METHOD FOR DETECTING A LEAK IN FLOWING ELECTROLYTE BATTERIES

RELATED APPLICATIONS

BACKGROUND OF THE INVENTION

1. Field of the Invention

The invention is directed to flowing electrolyte batteries, and in particular to a leak sensor for use in association with flowing electrolyte batteries such as zinc/bromine batteries. It will be understood that the application is not limited to any zinc/bromine batteries or to any other particular flowing electrolyte battery.

2. Background Art

Flowing electrolyte batteries (Zn—Br batteries, V-Redox batteries, etc) are well known in the art for their quality power providing characteristics and their cycling ability. Generally, such batteries rely on the circulation, by pumps, of electrolyte. As the circulation of electrolyte includes a multitude of components, fittings and conduits, a potential always exists for failure of one of these components. Such failure will generally result in a leak of electrolyte.

In addition, since many such batteries require cooling systems which likewise comprise a multitude of conduits, fittings and components, the cooling systems are likewise problematic. Failure in such components generally results in a leak of coolant. Further still, many such batteries, especially in industrial applications, are placed in a substantially sealed container which remains exposed to harsh environments. As such, damage to the sealed container often results in the collection of precipitation within the container.

Any leak of electrolyte or coolant, as well as any entry of outside moisture can have catastrophic results. Specifically, not only will it cause the battery to operate in a less than optimal condition, the battery may completely fail. For industrial applications, and especially when used as an emergency power supply, such batteries must be ready for immediate operation. If a battery fails, then it is incapable of providing power in an emergency. Thus, it is important to provide early notification of a leak in such a battery.

Moreover, in the event of a failure, it is important to contain any leaks, thereby precluding contamination of the battery by the leaking fluid. By limiting the contamination caused by the fluid leak, the battery can be more easily repaired and returned to operation.

Thus, it is an object of the invention to facilitate the containment of a leak within a flowing electrolyte battery.

It is another object of the invention to facilitate the detection of a leak of fluid within a flowing electrolyte battery.

SUMMARY OF THE INVENTION

The invention comprises a leak detection system for a flowing electrolyte battery. The leak detection system comprises a containment member associated with at least one of a stack of a flowing electrolyte battery and an electrolyte reservoir of a flowing electrolyte battery, and, means for sensing a fluid leak within the containment member.

In a preferred embodiment, the sensing means comprises a switch, a controller and a connector. The switch includes a first plate and a second plate. Fluid within the containment member (i.e., a leak) serves to electrically couple the first plate to the second plate, to, in turn, close the switch. The controller is associated with the switch, and, the controller is capable of sensing the condition of the switch. The connector is electrically associating the switch and the controller.

In such an embodiment, the sensing means further comprises a resistor positioned in parallel to the switch. In another such embodiment, the at least one switch comprises a plurality of switches positioned in parallel.

In a preferred embodiment, the containment member comprises a stack leak containment member associated at least one stack; and an electrolyte reservoir leak containment member associated with at least one reservoir. In one such embodiment, the sensing means is capable of sensing a leak in each of the stack leak containment member and the at least one electrolyte reservoir leak containment member.

In another aspect of the invention, the invention comprises a method for detecting leaks in a flowing electrolyte battery. The method comprises the steps of (a) providing at least one containment member for at least one of the stack and the reservoir; (b) providing at least one sensor; (c) positioning at least one sensor such that a leak collected in the at least one containment member triggers the sensor; (d) providing a controller; and (e) associating the controller with the at least one sensor, such that the controller is capable of electrically communicating with the sensor.

In one embodiment, the step of providing at least one containment member comprises the steps of (a) providing a stack leak containment member; (b) positioning the stack leak containment member such that a leak from the stack is collected by the stack leak containment member; (c) providing a reservoir leak containment member; and (d) positioning the reservoir leak containment member such that a leak from the reservoir is collected by the reservoir leak containment member.

In another embodiment, the step of providing a sensor comprises the steps of (a) providing a sensor for the stack leak containment member; and (b) providing a sensor for the reservoir leak containment member. In such a preferred embodiment, the step of positioning the at least one sensor comprises the steps of (a) positioning a sensor in the stack containment member such that a leak collected in the stack leak containment member triggers the sensor; and (b) positioning a sensor in the reservoir leak containment member such that a leak collected in the reservoir leak containment member triggers the sensor.

In another embodiment, the method further includes the step of sensing a fluid leak. Preferably, the method likewise includes the step of determining the type of fluid leak.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 of the drawings is a schematic representation of the present invention;
FIG. 2 of the drawings is a schematic representation of the sensor of the present invention;
FIG. 3 of the drawings is a schematic representation of multiple sensors of the present invention; and
FIG. 4 of the drawings is a schematic representation of a second embodiment of a sensor of the present invention.

DETAILED DESCRIPTION

While this invention is susceptible of embodiment in many different forms, there is shown in the drawings and will be
described in detail, one specific embodiment with the understanding that the present disclosure is to be considered as an exemplification of the principles of the invention and is not intended to limit the invention to the embodiment illustrated.

Leak detection system 10 is shown in FIG. 1 as comprising stack leak containment member 12, reservoir leak containment member 14 and means 16 for sensing a leak. Leak detection system 10 is for use in association with a flowing electrolyte battery, such as zinc/bromine battery 100. While various flowing electrolyte batteries are contemplated for use, the invention will be described with reference to a zinc/bromine battery solely as an example. Generally, zinc/bromine battery 100 includes one or more stacks, such as stack 102, electrolyte reservoir 104, circulating means 106 and means 108 for controlling the climate within battery 100. Stack 102 includes plurality of arranged anodes and cathodes so as to comprise a plurality of stacked cells. Electrolyte reservoir 104 stores the electrolyte which is circulated by circulation means 106 through stack 102. In certain embodiments, a climate control means 108 may be incorporated to either heat or cool the electrolyte so as to maintain the overall battery within operating parameters.

Electrolyte stack leak containment member 12 is shown in FIG. 1 as comprising base 30 and sides 12 which define cavity 34. As will be understood at least a portion of stack 102 is positioned within cavity 34 such that, in the case of an electrolyte leak in stack 102, such a leak will fill cavity 34. In embodiments such as the embodiment shown in FIG. 1, wherein two vertically oriented stacks 102, 102' form a tower, each stack has its own electrolyte leak containment member, 12, 12'. In such an embodiment, the upper electrolyte leak containment member 12 includes overflow opening 36, which, in turn, directs any overflow of electrolyte into the lower electrolyte leak containment member 12'. In this manner, the spread of electrolyte can be minimized.

Reservoir leak containment member 14 is shown in FIG. 1 as comprising base 40 and sides 42 which define cavity 44. The electrolyte reservoirs are positioned within the reservoir leak containment member such that any leak in the electrolyte reservoirs will be contained by the reservoir leak containment member. In addition, the reservoirs, and, in turn, the reservoir leak containment members are positioned below stack 102 such that, in the event of a leak which overflows electrolyte stack leak containment member 12 (or 12') will be directed into, and contained by, reservoir leak containment member 14.

Sensing means 16 is shown in FIG. 1 as comprising sensor 50, controller 52 and connector 54. Sensor 50, as shown in FIG. 2, includes base resistor 60 and switch 62. Switch 62 is in parallel with resistor 60 and includes surface 70 and surface 72. As will be explained in detail below, in the event of a leak, the leaking fluid contacts surface 70 and surface 72, to, in turn, close the circuit, essentially forming a switch. While other shapes are contemplated, the surfaces 70, 72 comprise mesh surfaces. Such mesh surfaces provide a relatively large surface area for contact of the fluid with the mesh surfaces. While various systems are contemplated, resistor 60 comprises a resistor having a value of 3000Ω, and the voltage applied to switch 62 and resistor 60 is 24V. Of course, various other circuits are contemplated, wherein the applied voltage may be either lower or higher, and, various resistors are contemplated for use. In other embodiments, the resistor may be omitted wherein the controller views the circuit as an open circuit until such time as the switch is closed.

Connector 54 connects controller 52 to sensor 50 such that controller 52 is capable of sensing the closing of a switch 62 of sensor 50. As will be explained below, if fluid from a leak provides a closed circuit across surfaces 70, 72, then the resistance of the parallel combination of the switch and the resistor effectively decreases, and the current in the system increases (i.e. voltage remains constant, and therefore voltage is equal to resistance times current). Controller 52 comprises a digital microcontroller capable of reading the current change across the resistor and the switch. Of course, various analog or digital systems are contemplated for use.

In operation, a flowing electrolyte battery is first equipped with leak detection system 10. Specifically, stack leak containment member 12 is provided for each stack and each stack is positioned so that a portion is within cavity 34. Additionally, electrolyte reservoirs 104 are positioned within electrolyte leak containment member 14.

Once the containment members are positioned, sensors 50 are positioned within the cavity of each stack leak containment member. Subsequently, sensors are likewise positioned within the reservoir leak containment member, and likewise in the bottom of the unit (in case of overflow from any of the containment members). Once positioned, each sensor is attached to one or more controllers, such as controller 52, via connectors 54. The sensors are positioned such that a leak that collects in any of the respective containment members (or at the bottom of the unit) will close a circuit about the surfaces 70, 72 of the respective switch 62, which can be sensed by controller 52. Generally, to achieve early recognition of leaks, the sensors are generally positioned proximate the lowest point of the respective containment member.

From time to time, the flowing electrolyte battery can experience an electrolyte leak in, for example stack 102. In such an instance, the electrolyte leak will collect in the respective stack leak containment member 12. As the level of electrolyte in the stack leak containment member increases, eventually, electrolyte will contact both surface 70 and surface 72 of switch 62, thereby effectively closing the circuit. As a result, the current in the circuit will tend to increase, and the increase is sensed by controller 50. Controller 50 can then provide some type of final output (i.e. audible, visual, radio, infrared, connection to a main control unit, etc.) so that a user can be informed of the leak.

Similarly, a leak in the reservoir will tend to cause electrolyte to enter into the reservoir leak containment member. As the level of electrolyte increases in the reservoir leak containment member, electrolyte will contact surfaces 70 and 72 of the sensor positioned within the reservoir leak containment member and the switch will be effectively closed by the electrolyte. In turn, the circuit will exhibit an increased current which will be sensed by the controller.

It will be understood that in certain embodiments which utilize a liquid coolant, a coolant leak can occur. Such a coolant leak will generally collect in the base of the unit or in the reservoir leak containment member. As with the electrolyte leak, as the coolant level rises, the coolant will contact the surfaces 70 and 72 of one of the sensors, thereby effectively closing the switch.

Again, the controller will recognize the closing of the switch. Indeed, any fluid collection (i.e. electrolyte leak, coolant leak, condensation, outside precipitation) within any of the containment members or proximate the base of the flowing electrolyte battery will trigger a sensor switch to close. Since each such fluid generally comprises a different resistivity (i.e. the electrolyte generally exhibits less electrical resistance than coolant or water (contaminated)), current changes sensed by the controller will be different based on the fluid that is causing the closing of the respective switch. In turn, the controller can be programmed to distinguish between the different leaks. In this case, if the controller
determines that the cause of the leak is condensation, there is no need to service the battery or to take the battery out of operation. In another embodiment, as shown in FIG. 3, the sensor may comprise a plurality of switches in parallel with a single resistor. In such an embodiment, each switch may be positioned in a different area, such as the stack leak containment member, the electrolyte reservoir leak containment member and the overflow area of the housing. As such, a leak in any one of these areas will cause fluid in the respective area to close the switch, and in turn, lower the overall resistance of the circuit. The lower resistance (and increased current) is then sensed by the controller which is attached to the sensor. In such an embodiment, the controller can signal a leak, however, the precise location of the leak is not known.

In another embodiment, as shown in FIG. 4, sensor 50 may include an additional switch, namely, switch 63 which is positioned in parallel to switch 62 and resistor 60. When installed, switch 63 is positioned lower than switch 62 such that a leak will first close switch 63 before the leak closes switch 62. As will be understood, a small leak will tend to close switch 62, whereas a large leak will tend to close switch 63 and switch 62. As a result, the controller will receive a first current reading increase as the leak closes switch 63 and a second current reading increase as the leak closes switch 62. Accordingly, the controller can be used to access the severity of the leak.

The foregoing description merely explains and illustrates the invention and the invention is not limited thereto except insofar as the appended claims are so limited, as those skilled in the art who have the disclosure before them will be able to make modifications without departing from the scope of the invention.

What is claimed is:

1. A method for detecting a leak in a flowing electrolyte battery, the flowing electrolyte battery including a plurality of stacked cells, a common electrolytic fluid circulating between respective interiors of the plurality of stacked cells, and a plurality of containment members, each containment member at least partially surrounding a respective one of the plurality of stacked cells and not others of the plurality of stacked cells, the method comprising the steps of:
capturing a leaking fluid in at least one of the plurality of containment members;
detecting a presence of the captured leaking fluid in the at least one of the plurality of containment members; and
determining that the leak has occurred according to the detection of the presence of the captured leaking fluid in the at least one of the plurality of containment members; wherein the step of capturing comprises capturing the leaking fluid in a first containment member at least partially surrounding a first of the plurality of stacked cells and directing the leaking fluid into a second containment member at least partially surrounding a second of the plurality of stacked cells, the second of the plurality of stacked cells being different from the first of the plurality of stacked cells.

2. The method of claim 1, the step of directing comprising directing the leaking fluid through an overflow opening in the first containment member and into the second containment member.

3. A method for detecting a leak in a flowing electrolyte battery, the flowing electrolyte battery including a plurality of stacked cells, a common electrolytic fluid circulating between respective interiors of the plurality of stacked cells, and a plurality of containment members, each containment member at least partially surrounding a respective one of the plurality of stacked cells and not others of the plurality of stacked cells, the method comprising the steps of:
capturing a leaking fluid in at least one of the plurality of containment members;
detecting a presence of the captured leaking fluid in the at least one of the plurality of containment members;
determining that the leak has occurred according to the detection of the presence of the captured leaking fluid in the at least one of the plurality of containment members; and
detecting a first depth of the captured leaking fluid in the at least one of the plurality of containment members.

4. The method of claim 3, further comprising a step of determining a severity of the leak based, at least in part, on the first depth of the captured leaking fluid in the at least one of the plurality of containment members.

5. The method of claim 4, further comprising a step of determining a severity of the leak based, at least in part, on a second depth of the captured leaking fluid in the at least one of the plurality of containment members, the second depth being different from the first depth.

6. The method of claim 3, further comprising determining a property of the leaking fluid based, at least in part, on an electrical resistivity of the leaking fluid.

7. The method of claim 6, further comprising discriminating between a presence of condensation, coolant, and/or uncirculated electrolytic fluid based, at least in part, on the electrical resistivity of the leaking fluid.

8. A method for detecting a leak in a flowing electrolyte battery, the flowing electrolyte battery including a plurality of stacked cells, a common electrolytic fluid circulating between respective interiors of the plurality of stacked cells, and a plurality of containment members, each containment member at least partially surrounding a respective one of the plurality of stacked cells and not others of the plurality of stacked cells, the method comprising the steps of:
capturing a leaking fluid in at least one of the plurality of containment members;
detecting a presence of the captured leaking fluid in the at least one of the plurality of containment members;
determining that the leak has occurred according to the detection of the presence of the captured leaking fluid in the at least one of the plurality of containment members;
collecting a second leaking fluid in a reservoir leak containment member at least partially surrounding an electrolyte reservoir, the electrolyte reservoir for supplying electrolytic fluid to the plurality of stacked cells;
detecting a presence of the second leaking fluid in the reservoir leak containment member; and
determining that the leak has occurred according to the presence of second leaking fluid in the reservoir leak containment member.

9. The method of claim 8, the step of capturing comprising directing the leaking fluid from the at least one of the plurality of containment members into the reservoir leak containment member.

10. A method for detecting a leak in a flowing electrolyte battery, the flowing electrolyte battery including a plurality of stacked cells and a common electrolytic fluid circulating between respective interiors of the plurality of stacked cells, the method comprising the steps of:
capturing leaking fluid in a first containment member at least partially surrounding a first of the plurality of stacked cells; and
directing the leaking fluid from the first containment member into a second containment member at least partially surrounding a second of the plurality of stacked cells;
detecting a presence of leaking fluid in the second containment member; and

determining that the leak has occurred according to the
detection of the presence of leaking fluid in the second containment member.

11. The method of claim 10, the step of directing comprising

directing the leaking fluid through an overflow opening in the first containment member and into the second containment member.

12. The method of claim 11, the flowing electrolyte battery comprising a housing at least partially surrounded at least the plurality of stacked cells and the first and second containment members.

13. The method of claim 10, further comprising discriminating between the presence of condensation, coolant, and/or uncirculated electrolyte fluid based, at least in part, on an electrical resistivity of the leaking fluid.

14. A method for determining a severity of a leak in a flowing electrolyte battery, the flowing electrolyte battery including a plurality of stacked cells and a common electrolytic fluid circulating between respective interiors of the plurality of stacked cells, the method comprising the steps of:

capturing a leaking fluid in a containment member;

positioning a first switch within the containment member at a first depth position;

positioning a second switch within the containment member at a second depth position, the second depth position being different from the first depth position; and
determining the severity of the leak based, at least in part, on the captured leaking fluid reaching one or both of the first and second depth positions of the first and second switches, respectively.

15. The method of claim 14, further comprising a step of closing the first or second switch upon the captured leaking fluid reaching the first or second depth position, respectively,

16. The method of claim 14, further comprising measuring an electrical resistance across one or both of the first and second switches.

17. The method of claim 14, the flowing electrolyte battery comprising a housing at least partially surrounding at least the plurality of stacked cells and the containment member.

18. The method of claim 14, further comprising discriminating between a presence of condensation, coolant, and/or uncirculated electrolyte fluid based, at least in part, on an electrical resistivity of the leaking fluid.

19. A method for detecting a leak in a flowing electrolyte battery, the flowing electrolyte battery including a plurality of stacked cells, a common electrolytic fluid circulating between respective interiors of the plurality of stacked cells, and first and second containment members, the method comprising the steps of:

capturing a first leaking fluid in the first containment member;

capturing a second leaking fluid in the second containment member different from the first containment member, the first and second leaking fluids leaking from different respective ones of the plurality of stacked cells within the flowing electrolyte battery;

detecting a presence of the first leaking fluid in the first containment member;
detecting a presence of the second leaking fluid in the second containment member; and
determining that the leak has occurred according to the detection of the presence of either the first leaking fluid in the first containment member or the second leaking fluid in the second containment member.
