine grid of conditions around a user-defined screening "lead." The chips can provide on-chip dilutions from stock solutions of the reagent constituents (e.g., salt, pH buffer, precipitant, and water). Figure 1 provides a schematic view of a 96-well optimization chip 100 that automatically sets up 96 fine grids from user-filled reservoirs. Multiple fluid ports and/or reservoirs may be provided, such as for salt 112, precipitant 114, pH buffer 116, water 118, protein 122, additive 124, and waste 126.

In one embodiment, the chip is provided as a component of a system generally including a microprocessor, one or more data output components and one or more data input components. In the operation of such a system, one or more dispensing reservoirs or wells of the chip may be loaded with one or more protein solutions. Dispensing wells may also be loaded with crystallization reagents, preferably 2, 3, 4, 5 or more crystallization reagents, which can be combined in the mixing wells to provide an array of crystallization conditions. The system is programmed to execute droplet operations, such as dispensing one or more sample droplets from the protein solution; transporting one or more of such sample droplets to a mixing well; dispensing one or more reagent droplets from the crystallization reagents; transporting one or more of such reagent droplets to at least a portion of the mixing wells to yield an array of wells comprising crystallization droplets, said array representing multiple crystallization conditions; and combining one or more sample droplets with each crystallization condition to potentially yield one or more

crystallization droplets comprising one or more protein crystals. It is understood in alternative embodiments that the mixing may take place on a chip but not necessarily in a well.

5 Similarly, the chip may include one or more dispensing wells with protein solution loaded therein and one or more mixing wells comprising crystallization droplets loaded therein, said crystallization droplets representing multiple crystallization conditions. The system may be programmed to execute steps, such as dispensing one or more sample droplets from the protein solution and transporting at least a portion of the dispensed sample droplets to the mixing wells. Typically, at least a portion of the mixing wells each
10 receives one or more of the sample droplets, thereby yielding an array of crystallization reagents comprising protein sample and having the capacity to one or more protein crystals.

A technique was surprisingly discovered which permits droplets with high concentrations of protein to be manipulated. In one embodiment, the protein solution has a concentration
15 which exceeds about 1 mg/mL, about 10 mg/mL, about 50 mg/mL, or about 100 mg/mL. Further, the system of the invention can operate using exceptionally low volumes of protein solution. For example, in some embodiments, the amount of protein solution required for each crystallization condition tested does not exceed about 100, 90, 80, 70, 60, 50, 40, 30, 20, or 10 nL.

20 Importantly, small protein droplet volumes mean faster equilibration or crystal formation. Crystals formed in small drops may perform better than larger ones in diffraction studies because they have the advantage of uniform and rapid freezing when transferred into liquid nitrogen. Liquids can be dispensed, transported, and mixed on-chip without the need for robotics. The system can be self-contained, which results in higher quality of
25 data due to consistency of the setup. Instrument manufacturing is much less costly than conventional robotic approaches, and disposable chips can be provided which are relatively inexpensive. Cost per screening condition is extremely low compared to conventional methods. Moreover, as the number of wells on the same chip goes up, cost per condition is decreased. For direct translation of crystallization hits to larger scale,
30 droplet volumes should be accurate and precise and in the current invention, the dispensed droplet volume is much more precise as compared to conventional methods, e.g., < 2%. Droplet operations and pathways are selected through a software control

panel to empower users to readily create any combination of optimization conditions. The flat geometry provides better visualization of crystals and enables image analysis of droplets due to uniform illumination. The invention is compatible with Society for Biomolecular Screening (SBS) multiwell plate footprint and well-to-well pitch for any further automation steps.

The chips of the invention are fabricated using a scalable architecture, which permits a large number of on-chip crystallization conditions. For example, the number of conditions can be greater than 50, 100, 500, 1000, 5000, 10,000, 50,000, 100,000, 500,000, or 1,000,000. The invention also provides a programmable droplet-based microfluidic well platform, e.g., a platform having greater than 50, 100, 500, 1000, 5000, 10,000, 50,000, 100,000, 500,000, or 1,000,000. The system of the invention can also include droplet control software and instrumentation.

In some embodiments, the chips can accomplish all steps of synthesis (e.g., making use of a variety of droplet operations) and analysis, including for example, sampling, sample preparation, sample-processing, mixing, incubation, detection, and/or waste handling. These steps can be handled on-chip without requiring a significant off-chip support system. In some embodiments, the invention can specifically exclude continuous-flow or droplet-based flow in fixed-channel-based microfluidics.

The invention is preferably provided as a bench-top instrument or as a handheld instrument. In one embodiment, discrete nanoliter-sized or sub-microliter-sized droplets are directly transported or manipulated using a microactuator structure described hereinbelow with reference to Section 8.8. In addition to transport, other microfluidic operations suitable for use in the invention include merging, splitting, mixing and dispensing of nanodroplets by varying the patterns of voltage activation. Large numbers of droplets can be simultaneously and independently manipulated allowing complex protocols to be flexibly implemented directly through software control. There is no joule heating or electrophoresis within the droplets and near 100% utilization of sample or reagent is possible because no priming is performed.

Further, the invention enables the splitting, dispensing, and/or transport of protein solutions having unprecedented high concentrations. For example, the invention includes chips, systems and methods of splitting, dispensing, and/or transporting protein solutions

having concentrations that exceed than about 1, 10, 20, 30, 40, 50, 60, 70, 80, 90, or 100 mg/mL. Further, in a preferred embodiment, the splitting is facilitated by doping the silicone oil with a surfactant. For example, the surfactant may be a lipophilic surfactant, such as Triton X-15. Other suitable filler fluids and surfactants are described hereinbelow with reference to Section 8.8.4.

Nucleation and growth phases can be separated by performing on-chip dilutions after nucleation is observed to favor growth and stop further nucleation, as such a dilution method was reported to yield 6x the number of crystals suitable for X-ray diffraction compared to conventional methods. Crystal harvesting can be automated by transport of crystal-laden droplets for automatic loading into capillaries for X-ray diffraction studies. The crystals can, for example, be loaded by capillary action. Alternatively, crystals can be loaded by active vertical axis actuation through electrostatics.

In one embodiment, the screening chip includes a multiwell plate (also referred to as a microtiter plate). The multiwell plate may be pre-loaded with crystallization reagents. The plate can also include a port for introduction of protein solution, and microfluidics for moving droplets of protein solution into and between wells of the plate. The chip can be provided as a component of a system programmed to separate the protein solution sample into multiple droplets, each of which is moved to a preloaded well where it is combined with the preloaded crystallization reagents. The contents of the wells or other regions of the chip can then be analyzed automatically or manually for the presence of crystals. In some embodiments, the dimensions may be set up to conform to the SBS footprint dimensions for comparable microplates, e.g., for a 96, 384 or 1536-well plate.

In another embodiment, the optimization chip includes multiwell plate with one or more access ports for inputting reagents, as well as one or more access ports for inputting protein solution. The multiwell plate may be pre-loaded with reagents. Examples of useful reagents include pH buffers, salts, precipitants and other crystallization reagents. The plate can also include a port for introduction of protein solution. A system including the chip can be programmed to effect droplet operations to separate the protein solution sample into multiple droplets, each of which is moved to a well or processing region, and to separate the reagent solutions into multiple droplets, each of which is moved to a well or processing region. The system can be programmed to permit the user to control mixing and dilution of reagents and protein sample so as to systematically vary conditions

in each well according to parameters set by the user. Ideally, these parameters are established based on prior analysis using a screening chip, as described above. Alternatively, results from a screening chip are used by the system to automatically select parameter variables for use in the optimization chip. The contents of the wells can then be analyzed automatically or manually for the presence of crystals. In some embodiments, the chip dimensions may conform to the SBS footprint dimensions for comparable microplates, e.g., for a 96, 384 or 1586-well plate. While there are no standards yet on higher number of wells in a microtiter plate, the technology of the invention enables scaling down to accommodate thousands of wells in the same SBS footprint.

8.2 Droplet-Based Protein Crystallization Examples

The following non-limiting examples are provided only for the purpose of illustrating various aspects of the invention and should not be construed as limiting the scope of the invention.

8.2.1 Microfluidic Platform Development & Material Compatibility

A prototype chip with sample injection elements, reservoirs, droplet formation structures, fluidic pathways and mixing areas, was fabricated to test the various components of the microfluidic platform. Droplets (25nL) of several model proteins (lysozyme, glucose isomerase, proteinase K, grp94, hsp90, and α -haemolysin) were reliably dispensed and manipulated on-chip using electrical fields. The protein concentrations were in range of tens of mg/mL which is typical for protein crystallization experiments. To manipulate this high concentration of proteins, the filler fluid (silicone oil) was modified with an oil-soluble surfactant. Crystallization reagents containing commonly used precipitants, salts, and buffers were also successfully dispensed and transported on-chip.

8.2.1.1 Microfluidic Platform Development

A programmable droplet-based chip was fabricated. The fully assembled chip also included a transparent top-plate containing access holes aligned to the loading ports. The overall chip size was 25 mm x 50 mm with 97 discrete electrodes at a 500 μ m pitch. The nominal droplet volume was ~25nL.

8.2.1.2 Dispensing and Transport of Proteins

Proteins tend to non-specifically adsorb to surfaces they come in contact with, especially hydrophobic ones. In addition to contamination, protein adsorption also renders surfaces permanently hydrophilic. This is detrimental to droplet manipulation since the chip surface cannot be switched back to being a hydrophobic surface by electric fields. Therefore any contact between a liquid droplet containing proteins and the chip surfaces should be avoided to prevent contamination and facilitate transport. The use of a low surface tension oil such as silicone oil helps in the transport of protein solutions on our chips. The oil forms a thin film between the droplet and the surfaces, thereby minimizing adsorption and contamination. However, the stability of the oil film decreases with increasing protein concentration (which lowers the interfacial tension with oil) and consequently droplets having higher protein content are expected to be more difficult to manipulate on-chip.

Crystallization experiments sometimes require high concentrations (tens of mg/mL) of protein to create super-saturation conditions. Means for performing operations, such as transporting, dispensing, and splitting, on high concentration of proteins with electric field-based manipulation on the chip were surprisingly discovered. The droplet formation process (using only electric fields) is more severely affected than transport due to protein adsorption, since the liquid in the reservoir has a much larger surface area to adsorb to than a unit droplet. For example, though 10mg/mL BSA droplets (manually dispensed) were transportable, droplet formation worked only for solutions with less than 0.01mg/mL BSA. Though it is possible to use external pressure sources to assist the droplet formation for high protein concentration solutions, it adds to the mechanical complexity of the system. It is therefore preferable to find a solution that would enable dispensing of high concentrations of proteins using only electric fields.

The on-chip compatibility of several model proteins including lysozyme, proteinase K, glucose isomerase, grp94, hsp90, and α -haemolysin were tested. A low viscosity silicone oil (<2cSt) was used as the filler fluid in all experiments. 0.1% (w/w) Triton X-15, a lipophilic surfactant, was added to the oil so that high concentrations protein droplets could be formed or dispensed from on-chip reservoirs. The surfactant lowered the surface tension of the oil and increased the stability of the oil film between the droplet and the chip surfaces which significantly reduced adsorption.

Using the surfactant modified silicone oil, fully automated droplet formation was possible up to protein concentrations of 10's mg/mL using voltages less than 50V (which is typically used for simpler liquids such as water). This is 3 orders of concentration improvement over the results obtained using unmodified silicone oil. The volume of each unit droplet was ~25nL. Table 1 lists the proteins with the highest concentration tested and found to be most compatible with the system of the present invention.

Table 1 – Protein Compatibility Chart

| Protein | Concentration |
|----------------------|---------------|
| Lysozyme | 75mg/mL |
| Glucose Isomerase | 30mg/mL |
| Proteinase K | 20mg/mL |
| Grp94 | 27mg/mL |
| Hsp90 | 30mg/mL |
| α -haemolysin | 10mg/mL |

8.2.1.3 Dispensing and Transport of Crystallization Reagents

Crystallization reagents usually consist of three components - a salt, precipitant and a buffer. Commonly used precipitants include inorganic salts, organic polymers such as polyethylene glycols (PEG), non-volatile organics such as 2-methyl-2,4-pentanediol (MPD) and volatile organics such as isopropanol. The individual components used in crystallization reagents span a wide range of physical and chemical properties, and it is important to evaluate their compatibility with the system. Salt concentrations can be as high as several moles per liter. The pH of buffers spans a large range from acidic (pH 3.0) to basic (pH 8.0). High molecular weight PEGs have viscosities as high as 100cP for a 50% (w/w) solution in water. Organics such as isopropanol have a low interfacial tension and may also partition into the oil. Surfactants (which lower interfacial tension) are also used in the crystallization of membrane proteins.

To demonstrate dispensing and transport of crystallization reagents on-chip, a representative subset of Hampton Research's sparse-matrix, Crystal Screen™, was chosen and which covered a range of the salts, buffers and precipitants. Table 2 lists the Crystal Screen™ reagents used in the compatibility experiments. Solutions containing 0.001%, 0.01% and 0.1% of Triton X-100 surfactant (v/v) were prepared in phosphate

buffer for studying the effect of interfacial tension on transport. The interfacial tension of the surfactant solution with oil varied between 7mJ/m^2 (0.1% Triton X-100) to 33mJ/m^2 (0% Triton X-100).

Table 2 – Crystal Screen™ reagents tested on-chip and their components

| Reagent | Salt | Buffer | Precipitant |
|---------|-------------------------|---------------------------------|------------------------------------|
| 1 | 0.02M Calcium chloride | 0.1M Sodium acetate, pH 4.6 | 30%v/v 2-methyl-2,4-pentanediol |
| 2 | | | 0.4M Potassium sodium tartrate |
| 3 | | | 0.4M Ammonium dihydrogen phosphate |
| 4 | | 0.1M Tris hydrochloride, pH 8.5 | 2M Ammonium sulfate |
| 5 | 0.2M tri-Sodium citrate | 0.1M Sodium HEPES, pH 7.5 | 30%v/v 2-methyl-2,4-pentanediol |
| 6 | 0.2M magnesium chloride | 0.1M Tris hydrochloride, pH 8.5 | 30%w/v polyethylene glycol 4000 |
| 7 | | 0.1M sodium cacodylate, pH 6.5 | 1.4M sodium acetate trihydrate |
| 8 | 0.2M tri-sodium citrate | 0.1M sodium cacodylate, pH 6.5 | 30%v/v isopropanol |
| 9 | 0.2M ammonium acetate | 0.1M tri-sodium citrate, pH 5.6 | 30%w/v polyethylene glycol 4000 |
| 13 | 0.2M tri-Sodium citrate | 0.1M Tris hydrochloride, pH 8.5 | 30%v/v polyethylene glycol 400 |
| 15 | 0.2M ammonium sulfate | 0.1M sodium cacodylate, pH 6.5 | 30%w/v polyethylene glycol 8000 |

5

Figure 2 plots the maximum droplet transfer frequency as a function of voltage for different surfactant solutions. The plot indicates that droplets with lower interfacial tension require less voltage to be transferred at a particular rate. However, the drop in voltage requirement is not significant and is only 10V for transfer at 12Hz. Droplet dispensing and transport worked for all the crystallization reagents tested. Table 2 above lists the individual salts, buffers and precipitants which constituted the tested reagents. Though 100% isopropanol is completely miscible with silicone oil, mixtures of isopropanol and water up to 80% isopropanol (v/v) were immiscible in silicone oil. Droplet manipulation using electric fields is independent of salt concentration from $1\mu\text{M}$ to 2M. The above results indicate that liquids with a wide range of properties are compatible with the system of the present invention.

8.2.2 Microbatch Protein Crystallization on the Bench

The effect of oils with varying viscosities and volatility on crystallization was tested on the bench using a crystal screen for hen egg white lysozyme. The oils tested were 1cSt, 1.5cSt and 2cSt silicone oil, paraffin oil, and fluorosilicone oil. Of all the oils tested, the 2cSt silicone oil had the right combination of low viscosity preferable for electric field mediated manipulations and low volatility required for long crystallization experiments, and therefore was used for the on-chip crystallization experiments. The addition of surfactants to the oil also did not affect the crystal formation process. Screening experiments were also performed on the bench for glucose isomerase and proteinase K to identify crystallization conditions that were subsequently tested on-chip.

8.2.2.1 Effect of Oils on Crystallization

Silicone oils, paraffin oils, or a mixture of the two are the most commonly used oils in microbatch-in-oil crystallization. A combination of fluorosilicone oil (dense) and paraffin oil (light) has also been used in a specific case of microbatch referred to as the floating-drop method.

1cSt silicone oil, 1.5cSt silicone oil, 2cSt silicone oil, paraffin oil and a fluorosilicone oil were tested as potential candidates for on-chip microbatch-in-oil crystallization. A crystal screen for lysozyme was used to evaluate the oils on the bench. 75mg/mL lysozyme was prepared in 0.1M sodium acetate buffer, pH 4.6. Twelve different concentrations of NaCl in water (1.2M to 3.0M in steps of 0.2M) were used as the precipitant. The screens were set up in 96-well plates. At first, 100 μ L of the oil was dispensed into the wells, followed by 5 μ L of the 75mg/mL lysozyme sample. 5 μ L of the different precipitant solutions were then added gently to the sample and allowed to mix without any stirring. A floating-drop microbatch experiment was set up in a similar fashion using fluorosilicone oil as the heavier oil and paraffin oil as the lighter oil. The wells were closed with a lid but not completely sealed. The wells were inspected after 1 day, 2 days, 3 days and 1 week.

Basic droplet manipulation experiments were also performed on-chip using paraffin oil and fluorosilicone oil to evaluate the compatibility of the oil with the platform. Low viscosity silicone oils (< 2cSt) have also already been shown to be compatible with the microfluidic platform of the present invention.

With the exception of 1cSt silicone oil, all the other experiments gave similar crystals (size, shape and number) in wells with 1.2-2.2M NaCl. A mixture of crystals and precipitate was seen in wells with 2.4-2.6M NaCl. The proteins completely precipitated out in wells with higher NaCl concentration. 1cSt silicone oil was 100% volatile and evaporated within 1 day of setting up the experiment, causing the protein solution to dry out. 1.5cSt silicone oil also evaporated over the course of several days. 1cSt and 1.5cSt silicone oil can still be used for on-chip crystallization if the system is completely sealed. 2cSt silicone oil was non-volatile, but the crystals still dried out after 2-3 weeks due to the high water vapor permeability of silicone oils.

The high viscosity of paraffin oil required substantially higher voltages for droplet manipulation on-chip. The fluorosilicone oil dissolved the hydrophobic coating and was therefore not suitable for use on these chips. Of all the oils tested, 2cSt silicone had the best combination of low viscosity and low volatility for use on-chip. Even though the paraffin oil/silicone oil mixture is compatible with the chips, pure silicone oils are preferred. Table 3 summarizes the various results obtained from the experiments described above.

Table 3 - Filler fluid suitability for on-chip crystallization

| Oil | Bench experiments | On-chip compatibility | Overall compatibility |
|---------------------|----------------------------------------------------------|----------------------------------------------------------------------------------------|---------------------------------|
| 1cSt silicone oil | 100% volatile. All the oil evaporates in less than a day | Compatible | Compatible (in a sealed system) |
| 1.5cSt silicone oil | Oil evaporates within a few days. | Compatible | Compatible (in a sealed system) |
| 2cSt silicone oil | Non-volatile. Fully compatible | Compatible | Fully Compatible |
| Paraffin oil | Non-volatile. Fully compatible | High viscosity required substantially higher voltages for droplet manipulation on-chip | Partially compatible |

8.2.2.2 Protein crystallization on the bench

Protein crystallization screens were set up for three model proteins – lysozyme, proteinase K and glucose isomerase. 2cSt silicone oil with 0.1% Triton X-15 was used as the oil

medium to simulate conditions similar to those on chip. The screens were set up in 96-well plates. 100 μ L of the oil was first dispensed into the wells followed by 5 μ L of the protein sample. 5 μ L of the precipitant solutions was then added gently to the sample and allowed to mix without any stirring.

- 5 Lysozyme – 75mg/mL lysozyme was prepared in 0.1M sodium acetate buffer, pH 4.5. A concentration gradient of sodium chloride in water (1.2M to 3.0M) was used as the precipitant. Table 4 summarizes the results of the lysozyme screen.

Table 4 – Lysozyme screen results

| Precipitant (NaCl) | After 2 days |
|--------------------|--------------------------|
| 1.2M | Crystals |
| 1.4M | Crystals |
| 1.6M | Crystals |
| 1.8M | Crystals |
| 2.0M | Crystals |
| 2.2M | Crystals |
| 2.4M | Precipitate and crystals |
| 2.6M | Precipitate and crystals |
| 2.8M | Precipitate |
| 3.0M | Precipitate |
| 3.2M | Precipitate |

- 10 Proteinase K – 20mg/mL proteinase K was prepared in 25mM HEPES buffer, pH 7.0. Reagents from Hampton's Crystal Screen™ (indicated in Table 5) were used as the precipitant. Table 5 summarizes the results of the proteinase K screen.

Table 5 – Proteinase K screen results

| Precipitant (Crystal Screen™) | After 2 days |
|-------------------------------|--------------|
| Reagent 6 | Crystals |
| Reagent 12 | Clear |
| Reagent 17 | Crystals |
| Reagent 19 | Clear |
| Reagent 22 | Crystals |
| Reagent 28 | Crystals |
| Reagent 30 | Crystals |

| Precipitant (Crystal Screen™) | After 2 days |
|----------------------------------|--------------|
| Reagent 31 | Crystals |
| Reagent 36 | Crystals |
| Reagent 39 | Crystals |
| Reagent 40 | Crystals |
| Reagent 41 | Crystals |
| Reagent 42 | Crystals |
| Reagent 43 | Clear |
| Reagent 48 | Crystals |

Glucose isomerase – 30mg/mL glucose isomerase was prepared in deionized water. Reagents from Hampton's Crystal Screen™ (indicated in Table 6) were used as the precipitant. Table 6 summarizes the results of the glucose isomerase screen.

5 Table 6 – Glucose isomerase screen

| Precipitant (Crystal Screen™) | After 2 days |
|----------------------------------|--------------|
| Reagent 9 | Crystals |
| Reagent 10 | Crystals |
| Reagent 14 | Crystals |

The presence of 0.1% Triton X-15 surfactant in the oil did not affect crystallization on the bench.

8.2.3 Protein Crystallization On-Chip & System Integration

10 Lysozyme, proteinase K and glucose isomerase were crystallized on-chip using the surfactant-modified 2cSt silicone oil as the filler fluid. Droplets of the protein and precipitant were automatically dispensed, mixed, and incubated on-chip. The precipitant was chosen from the results of the screening experiments on the bench. Crystals typically

appeared after 1 day and the shape and size of the crystals were similar to those obtained on the bench. A coarse crystallization screen was also set up on-chip for lysozyme varying the precipitant (NaCl) concentration. Four different precipitant concentrations were automatically generated on-chip by dilution (3:0, 2:1, 1:2, 0:3) and mixed with a 25nL lysozyme droplet. The results compared favorably with experiments on the bench.

8.2.3.1 Protein Crystallization On-Chip

Three model proteins, lysozyme, proteinase K and glucose isomerase were crystallized on-chip using 2cSt silicone oil with 0.1% Triton X-15 as the filler fluid. Protein concentrations were identical to those used on the bench. 1.8M sodium chloride in water was used as the precipitant for lysozyme. Crystal Screen™ Reagent 6 (0.2M MgCl₂, 0.1M Tris HCl, pH 8.5, 30%w/v PEG 4000) was used as the precipitant for proteinase K, and Crystal Screen™ Reagent 14 (0.2M CaCl₂, 0.1M HEPES-Na, pH 7.5, 28% v/v PEG 400) was used as the precipitant for glucose isomerase. 25nL droplets of the protein and the crystallization reagent were automatically dispensed, mixed, and incubated on-chip.

Crystals appeared after 1 day for all the three proteins tested. The crystal size and shapes were similar to those obtained on the bench. Figure 3 shows lysozyme crystals formed on-chip at 20× magnification. The size of the crystals was ~140μm. Figure 4 shows crystals of glucose isomerase on-chip at 20× magnification and Figure 5 shows crystals of proteinase K at a 40× magnification. The glucose isomerase crystals were ~70μm and the proteinase K crystals were ~50μm.

8.2.3.2 Coarse Matrix Screen for Lysozyme

As a demonstration and integration of all the functions, the experiment integrated dispensing, transport, and mixing of a lysozyme droplet with 4 different concentrations of a precipitant (NaCl) to create a screen on the chip. The lysozyme sample (75mg/mL) and two different concentrations of NaCl (1.2M and 3.0M) were injected into on-chip reservoirs. Intermediate concentrations of 1.8M and 2.4M NaCl were automatically generated on-chip by dispensing and mixing 2 droplets of 1.2M NaCl with 1 droplet of 3.0M NaCl and 1 droplet of 1.2M NaCl and 2 droplets of 3.0M NaCl respectively. One ~25nL droplet of 75mg/mL lysozyme was then dispensed and mixed with 3 droplets each

of the 1.2M, 1.8M, 2.4M and 3.0M NaCl solutions. A similar experiment was set up on the bench as a control.

Crystals were observed using 1.2M and 1.8M NaCl both on-chip and on the bench after a day. Images of the results obtained for the different precipitant conditions on-chip are shown in Figures 6A-6D. This experiment demonstrated two important aspects of the protein crystallization process. The first aspect relates to fluidic operations involved in the setup of coarse screen. Once the samples and reagents are loaded, a comprehensive screening experiment can be set up using a very small quantity of protein without any manual intervention. For example, 4 different conditions were set up using only 100nL of protein. The second aspect relates to automatic dilution of precipitants for optimization. It was shown that using two different concentrations of the precipitant, intermediate concentrations can be generated automatically on-chip. This forms the basis of an optimization experiment in which a matrix of conditions is usually set up around a "lead" seen in the coarse screen.

Among other things, the work described herein demonstrates a nanodroplet-handling platform for manipulating a wide variety of proteins and reagents, the compatibility of crystal nucleation and formation with electric field mediated droplet operations, favorable translation between on-chip nano-batch and off-chip micro-batch, and screening of multiple conditions and on-chip setup of dilutions for optimization.

8.3 Droplet-Based Protein Crystallization Further Examples

Further examples relevant to the design, development, fabrication, and validation of a digital microfluidic protein crystallization chip are included hereinbelow and include a screening chip which requires only one drop of protein (4 μ L) for screening with 384 pre-filled reagents and an optimization chip which requires 1 μ L of protein for fine grid optimization with 96 reagents constituted fully on-chip from the individual components of a screening reagent that yielded a lead.

Separation of screening and optimization chips. The requirements for screening and optimization are different, so two different chips can be used, even though the digital microfluidic multiwell chip can serve as the basic platform for each. Alternatively, a single chip with two different regions (screening and optimization) can be used. In the

5 screening phase, researchers typically screen a protein with a known set of reagents where the concentrations of the constituents are pre-set in a coarse grid covering a broad range of crystallization space. Therefore, the screening chips and/or cartridges including the screening chips can be pre-loaded with known reagents saving the user from having to load 384 wells. In the optimization phase, however, researchers pick a coarse grid condition that yielded a lead during screening and then prepare a fine grid of reagent concentrations by performing a number of dilutions. Therefore, the optimization chip can set up 96 conditions through on-chip dilutions from a few reservoirs filled with the stock solutions of the constituents. The dimensions of both the chips can conform to the SBS standard multiwell plate footprints (85.48×127.76 mm²) and well-to-well pitch (9/4.5/2.25 mm for 96/384/1536 respectively) so that the chips are readily compatible with robotic plate-handling equipment.

15 Only about half of all proteins crystallized, using any method, have turned out to be useful in determining the 3D structure. The reason is that the “leads” obtained during screening may not form large crystals in the optimization phase. Vapor diffusion (VD) and free interface diffusion (FID) are particularly challenging to optimize because a large crystallization space is sampled in the process, which is advantageous, but the exact conditions for crystallization are not known.

20 A microbatch method lends itself readily for translation from low volumes on-chip to larger volumes on the bench if the volume of the reagent and the protein are known accurately. The precision of droplet dispensing on our platform allows for accurate translation of optimized crystallization conditions from nanoliter-level on-chip to microliter-level on the bench.

8.3.1 Digital Microfluidic Multiwell Plate

25 A scalable architecture can be used to make a chip with 384 on-chip crystallization conditions. A programmable droplet-based microfluidic 384-well platform can also be made, along with relevant droplet control software and instrumentation. The key fluid handling capabilities for protein crystallization was demonstrated and the protein required for each screening condition can further be scaled down from 25 nL to sub-nanoliters.

8.3.1.1 Screening and Optimization on Digital Microfluidic Chips

Screening-Chip Architecture

An important issue in the design of the screening chip is the routing complexity of the electrical signals that control the well-plate electrodes. To reduce the product cost and simplify design, it is useful to minimize the number of electrodes needed to provide droplet pathways from the protein reservoir to the screening wells.

Algorithms for fault tolerance can also be developed to get around the unlikely event of a protein droplet getting stuck on a pathway. Each protein sample loaded into a reservoir is very precious so instead of throwing away the chip because of one fault, the algorithm can adaptively find a path for other droplets that avoids the fault by configuring multiple mutually-disjoint paths from a designated reservoir to the well.

Optimization Chip Architecture

From Figure 7, it can be seen that the microfluidic chip 700 design of this specific embodiment of the invention preferably has 77 electrodes 702 to transfer droplets 704 between four wells 706 (see also Figures 8 and 10). To independently control all 384 wells, it would require 1000's of input/output electrical pads which becomes very expensive. As such, a 4-"pin-limited" design was implemented where every fourth electrode is connected together to perform droplet operations between wells.

In pin-limited designs, the simultaneous movement of multiple droplets is restricted where two or more moving droplets might get inadvertently coupled. A method can be developed to analyze interferences between droplets in every clock cycle. In some steps of the fine grid setup process, interference may be inevitable, then one droplet may have to undergo a stall cycle (i.e., stay in its current location). For both 96 and 384 well-plate arrays, the minimum number of independent control pins sufficient to provide full control can be identified (especially desirable for concurrently executing multiple steps during fine grid setup) of a single droplet. For any electrode in the array, the control pins for all its adjacent electrodes are preferably distinct. Pin layouts can be identified, i.e., assignments of control signals to electrodes, such that maximum freedom of movement of groups of droplets in the array can be ensured.

For the optimization chip, droplet routing can be managed between loading reservoirs and wells as well as between intermediate reservoirs and wells. Droplet routes can be identified with minimum lengths, where route length is measured by the number of electrodes in the path from the starting point to the destination. During droplet routing, it is preferable for a minimum spacing between droplets to be maintained to prevent accidental mixing, except when droplet merging is desired. For multiple droplet routes that may intersect or overlap with each other, fluidic constraint rules must be introduced to avoid undesirable behavior.

Algorithms can be used to schedule droplet operations based on optimal utilization of the stock solutions without requiring users to refill the stock solutions. State-of-the-art in computer architecture can be leveraged to build a microfluidic “compiler” for the optimization chip as there are a number of similarities between the fine grid setup problem and the problem of compiling a program written in a high-level programming language (such as C/C++). The compiler typically decomposes user-level code to a series of hardware instructions based on the instruction-set architecture of the underlying microprocessor. Next, the compiler determines parallelism between instructions, maps these instructions to functional units, allocates the hardware registers for instruction execution, and performs instruction scheduling. The microfluidic compiler can view the given stock solutions as the initial values of variables in the user program and fine grid conditions can serve as the final values of another set of variables. The latter set of variables can be controlled by manipulating the initial set of variables as well as additional intermediate variables. Once the compiler determines the set of microfluidic operations required for fine grid setup, a graph model can again be used to describe the fine grid setup protocol, where the vertex set is in one-to-one correspondence with the set of operations and the edge set represents dependencies between the operations. Next, a synthesis tool can be developed to generate detailed implementations from the sequencing graph model.

The proposed synthesis tool can perform both architectural-level synthesis (e.g., scheduling and resource binding) and geometry-level synthesis (e.g., layout of module placement and routing) for a fine grid setup based on user-defined concentrations. The output of the synthesis process can include a mapping of operation to wells, a schedule for the various operations, and the placement of the modules. The synthesis procedure can identify a desirable design point that satisfies the input specifications and also

optimizes some figures of merit, such as the volumes of the stock solutions and number of wells for fine grid setup. All these steps can be transparent to the user.

8.3.1.2 Design and Fabrication of Digital Microfluidic Chips

Dispensing reservoirs and transport electrodes can be made so that droplet volume (determined by the electrode area and gap height) can be scaled down from 25 nL (500×500×100 μm^3) to 10.5 nL (375×375×75 μm^3), e.g., as shown in Figures 8 and 9. The number of wells can, for example, be 24, 96, 384, or even 1536. Referring to Figure 8, a screening chip pre-filled with 384 reagents for crystallization is shown. Overall dimensions conform to SBS multiwell plate. The 96-well modules 800 can, for example, have input ports 802 and a dispensing reservoir 804 with a sample loading port designed to accept about 1 μL of protein. Other dispensing reservoirs can be provided. The zoom-in view depicts, as an example, protein and reagent sample mixes 808, pre-loaded reagents 812, and a protein droplet 814 en route. A combination of 4 such 96-well modules yields a 384-well plate and a further combination of 16 yields a 1536-well plate. The pitch 906 in each of the 96-well modules is that of a 1536-well plate i.e., 2.25mm which can accommodate a 6×6 pattern of 375×375 μm^2 electrodes. The line spacing between the electrodes can be ~1 mil (25.4 μm), the gap height formed by a photopatternable gasket can, for example, can be about 3 mils (76.2 μm), and multiple layers can be used to perform electrical routing. The digital microfluidic chips can be fabricated in printed circuit board (PCB) processes that have been adapted to various fabrication needs. PCB processes allow the manufacture of the chips inexpensively and therefore enable widespread adoption.

Figure 9 schematically depicts an optimization chip that automatically sets up 96 fine grid conditions. 96 optimization wells in 1536-pitch occupy only 1/16th area. The zoom-in depicts reagents, appropriately diluted on-chip, transported to a well. For example, pH buffer droplet A 902, precipitant droplet B 904, and salt droplet C 906 are shown being transported.

Further description of the architecture and operation of a typical droplet microactuator capable of being used with this aspect can be found hereinbelow with reference to Section 8.8.

8.3.2 Reagent Loading & Pre-Processing On-Chip

Separate screening and optimization chips were developed. For the screening chip, for example, a loading and packaging scheme can be developed to pre-fill coarse grid reagents in all the 384 wells. For the optimization chip, for example, a system of the invention can be programmed to automatically constitute a fine grid of 96 conditions. On-chip dilutions can also be performed from stock solutions of the reagent constituents (e.g., salt, pH buffer, precipitant, and water) for the optimization chip.

8.3.2.1 Screening Chip with 384-Wells Pre-Filled with Reagents

Protein crystallization is an empirical science that has benefited from the development of sparse matrix screens that coarsely sample large regions of crystallization space. Sparse matrix of reagents, described by Jancarik and Kim, has been successfully used as an initial screen for crystallizing more than 1000 proteins. Typical initial screens performed in structural biology labs (for example, the Hampton Research Crystal Screens I and II) consist of 50-100 different reagents and typically consume 200 – 400 μ L of concentrated protein sample. Hampton Research also sells about 900 additional crystal screening reagents many of which are variants of Crystal Screens I and II. 1536 reagents can be used for microbatch screening and the screening chips can be filled with 384 reagents to save the user from having to load all the wells.

8.3.2.2 Choice of Reagents

In one embodiment, the screening chips can have 384 reagent wells on-chip. For example, five (5) different chips can be made with different combinations of pre-filled reagents. One of these chips can contain sparse matrix conditions and a few combinations of salts, PEG/salts, PEG/buffer, and other precipitants totaling 384 conditions. The remaining four (4) chips can be based on HWT's 1536 reagents, which include 46 salts at 10 different concentrations (460), 3 distinct PEGs at 5 different concentrations combined with each of the 46 salts (690), eight different PEGs ranging in molecular weight from 200 to 35,000Da at 5 concentrations combined with buffers ranging in pH from 4.8 to 10.4 (226), 20-step fine screens of ammonium sulfate, lithium chloride, and potassium thiocyanate (60), and sparse matrix based on Crystal Screens I and II (100) adding up to a total of 1536 conditions. An example of the screening chip is found in Table 7.

Table 7 - Digital microfluidic screening chip specifications

| | |
|--------------------------------|--------------------------------------|
| Protein Sample Reservoir | 1 |
| Reagents Pre-filled | 384 |
| Screening Wells | 384 |
| Protein Reservoir Capacity | 400 droplets |
| Unit droplet volume | ~10 nL |
| Total Protein Volume Required | 4 μ L |
| SBS multi-well plate Footprint | 88.48 \times 127.76mm ² |
| Well-to-well pitch | 2.25mm |

8.3.2.3 Chip Layout

5 The overall chip size can be that of a standard SBS multi-well plate. Thus, 384 wells can be arranged in 1536-well pitch (2.25mm) with electrode pathways to connect these wells to reagent and protein input loading ports. Reagent and protein droplets can be transported along these pathways from their input loading ports to the wells and other droplet operations can be conducted. 384 wells in a 1536-well pitch occupy only 1/4th area of the digital microfluidic multiwell plate. The rest of the chip real estate can be used for accommodating the reagent and protein input wells. In addition to the protein reservoir that a user loads, two additional reservoirs can be included that the user can load. These additional reservoirs can, for example, be loaded with any user-selected additives such as glycerol or detergents. Additives can stabilize the proteins, e.g., to improve the quality and size of protein crystals. In another embodiment, the number of wells can be increased on-chip, as described in more detail above.

8.3.2.4 Reagent Loading Schemes

20 In order to not burden the user with filling 384 wells, all the reagents can be pre-filled and packaged in a facility so that the user only needs to introduce a drop of protein to the chip. For effective translation from nanobatch on-chip to microbatch off-chip, it is essential to tightly control the volume of the droplets. The droplets dispensed on the digital microfluidic platform are very precise with a CV < 2% in nanoliter range. This precision can be exploited in various reagent pre-filling schemes in conjunction with other loading methods. Outlined hereinbelow are a variety of suitable loading mechanisms:

- 5 1. *Electric Field Mediated Dispensing:* 384 loading reservoirs around the periphery can be loaded with respective reagents and the chip can be programmed to dispense a 10 nL droplet from all these wells and transport a droplet into each of the 384 screening wells. Each loading reservoir can, for example, hold at least 100 nL. This scheme has been demonstrated for dispensing 25 nL droplets from 4 loading reservoirs.
- 10 2. *Pressure-Assisted Electric Field Mediated Dispensing:* 12 loading ports in 96-well pitch can be placed on either side of the chip. 12 syringe pumps, arranged in 96-well pitch, can be arranged to first sip the reagents from a 96-deep well block of reagents. All the 12 pumps can be interfaced to the 12 loading ports to push the reagents and electric field can be used to create a surface energy well to trap a droplet. These droplets can then be transported away to the screening wells. This method has been successfully used to dispense multiple droplets simultaneously, and it is readily scalable to load 1536 reagents.
- 15 3. *Multi-well Bulb Droppers:* In this scheme, reagents can be prepared in a 384-deepwell plate. An array of droppers can be used to sip the reagents from the deepwell plate and drop the reagents into the loading ports on-chip surrounding 384-wells. 10 nL droplets can be dispensed from these loading ports and transported to the screening wells.
- 20 4. *Robotic Pipetting:* Robotic pipetting can deliver precise volumes into the screening wells.

8.3.2.5 Protein Loading

25 The chip can be programmed to precisely dispense 10 nL droplets 384 times from a single protein reservoir. This reservoir can be constructed to hold about 4 μ L of protein. A polypropylene or polyethylene or polyester or silicone or any tape can be used as a sealing film to prevent evaporation through the loading ports during incubation. Microbatch experiments typically require a higher protein concentration compared to vapor diffusion experiments. In 800 experiments surveyed in the literature, 4 were set up at < 2mg/ml and 4 were set up at >300mg/ml and a majority of the rest are set up in the 5

to 10 mg/ml range of protein concentration. Dispensing and transport of protein droplets with concentrations of 75 mg/ml has been demonstrated.

8.3.2.6 Optimization Chip Programmed to Set Up 96 Conditions

5 In this embodiment, an optimization chip is made and the system is programmed to set up 96 conditions from 2 reservoirs of stock solutions, 2 reservoirs of buffer, and 1 reservoir of water. Sparse matrix screening for crystallization requires a relatively predictable amount of protein and can be done in a single experiment. However, it is often the refinement of the initial crystallization hit that takes the longest time and uses the most material. Typically, upon getting a hit from a sparse matrix screen, an investigator will
10 construct a series of grids around the index condition. Microbatch particularly requires fine grids for optimization after screening. This process involves a number of labor-intensive dilutions. It is very difficult to do this with current technologies on small volumes of proteins. In addition, human pipetting is only reliable in the microliter range with about $\pm 10\%$ volume variability and in a very fine grid this level of variability will
15 not provide enough resolution between different conditions. Robotic pipetting is another option, but robots that are precise and accurate in single-digit nanoliter dispensing are costly. Therefore, the chips of the invention, which can dispense with $< 2\%$ CV in the nanoliter-regime are a very cost-effective alternative to expensive fluid handling robots. A major advantage of digital microfluidics is the software programmability of fluidic
20 operations due to electronic control of liquids. Therefore, this versatile feature can be exploited by fabricating chips that perform all the dilutions and create, initially, 96 fine grid conditions from 3 user-loaded constituent stock solutions of the salts, precipitants, and buffers.

25 The main difference between the screening and the optimization chip is that for the screening chip the reagents are pre-filled as the constituents of the reagents are discrete and fixed and for the optimization chip the reagents are constituted on-chip because the constituents of the reagents span the entire crystallization space and vary based on the lead condition. Other than robotic pipetting, no other microfluidic technology offers such high levels of programmability as is required for on-chip dilutions.

30 On-chip optimization is best illustrated by an example. Hsp90 crystallizes at a slightly acidic pH with PEG 4000 as the precipitant and ammonium phosphate as the salt. For

example, 96 conditions were set up in a fine grid as follows: pH 4.6 and 5.6 (2 conditions), PEG 4000 in steps of 2% at 8%, 10%, 12%, 14%, 16%, 18%, 20%, 22% (8 conditions), and ammonium phosphate in factors of 2 at 50mM, 100mM, 200mM, 400mM, 800mM, and 1600mM (6 conditions).

5 From the above screen, Hsp90 crystallized at pH 4.6, 10% PEG, and 0.2M ammonium phosphate. If the user loads 2.5M ammonium phosphate into one of the on-chip stock solution reservoirs, there are a few ways of constituting 0.2M on-chip. In one scheme, 2 droplets of 2.5M solution can be mixed in an intermediate reservoir with 23 droplets of water in one step to get 0.2M solution. In this scheme, a total of 25 droplets are
10 dispensed and used. In another scheme where intermediate dilutions are utilized, 2.5M would be first diluted to 1M in an intermediate reservoir by mixing 2 droplets of 2.5M solution with 3 droplets of water. In another intermediate reservoir, 1 droplet of 1M solution can be mixed with 4 droplets of water to get 0.2M solution. In this scheme, only 10 droplets are dispensed and used. This example serves to illustrate that dilutions can be
15 performed to minimize reagent consumption for fine grid setup on-chip which minimizes the number of dispensing steps, thereby reducing the overall error in volume.

Reservoirs can be included for HCl, NaOH, and/or other reagent buffers to constitute a full range of pH values (e.g., pH 1-7 at various increments) on-chip through dilutions. Among other things, the advantages of using the envisioned chip for setting up the fine
20 grid conditions are: low volume of protein used per condition (10nL), automatic setup of 96 conditions inexpensively, and precision in droplet volumes (<2% CV). An example of the optimization chip is found in Table 8.

Table 8 - Digital microfluidic optimization chip specifications

| | |
|--------------------------------|-----------------------------|
| Protein Sample Reservoir | 1 |
| Reagents filled by user | 5 |
| Optimization Wells | 96 |
| Protein Reservoir Capacity | 100 droplets |
| Unit droplet volume | ~10 nL |
| Total Protein Volume Required | 1 μ L |
| SBS multi-well plate Footprint | 88.48×127.76mm ² |
| Well-to-well pitch | 2.25mm |

5 The optimization chips can, for example, include 5 loading ports; one each for the stock solutions of salt and precipitant, water, and two for buffers. Each chip can be capable of constituting 96 combinations of reagents from these 5 reservoirs. Two (2) additional loading ports can also be included for the optional inclusion of additives in the optimization phase. 96 optimization wells in a 1536-well foot print occupy 1/16th of the chip area and the rest of the area can be used for the stock solution, intermediate, and waste reservoirs.

10 Fine grids can be set up on-chip in a variety of ways based on the condition that the smallest droplet that could be generated is 10 nL. If the stock solution reservoirs are large enough, large numbers of droplets could be combined directly with water droplets to set up any condition. This method minimizes the number of dilutions but requires many dispensing steps. Another method is to constitute the desired concentrations by using serial dilutions (binary, decade etc). Yet another method, as illustrated in the example, would combine both the above methods where a stock solution would be diluted in one
15 step to within the proximity of required concentration and from that intermediate reservoir fewer droplets would be directly dispensed to set up the fine grid conditions. Based on the design architecture optimizing the layout and electrical connections, an optimum combination of reservoirs can be chosen for direct dispensing and serial dilutions.

20 The goal in these experiments is to rapidly mix 2–3 droplets within a reservoir. A number of schemes can be developed to perform rapid mixing within the reservoirs. For example, an n -electrode \times n -electrode array can be used within the reservoir to rotate a droplet to enhance mixing.

25 For some user-defined concentrations of stock solution, it may not be easy to set up the required concentration range for the 8 \times 6 conditions with the required intervals between the concentrations. For such cases, as an alternative, the software can be designed to calculate an optimum initial concentration of the stock solutions and prompt the user to load the same. Some of the additives, such as acetone, ethanol, methanol etc., may be miscible with the surrounding oil but it has been found that these additives do not
30 partition into oil at the concentrations at which they are typically used (usually < 40% w/v). However, the miscibility of any organic compounds is to be determined by the end user and an appropriate immiscible medium is to be used.

8.3.3 Protein Crystallization Screening and Optimization

In a demo of screening chip operation, 4 μ L of protein can be loaded into a screening chip using a pipettor, screen script routine run, 384 protein droplets automatically dispensed and mixed up with 384 pre-filled reagents.

5 In a demo of an optimization chip operation, the user can load 1 μ L of protein and stock solutions of salt and precipitant, buffers, and water using a pipettor, input concentration range and interval for a fine grid, run fine grid script routine, inform the user via software if any modifications to the stock solutions are required, cause the chip to constitute 96 fine grid conditions, dispense 96 protein droplets, and mix them with the reagents. If any
10 reservoirs do not dispense, then the chip can automatically detect and run a reload script or if any droplet gets stuck on a pathway the software can automatically detect the failure and work around the fault. The user can incubate the chip and periodically check for crystals.

15 8.3.3.1 Crystal Screening in 384-Well Digital Microfluidic Systems

The user can replicate the initial screening step of protein crystallization using a screening chip and compare the results to those obtained by conventional microbatch crystallization. Several proteins can be subjected to this screening in order to assess comparisons with traditional microbatch screening.

20 The droplets in the chips can be flat and shaped as hockey pucks rather than as spherical droplets. This is advantageous for automated crystal scoring since image distortion due to optical aberrations would not be a concern. An x-y micrometer stage can be adapted to fit on a standard stereo-zoom microscope and the screening chip can be viewed manually or automatically translated to score for crystal hits within the wells by using image
25 processing.

PCB chips are usually opaque but can be made transparent by filling the via-holes with a transparent epoxy if needed for visualization or polarization microscopy. In order to eliminate the possibility of finding salt crystals, the user can run a negative control chip to identify salt crystal formation or add a droplet of coomassie blue or methylene blue which

fill the solvent channels in protein crystals. This selectively colors protein crystals blue and leaves salt crystals clear.

8.3.3.2 Optimization of Crystallization Hits Using the Optimization Chip

5 After obtaining the screening conditions, an optimization grid typically has to be set up. Within these grids, the concentration of one or two of the components of the sparse matrix crystallization reagent is varied. The choice of variable component and the grid size are based on the investigator's experience, and are limited by the amount of protein on hand, the geometry of the crystallization apparatus, and the time allotted to the experiment. Optimization is often an iterative process, as first one grid and then another is tested until the parameters governing crystallization in that particular region of crystallization space are understood. This is, however, a strategy that is limited in its breadth. For example, even in a simple crystallization setup there may be several components to vary, including precipitant and salt concentration, buffer pH, additives, as well as protein concentration, in addition to environmental variables such as temperature. A standard optimization strategy would usually first focus on constructing a grid of precipitant versus salt, wherein the precipitant concentration would be varied linearly and the salt concentration varied by a multiplicative factor (e.g. 2). After several days, the experiment would be evaluated and additional grids set up. A much more efficient strategy for optimization would vary as many components as possible in the same experiment. This becomes an attractive option especially if the sample requirements remain modest and the labor of setting up the multi-dimensional grids can be automated. The optimization chip offers both of these benefits, and the purpose of this experiment is to demonstrate that optimization grids can be constructed around an index sparse matrix condition that reproduces the original crystal and parameterize its growth conditions.

For any protein, a grid of conditions can be set up around the sparse matrix condition that yielded crystals. 96 conditions can be set up, varying at least 3 components: precipitant, salt, and pH. Initially the precipitant can be varied linearly, while the salt is varied by factors of 2, and the pH adjusted in 1 pH unit increments. Reagent droplets can be constituted from concentrated stock components and water on-chip, and then mixed with an equal volume of protein in an optimization well. For protein-ligand co-crystallization, after formation of crystals (for e.g., Hsp90) on-chip, the user can demonstrate soaking

drugs (for example, radicicol, an antifungal antibiotic) with existing protein crystals on the optimization chip. If the crystals do not crack or become damaged, then the drug-bound protein crystals can be harvested in a capillary tube for X-ray diffraction. Protein-drug co-crystallization conditions can be similar to the protein-only crystallization conditions. The optimization chip can be also combined with the multiwell bulb dropper dispensing scheme to load 96 drug compounds from a high-throughput screening microplate directly onto this chip. In this case, the chip can be programmed to set up a single condition, which is known to give crystals, in all 96 wells. In this manner, multi-drug-single-crystal soaking studies can be performed. This demonstrates a few additional uses beyond optimization for the technology.

Bodenstaff et al., on the other hand, observed additional crystal forms, not observed in larger volumes, in 200-500 pL of lysozyme droplets. In cases where only tiny crystals are produced on the chips, or even different forms of crystals are observed, then a microfocus synchrotron beamline can be used for the analysis of the crystals. Such beamlines have proven to be useful for small crystal sizes in recent years. This becomes feasible since the chip allows for the movement of the drops containing crystals into a position on-chip where the crystals could be harvested into a capillary tube.

In short, this work demonstrates manipulation and setup of hundreds of droplets, a high throughput 384-well screening chip, and a programmable optimization chip for automated setup of optimization conditions through multiple dilutions programmed on-chip.

8.4 Droplet-Based Multiwell Plate Overview

According to another aspect, the chip of the present invention typically avoids the requirement for a continuous-flow approach, though chips of the invention may in some cases be supplemented by such an approach. Systems including chips of the invention provide flexibility and programmability that is comparable to robotic systems. The chips of the invention can manipulate droplets as small as a few nanoliters in volume. In certain embodiments, the chip of the invention specifically avoids networks of microchannels, external pumps, valves, high-voltage supplies and/or centrifugal force, though such components may be employed to supplement certain aspects of the invention. The system of the invention is scalable and allows multiple liquid droplets to be processed in parallel. The chip of the invention can be manufactured in a highly

compact form, and it is inexpensive to manufacture. A schematic example chip 1000 is illustrated in Figure 10 and includes a 96 well array 1002, a droplet transport network of electrodes 1004 for transporting droplets 1006, and a sample input module 1008.

8.4.1 Well Configurations

5 In one embodiment, the chips of the invention include a regular array of microliter-volume wells or reservoirs. The chip may also include a fluidic input module for loading bulk sample or reagent. A network of droplet transport pathways interconnects each of the wells and discrete nanoliter quantities of liquid can be transported between any two wells or inputs, e.g., to automatically and precisely generate an array of screening
10 conditions. The wells and array of electrodes can be used to conduct a variety of droplet operations.

In some embodiments, wells can be physically defined by a polymer gasket material and linked together by a droplet transporter network defined by the pattern of electrodes on the chip surface. The standard pitch of the discrete electrode elements in the network
15 establishes a unit droplet volume for the entire system. An open architecture in which reservoirs are defined by placement of reservoir electrodes is also possible.

In one embodiment, the chip dimensions conform to standard Society for Biomolecular Screening microplate (multiwell plate) dimensions, such as the dimensions set forth in
20 "ANSI/SBS 1-2004: Microplates - Footprint Dimensions," as updated on January 9, 2004; "ANSI/SBS 2-2004: Microplates - Height Dimensions," as updated on January 9, 2004; "ANSI/SBS 3-2004: Microplates - Bottom Outside Flange Dimensions," as updated on January 9, 2004; and "ANSI/SBS 4-2004: Microplates - Well Positions," as updated on January 9, 2004. The entire disclosure of each of these documents is incorporated herein by reference for its teaching concerning microplate standards. For
25 example, the design can be provided in standard 96 or 384-well or 1536-well format, as well as other custom formats. Use of standard well layout and spacing permits the chips of the invention to be compatible with conventional microplate equipment, such as pipette dispensers and read-out equipment. Standardized embodiments will enable integration of the chips of the invention into existing microplate systems and workflows.

5 Certain designs may combine microplate standards on a single device. For example, one portion of the chip may conform to 96-well format for loading of samples, while another portion conforms to 384 or 1536-format for arraying of reactions. Other designs may divide the chip into modules designed to perform different functions where some modules conform to multiwell plate spacing for loading, storing or detection of reagents or reactions while other modules may have structures designed to perform specific operations or procedures.

10 The chips of the invention are highly flexible and can accommodate specialized, non-standard conformations. Further, the number of wells on the chips of the invention can be much larger than provided for in existing microplate specifications. For example, chips of the invention can incorporate greater than 1,000, 5,000, 10,000, 15,000, 20,000, 25,000, 30,000, 35,000, 40,000, 45,000, 50,000, 55,000, 60,000, 65,000, 70,000, 75,000, 80,000, 85,000, 90,000, 95,000, 100,000, 200,000, 300,000, 400,000, 500,000, 600,000, 700,000, 800,000, 900,000, or even 1,000,000 sub-nanoliter reactions on a single plate.

15 Specifications for one embodiment of a 96 well plate are as follows in Table 9.

Table 9: Example specifications for 96 wells on a 128 mm x 86 mm plate (chip) size.

| Specification | Value |
|---------------------------|--------------------------------------|
| Well pitch | 9 mm |
| Array size | 12 x 8 (96 wells) |
| Transport electrode width | 0.75 mm |
| Unit droplet diameter | 0.75 mm |
| Unit droplet volume | 80 nL |
| Well volume | 800 nL (10 unit droplet volumes) |
| Plate spacing | 0.15 mm |
| Input ports | 10 |
| Input port volume | 8 μ L (100 unit droplet volumes) |
| Overall chip size | 128 mm x 86 mm |

20 A relatively low-density (96 – 1536 wells) PCB-based platform provides a basic and inexpensive assay automation tool. For example, referring to Figure 11, in one embodiment, the invention provides a microactuator 1100 comprising a PCB-based chip 1102 that will plug into a base 1104 that conforms to the size and shape of a standard

multiwell plate. The PCB chip 1102 can have a top plate 1106, a 96-well array 1108, and a fluid input module 1112. The base 1104 can have electrical contacts 1114 and a controller circuit board 1116. All of the electronics required to operate the chip 1102 can be integrated into the base 1104, e.g., with the electrical contacts 1114 distributed on the top-side of the base 1104 to make contact with the backside of the chip 1102. The entire instrument can be powered and controlled from a standard USB port 1118 or even operated as a stand-alone instrument. Power can be provided by batteries located within the plate so that the stand-alone plate provides completely automated fluid handling in the same form factor as a standard plate. This embodiment of an automated multiwell platform can perform many of the functions of a robotic system at a tiny fraction of the cost, and will be particularly useful in low and moderate throughput environments, including much of academic research, where the expense of robotic automation may be difficult to justify. Fluid handling capability is completely integrated within the unit which has standard plate dimensions and is compatible with conventional plate readers and handling equipment.

Larger chips with extremely high levels of throughput and cost savings will be useful in a variety of settings, such as drug discovery applications. In one embodiment, the invention is useful for high-throughput biological assays. For example, the chip can be programmed to execute on-chip dilutions and cell-handling protocols. Scaling of droplet volumes on a fully populated 128 mm x 86 mm plate (chip) size at different well pitches can be seen in Table 10.

Table 10: Scaling of droplet volumes at different well pitches.

| Well Pitch (mm) | Rows | Cols | Total wells | Well volume (nL) | Unit drop diameter (μm) | Plate spacing (μm) | Unit drop volume (nL) | Min. feature (μm) |
|-----------------|------|------|-------------|------------------|-------------------------|--------------------|-----------------------|-------------------|
| 9.00 | 12 | 8 | 96 | 6750 | 1500 | 300 | 675 | 75.0 |
| 4.50 | 24 | 16 | 384 | 844 | 750 | 150 | 84.4 | 37.5 |
| 2.25 | 48 | 32 | 1536 | 105 | 375 | 75.0 | 10.5 | 18.8 |
| 1.13 | 96 | 64 | 6,144 | 13.2 | 188 | 37.5 | 1.32 | 9.38 |
| 0.563 | 192 | 128 | 24,576 | 1.65 | 93.8 | 18.8 | 0.165 | 4.69 |
| 0.281 | 384 | 256 | 98,304 | 0.206 | 46.9 | 9.38 | 0.0206 | 2.34 |
| 0.141 | 768 | 512 | 393,216 | 0.0257 | 23.4 | 4.69 | 0.00257 | 1.17 |
| 0.070 | 1536 | 1024 | 1,572,864 | 0.00322 | 11.7 | 2.34 | 0.000322 | 0.586 |

Mixing or dilution ratios can be established programmably by controlling the number and distribution of constituent droplets delivered to each well. Furthermore, liquid which has been mixed within a well may be subsequently dispensed from that well in the form of unit-sized droplets for transport to another well, for example, to perform serial dilution assays.

8.4.2 Fluid Input

The invention includes a fluidic input module for loading and storage of samples and reagents. In one embodiment, a basic input module allows samples to be loaded using a pipettor or other device and automatically subdivides and distributes input fluid as discrete droplets to the multiwell array. When present, the input module serves as the interface between conventional fluid handling technology and the microfluidic chip architecture.

The fluid input module generally can include one or more sample loading reservoirs integrated with the multiwell array. The loading reservoirs may include a liquid reservoir connected to the network. The loading reservoirs are interfaced to the outside of the chip and will typically have much larger capacities than individual processing wells where the liquid is completely loaded or they may have smaller capacities but serve as an interconnection between the chip and the outside world where the liquid is continually fed. As a general rule, the target capacity of the loading reservoirs can be a multiple of the number of wells times the unit volume in cases where the liquid is completely loaded.

Thus, at least one unit droplet of each sample or reagent can be distributed to each well on the plate. Frequently used reagents such as dilution buffers can be loaded in multiple ports for greater parallelism or continually fed in through at least one dedicated loading port.

A general discussion of input reservoirs used in connection with the droplet microactuator of the present invention can be found hereinbelow with reference to Section 8.8.6.1.

8.4.3 Screening Capabilities

The invention provides a high-throughput interface for screening of large diverse libraries. Clearly, if thousands of compounds must be loaded at the chip's fluidic interface using conventional robotics, then the advantage of this platform is severely diminished. As such, while in some embodiments this limited approach was used for loading of small numbers of reagents for on-chip titration, in other embodiments a means was employed for rapidly populating the wells with a large number of different compounds. Various alternative embodiments may, for example, include 1) an interface in which droplets of compound are separated by plugs of oil in a long pre-loaded capillary (e.g., glass capillary) which when connected to the chip allows droplets of compound to be captured and routed on the chip as they are pumped out of the capillary, 2) an approach in which compounds are pre-stamped onto the chip and allowed to dry using a high-speed reagent stamping or printing process, or 3) a direct plate to chip interface in which the contents of conventional 1536 or 384 or 96 well plates can be transported to the chip in parallel by pressurizing the liquid to pass through openings at the bottom of the wells which are aligned to an array of chip inputs.

In some embodiments, the invention provides electronics and detectors integrated directly on the chip substrate to enable higher throughput and rapid readout of results. The use of glass or silicon substrates permit integration of microelectronic circuits and the array of droplet control electrodes on a single substrate. Integration of the drive electronics onto the chip would vastly increase the available number of electronic control signals permitting greater throughput and protocol optimization. The LCD screen found on a typical PDA such as a PalmPilot™ is roughly the same size as a multi-well plate and contains a 480 x 320 array of 153,600 independently controllable electrodes demonstrating that chip-level integration of electronics can be both feasible and relatively inexpensive. Integration of electronics onto the substrate provides the additional advantage that optical or electrochemical sensors could be integrated with the chip as well.

8.5 Droplet-Based Multiwell Plate Examples

The following non-limiting examples are provided only for the purpose of illustrating various aspects of this aspect of the invention and should not be construed as limiting the scope of the invention.

8.5.1 Scalable Chip Architecture for Droplet Distribution

8.5.1.1 Well Design

Individual wells can be defined on the chip using the same photopatternable polymer material (e.g., dry film soldermask) that defines the input reservoirs and provides the stand-off between the two plates in the fully-assembled device. Each well can be designed with at least a single major opening to permit communication between the interior of the well and the distribution network for dispensing of droplets into and out of the well. Several minor openings may also be included to allow air bubbles to escape during filling of the device with oil.

The following parameters can be varied to optimize the performance (dispensed droplet volume variation, liquid capacity, ease of filling with oil, and resistance to shake-up during handling) of each well: major opening width and length, interior shape and size, location and size of minor openings, size and shape of electrodes, and chamber height.

The consistency of dispensed droplet volumes and liquid capacity of the wells have important consequences with respect to the capability of performing multi-step dilutions or mixing within the chambers. For example, if the volume of the dispensed droplet is found to depend on the volume of liquid remaining in the well, this issue can be corrected at the program compiler level by accounting for this variation.

8.5.1.2 Transporter Network Design

The droplet distribution network linking the individual chambers is another component of the multiwell array subsystem of the proposed platform. While the layout of the network is straightforward owing to the regularity imposed by the array, electrical connectivity and control of the electrodes presents a serious optimization challenge. Thus, for example, in an embodiment in which 10 transport electrodes are associated with each cell, up to 1,000 independent electrical control signals are required. In practice, no more than a few hundred signals can be inexpensively managed. One solution to this problem is to provide multiplexing of electrode control signals. That is, multiple electrodes are connected to a single signal and activated or deactivated together. For example, a transport line of arbitrary length can be implemented as a line of electrodes where every electrode is connected to one of three signals which are operated out of phase to transport

all droplets on the line in unison. In this manner, many droplets can be arbitrarily manipulated in parallel, but the design and operation of the device is considerably more complex owing to lack of independent control of each electrode.

5 The fabricated multiwell platform can be arranged to provide optimal droplet routing. Due to the limited number of electronic control signals, droplets are preferably not routed independently of each other. In addition, fluidic constraints and overlapping droplet routes will dictate careful droplet scheduling. Computationally tractable algorithms can be used for the simultaneous coordination of a potentially large number of droplets. Limited row-column addressing schemes, where only entire rows and columns of droplets
10 can be addressed, can be employed. The insertion of "wait cycles" at appropriate points during sample delivery, mixing, and dilution can also be employed.

8.5.2 Fluidic Input Module

The fluidic input module can include a smaller array of relatively large (~10 μ L) reservoirs which can be pipette-loaded through access holes in the chip. The reservoirs
15 store sample or reagent and dispense unit-sized droplets on demand for transport to particular well locations. The design of the input module is made challenging both by the need to physically interface with the outside world and by the need to precisely dispense the unit-sized droplets from a large, arbitrary volume.

Dispensing of unit droplets from the fluidic input is considerably more challenging than
20 dispensing from the wells because the volume of the liquid reservoir compared to the dispensed droplet is considerably larger and more variable. Dispensing of droplets becomes inherently more challenging at larger ratios due to the larger difference in curvature between the initial and final droplets. As described by the Young-Laplace equation, this curvature difference creates a pressure gradient inside the liquid which
25 opposes further deformation of the surface. Thus more energy is required to dispense droplets at large ratios (e.g., 100:1) than at smaller ones (e.g., 10:1). Furthermore, larger droplets of liquid are more susceptible to gravitational, buoyant and inertial effects because surface-tension is less dominant at this scale, leading to less reliable and repeatable manipulation of droplets by surface-tension-based effects.

In one embodiment, this problem is addressed using a multi-stage input comprised of a larger outer reservoir directly connected to a loading hole and outside world and a smaller inner reservoir connecting the outer reservoir with the multi-well array. The smaller inner reservoir is periodically reloaded from the larger reservoir and dispenses droplets directly onto the transport network. Dispensing of liquid from the larger to smaller reservoir need not be very precise, while the relative stability of the smaller reservoir volume ensures reproducibility of the unit droplet volume.

For example, one embodiment includes a fluid input module with fixed outer reservoir volume of 10 μL (100 unit droplets of 100 nL each) and inner reservoirs of various volumes ranging from 5 μL (50 unit droplets of 100 nL each) to 1.0 μL (10 unit droplets of 100 nL each). The entire 10 μL volume can be dispensed, reloading the smaller reservoir as many times as required, and the volume of each unit-droplet can be measured. The performance of each design in terms of volume reproducibility and throughput (including reload cycle time) can then be determined.

8.6 Droplet-Microactuator Stamping Platform Overview

One further aspect of the present invention provides a droplet microactuator stamping platform. The platform provides, among other things, a system for droplet microactuator manipulation (e.g., dispensing, transport, mixing) of all fluids necessary for preparing samples for stamping operations. In particular, the invention provides mixing of MALDI matrix on-chip with samples and stamping onto a MALDI plate. Figures 12 and 13 illustrate two embodiments of droplet microactuator designs of the invention suitable for use as stamping platforms, wherein Figure 12 is an electrowetting chip similar to that used in experiments described herein and Figure 13 is an electrowetting chip on a 384 well footprint with 16 wells.

The invention includes openings for transporting droplets out of the chip to be stamped on a substrate. For example in one embodiment, the openings transport the droplets onto a plate. Typically, the surface of the plate will be substantially hydrophobic and will include hydrophilic spots where the samples will be deposited, e.g., for MALDI analysis samples will be deposited on these spots and will be interrogated by laser.

One key aspect of the invention is the ability to transport on a droplet microactuator the reagents and samples encountered in a typical MALDI-MS experiment. It was surprisingly found that droplets including proteins at concentrations relevant to MALDI-MS can be dispensed from on-chip reservoirs and transported on the droplet microactuator. Further, it was discovered that MALDI matrix containing acetonitrile can be dispensed, transported and manipulated on the droplet microactuator. Moreover, it was discovered that filler fluids used in electrowetting are compatible with MALDI-MS.

Certain embodiments of the droplet microactuator of the invention are capable of dispensing and transporting sample droplets that include proteins. A technique was surprisingly discovered which permits droplets with high concentrations of protein to be manipulated. In one embodiment, the protein solution has a concentration which exceeds about 1 mg/mL, about 10 mg/mL, about 50 mg/mL, or about 100 mg/mL.

Various embodiments of the droplet microactuator are also capable of manipulating reagent droplets comprising MALDI matrix. In a preferred embodiment, the droplet microactuator can dispense and transport reagent droplets comprising acetonitrile. The acetonitrile is typically provided in an amount which is sufficient to keep miscibility of the acetonitrile in the filler fluid at a level which is not unduly detrimental to the effectiveness of the stamping device. In one embodiment, the MALDI matrix comprises from about 40% to about 75% acetonitrile. In another embodiment, MALDI matrix comprises from about 50% to about 70% acetonitrile. In certain embodiments, the MALDI matrix may also include TFA. For example, in one embodiment, the MALDI matrix includes from about 0.05% to about 1% TFA. Thus, for example, in a preferred embodiment, the MALDI matrix includes from about 50% to about 70% acetonitrile and from about 0.05% to about 1% TFA.

The droplet microactuator typically includes a filler fluid, discussed in more detail hereinbelow with reference to Section 8.8.4. The filler fluid surrounds the droplets being transported. Low viscosity oils are preferred, preferably silicone oil. The MALDI-MS of silicone oil was evaluated and it was surprisingly found that the oil is highly compatible with MALDI-MS, producing no discernable peaks. Figure 14 illustrates the MALDI-TOF MS spectrum of oil used in examples defined herein.

The system of the present invention is generally programmed and configured to mix sample droplets with MALDI matrix droplets on-chip to yield MALDI-ready droplets and to direct the MALDI-ready droplets to a port where some portion or the entire droplet can exit the droplet microactuator to be deposited on a MALDI substrate. In operation, droplets of sample and MALDI matrix are dispensed from on-chip reservoirs, mixed and spotted onto a substrate through an opening in the top plate (see aperture 1518 in Figure 15). Passive stamping sometimes results in dead volume in the opening. In one embodiment, this problem is resolved by adding a small quantity of oil through one of the oil loading ports which provides enough pressure to force the liquid out of the opening completely.

In one embodiment, the sample and the MALDI matrix are merged at a stamping hole. Mixing is significantly faster using this approach due to the larger surface area available for diffusion in the hole.

Preferably, cross-contamination is reduced to a level at which it does not significantly impact analysis of deposited samples. In some embodiments, cross-contamination is reduced by reducing the acetonitrile concentration in the sample by dilution. Cross-contamination may also be reduced by minimizing the overlapping paths between different samples.

8.6.1 Droplet Manipulation

The stamping platform of the invention makes use of a droplet microactuator chip which is useful for effecting droplet operations, such as dispensing, splitting, transporting, merging, mixing, agitating, and the like. Preferably, droplet manipulation is accomplished using electric field mediated actuation, as described hereinbelow with reference to Section 8.8. As illustrated in Figure 15, the basic droplet microactuator 1500 includes two parallel plates, top plate 1502 and bottom plate 1504, separated by a gap 1506 formed such as through the use of spacers 1508. One or both of the plates 1502, 1504 includes one or more paths or networks of substantially planar control electrodes 1512 and corresponding reference electrodes 1514 for performing droplet manipulations. Droplets 1516 are interposed in the space 1506 between the plates 1502, 1504 on these paths or networks. Space 1506 surrounding the droplets is typically filled with a filler fluid as described hereinabove. Top plate 1502 may include a stamping aperture 1518 for

the passing of a droplet 1516 through to a stamping plate 1522. The droplet microactuator 1500 works with a wide variety of liquid droplets, though conductive liquids are preferred.

5 Droplet transport for stamping occurs along the path or network of control electrodes. The path or network requires interconnections to electrically connect electrodes to contact pads for connection to external circuitry and may also include interconnections for connecting certain electrodes together. The droplet microactuator operates by direct manipulation of discrete droplets, e.g., using electrical fields. By applying different voltages to adjacent control electrodes, a local and electrically controllable energy gradient can be established. A droplet adjacent to an energized electrode will move to align itself with the energized electrode, i.e., the droplet will be transported to the position of that electrode. A series of successive transfers will transport droplets along the path or network of control electrodes. In addition to transport, other operations including merging, splitting, mixing and dispensing of droplets can be accomplished in the same manner by varying the patterns of voltage activation.

Further description of architecture and operations involving a droplet microactuator of the present invention can be found hereinbelow with reference to Section 8.8.

8.7 Droplet-Microactuator Stamping Platform Examples

20 The ensuing examples are illustrative of various embodiments of the invention, and should not be interpreted as limiting the scope of the invention. The examples provide, among other things, a demonstration of the feasibility of the droplet microactuator stamping platform described herein, including validation of on-chip manipulation (dispensing, transport, mixing) of all fluids of interest for the proposed application on a coplanar platform, and mixing of MALDI matrix on-chip with samples and stamping onto a MALDI plate.

8.7.1 Material and Methods

Protein samples were provided by LEAP or were obtained from SIGMA. MALDI-TOF MS was done by Global Peptide Services, Colorado. Figure 12 shows a chip used in the experiments. Figure 16 shows time lapsed images of a stamping experiment

accomplished using the chip of Figure 12. Figure 13 shows another chip which was fabricated on a 384-well pitch with 16 wells.

8.7.2 Material compatibility studies

The compatibility of the various materials encountered in a typical MALDI-MS experiment was established by demonstrating the following.

- 1) Dispensing and transport of a representative set of protein droplets at concentrations relevant to MALDI-MS from on-chip reservoirs.
- 2) Dispensing and transport of MALDI matrix which contains acetonitrile.
- 3) Compatibility of filler fluids used in electrowetting with MALDI-MS

8.7.2.1 Protein Compatibility

Table 11 lists proteins that were tested on the system along with the highest tested concentrations. Note that some of these concentrations are the highest "tested" and up to 10s of mgs/mL of protein has been successfully dispensed and transported on the chips. This is three orders of magnitude higher than what is typically seen in MALDI-MS applications.

Table 11 - Protein compatibility chart

| Protein | Highest concentration tested |
|-------------------|------------------------------|
| BSA | 90 fmol/uL (6ug/mL) |
| Bovine insulin | 100 pmol/uL (573ug/mL) |
| Lysozyme | 75 mg/mL |
| Glucose isomerase | 10 mg/mL |
| Proteinase K | 10 mg/mL |

The BSA sample was in 25% ACN (provided by LEAP Tech) and the bovine insulin (from SIGMA) was in 1% TFA. In addition to the above proteins, the manipulation of sample matrices containing high concentration of proteins such as whole blood, plasma and serum have been shown.

8.7.2.2 Solvent/MALDI Matrix Compatibility

5 The most commonly used solvent to prepare a MALDI matrix is 50-70% acetonitrile with 0.05-1% TFA. Though 100% acetonitrile is partially miscible (3-5%) in the oils typically used for electrowetting, a mixture of acetonitrile and water (up to 70% ACN) was not measurably miscible in oil. Droplets were successfully manipulated containing up to 70% acetonitrile on the system. MALDI matrix droplets containing 50% ACN and 0.05% TFA was also successfully dispensed and manipulated on the chip.

8.7.2.3 Filler Fluid Compatibility

10 In order to prevent fouling of the surfaces, the use of low viscosity oils is preferred as the filler media surrounding the droplets. The MALDI-MS of the silicone oil commonly used was evaluated and no discernable peaks > 3000 Da were found. Figure 14 shows the mass spectra of oil. The small peak which is visible at 8212 Da is from the MALDI matrix.

8.7.3 System scaling and integration

15 System integration and scaling was demonstrated as follows:

- 1) Mixing of protein droplets with MALDI matrix droplets on-chip.
- 2) Passive stamping through an opening or an "open" system onto a top plate which is hydrophobic all over the surface except for the hydrophilic spots where the MALDI samples will be interrogated by laser.
- 20 3) Evaluating the effect of cross contamination between the droplets either mediated through oil or the surfaces.
- 4) Determining the effect of aspect ratios on stamping.
- 5) Investigating use of droplets digitized and deposited directly from the well plate obviating the need for a top plate. Determine operational limitations of this approach.

8.7.3.1 Stamping of Single Sample

Figure 15 illustrates the setup used to perform the MALDI stamping experiment. BSA (90nM in 25% ACN) was used as the model protein for the stamping experiments. Droplets of sample and MALDI matrix were formed from on-chip reservoirs, mixed and passively spotted onto a glass plate through an opening in the top plate. The droplets were approximately 100nL each. Passive stamping sometimes resulted in dead volume being left over in the opening. This problem was resolved by adding a small quantity of oil through one of the oil loading ports which provides enough pressure to force the liquid out of the hole completely.

In a variation of the stamping experiment described above, the sample and the MALDI matrix were merged at the stamping hole. Mixing is expected to be significantly faster using this approach due to the larger surface areas available for diffusion in the hole.

8.7.3.2 Stamping of Multiple Samples

The previous experiment was scaled up to demonstrate the passive stamping of four different BSA droplets. The mixing with the matrix was done at the stamping hole in this experiment.

8.7.3.3 Cross-Contamination Studies

Cross-contamination studies were performed to evaluate the carryover of protein samples from one droplet to another. In the first experiment, several droplets (total volume ~500nL) of 100pmol/uL insulin (total insulin manipulated = 50pmol) in 1% TFA were moved across 6 electrodes several times and collected through the stamping hole. The total time the insulin droplets resided on the 6 electrodes was approximately 5 minutes. A water droplet was also moved on the same path as the protein droplet for approximately 5 minutes and collected through a different stamping hole. 5uL of matrix was added to both the samples and MALDI-TOF MS was done by spotting the entire sample. Figure 17 illustrates MALDI-MS for a blank droplet after cross-contamination experiments without acetonitrile in the system. The figure shows the spectrum and no peaks are visible at the molecular weight of insulin. The lowest detectable concentration obtained by doing MS analysis on a dilution curve was 2.5fmol of insulin. As such, the cross-

contamination from a 50pmol sample is below 2.5fmoles (carryover of 0.005%) and is not detectable by the instrument used.

In the second experiment the protein sample and a blank sample were both premixed with the MALDI matrix to see if the presence of acetonitrile increased the possibility of contamination. Four 100nL droplets of 100pmol/uL insulin (40pmol) with matrix were transported across 12 electrodes serially and discarded to waste. Four 100nL droplets of the blank droplet (with matrix) was moved along the same path and collected through a stamping hole. The collected droplet was stamped as is without any additional matrix added to it. Figure 18 illustrates MALDI-MS for a blank droplet after cross-contamination experiments without acetonitrile in the system according to this experiment. The figure shows the zoomed mass spectrum of the blank droplets and a peak is visible at the molecular weight of insulin. This indicates that there is some cross-contamination. To estimate the levels of cross-contamination a log dilution series of insulin between 2.5fmoles and 250pmoles was also analyzed using MALDI-MS. The intensity of the peak (baseline corrected) for the different samples analyzed is shown in Table 12.

Table 12 - Mass-spec peak intensity for different samples

| Sample | Peak intensity (baseline corrected) |
|----------|-------------------------------------|
| 250 pmol | 1743 |
| 25 pmol | 4339 |
| 2.5 pmol | 5816 |
| 250 fmol | 333 |
| 25 fmol | 114 |
| 2.5 fmol | no peak |
| Blank | 383 |

From the table, it can be inferred that the cross-contamination from a 40pmol sample is around 250 fmol which amounts carryover of 0.625%. A similar carryover was seen when both the sample and the blank were collected through the same hole.

This cross-contamination can be attributed to the presence of acetonitrile in the samples (from the matrix) since no contamination was observed using an aqueous sample of

5 proteins. Without wishing to be bound by a particular theory, it is suspected that microdroplets are ejected during manipulation. It is believed that by changing the geometry of the electrodes, the ejection of microdroplets can be reduced or eliminated. Cross-contamination can also be minimized by reducing the acetonitrile concentration in the sample by dilution, and by minimizing the overlapping paths between different samples.

8.7.4 Stamping Platform Conclusions

10 Among other things, the work described herein demonstrates the feasibility of the stamping platform of the invention. A droplet microactuator of the invention can dispense and transport protein samples with high protein content, MALDI-specific solvents, and MALDI matrix. An oil matrix can be used to prevent proteins from sticking to electrodes. There are limitations on the percentage of acetonitrile solvent in the sample liquids used but these limits do not substantially impair the utility of the device. Mixing of the MALDI matrix with sample materials on chip can be accomplished as expected.

15 Stamping through a hole in the top plate is a feasible embodiment of the invention. Less than 1% carryover appears to occur when very low protein concentration solution droplets follow the same path as high protein concentration solution droplets.

8.8 Droplet Microactuator Architecture and Operation

20 The various aspects of the present invention discussed hereinabove generally include a droplet microactuator controlled by a processor. For example, the processor may, among other things, be programmed to control droplet manipulations on a droplet microactuator. A wide variety of droplet microactuator configurations is possible. Examples of components which may be configured into a droplet microactuator of the invention include various filler fluids which may be loaded on the droplet microactuator; fluid

25 loading mechanisms for introducing filler fluid, sample and/or reagents onto the droplet microactuator; various reservoirs, such as input reservoirs and/or processing reservoirs; droplet dispensing mechanisms; means for controlling temperature of the droplet microactuator, filler fluid, and/or a droplet on a droplet microactuator; and magnetic field generating components for manipulating magnetically responsive beads on a droplet

30 microactuator. This section discusses these and other aspects of the droplet microactuator and their use in the systems of the invention.

8.8.1 Droplet Microactuator

The various aspects discussed hereinabove can make use of a droplet microactuator, sometimes referred to herein as a chip. The droplet microactuator can include a substrate with one or more electrodes arranged for conducting one or more droplet operations. In some embodiments, the droplet microactuator can include one or more arrays, paths or networks of such electrodes. A variety of electrical properties may be employed to effect droplet operations. Examples include electrowetting and electrophoresis.

In one embodiment, the droplet microactuator includes two or more electrodes associated with a substrate, and includes a means for permitting activation/deactivation of the electrodes. For example, the electrodes may be electronically coupled to and controlled by a set of manual switches and/or a controller. The droplet microactuator is thus capable of effecting droplet operations, such as dispensing, splitting, transporting, merging, mixing, agitating, and the like. Droplet manipulation is, in one embodiment, accomplished using electric field mediated actuation. Electrodes will be electronically coupled to a means for controlling electrical connections to the droplet microactuator.

The basic droplet microactuator includes a substrate including a path or array of electrodes. In some embodiments, the droplet microactuator includes two parallel substrates separated by a gap and an array of electrodes on one or both substrates. One or both of the substrates may be a plate. One or both substrates may be fabricated using PCB, glass, and or semiconductor materials as the substrate. Where the substrate is PCB, the following materials are examples of suitable materials: Mitsui BN-300; Arlon 11N; Nelco N4000-6 and N5000-30/32; Isola FR406, especially IS620; fluoropolymer family (suitable for fluorescence detection since it has low background fluorescence); and the polyimide family. Various materials are also suitable for use as the dielectric component of the substrate. Examples include: vapor deposited dielectric, such as parylene C (especially on Glass), and parylene N; Teflon AF; Cytop; and soldermasks, such as liquid photoimageable soldermasks (e.g., on PCB) like Taiyo PSR4000 series, Taiyo PSR AUS series (good thermal characteristics for applications involving thermal control), and Probimer 8165 (good thermal characteristics for applications involving thermal control); dry film soldermask, such as those in the Dupont Vacrel family; and film dielectrics, such as polyimide film (Kapton), polyethylene, and fluoropolymers like FEP, PTFE. Some or all of the substrate may also include a hydrophobic coating. Suitable examples include

Teflon AF; Cytop; coatings in the Fluoropel family; silane coatings; fluorosilane coatings; and 3M Novec electronic coatings.

Where the droplet microactuator includes two plates, droplets may be interposed in the space between the plates. Space surrounding the droplets typically includes a filler fluid. The droplet microactuator can conduct droplet operations using a wide variety of fluid droplets, though conductive fluids are preferred. Filler fluids are discussed in more detail hereinbelow with reference to Section 8.8.4.

Surfaces of the droplet microactuator are typically coated with a hydrophobic coating. For applications involving thermal cycling, a hydrophobic coating should be selected that is resistant to thermal stress during prolonged thermocycling operation. Examples of suitable thermal resistant materials include soldermasks such as Probimer[®] 8165 which has been developed for use in the automotive industry and has excellent thermal shock resistance, and PCB board materials such as Mitsui BN-300 which is resistant to high temperature and warpage.

Droplet transport occurs along a path or network of control electrodes. The array or path includes electrical connections for electrically coupling electrodes to external circuitry. The array or path may also include electrical connections for electrically coupling certain electrodes together. The electrodes can be controlled via the external circuitry by a processor. Droplet operations may be effected by supplying voltage to the electrodes. While the preferred voltage varies depending on the thickness of the dielectric, for a dielectric constant in the range of 2-100 and thickness in the range of 1 nm to 10 mm, the preferred energy per unit area limits are in the range of about 300 microjoule/sq meter to about 300000 microjoule/sq meter. The preferred activation voltage is in the range of about 1mV to about 50kV, or about 1V to about 10kV, or about 5V to about 1000V, or about 10V to about 300V.

Typically, the electrodes are fired via a voltage relay. The droplet microactuator operates by direct manipulation of discrete droplets, e.g., using electrical fields. For example, a droplet adjacent to an energized electrode with surrounding electrodes grounded will transport to align itself with the energized electrode, i.e., the droplet will be transported to the position of that electrode. A series of successive transfers will transport droplets along the path or network of control electrodes. In addition to transport, other operations

including merging, splitting, mixing and dispensing of droplets can be accomplished in the same manner by varying the patterns of voltage activation.

It should be noted that electrodes can be activated in a variety of ways. For example, an electrode can be activated by applying a DC potential. Similarly, an electrode can be activated by applying an AC potential, so that the activated electrode has an AC potential and an unactivated electrode has a ground or other reference potential. In another aspect, the potential may be applied by repeatedly activating an electrode and then inverting it. An AC mode can be effected by using software to rapidly switch between polarities of the outputs.

In some embodiments the invention employs droplet operation structures and techniques described in U.S. Patent 6,911,132, entitled "Apparatus for Manipulating Droplets by Electrowetting-Based Techniques," issued on June 28, 2005 to Pamula et al.; U.S. Patent Application No. 11/343,284, entitled "Apparatuses and Methods for Manipulating Droplets on a Printed Circuit Board," filed on January 30, 2006; U.S. Patents 6,773,566, entitled "Electrostatic Actuators for Microfluidics and Methods for Using Same," issued on August 10, 2004 and 6,565,727, entitled "Actuators for Microfluidics Without Moving Parts," issued on January 24, 2000, both to Shenderov et al.; U.S. Patent Publication No. 20060254933, entitled "Device for transporting liquid and system for analyzing" published on November 16, 2006 to Adachi et al.; International Patent Application No. PCT/US 06/47486, entitled "Droplet-Based Biochemistry," filed on December 11, 2006; and International Patent Application No. PCT/US 06/47481, entitled "Droplet-Based Pyrosequencing," filed on December 11, 2006, the disclosures of which are incorporated herein by reference for their teachings concerning structures and techniques for conducting droplet operations.

Droplet operations can be rapid, typically involving average linear velocities ranging from about 0.01 cm/s to about 100 cm/s, or from about 0.1 cm/s to about 10 cm/s, more preferably from about 0.5 cm/s to about 1.5 cm/s. Moreover, droplets may typically be manipulated at a frequency of manipulation ranging from about 1 Hz to about 100 KHz, preferably from about 10 Hz to about 10 KHz, more preferably from about 25 Hz to about 100 Hz. In addition to being rapid, droplet manipulations using the droplet microactuator are also highly precise, and multiple droplets can be independently and simultaneously manipulated on a single droplet microactuator.

Discrete droplet operations obviate the necessity for continuous-flow architecture and all the various disadvantages that accompany such an architecture. For example, near 100% utilization of sample and reagent is possible, since no fluid is wasted in priming channels or filling reservoirs. Further, as noted above, droplet movement can be extremely rapid.

5 The droplet microactuator may in some cases be supplemented by continuous flow components and such combination approaches involving discrete droplet operations and continuous flow elements are within the scope of the invention. Continuous flow components may be controlled by the controller. Nevertheless, in certain other embodiments, various continuous flow elements are specifically avoided in the droplet

10 microactuator of the invention and/or methods of the invention. For example, in certain embodiments, one or more of the following components is excluded from a droplet microactuator and/or methods of the invention: microchannels; fixed microchannels; networks of microchannels; pumps; external pumps; valves; high-voltage supplies; centrifugal force elements; moving parts.

15 Electric field mediated actuation also obviates the need for other droplet operations and all the various disadvantages that accompany such techniques. It will be appreciated that the droplet microactuator may nevertheless be complemented or supplemented with other droplet manipulation techniques, such as electrical (e.g., electrostatic actuation, dielectrophoresis), magnetic, thermal (e.g., thermal Marangoni effects, thermocapillary),

20 mechanical (e.g., surface acoustic waves, micropumping, peristaltic), optical (e.g., opto-electrowetting, optical tweezers), and chemical means (e.g., chemical gradients). When these techniques are employed, associated hardware may also be electronically coupled to and controlled by the controller. However, in other embodiments, one or more of these droplet operation techniques is specifically excluded from a droplet microactuator of the

25 invention.

The droplet microactuator can be manufactured in a highly compact form and can be driven using a very small apparatus. For example, droplet microactuator and apparatus may together be as small as several cubic inches in size. The droplet microactuator requires only small amounts of electrical power and can, for example, readily be operated

30 using batteries. The droplet microactuator can perform droplet operations using extremely small droplets. Droplets are typically in the range of from about 1 fL to about 1 mL, more preferably from about 100 pL to about 1 μ L, still more preferably from about 10 nL to about 1 μ L.

The use of discrete droplets for on-chip processing instead of continuous flows provides several important advantages. Since sample fluid need not be expended for priming of channels or pumps virtually all of the sample fluid can be used for analysis and very small volumes of sample (e.g., less than about 100 μL or less than about 50 μL or less than about 25 μL) can be analyzed. The same advantages apply to the use of reagents where reducing the volume of reagents consumed has the advantage of reducing the cost of the analysis. The use of discrete small-volume droplets also permits a large number of reactions to be performed in a small footprint (e.g. greater than 10 per cm^2 or greater than 100 per cm^2 or greater 1,000 per cm^2 or greater than 10,000 per cm^2).

Various components of the invention may be included as components of the droplet microactuator. In fact, an entire system of the invention may be provided as an integrated droplet microactuator. In some embodiments, the droplet microactuator includes various sensors and means for electronically coupling the sensors to external circuitry. In other embodiments, the droplet microactuator includes heaters and/or magnetic field generating elements and means for coupling such elements to external circuitry. Further, a droplet microactuator including any one or more of the reagents described herein in a reservoir or in droplet form is also an aspect of the invention.

Optical windows can be patterned in the electrodes to enhance the capability of performing optical detection on the chip. Where the electrode is formed in an opaque material on a transparent substrate, a window in the electrode can be created permit light to pass through the substrate. Alternatively, when the electrode material is transparent, a mask can be created to eliminate stray light. Additionally, the opening can be patterned as a diffraction grating. Adaptive optical windows can be created as well, using a second electrowetting layer. For example, opaque oil (e.g. oil dyed black) can be used with a transparent droplet to create a temporary and movable optical window.

8.8.2 Droplet Microactuator Fabrication

Droplet microactuators can be made using standard microfabrication techniques commonly used to create conductive interconnect structures on microdroplet microactuators and/or using printed-circuit board (PCB) manufacturing technology. Suitable PCB techniques include those described in U.S. Patent Application No. 11/343,284, entitled "Apparatuses and Methods for Manipulating Droplets on a Printed

Circuit Board,” filed on January 30, 2006, the entire disclosure of which is incorporated herein by reference. These techniques permit the droplet microactuator to be manufactured in bulk at very low cost. Low cost manufacture enables economical production of droplet microactuators, even for use as one-use disposables. Thus, the invention provides a method in which droplet microactuators are supplied to users as components of disposable cartridges for use in systems of the invention.

Designs can also be implemented on glass or silicon using conventional microlithography techniques with the capability of producing much smaller features than are typical in a PCB process. Even, for example, for a 1,572,864-reservoir droplet microactuator with 70 μm reservoir spacing and 3 fL reservoir volume, the minimum required lithographic feature size is $\sim 0.5 \mu\text{m}$ which is well within the capabilities of conventional microlithographic techniques currently used in the semiconductor industry.

Because the chip can be loaded directly using manual or robotic pipette dispensers and can be analyzed using standard plate reading equipment, it will easily integrate into existing laboratory work flows. This is a significant advantage over other microfluidic approaches which may require adaptation of the assays to continuous-flow format or specialized equipment for sample handling and read-out.

8.8.3 Cartridge

In some embodiments, the invention includes a cartridge for coupling to the droplet microactuator. It will be appreciated that a cartridge, while not necessary to the operation of the invention, may be convenient in some circumstances. When present, the cartridge may include a means for electrically coupling the path or network of the droplet microactuator to a processor, e.g., a processor of a droplet microactuator system of the invention. In this embodiment, the electrical connection is: electrodes---cartridge---processor, where there may be additional elements between the three. In another embodiment, the cartridge may include means for physically coupling to the droplet microactuator. In this embodiment, the electrical connection may be: electrodes---processor---cartridge. Alternatively, the cartridge may lack electrical components altogether.

When present, the cartridge may include reservoirs for one or more reagents, e.g., pre-loaded reagents. The droplet microactuator may be configured so that a fluid path may be established between the cartridge reservoirs and the interior of the droplet microactuator for flowing reagents, sample and/or filler fluid from the cartridge onto the droplet microactuator. For example, preloaded cartridge reservoirs may be dispensed into the droplet microactuator prior to, during, or after coupling of the cartridge to the analyzer. The cartridge may be sealed, self-contained and/or disposable. It may be supplied with or without a droplet microactuator. Such cartridges can be used to ensure repeatable assay conditions, permit safe handling and disposal of infectious or hazardous material, and/or reduce cross-contamination between runs. The cartridge may, for example, include a machined plastic part. It may be affixed to and provided in combination with the droplet microactuator.

The cartridge materials are selected to provide storage of reagents without degradation or contamination of the reagents. Moreover, they should be selected to provide reliable operation at elevated temperature and to ensure compatibility with the real-time chemistry. They may, for example, include molded plastic components. In some embodiments, sealed, disposable test cartridges enhance operator safety and facilitate safe disposal.

Various components of the droplet microactuator system may be included on the cartridge. For example, the top-plate, which encloses the interior space of the droplet microactuator, may be provided as a component of the cartridge. Various sensors may also be included as components of the cartridge.

8.8.4 Filler Fluid

The droplet microactuator of the invention includes one or more free (i.e., fluid-fluid) interfaces. Examples include a liquid-liquid or liquid-gas interface. Typically chemistry is performed in the primary (droplet) phase, and the secondary phase serves as a filler fluid separating the droplets from each other. The secondary phase can, for example, be a liquid, gel, and/or a gas. Where the secondary phase includes a liquid, the liquid is sufficiently immiscible with the primary liquid phase to permit the droplet microactuator to conduct one of more droplet operations.

It should also be noted that the droplet microactuator may include more than two phases. For example, in one embodiment the droplet microactuator operates based on an aqueous-oil-air three-phase system. In a related environment, the droplet microactuator may operate based on an aqueous-first oil-second oil three-phase system, such as a system including an aqueous droplet surrounded by silicon oil, which is in turn surrounded by a fluorosilicon oil. Generally, three-phase systems will include three components which are mutually immiscible or substantially immiscible.

In another embodiment, oil or another immiscible liquid may be used as a droplet encapsulant for electrowetting. For example, a droplet can be encapsulated in a shell of oil by moving the droplet through an air/oil interface. Each droplet would then have its own local bath of oil with the space between encapsulated droplets filled with either air or a third immiscible liquid. Among other advantages, this approach is useful for minimizing the transfer of material between droplets in the system by partitioning into the oil phase while retaining the advantageous properties of the oil with respect to evaporation and fouling of the surface. This approach may also be used to facilitate electrowetting of non-electrowettable liquids which are immiscible with electrowettable liquids. In a specific embodiment of this concept the immiscible liquid can be chosen to be crosslinkable (by UV, heat, moisture or chemically) to create capsules of liquids with solid shells, for drug delivery synthesis applications.

Further, in some applications it may be desirable or necessary to perform certain operations in an immiscible liquid, such as oil, and others in air. The invention includes hybrid systems in which droplet manipulation is performed both in air and in an immiscible liquid filler fluid such as oil. For example, samples may be processed under oil and then transported into an air-medium portion for evaporation for subsequent analysis, for example, by MS. Conversely, a sample could be collected in air and then processed with droplets under oil. Thus, the droplet microactuator may include a transport path for moving droplets from a droplet microactuator surface in a space filled with filler fluid to a droplet microactuator open to the atmosphere or including a gaseous filler fluid.

The filler fluid may be any fluid in which the droplet microactuator can, under the right conditions, conduct one or more droplet operations. It should be noted that certain filler fluids may be solids or highly viscous fluids under certain conditions, e.g., during

transport, while they are transformed into fluids for operation, e.g., by heating. The filler fluid may be a liquid or gas during operation of the droplet microactuator. Examples of suitable liquid filler fluids include, without limitation, silicone oils; fluorosilicone oils; hydrocarbons, including for example, alkanes, such as decane, undecane, dodecane, tridecane, tetradecane, pentadecane, hexadecane; aliphatic and aromatic alkanes such as dodecane, hexadecane, and cyclohexane, hydrocarbon oils, mineral oils, paraffin oils; halogenated oils, such as fluorocarbons and perfluorocarbons (e.g. 3M Fluorinert liquids); mixtures of any of the foregoing oils in the same class; mixtures of any of the foregoing oils in different classes. Examples of suitable gas filler fluids include, without limitation, air, argon, nitrogen, carbon dioxide, oxygen, humidified air, any inert gases. In one embodiment, the primary phase is an aqueous solution, and the secondary phase is air or an oil which is relatively immiscible with water. In another embodiment, the filler fluid includes a gas that fills the space between the plates surrounding the droplets. A preferred filler fluid is low-viscosity oil, such as silicone oil. Other suitable fluids are described in U.S. Patent Application No. 11/639,594, entitled "Filler Fluids for Droplet Operations" filed on December 15, 2006, the entire disclosure of which is incorporated herein by reference. The fluid may be selected to prevent any significant evaporation of the droplets.

The phases of the fluids used in the protocols of the invention may be selected to facilitate protocols of the invention without undue formation of bubbles, loss of reagent to the filler fluid, and/or adherence of reagent to the droplet microactuator surface.

In certain embodiments of the invention the filler fluid may be selected to reduce or prevent evaporation of sample, reagent, or other droplets utilized in the protocols of the invention. The filler fluid may be selected to prevent sample, reagent, or other droplets utilized in the protocols of the invention from evaporating and becoming too small for further effective manipulation. Similarly, the filler fluid can be selected to prevent evaporation of sample, reagent, or other droplets utilized in the protocols of the invention from detrimentally concentrating species within the droplets in a manner which results in an unduly adverse affect on the intended use of the droplet. Moreover, the filler fluid may be selected to reduce or prevent transport of material from sample, reagent, or other droplets utilized in the protocols of the invention across the phase boundary to maintain droplet volume and/or ensure reliable microfluidic operation and/or assay results. Miscibility between phases can sometimes result in shrinking (or swelling) of the droplet

phase. To prevent or reduce this problem, one or more phases of the system may be saturated with the equilibrium concentration of another phase to reduce shrinking or swelling. Thus, for example, the filler fluid may be saturated with the equilibrium concentration of the solvent for sample, reagent, or other droplets utilized in the protocols of the invention, and/or one or more of the sample, reagent, and/or other droplets utilized in the protocols of the invention may be saturated with the equilibrium concentration of the filler fluid.

In some embodiments, a liquid filler fluid is selected to minimize contact between the droplet and droplet microactuator surfaces. That is, a film of liquid may exist between the droplet and surface which prevents material within the droplet from coming into contact with and adhering to the coated surface. This approach helps to prevent fouling of the surface and related interference with droplet transport. For example, it has been observed that high concentrations of certain proteins in water droplets readily stick to certain hydrophobic surfaces spoiling the hydrophobic nature of these surfaces; whereas, the same droplets can be moved across the same surfaces without appreciable adhesion of proteins if bathed in an oil which minimizes contact between the two surfaces. This approach may also help to avoid cross-contamination between droplets caused by deposition of material from one droplet which is then picked up by a second droplet. In a similar embodiment, a film between the droplet and droplet microactuator surface can be used to lubricate the droplet by preventing friction-like physical interactions between the droplet and surface during droplet operations.

In one embodiment, the invention provides a thin coating of a liquid filler fluid layer in an otherwise gas filled system. For example, the invention provides a microfluidic system including an open or enclosed system including a thin layer of filler fluid, such as oil, layered on a droplet microactuator surface, wherein the system is otherwise filled with a gas. The oil is of sufficient thickness to provide lubrication and contamination of droplet microactuator surfaces and contamination of droplets via droplet microactuator surfaces. Preferably the oil is selected to minimize transport of material between the droplet and oil phases. One advantage of this approach is reduction of carry-over in the droplet microactuator. The surface may in some embodiments be treated by coating it with the filler fluid while operating in air. This approach is also useful for loading operations as a means to retain the lubricating effect of oil while avoiding trapping of oil bubbles in the bulk filler fluid.

5 Treatment of a Teflon AF surface with silicone oil can provide some of the lubrication benefit of silicone oil filler fluid even when operating in air. This approach can be used to prime the droplet microactuator with a lubricating layer of oil, followed by replacement with air to allow samples to be loaded without introduction of bubbles, followed by re-introduction of oil to prevent evaporation of the samples. Thus the benefits of each kind of system are available depending on the type of microfluidic processing to be carried out.

10 In another embodiment, the filler fluid can be completely exchanged at different steps within a protocol. For example, a gas filler fluid can be introduced during sample loading to prevent trapping of air bubbles and then a liquid filler fluid can be pumped in to prevent evaporation of the liquid. Different types of filler fluid can be pumped into or out of the system depending on the particular assay steps to be performed.

15 In yet another embodiment, multiple filler fluids can be used within a single system. For example, a droplet microactuator can be selected to have separate gas filled and liquid filled regions. Operations on certain types of droplets can be segregated between the different filler fluid regions.

20 The filler fluid may be selected based on its refractive index to either match the droplet to prevent refraction of light passing through or near the droplet. Alternatively the filler fluid may be selected with a refractive index that differs from the droplet to provide contrast for certain types of optical measurements or optical manipulations. A filler fluid may be chosen to have a lower index of refraction than the primary liquid so that light can be transmitted through the primary liquid by total internal reflection. The primary phase can include highly elongated droplets which can serve as "light pipes" to convey light between two locations, e.g. to facilitate optical analyses.

25 The filler fluid may be selected based on its color to facilitate direct or indirect visualization of the droplet, e.g., by providing contrast between the sample, reagent, and/or other droplets used in the protocols of the invention and the filler fluid. This approach can enhance visualization of the different phases, for example to distinguish droplets from filler fluid or from air bubbles. In optical applications, the differential absorbance of the two phases can be used to modulate the color of light passing through the system. As another example, in applications where fluorescence measurements are made within droplets it may be desirable for the oil to include molecules, such as dyes, that

30

absorb the emitted wavelength of light to minimize cross-talk between reactions occurring in adjacent droplets.

5 The filler fluid may be selected to have particular thermal properties that can either thermally insulate the droplets or conduct heat away from the droplets. For example, in the amplification protocols of the invention, a thermally conductive or low heat capacity filler fluid may be desirable to permit rapid changes in temperature. For applications where a steady temperature is required, a thermally insulating or high heat capacity filler fluid can be used to provide temperature stability.

10 The filler fluid may be selected to undergo a phase change upon presentation of an appropriate stimulus. For example, a wax-like filler fluid (e.g. paraffin wax or octadecane) can be used where the filler fluid is changed from solid to liquid form by application of heat. Lowering the temperature would return the filler fluid to a solid so that droplets would be contained within a solid matrix. Encapsulation of the liquid phase within a solid may facilitate storage and handling of the sample, reagent, and/or other
15 droplets utilized in the protocols of the invention and/or allow for safe and convenient disposal of the materials following use of the droplet microactuator. The filler fluid can be stored as a solid on the droplet microactuator, in a cartridge-based reservoir, or elsewhere, and heated to permit the fluid to flow into and fill the droplet microactuator. Or the immiscible filler fluid can be selected to be crosslinkable (by UV, heat, moisture
20 or chemically) to create capsules of liquids within a solid shell.

The filler fluid may be selected to have particular gas permeability or saturation properties. In certain applications a reaction occurring inside the droplet may consume oxygen or other gas which may need to be replenished by gas contained within or transported through the filler fluid. For example, some fluorinated oils have useful gas
25 permeability properties for such applications. Alternatively, the filler fluid may be selected to exclude certain gases from the droplet, for example to maintain anaerobic conditions within the droplet. The filler fluid may be selected to have a certain degree of miscibility or partitioning into the droplet phase. Usually, complete or substantially complete lack of miscibility between the droplet and filler fluid is desired, but some
30 applications may benefit from some limited degree of miscibility between the phases or partitioning of particular molecules between the phases, e.g., liquid-liquid extraction applications. In certain applications where dissolved gases in the filler fluid may be

problematic, a means for degassing the filler fluid prior to or during use may need to be provided. For example, filler fluid may be degassed by incubation under vacuum, heating, sparging or by centrifugation.

5 The filler fluid may be selected to have a particular surface or interfacial tension with the droplet phase or with the droplet microactuator surfaces. Surfactants can be added to the filler fluid to stabilize liquid films that may be present between the droplet and solid phases. Examples of suitable surfactants include nonionic low HLB (hydrophile-lipophile balanced) surfactant. The HLB is preferably less than about 10 or less than about 5. Suitable examples include: Triton X-15 (HLB=4.9); Span 85 (HLB 1.8); Span 10 65 (2.1); Span 83 (3.7); Span 80 (4.3); Span 60 (4.7); and fluorinated surfactants.

Surfactants are preferably selected and provided in an amount which (1) results in more droplet operations on the droplet microactuator as compared to corresponding droplet microactuator without the surfactant; or (2) makes one or more droplet operations possible on the droplet microactuator as compared to corresponding droplet microactuator without the surfactant; or (3) makes one or more droplet operations more reliable on the droplet microactuator as compared to corresponding droplet microactuator without the surfactant. In a related example, surfactants are preferably selected and provided in an amount which makes one or more droplet operations possible or more reliable for droplets including one or more specific reagents or mixtures on the droplet microactuator as compared to droplet operations for the same droplets including one or more specific reagents or mixtures on a corresponding droplet microactuator without the surfactant. In another related example, surfactants are preferably selected and provided in an amount which makes one or more droplet operations possible or more reliable for one or more droplets including amphiphilic molecules on the droplet microactuator as compared to droplet operations for the same droplets including amphiphilic molecules on a corresponding droplet microactuator without the surfactant.

In a preferred embodiment, the surfactant is added to the filler fluid in an amount which ranges from about 0.001 to about 10 % w/w, or about 0.001 to about 1 % w/w, or about 0.001 to about 0.1 % w/w. For example, in one embodiment the filler fluid is 2 cSt silicone oil and the surfactant is Triton X-15 in an amount which ranges from about 0.001 to about 10 % w/w, or about 0.001 to about 1 % w/w, or about 0.001 to about 0.1 % w/w. The solid-liquid interfacial tension may be adjusted to control the wetting of the filler

fluid on the droplet microactuator surfaces, for example, to control the formation, thickness or behavior of thin films of the filler fluid between the droplet and droplet microactuator surfaces or to control the wetting behavior of the fluid when filling or emptying it from the droplet microactuator.

5 By doping filler fluid with surfactant, it was discovered that it is possible to increase the concentrations of compatible protein solutions by more than 3 orders of magnitude, from mg/L to mg/mL. The inventors were able to reliably dispense and transport 25 nL droplets of 75 mg/mL lysozyme solution using the new filler fluid. For example, the filler fluid may be silicone oil doped with a surfactant, such as Triton X-15. Preferably
10 the surfactant is a lipophilic surfactant. In one embodiment, 0.1% (w/w) Triton X-15, a lipophilic surfactant, was added to the oil so that high concentrations protein droplets could be formed or dispensed from on-chip reservoirs. Droplet transport for all compatible fluids is fast (typically about 3-10 cm/sec) and reliable (>25,000 operations). In one embodiment, the filler fluid includes a surfactant dopant in an amount which
15 results in an increase in the concentration of a protein that can be reliably dispensed on the droplet microactuator.

The filler fluid may be selected to have a particular viscosity or volatility. For example, a low viscosity liquid (e.g. 0.65 cSt. Silicone oil) facilitates transport of droplets while a low volatility filler fluid (e.g., 2, 5 or 10 cSt. Silicone oil) may be desirable to prevent loss
20 of filler fluid by evaporation. In some applications, evaporation of the filler fluid can be desired, so a low volatility filter fluid may be selected. The filler fluid may be selected to have a particular viscosity dependence on temperature, since the viscosity of the filler fluid affects the fluid dynamics and the temperature on the droplet microactuator may vary.

25 The filler fluid may be selected to have particular electrical properties. For example, certain applications including electrowetting favor the use of a filler fluid that is non-conductive (e.g., silicone oil). Or the dielectric permittivity can be selected to control the coupling of electrical energy into the system from external electrodes. In certain applications a non-conductive filler fluid can be employed as an electrical insulator or
30 dielectric in which the droplet floats just above the electrodes without physically contacting them. For example, in an electrowetting system a layer of filler fluid (e.g.,

silicone oil) between the droplet and electrode can be used to provide electrostatic control of the droplet. Filler fluids may be deionized to reduce conductivity.

5 The filler fluid may be selected to have a particular density relative to the droplet phase. A difference in density between the two phases can be used to control or exploit buoyancy forces acting upon the droplets. Examples of two-phase systems useful in this aspect of the invention include water/silicone oil, water/flourinert, and water/fluorosilicone oil. When one phase is buoyant, then that effect can be exploited in a vertical configuration as a means to transport one phase through the other. For example, a waste or collection well can exist at the top or bottom of the droplet microactuator where
10 droplets are delivered to that reservoir by simply releasing them at an appropriate point and allowing them to float or sink to the target destination. Such an approach may be suitable for use in removing reactant from a droplet microactuator, e.g. removing fluid containing amplified nucleic acid for use in other processes. Density differences can also be used as a means to control or engineer contact between the droplets and droplet
15 microactuator surfaces. For example, a droplet not normally contacting a top-plate can be released to sink or float to that surface to contact it. Density differences and buoyancy effects can also be exploited for sensing applications in which the movement of droplets is detected and related to a change in position, orientation or acceleration.

20 The filler fluid is selected for material compatibility with the droplet microactuator surfaces. For example, certain filler fluids can etch, dissolve, contaminate, absorb into or otherwise be incompatible with certain droplet microactuator materials. For example, fluorinated hydrocarbons, such as Fluorinert, may be incompatible with Teflon AF or Cytop surfaces because of their tendency to dissolve these materials, while silicone oils may be incompatible with PDMS surfaces due to the tendency of these materials to
25 dissolve each other.

The invention may include means for controlling the introduction or circulation of the filler fluid within the droplet microactuator, cartridge and/or system. In one mode of operation the filler fluid is injected once during the initialization of droplet microactuator operation. The filler fluid may be provided from an external source using a syringe,
30 dropper, pipettor, capillary, tube or other means. Alternatively, the filler fluid may be provided from a reservoir internal to the droplet microactuator assembly or cartridge. As

an example, the fluid can be contained within a sealed pouch which is punctured or compressed to transfer the liquid into the droplet microactuator.

In another mode of operation a means can be provided for multiple introductions or recirculation of one or more filler fluids within the droplet microactuator. A secondary fluid-handling system can be provided to inject and to remove fluid from within the droplet microactuator. Pressure, gravity or other means such as the use of thermal gradients can be used to transport the filler fluid into or out of the droplet microactuator. Such a system can, for example, be used for the following purposes:

- (1) To replenish filler fluid lost to evaporation or leakage over time. A slow steady flow or periodic injection of filler fluid can be employed to make up for any loss of filler fluid volume.
- (2) To provide "clean" filler fluid either continually or periodically to reduce contamination between droplets. The filler fluid can be cleaned either by completely replacing it or by circulating it through a filter or bed of absorbent material selected to remove contaminants.
- (3) To provide a means for transporting droplets to waste. For example, at the end of an assay, droplets can be released and allowed to flow with the filler fluid to the outlet providing a means to "flush" the droplet microactuator. Flushing the droplet microactuator can be performed to reset the status of the droplet microactuator in preparation to perform additional assays.
- (4) To exchange the filler fluid when different fluids may be desired for certain steps, for example to replace oil with air to allow drying of droplets, or to replace one oil with a different oil.
- (5) To provide a means of controlling the temperature of the droplets by heating or cooling the fluid as it is circulated through the droplet microactuator. The temperature of the filler fluid entering and leaving the droplet microactuator can be directly measured and the temperature and flow rate of the filler fluid can be adjusted to provide optimal temperature control inside the droplet microactuator.

Local regions of filler fluid or even individual units of filler fluid for each droplet can be used. For example aqueous droplets can be encapsulated in an individual shell of fluid, such as oil, which moves along with that droplet. Each such droplet would then have its own local fluid bath with the space between encapsulated droplets filled with third immiscible liquid such as air or fluorosilicone oil. This approach can be used to minimize the transfer of material between droplets in the system by partitioning into the oil phase while retaining the advantageous properties of the oil with respect to evaporation and fouling of the surface. The shells of oil can be created by simply moving the droplet through an oil interface, pinching off a unit of oil as the droplet creates a bulge along the interface.

Hybrid systems can be implemented in which different regions of the droplet microactuator are filled with different fluids. For example, samples can be processed under oil and then transported into an air portion to be evaporated for subsequent analysis by MS. Conversely, a sample can be collected in air and then processed under oil.

Magnetically responsive beads can be used to move material between oil and water phases on a droplet microactuator. Generally, water-soluble compounds or materials tend to remain within the droplets, unable to cross the oil-water meniscus in significant quantities, and oil-soluble compounds or materials remain in the lipophilic filler fluid. When the material is attached to magnetically responsive beads, a magnetic field may be used to move the beads and attached material across the oil-water boundary. The beads need to be selected such that they have sufficient affinity for oil and water so that they can readily cross the meniscus. This operation is useful for drying or concentrating materials and can also be used to facilitate washing and/or dilution. For example, material bound to a magnetically responsive bead can be removed from one droplet and transferred by way of the filler fluid to another droplet.

Filler fluid can be circulated through the droplet microactuator to reduce contamination during and/or between runs. Filler fluid can be continually or periodically flowed through the droplet microactuator, so that fresh filler fluid is constantly supplied to the droplet microactuator. In addition to removing contaminants contaminated oil, this technique could be used at the end of a run to clear droplets from the array by removing the voltage so that droplets are released and flow with the oil to an exterior of the droplet microactuator and/or into a waste reservoir.

8.8.5 Droplet Microactuator Loading

The droplet microactuator as contemplated herein generally includes one or more input ports for the introduction of one or more filler fluids, reagents and/or samples (e.g., reagents and/or samples for conducting protocols and/or assays as described elsewhere herein) into the droplet microactuator. In some embodiments, samples or reagents are loaded via the input ports using conventional robotics. In one alternative embodiment, droplets of sample or reagent are separated by plugs of oil in a long pre-loaded capillary (e.g., a glass capillary) which when connected to the droplet microactuator allows droplets of sample or reagent to be captured and routed on the droplet microactuator as they are pumped out of the capillary into the input port. Another loading technique involves pre-stamping reagents onto the droplet microactuator and allowing them to dry, e.g., using a high-speed reagent stamping or printing process. Yet another approach involves the use of a direct plate-to-droplet microactuator interface in which the contents of plates, e.g., 1536 or 384 or 96 well plates, are transported onto the droplet microactuator in parallel by using pressure to force the contents through input ports aligned with wells. Loading hardware may in some embodiments be electronically coupled to and controlled by the controller.

The droplet microactuator can be associated with or coupled with a fluidic input module for loading and storage of sample and/or reagent. For example, a basic input module allows samples to be loaded using a pipettor or other device. The system may be programmed to subdivide and dispense input fluid as discrete droplets which can be transported on the control electrodes networks or pathways.

8.8.6 Reservoirs

The droplet microactuator as contemplated herein may include various reservoirs (sometimes referred to herein as "wells"), such as input reservoirs and/or processing reservoirs.

8.8.6.1 Input Reservoirs

In some embodiments, the droplet microactuator includes one or more input reservoirs (also referred to as "loading wells") in fluid communication with one or more input ports, typically in direct fluid communication with the input ports. The input reservoir(s) serve

as reservoirs for storage of bulk source material (e.g. reagents or samples) for dispensing droplets (e.g. reagent droplets or sample droplets). Thus, the input reservoir(s) may, for example, serve as sample wells or reagent wells.

5 The input reservoirs generally include one or more well reservoirs defining an interior space and an opening. The interior space defined by the well walls is at least partially isolated by the well walls from the remainder of the interior of the droplet microactuator. The reservoir may be adjacent (in any direction, e.g., vertically or laterally) to a port suitable for introduction of fluid from an exterior of the droplet microactuator into the input reservoir. One or more openings in the reservoir walls may be provided to enable
10 fluid communication with the interior volume of the droplet microactuator for dispensing of droplets into this interior volume. The opening(s) may permit fluid to flow or be transported into the interior volume of the droplet microactuator onto the path or network of electrodes. Input reservoirs may also include one or more vents for permitting displacement of filler fluid from the input reservoir as fluid is introduced into or removed
15 from the well via the port or the opening.

The input reservoirs may further include one or more planar control electrodes in a top or bottom plate adjacent to or within the space defined by the well walls. The planar electrodes can be electronically coupled to and controlled by the controller. In a preferred embodiment, the planar electrode has two or more branches or rays, such that activation
20 of the control electrode during droplet dispensing in the presence of a fluid exerts a "pull" on the fluid in a direction which is generally opposite to the direction of droplet dispensing. In some cases, the shape of the electrode results in a multi-vector pull having a mean vector which has a direction generally opposite to the direction of the droplet being dispensed.

25 Well walls may, for example, be formed by protrusions from the top or bottom plates, and/or may be formed by deposition of a wall-forming material on a surface of the top or bottom plate. For example, well walls may be formed from a soldermask material or polymeric gasket material deposited and patterned on the surface. In some embodiments a source of continuous or semi-continuous sample or reagent flow is coupled in fluid
30 communication with one or more of the input ports.

5 It should be noted that while droplet dispensing may be conducted from defined reservoirs, in some embodiments, droplet dispensing is conducted without the use of physically defined reservoirs. Dispensing may proceed from source droplet which is confined during droplet dispensing, e.g., by electrowetting forces or by hydrophilic surfaces.

8.8.6.2 Processing Reservoirs

10 The droplet microactuator may also include one or more processing wells, areas, or reservoirs. These reservoirs serve as a location for executing various droplet processing steps, such as mixing, heating, incubating, cooling, diluting, titrating, and the like. The droplet microactuator includes one or more paths or networks of control electrodes sufficient to transport droplets from the one or more input ports to the one or more processing reservoirs. In some cases the processing reservoirs are simply components or sections of these paths or networks. In other embodiments, the processing reservoirs are defined processing reservoirs. Such reservoirs may, for example, be structured generally
15 in the same manner as the input reservoirs described above. However, the processing reservoirs are typically not in direct fluid communication with the input ports, i.e., droplet transport along the one or more paths or networks of control electrodes is required add reagent or sample to the processing reservoir(s). In some cases, the processing reservoirs include a path or network of reservoirs therein to permit droplet operations within the processing reservoirs. Other configurations of the reservoirs or wells of various aspects
20 of the present invention are discussed hereinabove with reference to Section 8.4.1.

Mixing or dilution ratios can be established programmably by controlling the number and distribution of constituent droplets delivered to each reservoir. Furthermore, liquid which has been mixed within a reservoir may be subsequently dispensed from that reservoir in
25 the form of unit-sized droplets for transport to another reservoir, for example, to perform serial dilution assays.

8.8.7 Thermal Control

30 The droplet microactuator of the invention may include a means for controlling the temperature of the droplet microactuator or a region of the droplet microactuator. Among other things, thermal control is useful for various protocols requiring heating or cooling

steps. Examples include amplification protocols requiring thermal cycling and various assays that require incubation steps.

8.8.7.1 Thermal Control Designs

5 In general, thermal control may be provided in three ways: (1) thermal control of the entire droplet microactuator; (2) thermal control of a region of a droplet microactuator using a heater that is in contact with or in proximity to the controlled region; and (3) thermal control of a region of the droplet microactuator using a heater that is integrated into the droplet microactuator (e.g., in the substrate comprising the path or array of electrodes and/or in a top plate of the droplet microactuator, when present).
10 Combinations of the foregoing approaches are also possible.

In an integrated heater approach, temperature zones can be created and controlled using thermal control systems directly integrated into the droplet microactuator. Integration of thermal control through thin-film heating elements fabricated directly on the droplet microactuator is also useful to maximize the speed, throughput and quality of
15 amplification reactions on the droplet microactuator. Due to their small thermal mass, droplets can be thermally cycled extremely rapidly. Thermal control is enhanced by locating the heating elements proximate to the droplets and reducing the parasitic thermal losses between the heater and the droplet. Heating elements can be integrated into the top plate and/or bottom plate of the droplet microactuator.

20 Integrating heating elements onto the droplet microactuator also enables the use of multiple distinct thermal zones within the droplet microactuator. This permits multiple steps in an analysis, such as sample preparation and thermal cycling, requiring different temperatures to be performed simultaneously on different portions of the droplet microactuator. Droplets can be physically transported or “shuttled” between zones of
25 different fixed temperatures to perform the thermal cycling aspects of the amplification reaction. This approach can produce even faster reactions, since heating and cooling of the entire thermal zones is no longer rate-limiting. Instead, heating and cooling rates are determined by the time required to transport the droplets between the zones and the time required for the droplet temperature to equilibrate to the temperature of the zone once it
30 arrives within the zone, both of which are expected to be very fast. A further advantage is that reaction steps can be “queued” rather than “batched” to permit greater operational

flexibility. For example, discrete samples can be continuously fed into the droplet microactuator rather than being delivered at a single point in time.

5 Droplets may be thermally cycled in batch mode using a single heater or in flow-through mode by circulating the droplets through distinct temperature zones created by the heating elements. The essential difference between batch and flow-through modes is that in batch mode thermal control is effected by varying the temperature of the heater while in flow-through mode, thermal cycling is effected by transporting the droplets among distinct constant temperature zones. In the "batch" method a single integrated thin-film heater on the droplet microactuator was used to thermally cycle static droplets located within the heater zone. In the "flow-through" method, two distinct fixed temperature zones were created on the droplet microactuator and thermal cycling was performed by shuttling the droplets between the two zones.

15 In the "batch" case, the thermal mass of the heater itself as well as thermal losses may be minimized through the use of thin-film heaters placed directly adjacent to the droplets. Because the thermal masses, including the droplet itself, are so small, rapid temperature changes can be effected. Passive cooling (in filler fluid) is also rapid because the total energy input into the system is extremely small compared to the total thermal mass.

20 For "flow-through" heating, a larger thermal mass is desirable because it helps to stabilize the temperature while a slower ramp rate is tolerable because the heater temperature is not varied once it reaches its set point. A flow-through system can, for example, be implemented using block heaters external to the droplet microactuator which were more accurate and easier to control than thin-film heaters although, in principle either type of heater could be used to implement either method.

25 In another embodiment, temperature is controlled by flowing or recirculating heated filler fluid through the chip and around the droplets.

The droplet microactuator layout is scalable, such that a droplet microactuator may include a few as one heating zone up to tens, hundreds or more heating zones.

8.8.7.2 Heater Types

Heaters may be formed using thin conductive films. Examples of suitable thin films include Pt heater wires and transparent indium-tin-oxide (ITO). ITO provides better visualization of the droplets for real-time observation. A remotely placed conventional thermocouple (TC) for temperature regulation can also be used. In one embodiment, tiny metal (e.g., copper) vias in the PCB substrate are used to create tight thermal junctions between the liquid and the remote TC. Further, sample temperature can be determined by monitoring the copper via using a surface mount thermistor or an infrared sensor. One advantage of using a thermistor is that they are small enough (2 x 2 mm) to be soldered directly on the droplet microactuator, while an advantage of using IR is that it is non-contact method which would simplify the interfacing. Because the thermal conductivity of copper is at least 700 times greater than the FR-4 substrate (350 - 390 W/m·K versus 0.3-0.5 W/m·K) the temperature of a Cu via will accurately represent the temperature inside the liquid. Heaters may be integrated on the bottom and/or top (when present) plate of the droplet microactuator and on the bottom and/or top surface of either plate, or integrated within the structure of either plate.

In one flow-through embodiment, reduced thermal gradients can be provided by using heaters to create a continuous temperature gradient across the droplet microactuator (e.g., from 100 to 50 °C). The use of a continuous gradient will eliminate the need to overcome the steep temperature gradients found along the edge of the heater blocks. A controlled temperature gradient would also significantly enhance the functionality of the device by allowing protocols with arbitrary numbers of temperature points to be implemented. Furthermore, each reaction can be performed with a custom thermal protocol while only the temperatures of the two or more blocks would need to be thermally regulated. The droplets will be transported to and held at the appropriate location between the heaters to achieve a target temperature. The fluorescence of the droplets can be imaged using a fluorescence sensor as they are transported over a detection spot. The temperature of the upper and lower target temperatures can be varied by changing the location of the droplets.

In some embodiments, heaters located above the droplets may obscure the droplets thus interfering with real-time optical measurements. In such cases, the droplets can be transported out from underneath the heaters to a location which is preferred for optical detection (i.e. a detection spot). Droplets may be periodically transported out from

underneath the heaters to a detection spot on the droplet microactuator detection purposes, e.g. detection by fluorescence quantitation. Droplets may be routed into proximity with a sensor while cycling them from one temperature zone to another.

8.8.8 Detection

5 The droplet microactuator systems as contemplated herein may include on-chip and/or off-chip mechanisms for analyzing droplets. For example, the droplet microactuator may include one or more detection methods such as amperometry, potentiometry, conductometry, absorbance, chemiluminescence, and fluorescence. The droplet manipulation module and the detection module may in some embodiments be decoupled
10 by building them on separate substrates. Alternatively, the droplet microactuator may incorporate detection components. Thus, for example, the droplet microactuator may include one or more of the following, on-chip or off-chip: amperometry module arranged to measure current flowing through a droplet; potentiometry module including a measuring and a reference electrode arranged to measure equilibrium electrode potential
15 of a droplet; conductometry module arranged to measure conductivity of a droplet; absorbance module arranged to measure energy or light absorbance of a droplet; chemiluminescence module designed to measure light emission by chemical species in a droplet; fluorescence module designed to excite and measure fluorescence of the species in a droplet. Off-chip detection modules may, for example, be provided in a cartridge that
20 comprises the chip and/or in an analyzer into which the cartridge or chip may be inserted.

Preferred detection methods are absorbance, electrochemical, fluorescence, and chemiluminescence. In one embodiment, two or more of these methods are accomplished on a single droplet microactuator. In another embodiment, the droplet microactuator includes one detection module, but the system is programmed to conduct more than one
25 test using the module. In this embodiment, processed sample droplets requiring testing are sequentially moved into position for testing. Thus, multiple samples are multiplexed over a detection spot where a single detector is used.

Preferred assays for inclusion on the droplet microactuator include colorimetric assays (e.g., for proteins), chemiluminescence assays (e.g., for enzymes), enzymatic and
30 electrochemical assays (e.g., for metabolites, electrolytes, and gases), and conductometric assays (e.g., for hematocrit on plasma and whole blood). In one embodiment, a single

droplet microactuator includes modules for 2, 3, 4, 5 or more different kinds of assays. In another embodiment, a single droplet microactuator cartridge includes on-chip and/or off-chip modules for 2, 3, 4, 5 or more different kinds of assays. In yet another embodiment, a single droplet microactuator system includes on-chip, off-chip, on-cartridge and/or off-cartridge modules for 2, 3, 4, 5 or more different kinds of assays.

8.8.9 Droplet Operations

The droplet microactuator may conduct various droplet operations with respect to a droplet. Examples include: loading a droplet into the droplet microactuator; dispensing one or more droplets from a source droplet; splitting, separating or dividing a droplet into two or more droplets; transporting a droplet from one location to another in any direction; merging or combining two or more droplets into a single droplet; diluting a droplet; mixing a droplet; agitating a droplet; deforming a droplet; retaining a droplet in position; incubating a droplet; heating a droplet; vaporizing a droplet; cooling a droplet; disposing of a droplet; transporting a droplet out of a droplet microactuator; other droplet operations described herein; and/or any combination of the foregoing.

Droplet dispensing refers to the process of aliquoting a larger volume of fluid into smaller droplets. Dispensing is usefully employed at the fluidic interface, the input reservoirs, and at processing reservoirs. Droplets may be formed by energizing electrodes adjacent to the fluid reservoir causing a "finger" of fluid to be extended from the reservoir. When the fluid front reaches the terminal electrode, the intermediate electrodes are de-energized causing the fluid to retract into the reservoir while leaving a newly-formed droplet on the terminal electrode. As previously noted, one or more electrodes in the reservoir may also be energized to assist in separating the droplet being dispensed from the bulk fluid. Because the droplet conforms to the shape of the electrode, which is fixed, excellent accuracy and precision are obtained. Droplet dispensing is controlled by the controller. In some embodiments the invention employs droplet dispensing structures and/or techniques described in U.S. Patent 6,911,132, entitled "Apparatus for Manipulating Droplets by Electrowetting-Based Techniques," issued on June 28, 2005 to Pamula et al.; U.S. Patent Application No. 11/343,284, entitled "Apparatuses and Methods for Manipulating Droplets on a Printed Circuit Board," filed on January 30, 2006; U.S. Patents 6,773,566, entitled "Electrostatic Actuators for Microfluidics and Methods for Using Same," issued on August 10, 2004 and 6,565,727, entitled "Actuators for

Microfluidics Without Moving Parts,” issued on January 24, 2000, both to Shenderov et al., the disclosures of which are incorporated herein by reference.

5 In some embodiments, droplet operations are mediated by electrowetting techniques. In other embodiments, droplet operations are mediated by electrophoresis techniques. In still other embodiments, droplet operations are mediated by electrowetting techniques and by electrophoresis techniques.

10 In one embodiment, separations may be performed using a combination of electrowetting and electrophoresis. Electrowetting microactuation can be used to create a channel to perform electrophoresis; to deliver a sample to the channel or capture a sample fraction from channel following an electrophoretic separation. For example, for forming a channel, electrowetting can be used to deform (stretch) a droplet of separation medium in a long thin shape followed. In some cases, the channel may be polymerized, e.g., using UV polymerization. In other cases, the channel may be formed by using droplet operations to add droplets into a physically confined microchannel. In a related
15 embodiment, the effective length of an electrophoresis channel can be increased by capturing the fraction of interest in a droplet at the output and then returning it to the input in a cyclical fashion. Using the same principle, a series of progressively finer separation can be performed. Separations may also be accomplished using multiple different separation mediums at the same time.

20 Droplet splitting or dividing of droplets generally involves separating a droplet into two or more sub-droplets. In some cases, the resulting droplets are relatively equal in size.

Transporting involves moving a droplet from one location to another in any direction. Droplets may be transported on a plane or in three dimensions. It will be appreciated that a variety of droplet operations, such as dispensing and/or splitting may include a
25 transporting element, in which one droplet is transported away from another droplet.

Merging involves combining two or more droplets into a single droplet. In some cases, droplets of relatively equal size are merged into each other. In other cases, a droplet may be merged into a larger droplet, e.g., combining droplet with a larger volume present in a reservoir.

Mixing a droplet involves various droplet manipulations, such as transporting or agitating, that result in a more homogenous distribution of components within the droplet. In one mixing embodiment, a droplet positioned over an electrowetting electrode is rapidly and cyclically deformed in place by activating and deactivating the electrode, inducing fluid currents within the droplet which facilitate mixing. Frequency-dependent effects such as mechanical resonances may be used to tune the quality and speed of mixing. Compared to techniques which require transport of droplets on a surface for mixing this approach minimizes the area required for mixing. This mixing scheme can be employed without the presence of a top plate. Due to space-saving advantage, this scheme could provide for simplified mixing in reaction wells since only one electrode is needed.

Reagents or samples from reservoirs may be dispensed as discrete droplets for transport to other locations on the droplet microactuator.

The invention includes droplet operations using droplets comprising beads. A variety of such operations are described elsewhere herein. In one embodiment, beads are used to conduct droplet operations on reagents that are prone to interfere with droplet operations. For example, certain proteins may be prone to bind to surfaces of a droplet microactuator and/or to partition into the filler fluid. Immobilizing such compounds on hydrophilic beads can be used to facilitate droplet operations using the compounds. The compounds can be bound to the beads, and the beads can be contained within a droplet which is subjected to droplet operations.

In one particular dispensing operation, coagulation is used to separate serum from whole blood. Whole blood is loaded onto the chip and combined with a droplet comprising a coagulating agent. Following coagulation, droplets are dispensed from the sample. Because cells and platelets are trapped in place, the liquid dispensed from the sample will contain only serum.

8.9 System

The various aspects of the present invention may also include systems which include the droplet microactuator coupled to a processor which may be programmed to control the droplet microactuator. Various input means, such as keyboards, switches and touch

screens, and various output means, such as display screens, output ports, and wireless transmitting devices, may also be included in electronic communication with the processor. The droplet microactuator may be presented as a component of a cartridge for insertion in an analyzer. The cartridge may include one or more pre-loaded reagents, which are dispensed into the droplet microactuator prior to, during, or after insertion of the cartridge into the analyzer.

Systems can be programmed to execute a wide variety of protocols involving any number of droplet manipulations. Multiple droplets can be independently and simultaneously manipulated on a single droplet microactuator. The capacity to independently manipulate multiple droplets in parallel enables execution of complex protocols as a series of basic microfluidic instructions. Moreover, droplet microactuators are scalable, enabling systems that control tens, hundreds, thousands or more parallel droplet manipulations per droplet microactuator chip. For example, at any one moment, up to a maximum of every control electrode on the droplet microactuator may be engaged in a droplet operation.

The system can be programmed to enable users to input instructions for the execution of protocols. Existing protocols may be monitored and adjusted according to user requirements. Complex protocols can be implemented in which the outcome of one or more steps determines the selection of one or more subsequent steps. For example, a droplet in which a certain measured result is positive may be transported for further processing, while a droplet in which a result is negative may be discarded, or vice versa.

Flexibility of operations in the systems of the invention is much greater, for example, than the flexibility of robotic systems, which would require a massive assembly of robotics, a huge facility, and thousands of times the amount of reagents to achieve anything near the massively parallel operations that are enabled by the droplet microactuator. Nevertheless, in some embodiments, robotics may be useful for droplet microactuator or cartridge placement, reagent loading, placement of detectors for external measurements of on-chip phenomena, and the like.

8.10 Kit

A further aspect of the invention is a kit including reagents, sample collection devices, and/or a droplet microactuator or cartridge for conducting the methods of the invention.

5 10 **Concluding Remarks**

The foregoing detailed description of embodiments refers to the accompanying drawings, which illustrate specific embodiments of the invention. Other embodiments having different structures and operations do not depart from the scope of the present invention.

10 This specification is divided into sections for the convenience of the reader only. Headings should not be construed as limiting of the scope of the invention.

It will be understood that various details of the present invention may be changed without departing from the scope of the present invention. Furthermore, the foregoing description is for the purpose of illustration only, and not for the purpose of limitation, as the present invention is defined by the claims as set forth hereinafter.

15

We claim:

1. A screening chip comprising:
 - (a) a port for introduction of one or more crystallization reagents and/or one or more protein solutions; and
 - (b) a substrate comprising:
 - (i) an array of two or more mixing wells; and
 - (ii) electric field mediated microfluidics for moving droplets comprising the crystallization reagents and protein solutions into the mixing wells.
2. The screening chip of claim 1 wherein two or more of the wells are pre-loaded with a variety of crystallization reagents.
3. A system comprising the screening chip of claim 1 wherein:
 - (a) the chip is loaded with:
 - (i) one or more dispensing wells comprising protein solution loaded therein; and
 - (ii) two or more mixing wells comprising crystallization droplets loaded therein; and
 - (b) the system is programmed to execute steps comprising:
 - (i) dispensing one or more sample droplets from the protein solution;
 - (ii) transporting one or more of such sample droplets to a mixing well;

- (iii) dispensing one or more reagent droplets from the crystallization reagents;
 - (iv) transporting one or more of such reagent droplets to at least a portion of the mixing wells to yield an array of wells comprising crystallization droplets, said array representing multiple crystallization conditions; and
 - (v) combining a sample droplet with each crystallization reagent to potentially yield one or more crystallization droplets comprising one or more crystals.
4. The system of claim 3 wherein the protein solution has a concentration which exceeds about 1 mg/mL.
 5. The system of claim 3 wherein the protein solution has a concentration which exceeds about 10 mg/mL.
 6. The system of claim 3 wherein the protein solution has a concentration which exceeds about 50 mg/mL.
 7. The system of claim 3 wherein the protein solution has a concentration which exceeds about 100 mg/mL.
 8. The system of claim 3 wherein the volume of protein solution transported to each mixing well in the array of mixing wells comprising crystallization droplets does not exceed about 100 nL.
 9. The system of claim 3 wherein the volume of protein solution transported to each mixing well in the array of mixing wells comprising crystallization droplets does not exceed about 50 nL.
 10. The system of claim 3 wherein the volume of protein solution transported to each mixing well in the array of mixing wells comprising crystallization droplets does not exceed about 25 nL.

11. The system of claim 3 wherein the volume of protein solution transported to each mixing well in the array of mixing wells comprising crystallization droplets does not exceed about 10 nL.
12. A system comprising the screening chip of claim 1 wherein:
 - (a) the chip comprises:
 - (i) one or more dispensing wells comprising protein solution loaded therein; and
 - (ii) one or more mixing wells comprising crystallization droplets loaded therein, said crystallization droplets representing multiple crystallization conditions; and
 - (b) the system is programmed to execute steps comprising:
 - (i) dispensing one or more sample droplets from the protein solution; and
 - (ii) transporting at least a portion of the dispensed sample droplets to the mixing wells, wherein at least a portion of the mixing wells each receives one or more of the sample droplets, thereby yielding an array of crystallization reagents comprising protein sample and having the capacity to one or more protein crystals.
13. The system of claim 12 wherein the protein solution has a concentration which exceeds about 1 mg/mL.
14. The system of claim 12 wherein the protein solution has a concentration which exceeds about 10 mg/mL.
15. The system of claim 12 wherein the protein solution has a concentration which exceeds about 50 mg/mL.

16. The system of claim 12 wherein the protein solution has a concentration which exceeds about 100 mg/mL.
17. The system of claim 12 wherein the volume of protein solution transported to each mixing well to provide the array of crystallization reagents comprising protein sample does not exceed about 100 nL.
18. The system of claim 12 wherein the volume of protein solution transported to each mixing well to provide the array of crystallization reagents comprising protein sample does not exceed about 50 nL.
19. The system of claim 12 wherein the volume of protein solution transported to each mixing well to provide the array of crystallization reagents comprising protein sample does not exceed about 25 nL.
20. The system of claim 12 wherein the volume of protein solution transported to each mixing well to provide the array of crystallization reagents comprising protein sample does not exceed about 10 nL.
21. A system comprising the screening chip of claim 1 wherein the chip is programmed to separate a protein solution sample into multiple droplets and move each such droplet to a mixing well where it is combined with a pre-loaded crystallization reagent to yield a sample potentially comprising one or more crystals.
22. The screening chip of claim 21 wherein the sample droplets are surrounded by a filler fluid comprising silicone oil.
23. The screening chip of claim 22 wherein silicone oil is doped with a surfactant.
24. The screening chip of claim 22 wherein silicone oil is doped with a lipophilic surfactant.
25. The screening chip of claim 22 wherein silicone oil is doped with Triton X-15.

26. A device comprising the screening chip of claim 21 and a means for automatically analyzing each sample for the presence and/or type of crystal.
27. A device comprising the screening chip of claim 21 and a means for manually analyzing each sample for the presence and/or type of crystal.
28. A device comprising the screening chip of claim 21 and a means for crystal harvesting.
29. The device of claim 28 wherein the means for crystal harvesting comprises microfluidics for transport of crystal-laden droplets to bring said droplets into contact with one or more capillaries.
30. The device of claim 29 wherein the droplets enter the one or more capillaries by capillary action.
31. The device of claim 29 wherein the droplets enter the one or more capillaries by active vertical axis electrostatic actuation.
32. The screening chip of claim 1 wherein the chip comprises a grid of wells which is at least 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, or 40 by 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, or 40.
33. The screening chip of claim 1 wherein the chip comprises a grid of wells which includes at least 2, 3, 4, 5, 6, 7, 8, 9, 10, 20, 30, 40, 50, 60, 70, 80, 90, 100, 110, 120, 130, 140, 150, 160, 170, 180, 190, 200, 210, 220, 230, 240, 250, 260, 270, 280, 290, 300, 310, 320, 330, 340, 350, 360, 370, 380, 390, 400, 410, 420, 430, 440, 450, 460, 470, 480, 490, 500, 510, 520, 530, 540, 550, 560, 570, 580, 590, 600, 610, 620, 630, 640, 650, 660, 670, 680, 690, 700, 710, 720, 730, 740, 750, 760, 770, 780, 790, 800, 810, 820, 830, 840, 850, 860, 870, 880, 890, 900, 910, 920, 930, 940, 950, 960, 970, 980, 990, 1000, 1010, 1020, 1030, 1040, 1050, 1060, 1070, 1080, 1090, 1100, 1110, 1120, 1130, 1140, 1150, 1160, 1170, 1180, 1190, 1200, 1210, 1220, 1230, 1240, 1250, 1260, 1270, 1280, 1290, 1300, 1310,

1320, 1330, 1340, 1350, 1360, 1370, 1380, 1390, 1400, 1410, 1420, 1430, 1440, 1450, 1460, 1470, 1480, 1490, 1500, 1510, 1520, 1530, 1540, 1550, 1560, 1570, 1580, 1590, 1600, 1610, 1620, 1630, 1640, 1650, 1660, 1670, 1680, 1690, 1700, 1710, 1720, 1730, 1740, 1750, 1760, 1770, 1780, 1790, 1800, 1810, 1820, 1830, 1840, 1850, 1860, 1870, 1880, 1890, 1900, 1910, 1920, 1930, 1940, 1950, 1960, 1970, 1980, 1990 or 2000 reagent conditions.

34. The screening chip of claim 1 wherein the chip comprises a grid consisting of 96, 384 or 1536 wells.
35. An optimization chip comprising:
- (a) a port for introduction of one or more crystallization reagents and/or one or more protein solutions; and
 - (b) a substrate comprising:
 - (i) one or more reagent wells in fluid connection with a port;
 - (ii) one or more sample wells in fluid connection with a port;
 - (iii) two or more mixing wells; and
 - (iv) microfluidics for moving:
 - (1) droplets comprising the crystallization reagents from the reagent wells into the mixing wells; and
 - (2) droplets comprising the protein solutions into the mixing wells.
36. The optimization chip of claim 35 wherein the one or more reagent wells are pre-loaded with crystallization reagents.

37. The optimization chip of claim 35 wherein the one or more reagent wells are pre-loaded with 2, 3, 4, 5, 6, 7, 8, 9, 10 or more different crystallization reagents.
38. The optimization chip of claim 37 wherein the crystallization reagents comprise reagents selected from salt solutions, pH buffer solutions, organic acids, and polyethylene glycol.
39. The optimization chip of claim 37 wherein the chip is programmed to create systematically varied crystallization conditions by performing steps comprising (in any order):
- (a) separate a protein solution sample from a sample well into multiple sample droplets and move each such sample droplet to a mixing well;
 - (b) separate one or more reagents from a reagent well into multiple reagent droplets and move each such reagent droplet into a mixing well; and
 - (c) thereby combining one or more reagent droplets with one or more sample droplets to yield a crystallization sample potentially forming one or more crystals.
40. A device comprising the optimization chip of claim 39 and a means for automatically analyzing each sample for the presence and/or type of crystal.
41. A device comprising the optimization chip of claim 39 and a means for manually analyzing each sample for the presence and/or type of crystal.
42. A device comprising the optimization chip of claim 39 wherein the device is programmed to permit a user to control mixing of reagents and protein sample so as to systematically vary conditions in each well according to parameters set by the user.
43. A device comprising the optimization chip of claim 39 wherein the device is programmed to automatically select parameter variables for use in the optimization chip based on results from a screening chip.

44. The optimization chip of claim 35 wherein the chip comprises a grid of wells which is at least 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, or 40 by 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, or 40.
45. The optimization chip of claim 35 wherein the chip comprises a grid of wells which includes at least 2, 3, 4, 5, 6, 7, 8, 9, 10, 20, 30, 40, 50, 60, 70, 80, 90, 100, 110, 120, 130, 140, 150, 160, 170, 180, 190, 200, 210, 220, 230, 240, 250, 260, 270, 280, 290, 300, 310, 320, 330, 340, 350, 360, 370, 380, 390, 400, 410, 420, 430, 440, 450, 460, 470, 480, 490, 500, 510, 520, 530, 540, 550, 560, 570, 580, 590, 600, 610, 620, 630, 640, 650, 660, 670, 680, 690, 700, 710, 720, 730, 740, 750, 760, 770, 780, 790, 800, 810, 820, 830, 840, 850, 860, 870, 880, 890, 900, 910, 920, 930, 940, 950, 960, 970, 980, 990, 1000, 1010, 1020, 1030, 1040, 1050, 1060, 1070, 1080, 1090, 1100, 1110, 1120, 1130, 1140, 1150, 1160, 1170, 1180, 1190, 1200, 1210, 1220, 1230, 1240, 1250, 1260, 1270, 1280, 1290, 1300, 1310, 1320, 1330, 1340, 1350, 1360, 1370, 1380, 1390, 1400, 1410, 1420, 1430, 1440, 1450, 1460, 1470, 1480, 1490, 1500, 1510, 1520, 1530, 1540, 1550, 1560, 1570, 1580, 1590, 1600, 1610, 1620, 1630, 1640, 1650, 1660, 1670, 1680, 1690, 1700, 1710, 1720, 1730, 1740, 1750, 1760, 1770, 1780, 1790, 1800, 1810, 1820, 1830, 1840, 1850, 1860, 1870, 1880, 1890, 1900, 1910, 1920, 1930, 1940, 1950, 1960, 1970, 1980, 1990 or 2000 reagent conditions.
46. The optimization chip of claim 35 wherein the chip comprises a grid 96, 384 or 1586 wells.
47. A method of testing conditions for growing a crystal comprising:
- (a) providing the screening chip of claim 21;
 - (b) providing droplets in the crystal comprising a variety of potential conditions and the target molecule; and
 - (c) observing the droplets to identify crystal growth.

48. The method of claim 47 further comprising:
- (a) observing the droplets to identify nucleation;
 - (b) performing on-chip dilutions after nucleation is observed to favor growth;
and
 - (c) stopping further nucleation.
49. A droplet microactuator chip for creating an array of crystallization conditions, the chip comprising:
- (a) two or more processing reservoirs;
 - (b) two or more dispensing reservoirs collectively comprising two or more crystallization reagents; and
 - (c) a port for introducing a sample for crystallization analysis.
50. The droplet microactuator chip of claim 49 wherein the crystallization reagents comprise coarse grid reagents.
51. The droplet microactuator chip of claim 49 wherein the crystallization reagents comprise fine grid reagents.
52. The droplet microactuator chip of claim 49 wherein the crystallization reagents comprise one or more reagents selected from the group consisting of salts, pH buffers, precipitants, and water.
53. The droplet microactuator chip of claim 49 wherein the sample comprises a protein or peptide.
54. The droplet microactuator chip of claim 49 wherein the sample comprises a small molecule.

55. A system comprising the droplet microactuator of claim 49 programmed to conduct droplet operations sufficient to create an array of crystallization conditions for the sample on the droplet microactuator.
56. A substrate comprising:
- (a) one or more input ports for introduction of one or more reagents and/or samples;
 - (b) a regular array of processing wells; and
 - (c) a network of droplet transport pathways comprising pathways that provide direct or indirect droplet transport from each of the input ports to each of the one or more processing wells.
57. The substrate of claim 56 having footprint dimensions $85.48 \times 127.76 \text{ mm}^2$.
58. The substrate of claim 56 comprising 96 wells in an 8 by 12 format having a well-to-well pitch of 9 mm.
59. The substrate of claim 56 comprising 384 wells in a 16 by 24 format having a well-to-well pitch of 4.5 mm.
60. The substrate of claim 56 comprising 1,536 wells in a 32 by 48 format having a well-to-well pitch of 2.25 mm.
61. The substrate of claim 56 comprising 6,144 wells in a 96 by 64 format having a well-to-well pitch of 1.125 mm.
62. The substrate of claim 56 comprising 24,576 wells in a 192 by 128 format having a well-to-well pitch of 0.5625 mm.
63. The substrate of claim 56 comprising 98,304 wells in a 384 by 256 format having a well-to-well pitch of 0.28125 mm.

64. The substrate of claim 56 comprising 393,216 wells in a 768 by 512 format having a well-to-well pitch of 0.140625 mm.
65. The substrate of claim 56 comprising 1,572,864 wells in a 1536 by 1024 format having a well-to-well pitch of 0.0703125 mm.
66. A chip comprising the substrate of any of claims 49-65 further comprising a top plate mounted parallel to the substrate thereby creating a sealable interior volume between the substrate and the top plate.
67. The chip of claim 66 wherein the network of droplet transport pathways interconnecting each of the wells is arranged such that a droplet extracted from any well can be transported to any other well via the network.
68. The chip of claim 66 further comprising one or more ports for inputting a substance into one or more of the wells.
69. The substrate of claim 56 wherein the regular array of microliter-volume or nanoliter-volume wells comprises high volume storage wells and low volume processing wells.
70. The substrate of claim 56 further comprising:
 - (a) one or more storage wells and one or more supply droplet transport pathways interconnecting the one or more storage wells with the network of droplet transport pathways; and
 - (b) wherein the regular array of microliter-volume or nanoliter-volume wells comprises processing wells.
71. A chip comprising the substrate of claim 70 further comprising a top plate mounted parallel to the substrate thereby creating a sealable interior volume between the substrate and the top plate.

72. A system comprising the chip of claim 71 programmed to automatically extract droplets from the one or more storage wells and transport them to the processing wells to generate an array of screening conditions.
73. The chip of claim 71 further comprising a means for effecting a localized magnetic field.
74. The chip of claim 73 wherein the means for effecting the localized magnetic field is arranged to attract magnetic particles in a droplet on the chip during a splitting operation on the droplet such that upon completion of the splitting operation, at least about 99% of the magnetic particles remain in one droplet.
75. The chip of claim 74 wherein at least about 99.5% of the magnetic particles remain in one droplet.
76. The chip of claim 74 wherein at least about 99.9% of the magnetic particles remain in one droplet.
77. A system comprising the chip of claim 74 and a processor electronically coupled to the chip, wherein the processor is programmed to instruct the chip to execute a protocol for washing of the magnetic beads.
78. A system comprising the chip of claim 74 and a processor electronically coupled to the chip, wherein the processor is programmed to instruct the chip to execute an elution protocol.
79. The chip of claim 71 further comprising a means for localized heating of a processing well.
80. A system comprising the chip of claim 71 and lacking a means of thermocycling the entire chip.
81. The chip of claim 74 further comprising a heating element arranged to provide localized heating of a region of the network of droplet transport pathways.

82. The chip of claim 81 wherein the heating element is selected from the group consisting of thin film heaters; resistive trace heaters; light heaters; thermal heaters; joule heating comprising apparatus for passing current through a droplet; and infrared heaters.
83. A system comprising the chip of claim 81 and a processor electronically coupled to the chip and the heating element, wherein the processor is programmed to transport a droplet into proximity with the heating element to effect heating.
84. The system of claim 83 wherein the processor is programmed to repetitively transport a droplet into proximity with one or more of the heating element(s) to subject the droplet to a heating and cooling cycle.
85. The system of claim 83 wherein the processor is programmed to repetitively transport multiple droplets into proximity with one or more of the heating element(s) to subject the droplets to a heating and cooling cycle.
86. The system of claim 84 wherein the droplet comprises a PCR-ready solution, and the repetitive heating results in amplification of a DNA.
87. The system of claim 84 wherein the droplet comprises a PCR-ready solution and the repetitive heating is sufficient to result in amplification of a target DNA if the target DNA is present in the PCR-ready solution.
88. The system of claim 87 wherein the PCR-ready solution is substantially lacking in surfactant.
89. The system of claim 87 wherein the PCR-ready droplet is surrounded by a silicone oil.
90. The chip of claim 81 comprising two or more of the heating elements spaced to maintain temperature zones on the substrate.

91. The system of claim 84 wherein the processor is programmed to control the temperature of the heating element to effect heating of the droplet but without causing significant vaporization the droplet.
92. A diagnostic method comprising employing the system of claim 84 to analyze a sample for the presence or absence of a nucleic acid of interest.
93. The diagnostic method of claim 92 wherein the nucleic acid of interest comprises a nucleic acid of a pathogenic organism.
94. A stamping device comprising a droplet microactuator comprising:
- (a) a first plate comprising a path or network of control electrodes for transporting droplets on a surface thereof;
 - (b) a second plate mounted in a substantially parallel orientation with respect to the first plate creating an interior volume between the plates, the second plate comprising one or more stamping ports for transporting some portion or all of a droplet from the interior volume to an exterior location;
 - (c) a port for introducing fluid into the interior volume between the plates; and
 - (d) a path or network of reference electrodes corresponding to the path or network of control electrodes.
95. The stamping device of claim 94 further comprising one or more droplets in the interior volume on the network of control electrodes.
96. The stamping device of claim 95 wherein the one or more droplets comprises one or more droplets comprising a MALDI matrix.
97. The stamping device of claim 96 wherein the MALDI matrix comprises acetonitrile in an amount sufficient to keep miscibility of the acetonitrile in the

filler fluid at a level which does not eliminate the effectiveness of the stamping device.

98. The stamping device of claim 96 wherein the MALDI matrix comprises from about 40% to about 75% acetonitrile.
99. The stamping device of claim 96 wherein the MALDI matrix comprises from about 50% to about 70% acetonitrile.
100. The stamping device of claim 96 wherein the MALDI matrix comprises from about 0.05% to about 1% TFA.
101. The stamping device of claim 96 wherein the MALDI matrix comprises:
 - (a) from about 50% to about 70% acetonitrile; and
 - (b) from about 0.05% to about 1% TFA.
102. The stamping device of claim 94 further comprising one or more reagent reservoirs and one or more ports for introducing fluid into the one or more reagent reservoirs, wherein the one or more reagent reservoirs are situated in proximity to the path or network of the control electrodes such that reagent droplets can be dispensed onto the path or network of control electrodes.
103. The stamping device of claim 94 further comprising one or more sample reservoirs and one or more ports for introducing fluid into the one or more sample reservoirs, wherein the one or more sample reservoirs are situated in proximity to the path or network of the control electrodes such that sample droplets can be dispensed onto the path or network of control electrodes.
104. A system comprising:
 - (a) the stamping device of claim 94;

- (b) a computer processor electronically coupled to the stamping device and programmed to effect control of droplet operations on the stamping device;
- (c) one or more input devices electronically coupled to the computer processor; and
- (d) one or more output devices electronically coupled to the computer processor.

105. The system of claim 104 further comprising:

- (a) one or more reagent reservoirs and one or more ports for introducing fluid into the one or more reagent reservoirs, wherein the one or more reagent reservoirs are situated in proximity to the path or network of the control electrodes such that reagent droplets can be dispensed onto the path or network of control electrodes; and
- (b) one or more sample reservoirs and one or more ports for introducing fluid into the one or more sample reservoirs, wherein the one or more sample reservoirs are situated in proximity to the path or network of the control electrodes such that sample droplets can be dispensed onto the path or network of control electrodes.

106. The system of claim 105 wherein the system is controlled and configured to:

- (a) dispense a sample droplet from a sample reservoir onto the path or network of control electrodes;
- (b) dispense a MALDI matrix droplet from a reagent reservoir onto the path or network of control electrodes;
- (c) merge the sample droplet and MALDI matrix droplet to yield a MALDI-ready droplet; and

- (d) transport some portion or all of the MALDI-ready droplet through a stamping port.
107. The system of claim 106 wherein the steps are accomplished using multiple samples without significant cross-contamination among samples.
108. A method of stamping comprising employing the system of claim 106 to deliver one or more MALDI-ready droplets to a MALDI substrate.
