An aspect of the present invention is related to nucleic acid constructs capable of expressing a polypeptide, such as a consensus dengue prM: envelope epitope that elicits an immune response in a mammal against more than one subtype of dengue virus, and methods of use thereof. Additionally, there are DNA plasmid vaccines capable of generating in a mammal an immune response against a plurality of dengue virus subtypes, comprising a DNA plasmid and a pharmaceutically acceptable excipient, and methods of use thereof. The DNA plasmid is capable of expressing a consensus dengue antigen in a cell of the mammal in a quantity effective to elicit an immune response in the mammal that is cross reactive against all 4 dengue subtypes.

CROSS-REFERENCE TO RELATED APPLICATIONS

This application is the U.S. national stage application filed under 35 U.S.C. § 371 claiming benefit to International Patent Application No. PCT/US14/029531, filed Mar. 14, 2014, which is entitled to priority under 35 U.S.C. § 119(e) to U.S. Provisional Application No. 61/801,792, filed Mar. 15, 2013, each of which is hereby incorporated by reference in its entirety.

FIELD OF THE INVENTION

The present invention relates to improved dengue vaccines, improved methods for inducing immune responses, and for prophylactically and/or therapeutically immunizing individuals against dengue virus.

BACKGROUND

Dengue virus (DENV) is an emerging mosquito-borne pathogen that causes dengue fever (DF) and severe life threatening illness, dengue hemorrhagic fever/dengue shock syndrome (DHF/DSS). DENV is a small, enveloped, positive-stranded RNA virus that belongs to the Flaviviridae family. Four distinct subtypes or serotypes of dengue viruses (DV-1 to DV-4) are transmitted to humans through the bites of mosquito species Aedes aegypti and Aedes albopictus. It has been estimated that 50-100 million cases of DF and 250,000-500,000 cases of DHF occur every year. Dengue constitutes a significant international public health concern, as two-fifths of the world's population live in dengue endemic regions, and an estimated 50-100 million cases of dengue infection occur annually. Furthermore, 2.5 billion people are at risk for infection in subtropical and tropical regions of the world in the absence of effective intervention.

More than 100 tropical countries have endemic dengue virus infections, and DHF has been documented in >60 of these countries. Surveillance for DF/DHF is poor in most countries, and in the past has focused primarily on DHF; the number of DF cases that occur each year can therefore only be estimated. In 1998, however, major epidemics occurred throughout Asia and the Americas, with >1.2 million cases of DF/DHF reported to the World Health Organization (WHO). Global reports of DHF have increased on average by five-fold in the past 20 years. At the beginning of the 21st century it is estimated that between 50 and 100 million cases of DF and several hundred thousand cases of DHF occur each year, depending on the epidemic activity. The case fatality rate (CFR) varies among countries, but can be as high as 10-15% in some and <1% in others.

There are four dengue virus subtypes: dengue-1 (DV-1), dengue-2 (DV-2), dengue-3 (DV-3), and dengue-4 (DV-4). Each one of these subtypes form an antigenically distinct subgroup within the flavivirus family. They are enveloped, RNA viruses that encode ten proteins: three structural proteins and seven non-structural proteins. The structural proteins are capsid (C), envelope (E) and pre-membrane precursor (preM). The intracellular life cycle of DV begins with receptor-mediated endocytosis of the virus into cells followed by fusion of the viral envelope protein with the late endosomal membrane, which results in the release of the viral genome into the cytoplasm for replication.

Infection by DV may either be asymptomatic or characterized by fever, chills, frontal headache, myalgia, arthralgia and rash. Subsequent infection with different serotypes may result in more severe manifestations of the disease involving plasma leakage or hemorrhage (dengue hemorrhagic fever) and shock (dengue shock syndrome). Although extensive studies have been carried out over the years to understand the pathogenicity of DENV infection, little progress has been made in the development of specific anti-DV compounds. Currently there are no specific anti viral agents or vaccines against Dengue infections approved in the US.

The envelope (E) glycosylated protein, being the major structural protein present on the surface of the mature dengue virions, is a type I integral membrane protein. It has been demonstrated that the E protein of the mature Dengue forms homodimers in the anti-parallel manner (head to tail orientation). Each monomer is folded into three distinct domains, namely domain I (DI, the central N-terminal domain), domain II (DII, the dimerization domain), and domain III (PRM/E, immunoglobulin (Ig) like C terminal domain). The PRM/E domain of E protein consists of 100 amino acids (residues 303-393) of the C-terminus. This domain has been suggested to be the receptor recognition and binding domain. Ig-like fold present in the PRM/E protein is commonly associated with structures that have an adhesion function. This domain extends perpendicularly to the surface of the virus, with a tip that projects further from the virion surface than any other part of the E protein. In addition, studies have demonstrated that both recombinant PRM/E proteins and antibodies generated against PRM/E of E protein of flavivirus can inhibit entry of the flavivirus into target cells. Further, flavivirus with mutation in PRM/E of the E protein shows either attenuated virulence or the ability to escape immune neutralization.

Development of a safe and effective vaccine against dengue virus infection remains a principal public health goal. Given that the primary correlate of immunity to dengue virus is thought to be the presence of neutralizing antibodies, a prerequisite for comparing and optimizing vaccine candidates is the ability to precisely measure the neutralizing antibody responses evoked by vaccines. A combination of live attenuated virus-containing vaccines from all four serotypes has been shown to result in several complications (Guy B, Almond J W, Comp Immunol Microbiol Infect Dis. 2008 March; 31(2-3):239-52). Further, there are few reports on an adenovirus-based delivery of dengue antigens. Nevertheless, the one well recognized problem with adenovirus systems is a majority of the human population is known to have antibodies against one of the adenoviruses, and such pre-existing antibodies can cause these adenovirus-based vaccines to be ineffective.

Therefore, there remains a need to develop a vaccine that provides broad immunity against multiple and preferably all four serotypes of dengue virus, or universal immunity, and preferably a vaccine which is economical and effective across all serotypes. Further, there remains a need for an effective method of administering vaccines, such as DNA vaccines or DNA plasmid vaccines, to a mammal in order to provide immunization against dengue virus, either prophylactically or therapeutically.

SUMMARY OF THE INVENTION

One aspect of the present invention provides nucleic acid constructs capable of expressing a polypeptide that elicits an immune response in a mammal against more than one subtype of dengue virus. The nucleic acid constructs are
comprised of an encoding nucleotide sequence and a promoter operably linked to the encoding nucleotide sequence. The encoding nucleotide sequence expresses the polypeptide, wherein the polypeptide includes domain III of envelope protein (PRM/E domain or PRM/E) from at least two different dengue virus subtypes. The promoter regulates expression of the polypeptide in the mammal.

Another aspect of the present invention provides DNA plasmid vaccines that are capable of generating in a mammal an immune response against a plurality of dengue virus subtypes. The DNA plasmid vaccines are comprised of a DNA plasmid capable of expressing a consensus dengue antigen in the mammal and a pharmaceutically acceptable excipient. The DNA plasmid is comprised of a promoter operably linked to a coding sequence that encodes the consensus dengue PRM/E antigen. The consensus dengue antigen includes one or both of consensus PRM/E domains of dengue virus-subtype 1, dengue virus-subtype 2, dengue virus-subtype 3, or dengue virus-subtype 4.

Another aspect of the present invention provides methods of eliciting an immune response against a plurality of subtypes of a virus in a mammal, comprising delivering a DNA plasmid vaccine to tissue of the mammal, the DNA plasmid vaccine comprising a DNA plasmid capable of expressing a plurality of consensus antigens derived from the subtypes of the virus in a cell of the mammal to elicit an immune response in the mammal, the plurality of consensus antigens comprising an antigenic domain from at least two different subtypes of the virus, and electrophoretically cells of the tissue with a pulse of energy at a constant current effective to permit entry of the DNA plasmids into the cells.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 displays binding titers against all dengue PRM/E domain from subtype 1 for sera from D1prME vaccinated mice versus sera from DU vaccinated mice.

FIG. 2 displays binding titers against all dengue PRM/E domain from subtype 2 for sera from D2prME vaccinated mice versus sera from DU vaccinated mice.

FIG. 3 displays binding titers against all dengue PRM/E domain from subtype 3 for sera from D3prME vaccinated mice versus sera from DU vaccinated mice.

FIG. 4 displays binding titers against all dengue PRM/E domain from subtype 4 for sera from D4prME vaccinated mice versus sera from DU vaccinated mice.

FIG. 5 displays stained gels showing binding antibodies generated against prME proteins types D1, D2, D3, and D4.

FIG. 6 displays graphs showing neutralizing antibodies against each one of dengue PRM/E protein types (1 through 4) for control guinea pig sera.

FIG. 7 displays graphs showing neutralizing antibodies against each one of dengue PRM/E protein types (1 through 4) for DU guinea pig sera.

FIG. 8 displays graphs showing neutralizing antibodies against each one of dengue PRM/E protein types (1 through 4) for D1-D4 prME guinea pig sera combined (in one mixture).

FIG. 9 displays graphs showing neutralizing antibodies against each one of dengue PRM/E protein types (1 through 4) for D1-D4 prME guinea pig sera separate (administered separately).

FIG. 10 displays graphs showing neutralizing antibodies against each one of dengue PRM/E protein types (1 through 4) for D1 prME guinea pig sera.

FIG. 11 displays graphs showing neutralizing antibodies against each one of dengue PRM/E protein types (1 through 4) for D2 prME guinea pig sera.

FIG. 12 displays graphs showing neutralizing antibodies against each one of dengue PRM/E protein types (1 through 4) for D3 prME guinea pig sera.

FIG. 13 displays graphs showing neutralizing antibodies against each one of dengue PRM/E protein types (1 through 4) for D4 prME guinea pig sera.

FIG. 14 displays a graph showing neutralizing antibodies against Dengue 1 virus for sera from animals vaccinated with all four D1-D4 prME.

FIG. 15 displays a graph showing neutralizing antibodies against Dengue 2 virus for sera from animals vaccinated with all four D1-D4 prME.

FIG. 16 displays a graph showing neutralizing antibodies against Dengue 3 virus for sera from animals vaccinated with all four D1-D4 prME.

FIG. 17 displays a graph showing neutralizing antibodies against Dengue 4 virus for sera from animals vaccinated with all four D1-D4 prME.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

The following abbreviated, or shortened, definitions are given to help the understanding of the preferred embodiments of the present invention. The abbreviated definitions given here are by no means exhaustive nor are they contradictory to the definitions as understood in the field or dictionary meaning. The abbreviated definitions are given here to supplement or more clearly define the definitions known in the art.

Definitions

Sequence homology for nucleotides and amino acids as used herein may be determined using FASTA, BLAST and Gapped BLAST (Altschul et al., Nuc. Acids Res., 1997, 25, 3389, which is incorporated herein by reference in its entirety) and PAUP* 4.0b10 software (D. L. Swofford, Sinauer Associates, Massachusetts). Briefly, the BLAST algorithm, which stands for Basic Local Alignment Search Tool is suitable for determining sequence similarity (Altschul et al., J. Mol. Biol., 1990, 215, 403-410, which is incorporated herein by reference in its entirety). Software for performing BLAST analyses is publicly available through the National Center for Biotechnology Information. One measure of similarity provided by the BLAST algorithm is the smallest sum probability (P(N)), which provides an indication of the probability by which a match between two nucleotide sequences would occur by chance. For example, a nucleic acid is considered similar to another if the smallest sum probability in comparison of the test nucleic acid to the other nucleic acid is less than about 1, preferably less than about 0.1, more preferably less than about 0.01, and most preferably less than about 0.001. "Percentage of similarity" can be calculated using PAUP* 4.0b10 software (D. L. Swofford, Sinauer Associates, Massachusetts). The average similarity of the consensus sequence is calculated compared to all sequences in the phylogenetic tree.

As used herein, the term “nucleic acid construct” refers to the DNA or RNA molecules that comprise a nucleotide sequence that encodes protein. The coding sequence, or “encoding nucleic acid sequence,” can include initiation and termination signals operably linked to regulatory elements including a promoter and polyadenylation signal capable of
directing expression in the cells of the individual to whom the nucleic acid molecule is administered.

As used herein, the term “expressible form” refers to nucleic acid constructs that contain the necessary regulatory elements operably linked to a coding sequence that encodes a protein such that when present in the cell of the individual, the coding sequence will be expressed.

The term “constant current” is used herein to define a current that is received or experienced by a tissue, or cells defining said tissue, over the duration of an electrical pulse delivered to same tissue. The electrical pulse is delivered from the electroporation devices described herein. This current remains at a constant amperage in said tissue over the life of an electrical pulse because the electroporation device provided herein has a feedback element, preferably having instantaneous feedback. The feedback element can measure the resistance of the tissue (or cells) throughout the duration of the pulse and cause the electroporation device to alter its electrical energy output (e.g., increase voltage) so current in same tissue remains constant throughout the electrical pulse (on the order of microseconds), and from pulse to pulse. In some embodiments, the feedback element comprises a controller.

The term “feedback” or “current feedback” is used interchangeably and means the active response of the provided electroporation devices, which comprises measuring the current in tissue between electrodes and altering the energy output delivered by the EP device accordingly in order to maintain the current at a constant level. This constant level is preset by a user prior to initiation of a pulse sequence or electrical treatment. Preferably, the feedback is accomplished by the electroporation component, e.g., controller, of the electroporation device, as the electrical circuit therein is able to continuously monitor the current in tissue between electrodes and compare that monitored current (or current within tissue) to a preset current and continuously make energy-output adjustments to maintain the monitored current at preset levels. In some embodiments, the feedback loop is instantaneous as it is an analog closed-loop feedback.

The terms “electroporation,” “electro-permeabilization,” or “electro-kinetic enhancement” (“EPE”), as used interchangeably herein, refer to the use of a transmembrane electric field pulse to induce microscopic pathways (pores) in a bio-membrane; their presence allows biomolecules such as plasmids, oligonucleotides, siRNA, drugs, ions, and/or water to pass from one side of the cellular membrane to the other.

The term “decentralized current” is used herein to define the pattern of electrical currents delivered from the various needle electrode arrays of the electroporation devices described herein, wherein the patterns minimize, or preferably eliminate, the occurrence of electroporation-related heat stress on any area of tissue being electroporated.

The term “feedback mechanism” as used herein refers to a process performed by either software or hardware (or firmware), which process receives and compares the impedance of the desired tissue (before, during, and/or after the delivery of pulse of energy) with a preset value, preferably current, and adjusts the pulse of energy delivered to achieve the preset value. The term “impedance” is used herein when discussing the feedback mechanism and can be converted to a current value according to Ohm’s law, thus enabling comparisons with the preset current. In a preferred embodiment, the “feedback mechanism” is performed by an analog closed loop circuit.

The term “immune response” is used herein to mean the activation of a host’s immune system, e.g., that of a mammal, in response to the introduction of a dengue antigen, e.g., universal dengue antigen, via the provided DNA plasmid vaccines. The immune response can be in the form of a cellular or humoral response, or both.

The term “consensus” or “consensus sequence” is used herein to mean a synthetic nucleic acid sequence, or corresponding polypeptide sequence, constructed based on analysis of an alignment of multiple strains of a specific dengue subtype, which yields the consensus dengue sequences of subtype-1, subtype-2, subtype-3, subtype-4, and the universal dengue described below. The consensus universal dengue can be used to induce broad immunity against multiple subtypes or serotypes of dengue virus.

The term “adjuvant” is used herein to mean any molecule added to the DNA plasmid vaccines described herein to enhance antigenicity of the dengue antigen encoded by the DNA plasmids and encoding nucleic acid sequences described hereinafter.

The term “subtype” or “serotype” is used herein interchangeably and in reference to a virus, for example dengue virus, and means genetic variants of that virus antigen such that one subtype is recognized by an immune system apart from a different subtype. For example, dengue virus subtype 1 is immunologically distinguishable from dengue virus subtype 2.

One aspect of the present invention provides nucleic acid constructs capable of expressing a polypeptide that elicits an immune response in a mammal against more than one subtype of dengue virus. The nucleic acid constructs are comprised of an encoding nucleotide sequence and a promoter operably linked to the encoding nucleotide sequence. The encoding nucleotide sequence expresses the polypeptide, wherein the polypeptide includes a PRM/E domain from at least two different dengue virus subtypes. The promoter regulates expression of the polypeptide in the mammal.

In some embodiments the nucleic acid construct can further include an IgE leader sequence operatively linked to an N-terminal end of the coding sequence and operably linked to the promoter. Preferably, the IgE leader has the sequence of SEQ ID NO: 11. The nucleic acid construct can also comprise a polyadenylation sequence attached to the C-terminal end of the coding sequence. Preferably, the nucleic acid construct is codon optimized.

In some embodiments, the encoding nucleotide sequence encodes a polypeptide that includes PRM/E domain from Dengue virus-subtype 1, Dengue virus-subtype 2, Dengue virus-subtype 3, and Dengue virus-subtype 4. In preferred embodiments, the encoding nucleotide sequence is selected from the group consisting of:

Another aspect of the present invention provides DNA plasmid vaccines that are capable of generating in a mammal an immune response against a plurality of dengue virus subtypes. The DNA plasmid vaccines are comprised of a DNA plasmid capable of expressing a consensus dengue
antigen in the mammal and a pharmaceutically acceptable excipient. The DNA plasmid is comprised of a promoter operably linked to a coding sequence that encodes the consensus dengue antigen. The consensus dengue antigen is comprised of consensus PRM/E domains of dengue virus-subtype 1, dengue virus-subtype 2, dengue virus-subtype 3, or dengue virus-subtype 4. Preferably, the DNA plasmid comprises a consensus dengue antigen that encodes a consensus dengue antigen selected from the group consisting of: SEQ ID NO: 2, SEQ ID NO: 4, SEQ ID NO: 6, and SEQ ID NO: 8.

In some embodiments, the DNA plasmid further comprises an IgE leader sequence attached to an N-terminal end of the coding sequence and operably linked to the promoter. Preferably, the IgE leader has the sequence Met Arg Trp Thr Trp Ile Leu Phe Leu Val Ala Ala Ala Thr Arg His Ser.

The DNA plasmid can further include a polyadenylation sequence attached to the C-terminal end of the coding sequence. Preferably, the DNA plasmid is codon optimized.

In some embodiments, the pharmaceutically acceptable excipient is an adjuvant. Preferably, the adjuvant is selected from the group consisting of: IL-12 and IL-15. In some embodiments, the pharmaceutically acceptable excipient is a transfection facilitating agent. Preferably, the transfection facilitating agent is a polyion, polycation, or lipid, and more preferably poly-L-glutamate. Preferably, the poly-L-glutamate is at a concentration less than 6 mg/ml. Preferably, the DNA plasmid vaccine has a concentration of total DNA plasmid of 1 mg/ml or greater.

In some embodiments, the DNA plasmid comprises a plurality of unique DNA plasmids, wherein each of the plurality of unique DNA plasmids encodes a polypeptide comprising a prME dengue virus-subtype 1, dengue virus-subtype 2, dengue virus-subtype 3, or dengue virus-subtype 4.

The DNA plasmid vaccines can include a DNA plasmid comprising encoding nucleotide sequences: SEQ ID NO: 1, nucleotide sequence encoding SEQ ID NO: 2, nucleotide sequence encoding SEQ ID NO: 3, nucleotide sequence encoding SEQ ID NO: 4, nucleotide sequence encoding SEQ ID NO: 5, and nucleotide sequence encoding SEQ ID NO: 6, SEQ ID NO: 7 and SEQ ID NO: 8.

In some embodiments, the DNA plasmid vaccines comprises at least two different DNA plasmids that express a dengue virus prME. In some embodiments, the DNA plasmid vaccines can include four consensus dengue virus prME (subtypes 1-4).

In some embodiments, the mammal in which the DNA plasmid vaccines generate an immune response is a primate. Preferably, the primate is a human. The immune response can be either a humoral response or cellular response, and preferably both.

Another aspect of the present invention provides methods of eliciting an immune response against a plurality of dengue virus subtypes in a mammal, comprising delivering a DNA plasmid vaccine to tissue of the mammal and electroporating cells of the tissue with a pulse of energy at a constant current effective to permit entry of the DNA plasmids into the cells.

In some embodiments, the methods of eliciting an immune response includes a delivering step that comprises injecting the DNA plasmid vaccine into intradermic, subcutaneous or muscle tissue.

In some embodiments, the methods of eliciting an immune response can further comprise presetting a current that is desired to be delivered to the tissue; and electroporating cells of the tissue with a pulse of energy at a constant current that equals the preset current.

In some embodiments, the methods of eliciting an immune response further comprise measuring the impedance in the electroporated cells; adjusting energy level of the pulse of energy relative to the measured impedance to maintain a constant current in the electroporated cells. The measuring and adjusting steps preferably occur within a lifetime of the pulse of energy.

In some embodiments, the electroporating step comprises delivering the pulse of energy to a plurality of electrodes according to a pulse sequence pattern that delivers the pulse of energy in a decentralized pattern.

In some embodiments of the present invention, the DNA plasmid vaccines can further include an adjuvant. In some embodiments, the adjuvant is selected from the group consisting of: alpha-interferon, gamma-interferon, platelet derived growth factor (PDGF), TNFα, TNFβ, GM-CSF, epidermal growth factor (EGF), nerve growth factor (NGF), platelet derived growth factor (PDGF), transforming growth factor beta (TGF-β), chemokine (CTACK), epithelial thymus-expressed chemokine (TECK), mucose-associated epithelial chemokine (MEC), IL-12, IL-15, MHC, CD80, CD86 including IL-15 having the signal sequence deleted and optionally including the signal peptide from IgE. Other genes which may be useful adjuvants include those encoding: MCP-1, MIP-1-alpha, MIP-1p, IL-8, RANTES, L-lectin, P-lectin, E-lectin, CD34, GlyCAM-1, MadCAM-1, LFA-1, VLA-1, Mac-1, p150,95, PECAM, ICAM-1, ICAM-2, ICAM-3, CD2, LFA-3, M-CSF, G-CSF, IL-4, mutant forms of IL-18, CD40, CD40L, vascular growth factor, fibroblast growth factor, IL-7, nerve growth factor, vascular endothelial growth factor, Fas, TNF receptor, Fli, Apo-1, p55, WSL-1, DR3, TRAMP, Apo-3, AIR, LARD, NGRF, DR4, DR5, KILLER, TRAIL-R2, TRICK2, DR6, Caspase ICE, Fos, c-jun, Sp-1, Ap-1, Ap-2, p38, p55Rel, MyD88, IKK, TRAF-6, IkB, Inactive NK, SAP K, SAP-1, JNK, interferon response genes, NfkB, Bax, TRAIL, TRAIL-re, TRAIL-re, TRAIL-re, TRAIL-re, TRAIL-re, TRAIL-R3, TRAIL-R4, RANK, RANK LIGAND, OX40, OX40 LIGAND, NK2D, MICA, MICB, NKG2A, NKG2B, NKG2C, NKG2E, NKG2F, TAP1, TAP2 and functional fragments thereof. In some preferred embodiments, the adjuvant is selected from IL-12, IL-15, CTACK, TECK, or MEC.

In some embodiments, the pharmaceutically acceptable excipient is a transfection facilitating agent, which can include the following: surface active agents, such as immune-stimulating complexes (ISCOMS), Freund's incomplete adjuvants, LPS analog including monophosphoryl lipid A, muramyl peptides, quinone analogs, vesicles such as squalene and squalane, hyaluronic acid, lipids, liposomes, calcium ions, viral proteins, polyanions, polycations, or nanoparticles, or other known transfection facilitating agents. Preferably, the transfection facilitating agent is a polyanion, polycation, including poly-L-glutamate (LGS), or lipid. Preferably, the transfection facilitating agent is poly-L-glutamate, and more preferably, the poly-L-glutamate is present in the DNA plasmid vaccine at a concentration less than 6 mg/ml.

In some embodiments, the concentration of poly-L-glutamate in the DNA plasmid vaccine is less than 4 mg/ml, less than 2 mg/ml, less than 1 mg/ml, less than 0.75 mg/ml, less than 0.50 mg/ml, less than 0.250 mg/ml, less than 0.100 mg/ml, less than 0.050 mg/ml, or less than 0.010 mg/ml.

In some embodiments, the DNA plasmid vaccine can be delivered to a mammal to elicit an immune response; preferably the mammal is a primate, including human and nonhuman primate, a cow, pig, chicken, dog, or ferret. More preferably, the mammal is a human primate.
One aspect of the present invention relates to methods of eliciting an immune response against a plurality of subtypes of a virus in a mammal. The methods include delivering a DNA plasmid vaccine to tissue of the mammal, and electroporating cells of the tissue with a pulse of energy at a constant current effective to permit entry of the DNA plasmids into the cells. The DNA plasmid vaccine comprises a DNA plasmid capable of expressing a plurality of consensus antigens derived from the subtypes of the virus in a cell of the mammal to elicit an immune response in the mammal, the plurality of consensus antigens comprising an antigenic domain from at least two different subtypes of the virus.

One aspect of the present invention relates to methods of eliciting an immune response against a plurality of dengue virus subtypes in a mammal. The methods include delivering a DNA plasmid vaccine to tissue of the mammal, the DNA plasmid vaccine comprising a DNA plasmid capable of expressing a consensus dengue antigen in a cell of the mammal to elicit an immune response in the mammal, the consensus dengue antigen comprising consensus sequences coding for prME protein from at least two dengue subtypes, and preferably all four dengue subtypes. The dengue subtypes include subtype-1, subtype-2, subtype-3, and subtype-4. The methods of eliciting an immune response including electroporating cells of the tissue with a pulse of energy at a constant current effective to permit entry of the DNA plasmids in the cells.

In some embodiments, the methods of the present invention include the delivering step, which comprises injecting the DNA plasmid vaccine into intradermic, subcutaneous or muscle tissue. Preferably, these methods include using an in vivo electroporation device to preset a current that is desired to be delivered to the tissue; and electroporating cells of the tissue with a pulse of energy at a constant current that equals the preset current. In some embodiments, the electroporating step further comprises: measuring the impedance in the electroporated cells; adjusting energy level of the pulse of energy relative to the measured impedance to maintain a constant current in the electroporated cells; wherein the measuring and adjusting steps occur within a lifetime of the pulse of energy.

In some embodiments, the electroporating step comprises delivering the pulse of energy to a plurality of electrodes according to a pulse sequence pattern that delivers the pulse of energy in a decentralized pattern.

The present invention also comprises DNA fragments that encode a polypeptide capable of eliciting an immune response in a mammal substantially similar to that of the non-frAGMENT for at least one dengue virus subtype. The DNA fragments are fragments selected from at least one of the various encoding nucleotide sequences of the present invention, including SEQ ID NO: 1, nucleotide sequence encoding SEQ ID NO: 2, SEQ ID NO: 3, nucleotide sequence encoding SEQ ID NO: 4, SEQ ID NO: 5, nucleotide sequence encoding SEQ ID NO: 6, SEQ ID NO: 7 and SEQ ID NO: 8, and can be any of the following described DNA fragments, as it applies to the specific encoding nucleic acid sequence provided herein. In some embodiments, DNA fragments can comprise 30 or more, 45 or more, 60 or more, 75 or more, 90 or more, 120 or more, 150 or more, 180 or more, 210 or more, 240 or more, 270 or more, 300 or more, 320 or more, 340 or more, 360 or more nucleotides. In some embodiments, DNA fragments can comprise coding sequences for the immunoglobulin E (IgE) leader sequences. In some embodiments, DNA fragments can comprise fewer than 60, fewer than 75, fewer than 90, fewer than 120, fewer than 150, fewer than 180, fewer than 210, fewer than 240, fewer than 270, fewer than 300, fewer than 320, fewer than 340, or fewer than 360 nucleotides.

The present invention includes polypeptides encoded by the encoding nucleotide sequences and can include polypeptides having amino acid sequences of SEQ ID NOS: 2, 4, 6, and 8. The present invention also comprises polypeptide fragments that are capable of eliciting an immune response in a mammal substantially similar to that of the non-fragment for at least one dengue subtype. The polypeptide fragments are selected from at least one of the various polypeptide sequences of the present invention, including SEQ ID NOS: 2, 4, 6, and 8, and can be any of the following described polypeptide fragments, as it applies to the specific polypeptide sequence provided herein. In some embodiments, polypeptide fragments can comprise 15 or more, 30 or more, 45 or more, 60 or more, 75 or more, 90 or more, 100 or more, 110 or more, or 120 or more amino acids. In some embodiments, polypeptide fragments can comprise fewer than 30, fewer than 45, fewer than 60, fewer than 75, fewer than 90, fewer than 100, fewer than 110, or fewer than 120 amino acids.

The determination of a functional fragment eliciting an immune response in a mammal substantially similar to that of the non-fragment for at least one dengue subtype can be readily determined by one of ordinary skill. The fragment can be analyzed to contain at least one, preferably more, antigenic epitopes as provided by a publicly available database, such as National Center for Biotechnology Information (NCBI). In addition, immune response studies can be routinely assessed using mice and antibody titers and ELISpot analysis, such as that shown in the Examples below.

Vaccines

In some embodiments, the invention provides improved vaccines by providing proteins and genetic constructs that encode proteins with epitopes that make them particularly effective as immunogens against which immune responses can be induced. Accordingly, vaccines can be provided to induce a therapeutic or prophylactic immune response.

According to some embodiments of the invention, a vaccine according to the invention is delivered to an individual to modulate the activity of the individual's immune system and thereby enhance the immune response. When a nucleic acid molecule that encodes the protein is taken up by cells of the individual the nucleotide sequence is expressed in the cells and the protein is thereby delivered to the individual. Aspects of the invention provide methods of delivering the coding sequences of the protein on nucleic acid molecule such as plasmid.

According to some aspects of the present invention, compositions and methods are provided which prophylactically and/or therapeutically immunize an individual.

When taken up by a cell, the DNA plasmids can remain in the cell as separate genetic material. Alternatively, RNA may be administered to the cell. It is also contemplated to provide the genetic construct as a linear minichromosome including a centromere, telomeres and an origin of replication. Genetic constructs include regulatory elements necessary for gene expression of a nucleic acid molecule. The elements include: a promoter, an initiation codon, a stop codon, and a polyadenylation signal. In addition, enhancers are often required for gene expression of the sequence that encodes the target protein or the immunomodulating protein. It is necessary that these elements be operable linked to the
sequence that encodes the desired proteins and that the regulatory elements are operably in the individual to whom they are administered.

Initiation codons and stop codons are generally considered to be part of a nucleotide sequence that encodes the desired protein. However, it is necessary that these elements are functional in the mammal for whom the nucleic acid construct is administered. The initiation and termination codons must be in frame with the coding sequence.

Promoters and polyadenylation signals used must be functional within the cells of the individual.

Examples of promoters useful to practice the present invention, especially in the production of a genetic vaccine for humans, include but are not limited to promoters from simian virus 40 (SV40), mouse mammary tumor virus (MMTV) promoter, human immunodeficiency virus (HIV) such as the bovine immunodeficiency virus (BIV) long terminal repeat (LTR) promoter, Moloney virus, avian leukemia virus (ALV), cytomegalovirus (CMV) such as the CMV immediate early promoter, Epstein Barr virus (EBV), Rous sarcoma virus (RSV) as well as promoters from human genes such as human actin, human myosin, human hemoglobin, human muscle creatine and human metallothioneine; in other embodiments, promoters can be tissue specific promoters, such as muscle or skin specific promoters, natural or synthetic. Examples of such promoters are described in US patent application publication no. US20040175727, which is incorporated hereby in its entirety.

Examples of polyadenylation signals useful to practice the present invention, especially in the production of a genetic vaccine for humans, include but are not limited to SV40 polyadenylation signals, LTR polyadenylation signals, bovine growth hormone (BGH) polyadenylation signals, human growth hormone (hGH) polyadenylation signals, and human β-globin polyadenylation signals. In particular, the SV40 polyadenylation signal that is in pCEP4 plasmid (Invitrogen, San Diego, Calif.), referred to as the SV40 polyadenylation signal, can be used.

In addition to the regulatory elements required for DNA expression, other elements may also be included in the DNA molecule. Such additional elements include enhancers. The enhancer may be selected from the group including but not limited to: human actin, human myosin, human hemoglobin, human muscle creatine and viral enhancers such as those from CMV, RSV and EBV.

Genetic constructs can be provided with mammalian origin of replication in order to maintain the construct extrachromosomally and produce multiple copies of the construct in the cell. Plasmids pVAX1, pCEP4 and pREP4 from Invitrogen (San Diego, Calif.) contain the Epstein Barr virus origin of replication and nuclear antigen EBNA-1 coding region which produces high copy episomal replication without integration.

In order to maximize protein production, regulatory sequences may be selected which are well suited for gene expression in the cells the construct is administered into. Moreover, codons that encode said protein may be selected for which are most efficiently transcribed in the host cell. One having ordinary skill in the art can produce DNA constructs that are functional in the cells.

In some embodiments, nucleic acid constructs may be provided in which the coding sequences for the proteins described herein are linked to IgE signal peptide. In some embodiments, proteins described herein are linked to IgE signal peptide.

In some embodiments for which protein is used, for example, one having ordinary skill in the art can, using well known techniques, produce and isolate proteins of the invention using well known techniques. In some embodiments for which protein is used, for example, one having ordinary skill in the art can, using well known techniques, inserts DNA molecules that encode a protein of the invention into a commercially available expression vector for use in well known expression systems. For example, the commercially available plasmid pSE420 (Invitrogen, San Diego, Calif.) may be used for production of protein in Escherichia coli (E. coli). The commercially available plasmid pYES2 (Invitrogen, San Diego, Calif.) may, for example, be used for production in Saccharomyces cerevisiae strains of yeast. The commercially available MAXBACTM complete baculovirus expression system (Invitrogen, San Diego, Calif.) may, for example, be used for production in insect cells. The commercially available plasmid pcDNA or pcDNA3 (Invitrogen, San Diego, Calif.) may, for example, be used for production in mammalian cells such as Chinese hamster ovary (CHO) cells. One having ordinary skill in the art can use these commercial expression vectors and systems or others to produce a protein by routine techniques and readily available starting materials. (See e.g., Sambrook et al., Molecular Cloning a Laboratory Manual, Second Ed. Cold Spring Harbor Press (1989)). Thus, the desired proteins can be prepared in both prokaryotic and eukaryotic systems, resulting in a spectrum of processed forms of the protein.

One having ordinary skill in the art may use other commercially available expression vectors and systems or produce vectors using well known methods and readily available starting materials. Expression systems containing the requisite control sequences, such as promoters and polyadenylation signals, and preferably enhancers are readily available and known in the art for a variety of hosts. See e.g., Sambrook et al., Molecular Cloning a Laboratory Manual, Second Ed. Cold Spring Harbor Press (1989).

Genetic constructs include the protein coding sequence operably linked to a promoter that is functional in the cell line, or cells of targeted tissue, into which the constructs are transfected. Examples of constitutive promoters include promoters from cytomegalovirus (CMV) or SV40. Examples of inducible promoters include mouse mammary leukemia virus or metallothionein promoters. Those having ordinary skill in the art can readily produce genetic constructs useful for transfecting cells with DNA that encodes protein of the invention from readily available starting materials. The expression vector including the DNA that encodes the protein is used to transform the compatible host which is then cultured and maintained under conditions wherein expression of the foreign DNA takes place.

The protein produced is recovered from the culture, either by lysing the cells or from the culture medium as appropriate and known to those in the art. One having ordinary skill in the art can, using well known techniques, isolate protein that is produced using such expression systems. The methods of purifying protein from natural sources using antibodies which specifically bind to a specific protein as described above may be equally applied to purifying protein produced by recombinant DNA methodology.

In addition to producing proteins by recombinant techniques, automated peptide synthesizers may also be employed to produce isolated, essentially pure protein. Such techniques are well known to those having ordinary skill in the art and are useful if derivatives which have substitutions not provided for in DNA-encoded protein production.

The nucleic acid molecules may be delivered using any of several well known technologies including DNA injection (also referred to as DNA vaccination) with and without in...
vivo electroporation, liposome mediated, nanoparticle facilitated, recombinant vectors such as recombinant adenovirus, recombinant adenovirus associated virus and recombinant vaccinia. Preferably, the nucleic acid molecules such as the DNA plasmids described herein are delivered via DNA injection and along with in vivo electroporation.

Routes of administration include, but are not limited to, intramuscular, intranasally, intraperitoneal, intradermal, subcutaneous, intravenous, intramuscularly, intracutaneously and oral as well as topically, transdermally, by inhalation or suppository or to mucosal tissue such as by lavage to vaginal, rectal, urethral, buccal and sublingual tissue. Preferred routes of administration include intramuscular, intraperitoneal, intradermal and subcutaneous injection. Genetic constructs may be administered by means including, but not limited to, traditional syringes, needleless injection devices, "microprojectile bombardment gone guns", or other physical methods such as electroporation ("EP"), "hydrodynamic method", or ultrasound.

Examples of electroporation devices and electroporation methods preferred for facilitating delivery of the DNA vaccines of the present invention, include those described in U.S. Pat. No. 7,245,963 by Draghia-Akli, et al., U.S. Patent Pub. 2005/0052630 submitted by Smith, et al., the contents of which are hereby incorporated by reference in their entirety. Also preferred, are electroporation devices and electroporation methods for facilitating delivery of the DNA vaccines provided in co-pending and co-owned U.S. patent applications Ser. No. 11/874,072, filed Oct. 17, 2007, which claims the benefit under 35 USC 119(e) to U.S. Provisional Applications Ser. No. 60/852,149, filed Oct. 17, 2006, and 60/978,982, filed Oct. 10, 2007, all of which are hereby incorporated in their entirety.

U.S. Pat. No. 7,245,963 by Draghia-Akli, et al. describes modular electrode systems and their use for facilitating the introduction of a biomolecule into cells of a selected tissue in a body or plant. The modular electrode systems comprise a plurality of needle electrodes; a hypodermic needle; an electrical connector that provides a conductive link from a programmable constant-current pulse controller to the plurality of needle electrodes; and a power source. An operator can grasp the plurality of needle electrodes that are mounted on a support structure and firmly insert them into the selected tissue in a body or plant. The biomolecules are then delivered via the hypodermic needle into the selected tissue. The programmable constant-current pulse controller is activated and constant-current electrical pulse is applied to the plurality of needle electrodes. The applied constant-current electrical pulse facilitates the introduction of the biomolecule into the cell between the plurality of electrodes. The entire content of U.S. Pat. No. 7,245,963 is hereby incorporated by reference.

U.S. Patent Pub. 2005/0052630 submitted by Smith, et al. describes an electroporation device which may be used to effectively facilitate the introduction of a biomolecule into cells of a selected tissue in a body or plant. The electroporation device comprises an electro-kinetic device ("EKD device") whose operation is specified by software or firmware. The EKD device produces a series of programmable constant-current pulse patterns between electrodes in an array based on user control and input of the pulse parameters, and allows the storage and acquisition of current waveform data. The electroporation device also comprises a replaceable electrode disk having an array of needle electrodes, a central injection channel for an injection needle, and a removable guide disk. The entire content of U.S. Patent Pub. 2005/0052630 is hereby incorporated by reference.

The electrode arrays and methods described in U.S. Pat. No. 7,245,963 and U.S. Patent Pub. 2005/0052630 are adapted for deep penetration into not only tissues such as muscle, but also other tissues or organs. Because of the configuration of the electrode array, the injection needle (to deliver the biomolecule of choice) is also inserted completely into the target organ, and the injection is administered perpendicular to the target issue, in the area that is pre-delineated by the electrodes. The electrodes described in U.S. Pat. No. 7,245,963 and U.S. Patent Pub. 2005/0052630 are preferably 20 mm long and 21 gauge.

The following is an example of methods of the present invention, and is discussed in more detail in the patent references discussed above. The array thus configured to deliver to a desired tissue of a mammal a pulse of energy producing a constant current similar to a preset current input by a user. The electroporation device comprises an electroporation component and an electrode assembly or handle assembly. The electroporation component can include and incorporate one or more of the various elements of the electroporation devices, including: controller, current waveform generator, impedance tester, waveform logger, input element, status reporting element, communication port, memory component, power source, and power switch. The electroporation component can function as one element of the electroporation devices, and the other elements are separate elements (or components) in communication with the electroporation component. In some embodiments, the electroporation component can function as more than one element of the electroporation devices, which can be in communication with the other elements of the electroporation devices separate from the electroporation component. The present invention is not limited by the elements of the electroporation devices existing as parts of one electromechanical or mechanical device, as the elements can function as one device or as separate elements in communication with one another. The electroporation component is capable of delivering the pulse of energy that produces the constant current in the desired tissue, and includes a feedback mechanism. The electrode assembly includes an electrode array having a plurality of electrodes in a spatial arrangement, wherein the electrode assembly receives the pulse of energy from the electroporation component and delivers same to the desired tissue through the electrodes. At least one of the plurality of electrodes is neutral during delivery of the pulse of energy and measures impedance in the desired tissue and communicates the impedance to the electroporation component. The feedback mechanism can receive the measured impedance and can adjust the pulse of energy delivered by the electroporation component to maintain the constant current.

In some embodiments, the plurality of electrodes can deliver the pulse of energy in a decentralized pattern. In some embodiments, the plurality of electrodes can deliver the pulse of energy in the decentralized pattern through the control of the electrodes under a programmed sequence, and the programmed sequence is input by a user to the electroporation component. In some embodiments, the programmed sequence comprises a plurality of pulses delivered in sequence, wherein each pulse of the plurality of pulses is delivered by at least two active electrodes with one neutral electrode that measures impedance, and wherein a subsequent pulse of the plurality of pulses is delivered by a
different one of at least two active electrodes with one neutral electrode that measures impedance.

In some embodiments, the feedback mechanism is performed by either hardware or software. Preferably, the feedback mechanism is performed by a closed-loop circuit. Preferably, this feedback occurs every 50 µs, 20 µs, 10 µs or 1 µs, but is preferably a real-time feedback or instantaneous (i.e., substantially instantaneous as determined by available techniques for determining response time). In some embodiments, the neutral electrode measures the impedance in the desired tissue and communicates the impedance to the feedback mechanism, and the feedback mechanism responds to the impedance and adjusts the pulse of energy to maintain the constant current at a value similar to the preset current. In some embodiments, the feedback mechanism maintains the constant current continuously and instantaneously during the delivery of the pulse of energy.

A pharmaceutically acceptable excipient can include such functional molecules as vehicles, adjuvants, carriers or diluents, which are known and readily available to the public. Preferably, the pharmaceutically acceptable excipient is an adjuvant or transfection facilitating agent. In some embodiments, the nucleic acid molecule, or DNA plasmid, is delivered to the cells in conjunction with administration of a polynucleotide function enhancer or a genetic vaccine facilitator agent (or transfection facilitating agent). Polynucleotide function enhancers are described in U.S. Pat. Nos. 5,593,972, 5,962,428 and International Application Serial Number PCT/US94/00899 filed Jan. 26, 1994, which are each incorporated herein by reference. Genetic vaccine facilitator agents are described in U.S. Ser. No. 021,579 filed Apr. 1, 1994, which is incorporated herein by reference. The transfection facilitating agent can be administered in conjunction with nucleic acid molecules as a mixture with the nucleic acid molecule or administered separately simultaneously, before or after administration of nucleic acid molecules. Examples of transfection facilitating agents include surface active agents such as immune-stimulating complexes (ISCOMS), Freund's incomplete adjuvant, LPS analog including monophosphoryl lipid A, muramyl peptides, quinone analogs and vesicles such as squalene and squalene, and hyaluronic acid may also be used administered in conjunction with the genetic construct. In some embodiments, the DNA plasmid vaccines may also include a transfection facilitating agent such as lipids, liposomes, including lecithin liposomes or other liposomes known in the art, as a DNA-liposome mixture (see for example WO9324640), calcium ions, viral proteins, polyamines, polyacrylons, or nanoparticles, or other known transfection facilitating agents. Preferably, the transfection facilitating agent is a polyion, polyecation, including poly-L-glutamate (LGS), or lipid.

In some preferred embodiments, the DNA plasmids are delivered with an adjuvant that are genes for proteins which further enhance the immune response against such target proteins. Examples of such genes are those which encode other cytokines and lymphokines such as alpha-interferon, gamma-interferon, platelet derived growth factor (PDGF), TNFα, TNFβ, GM-CSF, epidermal growth factor (EGF), IL-1, IL-2, IL-4, IL-5, IL-6, IL-10, IL-12, IL-18, MHC, CD80, CD86 and IL-15 including IL-15 having the signal sequence deleted and optionally including the signal peptide from Igλ. Other genes which may be useful include those encoding: MCP-1, MIP-1α, MIP-1p, RANTES, L-selectin, P-selectin, E-selectin, CD34, GlyCAM-1, MadCAM-1, LFA-1, VLA-1, Mac-1, p150.95, PECAM, ICAM-1, ICAM-2, ICAM-3, CD2, LFA-3, M-CSF, G-CSF, IL-4, mutant forms of IL-18, CD40, CD40L, vascular growth factor, fibroblast growth factor, IL-7, nerve growth factor, vascular endothelial growth factor, Fas, TNF receptor, Filt, Apo-1, p55, WSL-1, DR3, TRAMP, Apo-3, AIR, LARD, NGFR, DR4, DR5, KILLER, TRAIL-R2, TRICK2, DR6, Caspase ICE, Fos, e-jun, Sp-1, Ap-1, Ap-2, p53, p65Rel, MyD88, IRAK, TRAF6, IkB, Inactive NIK, SAP K, SAP-1, JNK, interferon response genes, NFκB, Bax, TRAIL, TRAILrec, TRAILrec3R5, TRAIL-R3, TRAIL-R4, RANK, RANK LIGAND, Oxt40, Oxt40 LIGAND, NKG2D, MICA, MICB, NKG2A, NKG2B, NKG2C, NKG2E, NKG2F, TAP1, TAP2 and functional fragments thereof.

The DNA plasmid vaccines according to the present invention comprise DNA quantities of from about 1 nanogram to about 1 milligram; about 1 microgram to about 10 milligrams; preferably about 0.1 microgram to about 10 milligrams; or more preferably about 100 micrograms to about 1 milligram. In some preferred embodiments, DNA plasmid vaccines according to the present invention comprise about 5 nanogram to about 1000 micrograms of DNA. In some preferred embodiments, the DNA plasmid vaccines contain about 10 nanograms to about 800 micrograms of DNA. In some preferred embodiments, the DNA plasmid vaccines contain about 0.1 to about 500 micrograms of DNA. In some preferred embodiments, the DNA plasmid vaccines contain about 1 to about 350 micrograms of DNA. In some preferred embodiments, the DNA plasmid vaccines contain about 25 to about 250 micrograms of DNA. In some preferred embodiments, the DNA plasmid vaccines contain about 100 micrograms to about 1 milligram DNA.

The DNA plasmid vaccines according to the present invention are formulated according to the mode of administration to be used. In cases where DNA plasmid vaccines are injectable compositions, they are sterile, and/or pyrogen free and/or particulate free. An isotonic formulation is preferably used. Generally, additives for isotonicity can include sodium chloride, dextrose, mannitol, sorbitol and lactose. In some cases, isotonic solutions such as phosphate buffered saline are preferred. Stabilizers include gelatin and albumin. In some embodiments, a vasoconstruction agent is added to the formulation. In some embodiments, a stabilizing agent that allows the formulation to be stable at room or ambient temperature for extended periods of time, such as LGS or other polycations or polyanions is added to the formulation.

In some embodiments, methods of eliciting an immune response in mammals against a consensus dengue antigen include methods of inducing mucosal immune responses. Such methods include administering to the mammal one or more of CTACK protein, TECK protein, MEC protein and functional fragments thereof or expressible coding sequences thereof in combination with an DNA plasmid including a consensus dengue antigen, described above. The one or more of CTACK protein, TECK protein, MEC protein and functional fragments thereof may be administered prior to, simultaneously with or after administration of the DNA plasmid dengue vaccines provided herein. In some embodiments, an isolated nucleic acid molecule that encodes one or more proteins of selected from the group consisting of: CTACK, TECK, MEC and functional fragments thereof is administered to the mammal.

EXAMPLES

The present invention is further illustrated in the following Examples. It should be understood that these Examples, while indicating preferred embodiments of the invention, are
given by way of illustration only. From the above discussion and these Examples, one skilled in the art can ascertain the essential characteristics of this invention, and without departing from the spirit and scope thereof, can make various changes and modifications of the invention to adapt it to various usages and conditions. Thus, various modifications of the invention in addition to those shown and described herein will be apparent to those skilled in the art from the foregoing description. Such modifications are also intended to fall within the scope of the appended claims.

Preferably the DNA formulations for use with a muscle or skin EP device described herein have high DNA concentrations, preferably concentrations that include microgram to tens of milligram quantities, and preferably milligram quantities, of DNA in small volumes that are optimal for delivery to the skin, preferably small injection volume, ideally 25-200 microliters (μL). In some embodiments, the DNA formulations have high DNA concentrations, such as 1 mg/mL or greater (mg DNA/volume of formulation). More preferably, the DNA formulation has a DNA concentration that provides for gram quantities of DNA in 200 μL of formula, and more preferably gram quantities of DNA in 100 μL of formula.

The DNA plasmids for use with the EP devices of the present invention can be formulated or manufactured using a combination of known devices and techniques, but preferably they are manufactured using an optimized plasmid manufacturing technique that is described in U.S. application Ser. No. 12/126,611 which published as US Publication No. 20090004716, which published Jan. 1, 2009. In some examples, the DNA plasmids used in these studies can be formulated at concentrations greater than or equal to 10 mg/mL. The manufacturing techniques also include or incorporate various devices and protocols that are commonly known to those of ordinary skill in the art, in addition to those described in US Publication No. 20090004716 and those described in U.S. Pat. No. 7,238,522, which issued on Jul. 3, 2007. The high concentrations of plasmids used with the skin EP devices and delivery techniques described herein allow for administration of plasmids into the ID/SC space in a reasonably low volume and aids in enhancing expression and immunization effects. The publications, US Publication No. 20090004716 and U.S. Pat. No. 7,238,522, are hereby incorporated in their entirety.

Animal Received 3 Immunizations with 3P Collectra (ID), 3 Weeks Apart and Bleed Every 3 Weeks

**Dengue Li-Cor Assay**

2-fold serial dilutions of serum in 96-well plate: 50 μl/well

Add 50 pfu virus to each well: 50 μl/well Incubate @ 37°C for 1 hour to allow for neutralization

Add entire mixture (100 μl) to VERO cells (seed 1.5x10⁵/well) Incubate plates 4 days @ 37°C

Fix cells using 3.7% formaldehyde for 30 minutes

Wash and permeabilize using 0.1% TritonX-100/PBS

Perform cell-based ELISA:

Mouse 4G2 mAb

Biotinylated anti-mouse IgG

IRDye 800CW Streptavidin+5 mM DRAQ5 cocktail solution

Wash, dry and scan plates using Li-Cor Aerius system

Calculate 800 nm/700 nm ratios

... Dengue PRNT₅₀ Assay

**Day 1**

Plate VERO cells—6 well format (7.5x10⁵-1.0x10⁶ cells/well)

**Day 2**

Incubate 50 pfu virus/well+serum (1 hour @ 37°C)

Add mixture to monolayer (1 hour @ 37°C)

Overlay with 1% methyl-cellulose in 2% medium 199

Incubate for 5 days post-infection (37°C)

**Day 7**

Fix and stain with 0.05% Crystal violet/20% methanol mixture

(3 hours)

Wash plates with dH₂O, dry and count plaques

Calculate 50% reduction relative to virus only control

Neutralization titers are defined as the reciprocal of the highest serum dilution that reduces plaque count by >50% compared to controls without sera

Dengue prM—Rationale

prM prevents premature fusion of the E protein during virus maturation by forming a non-infectious immature virus particles, prM-E heterodimeric complex

The immature particles transit through a low pH environment of the Golgi compartment, at this stage, a reversible conformational change occurs in E protein prior to processing of prM.

After cleavage of prM to M by cellular serine protease in the trans-Golgi network results in an irreversible conformational change in E which maintains the integrity of the neutralizing epitopes.

### Sequence Listing

**<160> NUMBER OF SEQ ID NOS: 10**

**<210> SEQ ID NO 1**

**<211> LENGTH: 2100**

**<212> TYPE: DNA**

**<213> ORIGIN: Artificial Sequence**

**<220> FEATURES:***

**<223> OTHER INFORMATION: Den1-prME DNA sequence**

**<400> SEQUENCE: 1**

What is claimed:

1. A nucleic acid construct for expressing a polypeptide that elicits an immune response in a mammal against more than one subtype of Dengue virus, comprising:

   - an encoding nucleotide sequence that expresses the polypeptide, wherein the polypeptide includes consensus prME proteins from at least two different Dengue virus subtypes, and
   - a promoter that regulates expression of the polypeptide in the mammal and is operably linked to the encoding nucleotide sequence,

   wherein the encoding nucleotide sequence comprises at least two nucleic acid sequences selected from the group consisting of a nucleotide sequence encoding SEQ ID NO: 2, a nucleotide sequence encoding SEQ ID NO: 4, a nucleotide sequence encoding SEQ ID NO: 6, and a nucleotide sequence encoding SEQ ID NO: 8.
2. The nucleic acid construct of claim 1, further comprising an IgE leader sequence operatively linked to the 5'-end of the coding sequence and operably linked to the promoter.

3. The nucleic acid construct of claim 1, further comprising a polyadenylation sequence attached to the 3'-end of the coding sequence.

4. The nucleic acid construct of claim 1, wherein the nucleic acid construct is codon optimized.

5. The nucleic acid construct of claim 1, wherein the encoding nucleotide sequence encodes a polypeptide that includes at least two PrME proteins selected from the group consisting of dengue virus-subtype 1, dengue virus-subtype 2, dengue virus-subtype 3, and dengue virus-subtype 4.

6. The nucleic acid construct of claim 1, wherein the encoding nucleotide sequence comprises at least two nucleic acid sequences selected from the group consisting of SEQ ID NO: 1, SEQ ID NO: 3, SEQ ID NO: 5, and SEQ ID NO: 7.

7. A DNA plasmid vaccine for generating in a mammal an immune response against a plurality of dengue virus subtypes, comprising:

   at least one DNA plasmid for expressing at least one consensus dengue antigen in a cell of the mammal in a quantity effective to elicit an immune response in the mammal, wherein at least one consensus dengue antigen is selected from the group consisting of SEQ ID NO: 1, SEQ ID NO: 3, SEQ ID NO: 5, and SEQ ID NO: 7.

   the DNA plasmid comprising a promoter operably linked to a coding sequence that encodes the consensus dengue antigen.

8. The DNA plasmid vaccine of claim 7, wherein the DNA plasmid further comprises an IgE leader sequence attached to the 5'-end of the coding sequence and operably linked to the promoter.

9. The DNA plasmid vaccine of claim 7, wherein the DNA plasmid further comprises a polyadenylation sequence attached to the 3'-end of the coding sequence.

10. The DNA plasmid vaccine of claim 7, wherein the DNA plasmid is codon optimized.

11. The DNA plasmid vaccine of claim 7, wherein the pharmaceutically acceptable excipient is an adjuvant.

12. The DNA plasmid vaccine of claim 11, wherein the adjuvant is selected from the group consisting of: IL-12 and IL-15.

13. The DNA plasmid vaccine of claim 7, wherein the pharmaceutically acceptable excipient is a transfection facilitating agent.

14. The DNA plasmid vaccine of claim 13, wherein the transfection facilitating agent is a polyanion, polycation, or lipid.

15. The DNA plasmid vaccine of claim 13, wherein the transfection facilitating agent is poly-L-glutamate at a concentration less than 6 mg/ml.

16. The DNA plasmid vaccine of claim 7, wherein the DNA plasmid vaccine has a concentration of total DNA plasmid of 1 mg/ml or greater.

17. The DNA plasmid vaccine of claim 7, wherein the vaccine comprises a plurality of unique DNA plasmids, wherein each of the plurality of unique DNA plasmids encodes a polypeptide comprising at least one consensus PrME protein selected from the group consisting of SEQ ID NO: 2, SEQ ID NO: 4, SEQ ID NO: 6, and SEQ ID NO: 8.

18. The DNA plasmid vaccine of claim 7, wherein the encoding nucleotide sequence comprises one or more sequences selected from the group consisting of SEQ ID NO: 1, SEQ ID NO: 3, SEQ ID NO: 5, and SEQ ID NO: 7.

19. The DNA plasmid vaccine of claim 7, comprising at least two different DNA plasmids that express Dengue virus PrME protein, the plasmids selected from the group consisting of:

   a DNA plasmid comprising a sequence that encodes SEQ ID NO: 2;
   a DNA plasmid comprising a sequence that encodes SEQ ID NO: 4;
   a DNA plasmid comprising a sequence that encodes SEQ ID NO: 6; and
   a DNA plasmid comprising a sequence that encodes SEQ ID NO: 8.

20. The DNA plasmid vaccine of claim 7, comprising:

   the DNA plasmid comprising a sequence that encodes SEQ ID NO: 2;
   the DNA plasmid comprising a sequence that encodes SEQ ID NO: 4;
   the DNA plasmid comprising a sequence that encodes SEQ ID NO: 6; and
   the DNA plasmid comprising a sequence that encodes SEQ ID NO: 8.

21. The DNA plasmid vaccine of claim 7, wherein the nucleotide sequence encoding SEQ ID NO: 2 is SEQ ID NO: 1, wherein the nucleotide sequence encoding SEQ ID NO: 4 is SEQ ID NO: 3, wherein the nucleotide sequence encoding SEQ ID NO: 6 is SEQ ID NO: 5, and wherein the nucleotide sequence encoding SEQ ID NO: 8 is SEQ ID NO: 7.

22. The DNA plasmid vaccine of claim 7, wherein the mammal is a nonhuman primate.

23. The DNA plasmid vaccine of claim 7, wherein the immune response is selected from the group consisting of a humoral response, a cellular response, and a combination thereof.

24. A method of eliciting an immune response against a plurality of subtypes of a dengue virus in a mammal, comprising:

   delivering the DNA plasmid vaccine of claim 7 to tissue of the mammal, and
   electroporating cells of the tissue with a pulse of energy at a constant current effective to permit entry of DNA plasmids in said DNA plasmid vaccine into the cells.

25. The method of claim 24, wherein the delivering step comprises:

   injecting the DNA plasmid vaccine into intradermic, subcutaneous or muscle tissue.

26. The method of claim 24, further comprising:

   presetting a current that is desired to be delivered to the tissue, and
   electroporating cells of the tissue with a pulse of energy at a constant current that equals the preset current.

27. The method of claim 24, wherein the electroporating step further comprises:

   measuring the impedance in the electroporated cells;
   adjusting energy level of the pulse of energy relative to the measured impedance to maintain a constant current in the electroporated cells;
   wherein the measuring and adjusting steps occur within a lifetime of the pulse of energy.

28. The method of claim 24, wherein the electroporating step comprises:

   delivering the pulse of energy to a plurality of electrodes according to a pulse sequence pattern that delivers the pulse of energy in a decentralized pattern.
