VIRUS-LIKE PARTICLES AND METHODS OF USE

CROSS-REFERENCE TO RELATED APPLICATIONS

This application claims the benefit of the following U.S. Provisional Application
5 Nos.: 61/438,236, filed January 31, 2011, and 61/501,012, filed June 24, 2011, the entire contents of each of which are incorporated herein by reference.

STATEMENT OF RIGHTS TO INVENTIONS MADE UNDER FEDERALLY SPONSORED RESEARCH

10 Research supporting this application was carried out by the United States of America as represented by the Secretary, Department of Health and Human Services. This research was supported by the Intramural Research Program, Vaccine Research Center, NIAID of the National Institute of Health. The Government has certain rights in this invention.

15 BACKGROUND OF THE INVENTION

Alphaviruses comprise a set of genetically, structurally, and serologically related mosquito-borne viruses of the Togaviridae family. Twenty-seven known viruses and virus subtypes have been classified within the alphavirus genus, eleven of which are recognized to be pathogenic to humans. Eastern equine encephalitis virus (EEEV), Western equine
20 encephalitis virus (WEEV), Venezuelan equine encephalitis virus (VEEV), and Semliki Forest virus (SFV) are known to produce encephalitis, and infection by Chikungunya virus (CHIKV), O'nyong-nyong virus, Sindbis virus, Mayaro virus, Ross River virus, Barmah Forest virus, and Ockelbo virus result in acute onset of flu-like fever, followed by the development of a rash and arthritis. The evolution and spread of alphaviruses into new
25 geographic areas, and the disease severity resulting from alphavirus infection present a serious public health issue in the absence of a vaccines or anti-viral therapies.

Flaviviruses comprise a set of genetically, structurally, and serologically related mosquito-borne or tick-borne viruses of the Flaviviridae family that also pose current or potential threats to global public health. Yellow Fever Virus (YFV), Dengue Virus (DENV),
30 Japanese Encephalitis Virus (JEV), Tick-Borne Encephalitis Virus (TBEV), and West Nile Virus

(WNV) result in a range of symptoms ranging from flu-like symptoms such as fever, chills, and vomiting to severe symptoms such as muscular rigidity, photophobia, hyperexcitability, abnormal tremors and movements, incoordination, paralysis, sensory loss, convulsions,

respiratory dysfunction, and severe hemorrhages. Like other arthropod-borne viruses, the evolution and spread of flaviruses into new geographic areas, and the disease severity resulting from flavivirus infection present a serious public health issue in the absence of a vaccines or anti-viral therapies.

5

SUMMARY OF THE INVENTION

The present invention features compositions and methods for the prevention or treatment of a disease or disorder mediated by an alphavirus or a flavivirus (e.g., Chikungunya virus, WEEV, EEEV, VEEV, Ross River virus, or Barmah Forest virus).

10 Expression of alphavirus structural proteins, such as CHIKV, WEEV, EEEV, VEEV, Ross River virus, or Barmah Forest virus structural proteins, gives rise to virus-like particles (VLPs) that resemble replication-competent alphavirus. In some cases, expression of wild-type alphavirus proteins does not produce VLPs, such as EEEV and WEEV CBA, and one or more alterations in one or more of an alphavirus E2 protein or an alphavirus capsid protein
15 Nuclear Localization Signal (NLS) allows or enhances VLP production. As reported in detail below, an alphavirus VLP-based vaccine efficiently induced high-titer neutralizing antibodies against homologous and heterologous alphavirus strains in monkeys, and the immunized animals showed complete protection against a high titer of a heterologous alphavirus strain in a challenge study. Because VLP vaccines are known to have advantages such as safety and
20 high immunogenicity, it is desirable to use VLPs and a VLP vaccine strategy against pathogenic alphaviruses. In addition, based on the ability of VLPs to bind and deliver agents to a cell, it is desirable to produce alphavirus VLPs for delivering target agents to cells.

Similarly, expression of flavivirus structural proteins gives rise to VLPs that resemble replication-competent flavivirus. Therefore, it is desirable to use VLPs and a VLP vaccine
25 strategy against pathogenic flaviviruses. In addition, based on the ability of VLPs to bind and deliver agents to a cell, it is desirable to produce flavivirus VLPs for delivering target agents to cells.

Accordingly, the invention provides virus-like particles (VLP) having one or more alterations that enhance or allow VLP production, where the alteration is in one or more of an
30 E2 protein or an alphavirus capsid protein Nuclear Localization Signal (NLS).

In one aspect, the invention generally provides a virus-like particle (VLP) containing an alphavirus E2 protein containing at least one alteration that enhances VLP production, where the alteration is at an amino acid position corresponding to amino acid 234 or amino acid 251 in a Chikungunya virus (CHIKV) E2 protein.

In another aspect, the invention provides a VLP containing a Chikungunya virus (CHIKV) E2 protein containing an alteration at amino acid 234 and/or at amino acid 251.

In yet another aspect, the invention provides a VLP containing a WEEV E2 protein, where the WEEV E2 protein has an alteration at amino acid position 235.

5 In still another aspect, the invention provides a virus-like particle (VLP) containing a flavivirus envelop protein containing an alteration at an amino acid position corresponding to amino acid 234 or amino acid 251 in a Chikungunya virus (CHIKV) E2 protein.

In one aspect, the invention provides a virus-like particle (VLP) having one or more alterations that enhance or allow VLP production, wherein the alteration is in an alphavirus
10 capsid protein Nuclear Localization Signal (NLS).

In still another aspect, the invention provides an isolated polynucleotide encoding a VLP of a previous aspect or that is delineated herein.

In still another aspect, the invention provides an expression vector containing an isolated polynucleotide encoding a VLP of a previous aspect or that is delineated herein. In
15 one embodiment, the expression vector is capable of expression in a prokaryotic or eukaryotic cell. In another embodiment, the vector contains the CMV/R promoter.

In still another aspect, the invention provides a prokaryotic or eukaryotic cell containing the expression vector of any previous aspect or a vector that is described herein.

In still another aspect, the invention provides an immunogenic composition
20 containing an effective amount of the VLP of any previous aspect or that is delineated herein or an effective amount of the expression vector of any previous aspect, where administration of the immunogenic composition to a subject results in production of a VLP. In one embodiment, the VLP induces an immune response in the subject. In another embodiment, the immune response treats or prevents a virus infection in the subject. In yet another
25 embodiment, the VLP induces antibodies against homologous or heterologous strains of alphavirus or flavivirus. In one embodiment, the immunogenic composition further contains an adjuvant.

In another aspect, the invention provides an immunogenic composition or pan-alphavirus immunogenic composition containing at least two VLPs that are any one or more
30 of Eastern equine encephalitis virus (EEEV), Western equine encephalitis virus (WEEV), Venezuelan equine encephalitis virus (VEEV), Chikungunya virus (CHIKV), Ross River virus, Barmah Forest virus (BFV), Semliki Forest virus (SFV), O'nyong-nyong virus, Sindbis virus, Mayaro virus, or Ockelbo virus. In various embodiments of the above aspects or any other aspect of the invention delineated herein, VLPs have one or more alterations that

enhance VLP production, where the alteration is in an E2 protein or an alphavirus capsid protein Nuclear Localization Signal (NLS).

In another aspect, the invention provides an immunogenic composition containing at least two VLPs that are any one or more of a Yellow Fever Virus (YFV), Dengue Virus
5 (DENV), Japanese Encephalitis Virus (JEV), Tick-Borne Encephalitis Virus (TBEV), or West Nile Virus (WNV) protein.

In another aspect, the invention provides a method of inducing an immune response against a virus, including one or more of EEEV, WEEV, VEEV, CHIKV Ross River virus, or Barmah Forest virus, in a subject, involving administering to the subject an effective amount
10 of the immunogenic composition of any previous aspect or any other aspect of the invention delineated herein.. In one embodiment, the method induces neutralizing antibodies in the subject. In one embodiment, the method protects the subject against infection by the alphavirus and/or protects the subject against viremia or an inflammatory consequence of infection with said virus.

15 In another aspect, the invention provides a vaccine containing an effective amount of a VLP of any previous aspect or any other aspect of the invention delineated herein.

In another aspect, the invention provides a vaccine containing a polynucleotide encoding the VLP of any previous aspect or any other VLP delineated herein. In one embodiment, the vaccine is a DNA vaccine.

20 In another aspect, the invention provides a method for treating or preventing an a virus infection in a subject, involving administering to the subject an effective amount of the immunogenic composition of any previous aspect. In one embodiment, the vaccine or immunogenic composition is administered in one or more doses. In another embodiment, the vaccine or immunogenic composition is administered in one or more priming immunizations
25 and one or more boosting immunizations. In yet another embodiment, the priming immunizations are administered at one, two, three, four, five, six, seven, or eight week intervals. In still another embodiment, the boosting immunizations are administered two weeks, one month, two months, or three months after the priming immunization. In yet another embodiment, the administration of the vaccine or immunogenic composition protects
30 the subject against viremia or the inflammatory consequences of an alphavirus or flavivirus infection. In one embodiment, the administration of the vaccine or immunogenic composition protects the subject from lethality.

In another aspect, the invention provides a method for producing a VLP, the method involving expressing one or more of an alphavirus E2 protein having an alteration or an

alphavirus capsid protein having an alteration in an NLS in a eukaryotic cell, and isolating said VLP.

In another aspect, the invention provides a method for producing a VLP, the method involving expressing an alphavirus structural protein in a cell, thereby resulting in self-assembly of the VLP, where the cell expresses an alphavirus E2 protein that has i) an asparagine residue at the amino acid position corresponding to amino acid 234 in a CHIKV E2 protein, or ii) a modification at the amino acid position corresponding to amino acid 251 in the CHIKV E2 protein, and where the modification destabilizes the the alphavirus E2 protein during VLP budding. In one embodiment, the cell further expresses an alphavirus capsid (C) or an alphavirus envelope protein that is any one or more of E3, 6K, and E1. In another embodiment, the cell expresses an alphavirus polyprotein containing C-E3-E2-6K-E1. In yet another embodiment, the alphavirus envelope protein(s) or the alphavirus capsid protein is derived from EEEV, WEEV, VEEV, CHIKV, Ross River virus, Barmah Forest virus, SFV, O'nyong-nyong virus, Sindbis virus, Mayaro virus, or Ockelbo virus.

In another aspect, the invention provides a method for producing a VLP involving expressing an alphavirus capsid protein comprising an alteration in an NLS in a eukaryotic cell, and isolating said VLP.

In another aspect, the invention provides a method for enhancing VLP production, involving expressing an alphavirus structural protein of any previous aspect or any other aspect of the invention delineated herein in a cell under conditions that provide for self-assembly of the VLP.

In another aspect, the invention provides a method for producing a VLP, where the method involves expressing a flavivirus structural protein in a cell, thereby resulting in self-assembly of the VLP, where the cell expresses a flavivirus envelope protein that has i) an asparagine residue at the amino acid position corresponding to amino acid 234 in a CHIKV E2 protein, or ii) a modification at the amino acid position corresponding to amino acid 251 in the CHIKV E2 protein, and where the modification destabilizes the flavivirus envelope protein during VLP budding. In one embodiment, the cell further expresses a flavivirus capsid protein. In another embodiment, the flavivirus envelope protein or flavivirus capsid protein is derived from YFV, DENV, JEV, TBEV, or WNV.

In another aspect, the invention provides a method for enhancing VLP production in a cell involving altering an amino acid residue in an alphavirus E2 protein that corresponds to amino acid 234 and/or amino acid 251 in a CHIKV E2 protein; and expressing the alphavirus E2 protein in a cell; thereby resulting in self-assembly of the VLP. In one embodiment, the

method further involves expressing an alphavirus capsid (C) or an alphavirus envelope protein that is any one or more of E3, 6K, and E1 in the cell. In another embodiment, the method involves expressing an alphavirus polyprotein containing C-E3-E2-6K-E1 in the cell. In another embodiment, the alphavirus E2 protein contains an asparagine residue at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein. In another embodiment, the alphavirus E2 protein is altered at the amino acid position corresponding to amino acid 251 in the CHIKV E2 protein such that the alteration destabilizes the alphavirus E2 protein during VLP budding.

In another aspect, the invention provides a method for enhancing VLP production in a cell involving altering an amino acid residue in a flavivirus envelope protein that corresponds to amino acid 234 and/or amino acid 251 in a CHIKV E2 protein; and expressing the flavivirus envelope protein in a cell; thereby resulting in self-assembly of the VLP. In one embodiment, the method further contains expressing an flavivirus capsid protein in the cell. In another embodiment, the flavivirus envelope protein is altered such that it has an asparagine residue at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein. In still another embodiment, the flavivirus envelope protein is altered at the amino acid position corresponding to amino acid 251 in the CHIKV E2 protein such that the alteration destabilizes the flavivirus envelope protein during VLP budding. In another embodiment, the method further involves isolating the VLP.

In another aspect, the invention provides a VLP produced by the method of any above aspect or any other method described herein.

In another aspect, the invention provides a kit containing the VLP of any previous aspect, and directions for the use of said VLP or expression vector to generate an immune response in a subject.

In yet another aspect, the invention provides a method for introducing an agent into a cell involving packaging the agent into the VLP of any previous aspect, contacting a cell with the packed VLP; and allowing the packed VLP to enter the cell, thereby introducing the agent into the cell. In one embodiment, the agent is any one or more of a small molecule chemical compound, an antibody, a nucleic acid molecule, a polypeptide, or fragments thereof.

In various embodiments of the above aspects or any other aspect of the invention delineated herein, the VLP further contains an alphavirus (e.g., Eastern equine encephalitis virus (EEEV), Western equine encephalitis virus (WEEV), Venezuelan equine encephalitis virus (VEEV), Semliki Forest virus (SFV), Chikungunya virus (CHIKV), O'nyong-nyong virus, Sindbis virus, Mayaro virus, Ross River virus, Barmah Forest virus, or Ockelbo virus)

or flavivirus (e.g., Yellow Fever Virus (YFV), Dengue Virus (DENV), Japanese Encephalitis Virus (JEV), Tick-Borne Encephalitis Virus (TBEV), or West Nile Virus (WNV) protein) capsid (C) protein or an alphavirus envelop protein that is any one or more of E3, 6K, and E1.

In other embodiments, the VLP contains an alphavirus polyprotein containing C-E3-E2-6K-

5 E1. In other embodiments, the alphavirus E2 protein or the alphavirus capsid protein is a CHIKV or WEEV protein. In other embodiments, the alphavirus E2 protein(s) or the alphavirus capsid protein is derived from CHIKV strain 37997. In other embodiments, the alphavirus E2 protein(s) or the alphavirus capsid protein is derived from WEEV strain 71V-1658. In other embodiments, the alphavirus E2 protein has an asparagine residue at the
10 amino acid position corresponding to amino acid 234 in the CHIKV E2 protein. In still other embodiments, the alphavirus E2 protein has a modification at the amino acid position corresponding to amino acid 251 in the CHIKV E2 protein that destabilizes the E2 protein during VLP budding. In other embodiments, the alphavirus E2 protein contains alterations at an amino acid corresponding to amino acid 234 and at amino acid 251 in a Chikungunya
15 virus (CHIKV) E2 protein.

In various embodiments of the above aspects or any other aspect of the invention delineated herein, the alphavirus capsid protein is an EEEV, WEEV, VEEV, CHIKV Ross River virus, or Barmah Forest virus capsid protein. In various embodiments of the above aspects or any other aspect of the invention delineated herein, the one or more alterations is in
20 an NLS at amino acids 67-70 of an EEEV capsid protein; at amino acids 67-70 of an WEEV capsid protein; at amino acids 64-68 of an VEEV capsid protein; at amino acids 62-69 of a CHIKV capsid protein; at amino acids 71-74 of a Ross River virus capsid protein; or at amino acids 64-68 of a Barmah Forest virus capsid protein.

In various embodiments of the above aspects or any other aspect of the invention delineated herein, the alteration is a substitution in a charged amino acid of the NLS or basic
25 charged amino acid of the NLS. In some embodiments, the charged amino acid or basic charged amino acid is lysine or arginine. In certain embodiments, the lysine or arginine is substituted with a non-lysine or non-arginine amino acids. In specific embodiments, the lysine or arginine is substituted with asparagine or alanine.

30 In various embodiments of the above aspects or any other aspect of the invention delineated herein, the EEEV virus capsid protein NLS is altered at amino acid 67. In particular embodiments, the EEEV virus capsid protein NLS has a substitution K67N.

In various embodiments of the above aspects or any other aspect of the invention delineated herein, the WEEV virus capsid protein NLS is altered at one or more of amino

acids 67, 68, and 69. In particular embodiments, the WEEV capsid protein NLS comprises K67N, K68N, and/or K69N.

In various embodiments of the above aspects or any other aspect of the invention delineated herein, the VEEV virus capsid protein NLS is altered at one or more of amino acids 64, 65, and 67. In particular embodiments, the VEEV virus capsid protein NLS comprises K64N, K65A or K65N, and/or K67A or K67N.

In various embodiments, the Chikungunya virus capsid protein NLS is altered at one or more of amino acids 62, 63, 65, 66, 68, and 69. In particular embodiments, the Chikungunya virus capsid protein NLS comprises R62A, R63A, R65A, R66A, R68A and/or R69A.

In various embodiments of the above aspects or any other aspect of the invention delineated herein, the Ross River virus capsid protein NLS is altered at one or more of amino acids 71, 72, 73, and 74. In particular embodiments, the Ross River virus capsid protein NLS comprises R71N, R72N, R73N, and/or R74N.

In various embodiments of the above aspects or any other aspect of the invention delineated herein, the Barmah Forest virus capsid protein NLS is altered at one or more of amino acids 64, 65, 67, and 68. In particular embodiments, the Barmah Forest virus capsid protein NLS comprises K64A, K65A or K65N, K67A, K67N, K68A and/or K68N.

In various embodiments of the above aspects or any other aspect of the invention delineated herein, the VLP contains a protein or polynucleotide of interest for delivery to a cell. In another embodiment, the protein or polynucleotide of interest is derived from a pathogen, including a virus, bacteria, or fungus.

In various embodiments of the above aspects or any other aspect of the invention delineated herein, the expression vector is E37997, EOPY-1, CMV/R WEEV CBA87 strain capsid K67N VLP, CMV/R WEEV CBA87 strain capsid K67N K68N VLP, CMV/R WEEV CBA87 strain capsid K67N K68N K69N VLP, CMV/R VEEV TC83 strain K64N VLP, CMV/R VEEV TC83 strain K64N K65N VLP, CMV/R VEEV TC83 strain K65N K67N VLP, CMV/R VEEV TC83 strain K65A K67A VLP, CMV/R EEEV PE-6 strain capsid K67N VLP, CMV/R EEEV PE-6 strain capsid K67N E2 R239N VLP, CMV/R CHIKV(Strain 37997) Capsid R62A, CMV/R CHIKV(Strain 37997) Capsid R62A R63A, CMV/R CHIKV(Strain 37997) Capsid R62A R63A R65A K66A K68A K69A, CMV/R CHIKV(Strain 37997) Capsid R65A, CMV/R Ross River Virus T48 capsid R71N, CMV/R Ross River Virus T48 capsid R71N K72N, CMV/R Ross River Virus T48 capsid R71N

K72N K73N, CMV/R Ross River Virus T48 capsid R71N K72N K73N K74N, or CMV/R BFV VLP K64A.

In various embodiments of the above aspects or any other aspect of the invention delineated herein, the virus-like particle (VLP) or VLP expressing cell is exposed to a high pH condition at least about pH 7.2 (pH 7.2, 7.3, 7.4, 7.5, 7.6, 7.7, 7.8, 7.9, 8.0, 8.1, 8.2, 8.3, 8.4, 8.5, 8.6, 8.7, 8.8, or higher). In various embodiments, exposing VLP to high pH conditions during VLP production (in cell culture, during purification) increases VLP yield.

The invention provides immunogenic compositions featuring VLPs comprising polypeptides (e.g., CHIKV polypeptides, WEEV polypeptides) or polynucleotides for delivery to a mammalian cell. In certain embodiments, the invention provides compositions and methods for the prevention or treatment of CHIKV or WEEV viral disease. The invention also provides immunogenic compositions featuring VLPs comprising flavivirus polypeptides for the prevention or treatment of flavivirus viral disease. Compositions and articles defined by the invention were isolated or otherwise manufactured in connection with the examples provided below. Other features and advantages of the invention will be apparent from the detailed description, and from the claims.

Any compositions or methods provided herein can be combined with one or more of any of the other compositions and methods provided herein. The recitation of an embodiment for any aspect herein includes that embodiment as any single embodiment or in combination with any other embodiments or portions thereof.

Definitions

By “alphavirus structural protein” is meant a polypeptide or fragment thereof having at least about 80% amino acid sequence identity to a naturally occurring viral capsid or envelope protein and having immunogenic activity in a mammal. In one embodiment, the alphavirus structural protein has at least about 85%, 90%, 95% or greater amino acid sequence identity with a CHIKV, EEEV, WEEV, VEEV, Ross River virus, or Barmah Forest virus structural protein or immunogenic fragment thereof. In one embodiment, the protein exemplary alphaviruses include, but are not limited to, EEEV, WEEV, VEEV, SFV, CHIKV, O'nyong-nyong virus, Sindbis virus, Mayaro virus, Ross River virus, Barmah Forest virus, and Ockelbo virus.

By “flavivirus structural protein” is meant a polypeptide or fragment thereof having at least about 80% amino acid sequence identity to a naturally occurring viral capsid or

envelope protein and having immunogenic activity in a mammal. In one embodiment, the flavivirus structural protein has at least about 85%, 90%, 95% or greater amino acid sequence identity with a YFV, DENV, JEV, or TBEV structural protein or immunogenic fragment thereof.

5 By “agent” is meant any small molecule chemical compound, antibody, nucleic acid molecule, or polypeptide, or fragments thereof.

As used herein, the term “adjuvant” is meant to refer to a compound that, when used in combination with a specific immunogen in a formulation, will augment, alter or modify the resultant immune response. In certain embodiments, the adjuvant is used in combination
10 with a VLP. In other embodiments, the adjuvant is used in combination with a DNA vaccine. Modification of the immune response includes intensification or broadening the specificity of either or both antibody and cellular immune responses. Modification of the immune response can also mean decreasing or suppressing certain antigen-specific immune responses. In one embodiment, the adjuvant is Ribi adjuvant.

15 As used herein “alphavirus” is meant to refer to RNA-containing viruses that belong to the Flaviviridae family of viruses. Exemplary flaviviruses include but are not limited to EEEV, WEEV, VEEV, SFV, CHIKV, O'nyong-nyong virus, Sindbis virus, Mayaro virus, Ross River virus, Barmah Forest virus, and Ockelbo virus.

As used herein “flavivirus” is meant to refer to RNA-containing viruses that belong to
20 the group Flaviviridae family of viruses. Exemplary flaviviruses include but are not limited to YFV, DENV, JEV, and TBEV.

As used herein “inducing immunity” is meant to refer to any immune response generated against an antigen. In one embodiment, immunity is mediated by antibodies against an infectious agent, which is exhibited by a vertebrate (e.g., a human), that prevents
25 or ameliorates an infection or reduces at least one symptom thereof. VLPs or DNA vaccines of the invention can stimulate the production of antibodies that, for example, neutralize infectious agents, block infectious agents from entering cells, block replication of infectious agents, and/or protect host cells from infection and destruction. The term can also refer to an immune response that is mediated by T-lymphocytes and/or other white blood cells against
30 an infectious agent, exhibited by a vertebrate (e.g., a human), that prevents or ameliorates an infection (e.g., alphavirus or flavivirus) or reduces at least one symptom thereof.

By “ameliorate” is meant decrease, suppress, attenuate, diminish, arrest, or stabilize the development or progression of a disease or a symptom thereof.

By “alteration” is meant a change in an amino acid or nucleotide at a specified position with reference to a polypeptide sequence or polynucleotide sequence. As used herein, an alteration includes a substitution, deletion, or insertion of an amino acid or nucleotide at a specified position of a polypeptide or polynucleotide. In some embodiments, an alteration in an alphavirus capsid protein nuclear localization signal includes substitution of a charged amino acid (e.g., lysine or arginine) with an uncharged amino acid (e.g., alanine or asparagine, or any amino acid except a basic charged amino acid such as lysine or arginine).

By “alteration” is meant a change (increase or decrease) with reference to the expression levels or activity of a gene or polypeptide as detected by standard art known methods, such as those described herein. As used herein, an alteration includes a 10%, 25%, 50%, 75%, 100% or greater change in expression levels. An alteration includes a 10-, 20-, 50-, 70-, 80-, 90-, 100-, 200-, 500-, 1000-fold or greater change in expression levels.

By “analog” is meant a molecule that is not identical, but has analogous functional or structural features. For example, a polypeptide analog retains the biological activity of a corresponding naturally-occurring polypeptide, while having certain biochemical modifications that enhance the analog's function relative to a naturally occurring polypeptide. Such biochemical modifications could increase the analog's protease resistance, membrane permeability, or half-life, without altering, for example, ligand binding. An analog may include an unnatural amino acid.

In this disclosure, “comprises,” “comprising,” “containing” and “having” and the like can have the meaning ascribed to them in U.S. Patent law and can mean “includes,” “including,” and the like; “consisting essentially of” or “consists essentially” likewise has the meaning ascribed in U.S. Patent law and the term is open-ended, allowing for the presence of more than that which is recited so long as basic or novel characteristics of that which is recited is not changed by the presence of more than that which is recited, but excludes prior art embodiments.

“Detect” refers to identifying the presence, absence or amount of the analyte to be detected.

By “disease” is meant any condition or disorder that damages or interferes with the normal function of a cell, tissue, or organ. Examples of diseases include viral infections including but not limited to EEEV, WEEV, VEEV, SFV, CHIKV, O'nyong-nyong virus, Sindbis virus, Mayaro virus, Ross River virus, Barmah Forest virus, Ockelbo virus, YFV, DENV, JEV, and TBEV.

By “effective amount” is meant the amount of an agent required to ameliorate the symptoms of a disease relative to an untreated patient. The effective amount of active compound(s) used to practice the present invention for prevention or treatment of a disease varies depending upon the manner of administration, the age, body weight, and general health of the subject. Ultimately, the attending physician or veterinarian will decide the appropriate amount and dosage regimen. Such amount is referred to as an “effective” amount.

The invention provides a number of targets that are useful for the development of highly specific drugs to treat or prevent a diseases delineated herein. In addition, the methods of the invention provide a facile means to identify therapies that are safe for use in subjects. In addition, the methods of the invention provide a route for analyzing virtually any number of compounds for effects on a disease described herein with high-volume throughput, high sensitivity, and low complexity.

By “fragment” is meant a portion of a polypeptide or nucleic acid molecule. This portion contains, preferably, at least 10%, 20%, 30%, 40%, 50%, 60%, 70%, 80%, or 90% of the entire length of the reference nucleic acid molecule or polypeptide. A fragment may contain 10, 20, 30, 40, 50, 60, 70, 80, 90, or 100, 200, 300, 400, 500, 600, 700, 800, 900, or 1000 nucleotides or amino acids.

By “high pH” is meant a pH at least about 7.2 or greater (pH 7.2, 7.3, 7.4, 7.5, 7.6, 7.7, 7.8, 7.9, 8.0, 8.1, 8.2, 8.3, 8.4, 8.5, 8.6, 8.7, 8.8, or higher), including basic, alkaline, or non-acidic conditions. In various embodiments, exposing VLP to high pH conditions during VLP production (e.g., in cell culture, during purification) increases VLP yield.

“Hybridization” means hydrogen bonding, which may be Watson-Crick, Hoogsteen or reversed Hoogsteen hydrogen bonding, between complementary nucleobases. For example, adenine and thymine are complementary nucleobases that pair through the formation of hydrogen bonds.

By “isolated polynucleotide” is meant a nucleic acid molecule (e.g., a DNA) that is free of the genes which, in the naturally-occurring genome of the organism from which the nucleic acid molecule of the invention is derived, flank the gene. The term therefore includes, for example, a recombinant DNA that is incorporated into a vector; into an autonomously replicating plasmid or virus; or into the genomic DNA of a prokaryote or eukaryote; or that exists as a separate molecule (for example, a cDNA or a genomic or cDNA fragment produced by PCR or restriction endonuclease digestion) independent of other sequences. In addition, the term includes an RNA molecule that is transcribed from a DNA

molecule, as well as a recombinant DNA that is part of a hybrid gene encoding additional polypeptide sequence.

By an “isolated polypeptide” is meant a polypeptide of the invention that has been separated from components that naturally accompany it. Typically, the polypeptide is isolated when it is at least 60%, by weight, free from the proteins and naturally-occurring organic molecules with which it is naturally associated. Preferably, the preparation is at least 75%, more preferably at least 90%, and most preferably at least 99%, by weight, a polypeptide of the invention. An isolated polypeptide of the invention may be obtained, for example, by extraction from a natural source, by expression of a recombinant nucleic acid encoding such a polypeptide; or by chemically synthesizing the protein. Purity can be measured by any appropriate method, for example, column chromatography, polyacrylamide gel electrophoresis, or by HPLC analysis.

By “marker” is meant any protein or polynucleotide having an alteration in expression level or activity that is associated with a disease or disorder.

As used herein, “nuclear localization signal” or “NLS” is an amino acid sequence that, when present on the surface of a polypeptide, targets the polypeptide to the nucleus of the cell. NLS sequences are known in the art. See, for example, Goldfarb, D., and N. Michaud (1991) *Trends Cell Biol.* **1**, 20-24; Gorlich, D., and I. W. Mattaj (1996) *Science* **271**, 1513-1518). In one embodiment, an NLS includes one or more short sequences of positively charged amino acids, such as lysines or arginines. Consensus sequences for NLS include K-K/R-X-K/R (Schneider, J. et al. (1988) *Cell* **54**, 117-125) and two clusters of basic amino acids, separated by a spacer of about 10 amino acids, e.g., KR[PAATKKAGQA]KKKK (Dingwall et al., *J Cell Biol.* **107** (3): 841-9). With reference to the alphavirus amino acid sequences of the invention, NLS are present at amino acids 67-70 of an EEEV capsid protein (KRKK); at amino acids 67-70 of an WEEV capsid protein (KKKK); at amino acids 64-68 of a VEEV capsid protein (KKPKK); at amino acids 62-69 of a CHIKV capsid protein (RRNRKNKK); at amino acids 71-74 of a Ross River virus capsid protein (RKKK); and at amino acids 64-68 of a Barmah Forest virus capsid protein (KKPKK).

As used herein, “obtaining” as in “obtaining an agent” includes synthesizing, purchasing, or otherwise acquiring the agent.

By “reduces” is meant a negative alteration of at least 10%, 25%, 50%, 75%, or 100%.

By “reference” is meant a standard or control condition.

A “reference sequence” is a defined sequence used as a basis for sequence comparison. A reference sequence may be a subset of or the entirety of a specified sequence; for example, a segment of a full-length cDNA or gene sequence, or the complete cDNA or gene sequence. For polypeptides, the length of the reference polypeptide sequence will generally be at least about 16 amino acids, preferably at least about 20 amino acids, more preferably at least about 25 amino acids, and even more preferably about 35 amino acids, about 50 amino acids, or about 100 amino acids. For nucleic acids, the length of the reference nucleic acid sequence will generally be at least about 50 nucleotides, preferably at least about 60 nucleotides, more preferably at least about 75 nucleotides, and even more preferably about 100 nucleotides or about 300 nucleotides or any integer thereabout or therebetween.

By “specifically binds” is meant a compound or antibody that recognizes and binds a polypeptide of the invention, but which does not substantially recognize and bind other molecules in a sample, for example, a biological sample, which naturally includes a polypeptide of the invention.

Nucleic acid molecules useful in the methods of the invention include any nucleic acid molecule that encodes a polypeptide of the invention or a fragment thereof. Such nucleic acid molecules need not be 100% identical with an endogenous nucleic acid sequence, but will typically exhibit substantial identity. Polynucleotides having “substantial identity” to an endogenous sequence are typically capable of hybridizing with at least one strand of a double-stranded nucleic acid molecule. Nucleic acid molecules useful in the methods of the invention include any nucleic acid molecule that encodes a polypeptide of the invention or a fragment thereof. Such nucleic acid molecules need not be 100% identical with an endogenous nucleic acid sequence, but will typically exhibit substantial identity. Polynucleotides having “substantial identity” to an endogenous sequence are typically capable of hybridizing with at least one strand of a double-stranded nucleic acid molecule. By “hybridize” is meant pair to form a double-stranded molecule between complementary polynucleotide sequences (e.g., a gene described herein), or portions thereof, under various conditions of stringency. (See, e.g., Wahl, G. M. and S. L. Berger (1987) *Methods Enzymol.* 152:399; Kimmel, A. R. (1987) *Methods Enzymol.* 152:507).

For example, stringent salt concentration will ordinarily be less than about 750 mM NaCl and 75 mM trisodium citrate, preferably less than about 500 mM NaCl and 50 mM trisodium citrate, and more preferably less than about 250 mM NaCl and 25 mM trisodium citrate. Low stringency hybridization can be obtained in the absence of organic solvent, e.g.,

formamide, while high stringency hybridization can be obtained in the presence of at least about 35% formamide, and more preferably at least about 50% formamide. Stringent temperature conditions will ordinarily include temperatures of at least about 30°C, more preferably of at least about 37°C, and most preferably of at least about 42°C. Varying additional parameters, such as hybridization time, the concentration of detergent, e.g., sodium dodecyl sulfate (SDS), and the inclusion or exclusion of carrier DNA, are well known to those skilled in the art. Various levels of stringency are accomplished by combining these various conditions as needed. In a preferred embodiment, hybridization will occur at 30°C in 750 mM NaCl, 75 mM trisodium citrate, and 1% SDS. In a more preferred embodiment, hybridization will occur at 37°C in 500 mM NaCl, 50 mM trisodium citrate, 1% SDS, 35% formamide, and 100 µg/ml denatured salmon sperm DNA (ssDNA). In a most preferred embodiment, hybridization will occur at 42°C in 250 mM NaCl, 25 mM trisodium citrate, 1% SDS, 50% formamide, and 200 µg/ml ssDNA. Useful variations on these conditions will be readily apparent to those skilled in the art.

For most applications, washing steps that follow hybridization will also vary in stringency. Wash stringency conditions can be defined by salt concentration and by temperature. As above, wash stringency can be increased by decreasing salt concentration or by increasing temperature. For example, stringent salt concentration for the wash steps will preferably be less than about 30 mM NaCl and 3 mM trisodium citrate, and most preferably less than about 15 mM NaCl and 1.5 mM trisodium citrate. Stringent temperature conditions for the wash steps will ordinarily include a temperature of at least about 25°C, more preferably of at least about 42°C, and even more preferably of at least about 68°C. In a preferred embodiment, wash steps will occur at 25°C in 30 mM NaCl, 3 mM trisodium citrate, and 0.1% SDS. In a more preferred embodiment, wash steps will occur at 42°C in 15 mM NaCl, 1.5 mM trisodium citrate, and 0.1% SDS. In a more preferred embodiment, wash steps will occur at 68°C in 15 mM NaCl, 1.5 mM trisodium citrate, and 0.1% SDS.

Additional variations on these conditions will be readily apparent to those skilled in the art. Hybridization techniques are well known to those skilled in the art and are described, for example, in Benton and Davis (Science 196:180, 1977); Grunstein and Hogness (Proc. Natl. Acad. Sci., USA 72:3961, 1975); Ausubel et al. (Current Protocols in Molecular Biology, Wiley Interscience, New York, 2001); Berger and Kimmel (Guide to Molecular Cloning Techniques, 1987, Academic Press, New York); and Sambrook et al., Molecular Cloning: A Laboratory Manual, Cold Spring Harbor Laboratory Press, New York.

By “substantially identical” is meant a polypeptide or nucleic acid molecule exhibiting at least 50% identity to a reference amino acid sequence (for example, any one of the amino acid sequences described herein) or nucleic acid sequence (for example, any one of the nucleic acid sequences described herein). Preferably, such a sequence is at least 60%,
5 more preferably 80% or 85%, and more preferably 90%, 95% or even 99% identical at the amino acid level or nucleic acid to the sequence used for comparison.

Sequence identity is typically measured using sequence analysis software (for example, Sequence Analysis Software Package of the Genetics Computer Group, University of Wisconsin Biotechnology Center, 1710 University Avenue, Madison, Wis. 53705,
10 BLAST, BESTFIT, GAP, or PILEUP/PRETTYBOX programs). Such software matches identical or similar sequences by assigning degrees of homology to various substitutions, deletions, and/or other modifications. Conservative substitutions typically include substitutions within the following groups: glycine, alanine; valine, isoleucine, leucine; aspartic acid, glutamic acid, asparagine, glutamine; serine, threonine; lysine, arginine; and
15 phenylalanine, tyrosine. In an exemplary approach to determining the degree of identity, a BLAST program may be used, with a probability score between e^{-3} and e^{-100} indicating a closely related sequence.

By “structural polyprotein” is meant a composite amino acid molecule comprising at least two separable polypeptides that contribute to a viral capsid or envelope. In one
20 embodiment, the polypeptides are susceptible to cleavage with a viral enzyme (e.g., capsid autoprotease and signalases).

By “subject” is meant a mammal, including, but not limited to, a human or non-human mammal, such as a bovine, equine, canine, ovine, or feline.

Ranges provided herein are understood to be shorthand for all of the values within the
25 range. For example, a range of 1 to 50 is understood to include any number, combination of numbers, or sub-range from the group consisting 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, or 50.

As used herein, the terms “treat,” “treating,” “treatment,” and the like refer to reducing
30 or ameliorating a disorder and/or symptoms associated therewith. It will be appreciated that, although not precluded, treating a disorder or condition does not require that the disorder, condition or symptoms associated therewith be completely eliminated.

As used herein, the term “vaccine” refers to a composition to be used in generating an immune response. In particular embodiments, a vaccine of the invention contains VLPs,

DNAs, or other gene-based vaccine vectors in a form that is capable of being administered to a subject and which induces a protective immune response sufficient to induce immunity to prevent and/or ameliorate an infection and/or to reduce at least one symptom of an infection and/or to enhance the efficacy of another dose of VLPs or DNA vaccines. Typically, the vaccine comprises a pharmaceutically acceptable excipient, such as conventional saline or buffered aqueous solution medium in which the composition of the present invention is suspended or dissolved. In this form, the composition of the present invention can be used conveniently to prevent, ameliorate, or otherwise treat an infection. Upon introduction into a host, the vaccine induces an immune response including, but not limited to, the production of antibodies and/or cytokines and/or the activation of cytotoxic T cells, antigen presenting cells, helper T cells, dendritic cells and/or other cellular responses. In certain embodiments, a vaccine can also be a protein. For example, recombinant proteins have been produced by genetically engineering cells to produce one or more foreign genes, which in turn produce proteins that serve as the immunogen.

As used herein, the term “virus-like particle” (VLP) refers to a structure that in at least one attribute resembles a virus, but which has not been demonstrated to be infectious. Virus-like particles in accordance with the invention do not carry genetic information encoding the proteins of the virus-like particles. In general, virus-like particles lack a viral genome and, therefore, are noninfectious. In addition, virus-like particles can often be produced in large quantities by heterologous expression and can be easily purified.

As used herein, the term “virus budding,” “virus-like particle budding,” or “VLP budding” refers to the process of virion or VLP release from a host cell. This process includes steps associated with maturation, fusion, and cleavage.

Unless specifically stated or obvious from context, as used herein, the term “or” is understood to be inclusive. Unless specifically stated or obvious from context, as used herein, the terms “a”, “an”, and “the” are understood to be singular or plural.

Unless specifically stated or obvious from context, as used herein, the term “about” is understood as within a range of normal tolerance in the art, for example within 2 standard deviations of the mean. About can be understood as within 10%, 9%, 8%, 7%, 6%, 5%, 4%, 3%, 2%, 1%, 0.5%, 0.1%, 0.05%, or 0.01% of the stated value. Unless otherwise clear from context, all numerical values provided herein are modified by the term about.

The recitation of a listing of chemical groups in any definition of a variable herein includes definitions of that variable as any single group or combination of listed groups. The

recitation of an embodiment for a variable or aspect herein includes that embodiment as any single embodiment or in combination with any other embodiments or portions thereof.

Any compositions or methods provided herein can be combined with one or more of any of the other compositions and methods provided herein.

5

BRIEF DESCRIPTION OF THE DRAWINGS

Figures 1A-1D show the characterization of CHIKV E pseudotyped lentiviral vectors.

Figure 1A is a schematic representation of the CHIKV genome and CHIKV E expression vector used for incorporation of CHIKV E from strains 37997 and LR2006 OPY-1 into

10 pseudotyped lentiviral vectors. The CHIKV genome consists of nonstructural polyproteins

NS1, NS2, NS3 and NS4 and structural polyproteins capsid (C) and envelope (E: E3, E2, 6K and E1) (top). The polypeptide E genes from strains 37997 and LR2006 OPY-1 were inserted

into an expression vector (bottom). Figure 1B includes two graphs. The graph on the left shows the infectivity of the indicated pseudotyped lentiviral vectors in several CHIKV-

15 permissive cell lines, including 293A human renal epithelial, HeLa cervical epithelial, Vero renal epithelial, A549 squamous epithelial and baby hamster kidney (BHK) cells. The pseudotyped

vectors were standardized by HIV-1 Gag p24 (left) or the indicated concentration of p24 and used to infect 293A cells (right). After incubation with pseudotyped vectors for 24 hours,

cells were lysed and luciferase activity was measured. The experiment was performed in

20 triplicate. Figure 1C includes two graphs that show the pH-dependent entry of CHIKV

pseudotyped lentiviral vectors. Pseudotyped lentiviral vectors were incubated in the presence of the indicated amounts of ammonium chloride (left) and chloroquine (right). The experiment

was performed in triplicate. Data are presented as the percentage of activity at the indicated dose relative to activity with no treatment. Figure 1D is a graph showing

25 neutralization measured with pseudotyped lentiviral vectors in sera from mice injected with

CHIKV (strain S-27). Sera were incubated at the indicated dilutions with VSV-G, CHIKV strain 37997 or LR2006 OPY-1 E-pseudotyped lentiviral vectors and the mixture infected to

293A cells. Luciferase activity was analyzed 24 hours after infection. The experiment was performed in triplicate. No inhibition was observed with control non-immune antisera.

30

Figures 2A-2C show the schematic representation of plasmid expression vectors and

characterization of CHIKV VLPs. Figure 2A provides a schematic representation of CHIKV

C-E or E expression vectors used for DNA vaccine and VLP production. The CHIKV

structural polyproteins capsid plus envelope (C-E) or E alone from strains 37997 and

LR2006 OPY-1 were inserted into an expression vector. 293T cells were transfected with

each of the indicated plasmids. Expression was measured 48 hours after transfection by Western blotting with antisera reactive with CHIKV. Figure 2B includes a graph, Western blot, and electron micrograph. VLPs were purified from the supernatants of 293F cells transfected with C-E expression vector (C-E37997) (left). The supernatants were harvested 72 hours after transfection followed by OptiPrep density gradient centrifugation. Each fraction was characterized for its buoyant density (left upper panel) and protein content (left lower panel) by Western blot analysis with antisera to CHIKV. The fractionated VLPs were observed by transmission electron microscopy with magnification 20,000x (left, bar 100 nm) (right). Figure 2C provides a comparison of cryo-EM reconstructions of CHIKV VLP with Sindbis virus showing that CHIKV VLP is structurally similar to alphaviruses. Shaded-surface representation of the 3D density map of CHIKV VLP (left upper panel) and Sindbis virus (right upper panel) viewed along an icosahedral 2-fold axis. The white triangle marks the boundary of an icosahedral asymmetric unit. The numbers show the positions of the icosahedral 2-, 3-, and 5-fold axes limiting an asymmetric unit. The central cross-section through the cryo-EM maps of CHIKV VLP (left lower panel) and Sindbis virus (right lower panel). The orientations of the icosahedral (2-, 3-, and 5-fold) axes as well as the quasi-threefold (q3) axis are shown with white lines. Maps are calculated to 1.8 Å resolution.

Figures 3A-3D are graphs showing the neutralization of CHIKV strains 37997 and LR2006 OPY-1 after DNA or VLP vaccination in mice and monkeys. Sera from immunized mice 10 days after the final immunization were tested with CHIKV strain 37997 (Figure 3A) or LR2006 OPY-1 (Figure 3B) E pseudotyped lentiviral vectors. Mice were immunized with the indicated DNA or VLP₃₇₉₉₇. Each C-E or E (strain 37997 and LR2006 OPY-1, respectively) plasmid was injected at 0, 3 and 6 weeks. VLP₃₇₉₉₇ with or without Ribi adjuvant was injected at 2 and 6 weeks. The experiment was performed in triplicate. The symbols show the average of the five mice and bars show the standard error of the mean. The curve fit was calculated by Prism software. Figure 3C shows results from monkeys immunized with VLP₃₇₉₉₇ or PBS (control) at 0, 4, and 24 weeks. A neutralizing assay was performed with CHIKV strain 37997 (left panel) or LR2006 OPY-1 (right panel) E pseudotyped lentiviral vectors in sera collected from immunized monkeys at 10 days after each immunization. The symbols show the average of the six monkeys and bars show the standard error of the mean. Figure 3D shows the neutralizing activity against CHIKV LR2006 OPY-1 in immunized monkeys' sera after the 2nd and 3rd immunizations was

confirmed by a standard plaque reduction neutralization test (PRNT). The symbols show the average of the six monkeys and bars show the standard error of the mean.

Figures 4A-4D are graphs showing protection against CHIKV LR2006 OPY-1 challenge in monkeys immunized with VLPs and in a CHIKV mouse model after passive transfer of purified IgG. Figure 4A quantitates results obtained in monkeys injected with PBS (Control) or immunized with VLP₃₇₉₉₇. Monkeys were challenged with 10^{10} PFU of the CHIKV strain LR2006 OPY-1 15 weeks after the final boost. The peak viremia at 24 hours after challenge was measured by plaque assay. The serum dilutions started from 1:200 (limit of detection = 1000 PFU/ml). Error bars represent the standard error of the mean.

Figure 4B is a graph showing the percentage of monocytes in the monkeys' white blood cells. Monocyte percentage was measured using a hematology analyzer before and 7 days after challenge with CHIKV. Error bars represent the standard error of the mean. A non-parametric two *t*-test was used for statistical analysis (Control vs. VLPs at 7 days, $P = 0.0036$; Control at 0 days vs. 7 days, $P = 0.0015$; VLPs at 0 days vs. 7 days, $P > 0.5$). Figure 4C shows the number of viral RNA copies present following passive transfer of purified IgG from a monkey immunized with VLPs (Immune) or a control monkey (Control IgG) into mice (2 mg of total IgG per mouse, $n=5$ per group). Recipient mice were challenged 24 hours after IgG transfer with a lethal LR2006 OPY-1 challenge (30 PFU) by intradermal injection. The viremia in the mice after challenge was measured by quantitative RT-PCR (limit of detection = 40 RNA copies/ml). Error bars represent the standard error of the mean. Figure 4D shows a survival curve of mice passively transferred with control IgG or CHIKV immunized IgG against lethal LR2006 OPY-1 challenge.

Figure 5 shows the characterization of CHIKV E pseudotyped lentiviral vectors by buoyant density sedimentation and Western blot analysis. Plasmids encoding the indicated CHIKV Env strains were cotransfected with lentiviral expression vectors into 293T cells. Forty-eight hours after transfection, supernatants were harvested and run on sedimentation gradients as described previously. Quantification of gradient fractions is shown with the indicated strains, showing colocalization of Env with the Gag fraction of the expected buoyant density for lentiviral particles (1.08-1.1 g/ml) (upper panel). Western blot analysis of gradient fractions for CHIKV E1/E2 and Gag are shown (lower panel).

Figure 6A-6C show the schematic representation of plasmid expression vectors and characterization of chimeric CHIKV and WEEV VLPs. Figure 6A shows the schematic representation of the CHIKV genome and the chimeric CHIKV C-E expression vector used for VLP production from strains 37997 (blue) and OPY-1 (white). The CHIKV genome

consists of the nonstructural polyproteins nsP1, nsP2, nsP3, and nsP4 and the structural polyproteins capsid (C) and envelope (E3, E2, 6K and E1) (top). The schematic representation of chimeric genes from strains 37997 and OPY-1 are shown, 1: VLP_{OPY-1}, 2:

VLP_{C(37997)}, 3: VLP_{C-E3(37997)}, 4: VLP_{C-E2(37997)}, 5: VLP_{C-6K(37997)}, 6: VLP₃₇₉₉₇, 7: VLP_{OPY-1}

E2(37997), 8: VLP_{OPY-1 5'-E2(37997)} and 9: VLP_{OPY-1 3'-E2(37997)}. Figure 6B includes a Western

blot. 293F cells (Invitrogen, Carlsbad, CA.) were transfected with each of the indicated plasmids. Expression was measured 72 hours after transfection in the supernatant (top) and cell lysate (bottom) by Western blotting using antisera reactive with CHIKV as a primary antibody and goat anti-mouse immunoglobulins linked to horseradish peroxidase as a

secondary antibody. Figure 6C includes a stain for total protein. VLPs were purified from the supernatants of 293F cells transfected with the indicated plasmids. The supernatants were harvested 72 hours after transfection followed by OptiPrep buoyant density gradient centrifugation to purify VLPs. Coomassie staining analysis was used to characterize VLP fractions.

Figures 7A and 7B show structural models for CHIKV OPY-1 E1/E2 compared to the CHIKV E2 37997 sequence, and the effect of the single amino acid mutation, N234K on CHIKV VLP production. Figure 7A depicts the structure of the CHIKV E1/E2 complex (OPY-1 strain). The CHIKV E1/E2 (OPY-1 strain) was modeled from PDB accession number 3N42 and displayed using Pymol (www.pymol.org). E2 is shown in red and E1 is

shown in light blue. The green sphere is the E2 234 position; dark green spheres indicate the differences in amino acids between OPY-1 and 37997 in E2 amino acids 1-290. Figure 7B identifies the amino acids from the OPY-1 strain that were swapped into the NH₂-terminal E2 domain of chimeric VLP_{OPY-1 5'-E2 (37997)}. The following mutations were created: 1: I32V, 2:

S72N, 3: T74M, 4: L84F, 5: T124S, 6: E132D, 7: R140K, 8: A164T, 9: T182S, 10: I222V,

11: N234K, and 12: T284I. 13 is VLPOPY-1 5'-E2 (37997) (wild type). Each of the mutant VLPs were purified from supernatants of 293F cells transfected with the indicated plasmids.

The supernatants were harvested 72 hours after transfection followed by OptiPrep density gradient centrifugation. Expression was measured by Western blot using antisera reactive with CHIKV as a primary antibody and goat anti-mouse immunoglobulins linked to

horseradish peroxidase as a secondary antibody.

Figures 8A-8E show the effect of pH and amino acid mutations in the E2 ASR on VLP production. Figure 8A includes flow cytometry results. Envelope expression on transfected cell membranes was measured by flow cytometry with a CHIKV E1/E2 monoclonal antibody (red line) or a control mouse monoclonal antibody (black line) as a

primary antibody and goat anti-mouse immunoglobulins linked to Phycoerythrin as a secondary antibody. Figure 8B includes a Western blot. The indicated amino acid sequence from the 37997 strain was swapped into the E2 region of VLP_{OPY-1}. The following mutations were transfected into 293F cells. 1: VLP_{OPY-1}, 2: VLP_{OPY-1} K234N, 3: VLP_{OPY-1} E2(37997), and 4: VLP₃₇₉₉₇. The supernatants were harvested 72 hours after transfection followed by OptiPrep density gradient centrifugation. Expression was measured by Western blot using antisera reactive with CHIKV as a primary antibody and goat anti-mouse immunoglobulins linked to horseradish peroxidase as a secondary antibody. Figure 8C includes a Western blot. 24 hr after transfection of OPY-1, Tris-HCl buffer was added to change the pH to that indicated (left). 24 hr after transfection of the indicated plasmids, Tris-HCl buffer was added (+) (right). Expression of VLPs in the supernatant 48 hr after transfection was measured by Western blotting, with antisera reactive with CHIKV as a primary antibody and goat anti-mouse immunoglobulins linked to horseradish peroxidase as a secondary antibody. Figure 8D include structural models showing the form of CHIKV Envelope modified form PDB code 3N42. The E2 a.a. 170, 233, 252 and 256 positions in CHIKV OPY-1 are shown in blue. The E2 a.a. 234 position in CHIKV OPY-1 is shown in white. The E2 domain B is shown in green, the E2 domain A is shown in cyan, the E2 domain C is shown in pink, the E2 β -ribbon connector is shown in purple and the E2 ASR domain in the E2 β -ribbon connector is shown in red. The E1 is shown in yellow. Figure 8E includes a Western blot. 24 hr after transfection of the indicated plasmids, Tris-HCl buffer was added to change the pH to 7.9 (+). Expression in the supernatant 48 hr after transfection was measured by Western blotting, with antisera reactive with CHIKV as a primary antibody and goat anti-mouse immunoglobulins linked to horseradish peroxidase as a secondary antibody.

Figures 9A-9C show the ability of K234N WEEV VLPs on neutralizing antibody production. Figure 9A includes an amino acid alignment of CHIKV 37997, CHIKV OPY-1, Ross River, Sindbis, WEEV, EEEV, and WEEV E2 regions. The WEEV E2 235 amino acid position corresponding to E2 234 in CHIKV is highlighted in the box. The mutation K235N was swapped into WEEV. Figure 9B includes a Western blot. The wild type VLP_{WEEV} and the mutated plasmid, VLP_{WEEV} K235N, were transfected into 293F cells. Supernatants were harvested 72 hours after transfection followed by OptiPrep density gradient centrifugation. Expression was measured by Western blot using anti-WEEV antisera as a primary antibody and goat anti-mouse immunoglobulins linked to horseradish peroxidase as a secondary antibody. Figure 9C includes graphs showing the neutralization titers of sera from BALB/c mice immunized with WEEV 71V-1658 strain (left) or CHIKV LR2006 OPY-1

strain (right) E–pseudotyped lentiviral vectors. Mice were immunized intramuscularly with the indicated amount of VLPs. The experiment was performed in triplicate. The symbols show the average of the five mice, and error bars show the s.e.m. The curve fit was calculated by Prism software.

Figure 65B are Western Blots showing that NLS signal mutations in combination with high pH conditions increase EEEV and VEEV production.

Figures 66A-66C are graphs showing that multivalent Virus-Like Particle vaccine against Eastern, Western and Venezuelan Equine Encephalitis Virus protected mice against infection. Figure 66A is a graph showing that mice vaccinated with multivalent VLPs showed high levels of neutralizing antibodies against all the viruses. Figure 66B is a graph showing that high viremia was observed in the control, VEEV VLP and EEEV VLP groups but not in the WEEV VLPs and the trivalent groups. Figure 66C is a graph showing that mice immunized with WEEV VLPs controlled the challenge virus, while all control mice developed severe infections and died.

DETAILED DESCRIPTION OF THE INVENTION

The invention provides methods for enhancing alphavirus or flavivirus VLP production involving making one or more alterations in an E2 protein and/or a alphavirus capsid protein Nuclear Localization Signal (NLS).

The invention is based, at least in part, on the discovery that amino acid 234 in the CHIKV E2 protein plays an important role in allowing VLPs to bud efficiently from the cell membrane. Almost all alphaviruses have a lysine residue at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein. When this residue is converted from a lysine to an asparagine, use of the modified E2 protein in the alphavirus VLP expression system results in increased yield of VLPs. In addition, amino acid 251 in the CHIKV E2 protein has been shown to be important in stabilizing the E2 protein during viral budding. Modification of this residue to destabilize the E2 protein results also results in increased VLP synthesis. Therefore, use of an alphavirus E2 protein or a flavivirus envelope protein having a non-lysine residue (e.g., asparagine) at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein is a strategy for improving alphavirus VLP production, which will reduce the cost of making alphavirus VLP vaccines and delivery vehicles. Without being bound to a particular theory, it is believed that amino acid 234 resides within an acid sensitive (ASR) of the molecule. As shown herein, exposure of VLP to high pH conditions (pH > 7.2, e.g., pH 7.2, 7.3, 7.4, 7.5, 7.6, 7.7, 7.8, 7.9, 8.0, 8.1, 8.2, 8.3, 8.4, 8.5, 8.6, 8.7, 8.8, or higher), also improves VLP production.

The invention is also based, at least in part, on the discovery that amino acid 251 in the CHIKV E2 protein plays an important role in allowing VLPs to bud efficiently from the cell membrane. Amino acid 251 in the CHIKV E2 protein has been shown to be important in stabilizing the E2 protein during viral budding. Modification of this residue destabilizes the E2 protein during viral maturation, which results in increased VLP synthesis and VLP yield. Therefore, use of an alphavirus E2 protein having a modification at the amino acid position corresponding to amino acid 251 in the CHIKV E2 protein, which destabilizes the alphavirus E2 protein during viral budding, is another strategy for improving alphavirus VLP production.

The invention is also based, at least in part, on the discovery that alterations in the charged residues in the alphavirus capsid protein nuclear localization sequences provided or increased the expression of alphavirus VLPs and increased alphavirus VLP yields. Without being bound to a particular theory, the nuclear localization signal motif of the alphavirus capsid protein accumulates alphavirus capsid protein into the nucleus and prevents the secretion of alphavirus VLPs. It has been found that altering lysine and arginine residues in an alphavirus capsid protein NLS (e.g., to uncharged amino acids alanine or asparagine) improves alphavirus VLP production. Improvement in yields of alphavirus VLPs allows for their use as immunogenic compositions or vaccines, including a pan-alphavirus vaccine.

Accordingly, the invention provides nucleic acid molecules encoding alphavirus (e.g., CHIKV and WEEV) structural polypeptides, including an alphavirus E2 protein having a non-lysine residue (e.g., asparagine) at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein, expression vectors comprising these coding sequences, and methods of using these nucleic acid molecules for the preparation of virus-like particles. The invention also provides nucleic acid molecules encoding alphavirus (e.g., CHIKV and WEEV) structural polypeptides, including an alphavirus E2 protein having a modification at the amino acid position corresponding to amino acid 251 in the CHIKV E2 protein that destabilizes the E2 protein during viral budding, expression vectors comprising these coding sequences, and methods of using these nucleic acid molecules for the preparation of virus-like particles. The invention further provides immunogenic compositions containing one or more alphavirus (e.g., CHIKV and WEEV) structural polypeptides, including an E2 protein having a non-lysine residue (e.g., asparagine) at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein and/or a modification at the amino acid position corresponding to amino acid 251 in the CHIKV E2 protein that destabilizes the E2 protein during viral budding. In particular, the immunogenic composition (e.g., vaccine) contains envelope or capsid polypeptides sufficient to form a virus-like particle. In other embodiments, the invention provides DNA vaccines that provide for the expression of one or more viral polypeptides in the cell of a subject, including an alphavirus E2 protein having a non-lysine residue (e.g., asparagine) at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein and/or a modification at the amino acid position corresponding to amino acid 251 in the CHIKV E2 protein that destabilizes the E2 protein during viral budding.

The invention also provides nucleic acid molecules encoding flavivirus structural polypeptides, including an envelope protein having a non-lysine residue (e.g., asparagine) at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein, expression vectors comprising these coding sequences, and methods of using these nucleic acid molecules for the preparation of virus-like particles. The invention further provides immunogenic compositions containing one or more flavivirus structural polypeptides, including an envelope protein having a non-lysine residue (e.g., asparagine) at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein. In particular, the immunogenic composition (e.g., vaccine) contains envelope or capsid polypeptides sufficient to form a virus-like particle. In other embodiments, the invention provides DNA vaccines that provide for the expression of one or more viral polypeptides in the cell of a subject,

including a flavivirus envelope protein having an asparagine residue at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein.

Alphavirus and Flavivirus Polynucleotides

5 In general, the invention includes any nucleic acid sequence encoding a VLP having an alteration in a structural protein that enhances VLP expression in a mammalian cell. In one embodiment, the alphavirus polypeptide(s) includes at least an alphavirus E2 protein or capsid protein NLS comprising an alteration that increases VLP expression in a mammalian cell. In one embodiment, the alphavirus E2 protein has a non-lysine residue (e.g., asparagine)
10 at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein and/or a modification at the amino acid position corresponding to amino acid 251 in the CHIKV E2 protein that destabilizes the E2 protein during viral budding. In another embodiment, the alphavirus polypeptide(s) includes at least an alphavirus capsid protein having a non-lysine residue (e.g., alanine or asparagine) at an amino acid position corresponding to a lysine
15 residue in an alphavirus capsid protein NLS and/or a non-arginine residue (e.g., alanine or asparagine) at an amino acid position corresponding to an arginine residue in an alphavirus capsid protein NLS. In specific embodiments, the alphavirus capsid protein is a WEEV CBA87 strain capsid protein having one or more of the alterations K67N, K68N, and/or K69N. In certain embodiments, the alphavirus capsid protein is a VEEV TC83 strain capsid
20 protein having one or more of the alterations K64N, K65A, K65N, K67A, and/or K67N. In some embodiments, the alphavirus capsid protein is a EEEV PE-6 strain capsid protein having an alteration K67N. In particular embodiments, the alphavirus capsid protein is a CHIKV(Strain 37997) strain capsid protein having one or more of the alterations R62A, R63A, R65A, K66A, K68A, and/or K69A. In specific embodiments, the alphavirus capsid
25 protein is a Ross River Virus capsid protein having one or more of the alterations R71N, K72N, K73N, and/or K74N. In specific embodiments, the alphavirus capsid protein is a Barmah Forest Virus capsid protein having one or more of the alterations K64A, K64N, K65A, K65N, K67A, K67N, K68A and/or K68N. An isolated nucleic acid molecule can be manipulated by recombinant DNA techniques well known in the art. Thus, a nucleotide
30 sequence contained in a vector in which 5' and 3' restriction sites are known, or for which polymerase chain reaction (PCR) primer sequences have been disclosed, is considered isolated, but a nucleic acid sequence existing in its native state in its natural host is not. In certain exemplary embodiments, the vector comprises CHIKV 37997 or WEEV 71V-1658 nucleic acid segments, or fragments thereof. The vector may further comprise a CMV/R

promoter. The vector may also comprise the capsid protein, or a fragment thereof.

In other exemplary embodiments, in addition to the E2 protein, the vector comprises another envelope protein selected from the group consisting of E3, 6K, and E1. In certain examples, the vaccine may comprise capsid, E3, E2, 6K and E1. In other examples, the vaccine may comprise E3, E2, 6K and E1.

The invention also includes any nucleic acid sequence encoding a VLP comprising one or more flavivirus polypeptides or a fragment thereof, where the fragment induces an immune response. The flavivirus polypeptide(s) includes at least a flavivirus envelope protein having a non-lysine residue (e.g., asparagine) at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein. The flavivirus polypeptide(s) includes at least a flavivirus capsid protein having a non-lysine residue (e.g., alanine or asparagine) at an amino acid position corresponding to a lysine residue in a flavivirus capsid protein NLS and/or a non-arginine residue (e.g., alanine or asparagine) at an amino acid position corresponding to an arginine residue in a flavivirus capsid protein NLS. An isolated nucleic acid molecule can be manipulated by recombinant DNA techniques well known in the art.

In a particular embodiment, a nucleic acid molecule set forth in the sequences disclosed herein includes a nucleotide sequence encoding a polypeptide having at least about 50%, 60%, 70%, 75%, 80%, 81%, 82%, 83%, 84%, 85%, 86%, 87%, 88%, 89%, 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, or more identity (e.g., when compared to the overall length of the amino acid sequence) to a polypeptide encoding a protein selected from alphavirus capsid, E3, E2, 6K and E1, including CHIKV or WEEV capsid, E3, E2, 6K and E1; and flavivirus envelope and capsid.

In some embodiments of the invention, proteins may comprise mutations containing alterations which produce silent substitutions, additions, or deletions, but do not alter the properties or activities of the encoded protein or how the proteins are made. Nucleotide variants can be produced for a variety of reasons, e.g., to optimize codon expression for a particular host, see U.S. patent publication 2005/0118191, herein incorporated by reference in its entirety for all purposes.

In addition, the nucleotides can be sequenced to ensure that the correct coding regions were cloned and do not contain any unwanted mutations. The nucleotides can be subcloned into an expression vector (e.g., baculovirus) for expression in any cell. A person with skill in the art understands that various subcloning methods are available and are possible.

An isolated nucleic acid may be substantially purified, but need not be. For example, a nucleic acid that is isolated within a cloning or expression vector is not pure in that it may comprise only a tiny percentage of the material in the cell in which it resides. Such a nucleic acid is isolated, as the term is used herein, because it is readily manipulatable by standard techniques known to those of ordinary skill in the art.

Polypeptide Expression

In general, VLPs comprising one or more alphavirus polypeptides of the invention may be produced by transformation of a suitable host cell with all or part of a polypeptide-encoding nucleic acid molecule or fragment thereof in a suitable expression vehicle.

Those skilled in the field of molecular biology will understand that any of a wide variety of expression systems may be used to provide the recombinant protein. The precise host cell used is not critical to the invention. A polypeptide of the invention may be produced in a prokaryotic host (e.g., *E. coli*) or in a eukaryotic host (e.g., *Saccharomyces cerevisiae*, insect cells, e.g., Sf21 cells, or mammalian cells, e.g., NIH 3T3, HeLa, COS cells). Such cells are available from a wide range of sources (e.g., the American Type Culture Collection, Rockland, Md.; also, see, e.g., Ausubel et al., supra). Non limiting examples of insect cells are, *Spodoptera frugiperda* (Sf) cells, e.g., Sf9, Sf21, *Trichoplusia ni* cells, e.g., High Five cells, and *Drosophila* S2 cells. Examples of fungi (including yeast) host cells are *S. cerevisiae*, *Kluyveromyces lactis* (*K. lactis*), species of *Candida* including *C. albicans* and *C. glabrata*, *Aspergillus nidulans*, *Schizosaccharomyces pombe* (*S. pombe*), *Pichia pastoris*, and *Yarrowia lipolytica*. Examples of mammalian cells are COS cells, baby hamster kidney cells, mouse L cells, LNCaP cells, Chinese hamster ovary (CHO) cells, human embryonic kidney (HEK) cells, African green monkey cells, CV1 cells, HeLa cells, MDCK cells, Vero and Hep-2 cells. *Xenopus laevis* oocytes, or other cells of amphibian origin, may also be used. Prokaryotic host cells include bacterial cells, for example, *E. coli*, *B. subtilis*, and mycobacteria.

Methods of cloning said proteins are known in the art. For example, the gene encoding a specific alphavirus protein, e.g., a CHIKV, WEEV, EEEV, VEEV, Ross River virus, or Barmah Forest virus structural protein, or a specific flavivirus protein can be isolated by RT-PCR from polyadenylated mRNA extracted from cells which had been infected with said virus. The resulting product gene can be cloned as a DNA insert into a vector. The term “vector” refers to the means by which a nucleic acid can be propagated and/or transferred between organisms, cells, or cellular components. Vectors include plasmids, viruses,

bacteriophages, pro-viruses, phagemids, transposons, artificial chromosomes, and the like, that replicate autonomously or can integrate into a chromosome of a host cell. A vector can also be a naked RNA polynucleotide, a naked DNA polynucleotide, a polynucleotide composed of both DNA and RNA within the same strand, a poly-lysine-conjugated DNA or RNA, a peptide-conjugated DNA or RNA, a liposome-conjugated DNA, or the like, that is not autonomously replicating. In many, but not all, common embodiments, the vectors of the present invention are plasmids or bacmids.

The invention further provides nucleotides that encode proteins, including chimeric molecules, cloned into an expression vector that can be expressed in a cell that provides for the formation of VLPs. An “expression vector” is a vector, such as a plasmid, that is capable of promoting expression, as well as replication of a nucleic acid incorporated therein. Typically, the nucleic acid molecule to be expressed is “operably linked” to a promoter and/or enhancer, and is subject to transcription regulatory control by the promoter and/or enhancer.

In one aspect, the invention provides an expression vector for expressing an alphavirus VLP having one or more alterations in an E2 protein and/or an alphavirus capsid protein Nuclear Localization Signal (NLS). In one embodiment, the VLP comprises one or more alphavirus envelope proteins, and in particular a CHIKV or WEEV E2 envelope protein having a non-lysine residue (e.g., asparagine) at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein and/or a modification at the amino acid position corresponding to amino acid 251 in the CHIKV E2 protein that destabilizes the E2 protein during viral budding. In another embodiment, the VLP further comprises any one or more of alphavirus envelope proteins E3, 6K, and E1. In another embodiment, the VLP further comprises an alphavirus capsid protein. In related embodiments, the CHIKV or WEEV capsid protein is used. In another embodiment, the VLP comprises of capsid, E3, E2, 6K, and E1. In still another embodiment, the VLP comprises one or more flavivirus envelope proteins. In related embodiments, the VLP further comprises one or more flavivirus capsid proteins. In another embodiment, the expression vector is a mammalian expression vector or baculovirus vector.

In various embodiments, one or more charged residues in the nuclear localization sequence of an alphavirus (CHIKV, WEEV, EEEV, VEEV, Ross River virus, Barmah Forest virus) capsid protein are altered. In particular embodiments, the charged residues in the alphavirus capsid protein NLS are lysine and arginine. In specific embodiments, lysine and arginine in the alphavirus capsid protein NLS are replaced with an alanine or asparagine. In

related embodiments, one or more alterations in an alphavirus capsid protein Nuclear Localization Signal (NLS) provides or increases the expression of alphavirus VLPs and increased alphavirus VLP yields. In specific embodiments, the alphavirus capsid protein is a WEEV CBA87 strain capsid protein having one or more of the alterations K67N, K68N, and/or K69N. In certain embodiments, the alphavirus capsid protein is a VEEV TC83 strain capsid protein having one or more of the alterations K64N, K65A, K65N, K67A, and/or K67N. In some embodiments, the alphavirus capsid protein is a EEEV PE-6 strain capsid protein having an alteration K67N. In particular embodiments, the alphavirus capsid protein is a CHIKV(Strain 37997) strain capsid protein having one or more of the alterations R62A, R63A, R65A, K66A, K68A, and/or K69A. In specific embodiments, the alphavirus capsid protein is a Ross River Virus capsid protein having one or more of the alterations R71N, K72N, K73N, and/or K74N. In specific embodiments, the alphavirus capsid protein is a Barmah Forest Virus capsid protein having one or more of the alterations K64A, K64N, K65A, K65N, K67A, K67N, K68A and/or K68N.

The method of transformation or transfection and the choice of expression vehicle will depend on the host system selected. Transformation and transfection methods are described, e.g., in Ausubel et al. (supra); expression vehicles may be chosen from those provided, e.g., in Cloning Vectors: A Laboratory Manual (P. H. Pouwels et al., 1985, Supp. 1987).

A variety of expression systems exist for the production of the polypeptides of the invention. Expression vectors useful for producing such polypeptides include, without limitation, chromosomal, episomal, and virus-derived vectors, e.g., vectors derived from bacterial plasmids, from bacteriophage, from transposons, from yeast episomes, from insertion elements, from yeast chromosomal elements, from viruses such as baculoviruses, papova viruses, such as SV40, vaccinia viruses, adenoviruses, fowl pox viruses, pseudorabies viruses and retroviruses, and vectors derived from combinations thereof.

Constructs and/or vectors provided herein comprise alphavirus or flavivirus polynucleotides that encode structural polypeptides, including envelope proteins or capsid proteins or portions thereof as described herein. The vector may be, for example, a phage, plasmid, viral, or retroviral vector. The constructs and/or vectors that comprise the nucleotides should be operatively linked to an appropriate promoter, such as the CMV promoter, phage lambda PL promoter, the *E. coli* lac, phoA and tac promoters, the SV40 early and late promoters, and promoters of retroviral LTRs are non-limiting examples. Other suitable promoters will be known to the skilled artisan depending on the host cell and/or the

rate of expression desired. The expression constructs will further contain sites for transcription initiation, termination, and, in the transcribed region, a ribosome-binding site for translation. The coding portion of the transcripts expressed by the constructs will preferably include a translation initiating codon at the beginning and a termination codon appropriately positioned at the end of the polypeptide to be translated.

Expression vectors will preferably include at least one selectable marker. Such markers include dihydrofolate reductase, G418 or neomycin resistance for eukaryotic cell culture and tetracycline, kanamycin or ampicillin resistance genes for culturing in *E. coli* and other bacteria. Among vectors preferred are virus vectors, such as baculovirus, poxvirus (e.g., vaccinia virus, avipox virus, canarypox virus, fowlpox virus, raccoonpox virus, swinepox virus, etc.), adenovirus (e.g., canine adenovirus), herpesvirus, and retrovirus. Other vectors that can be used with the invention comprise vectors for use in bacteria, which comprise pQE70, pQE60 and pQE-9, pBluescript vectors, Phagescript vectors, pNH8A, pNH16a, pNH18A, pNH46A, ptrc99a, pKK223-3, pKK233-3, pDR540, pRIT5. Among preferred eukaryotic vectors are pFastBac1 pWINEO, pSV2CAT, pOG44, pXT1 and pSG, pSVK3, pBPV, pMSG, and pSVL. Other suitable vectors will be readily apparent to the skilled artisan.

Recombinant constructs can be prepared and used to transfect, infect, or transform and can express viral proteins, including those described herein, into eukaryotic cells and/or prokaryotic cells. Thus, the invention provides for host cells which comprise a vector (or vectors) that contain nucleic acids which code for alphavirus structural genes, including capsid, E3, E2, 6K, and E1 or portions thereof, and/or any chimeric molecule described above, and permit the expression of alphavirus structural genes, including capsid E3, E2, 6K, and E1, or portions thereof, and/or any chimeric molecule described above in said host cell under conditions which allow the formation of VLPs. The invention also provides for host cells which comprise a vector (or vectors) that contain nucleic acids which code for flavivirus structural genes, including capsid, envelope, or portions thereof, and/or any chimeric molecule described above, and permit the expression of flavivirus structural genes, including capsid, envelope, or portions thereof, and/or any chimeric molecule described above in said host cell under conditions which allow the formation of VLPs.

In one embodiment, said vector is a recombinant baculovirus. In another embodiment, said recombinant baculovirus is transfected into an insect cell. In a preferred embodiment, said cell is an insect cell. In another embodiment, said insect cell is a Sf9 cell.

In another embodiment, said vector and/or host cell comprises nucleotides that encode alphavirus genes, including capsid, E3, E2, 6K, and E1, or portions thereof as described

herein. In another embodiment, said vector and/or host cell consists essentially of alphavirus capsid, E3, E2, 6K, and E1, or portions thereof as described herein. In a further embodiment, said vector and/or host cell consists of alphavirus protein comprising capsid, E3, E2, 6K, and E1, or portions thereof, as described herein. These vector and/or host cell contain alphavirus
5 core, E3, E2, 6K, and E1, or portions thereof, as described herein, and may contain additional cellular constituents such as cellular proteins, baculovirus proteins, lipids, carbohydrates etc.

In another embodiment, said vector and/or host cell comprises nucleotides that encode flavivirus genes, including capsid, envelope, or portions thereof as described herein. In another embodiment, said vector and/or host cell consists essentially of alphavirus flavivirus
10 capsid, envelope, or portions thereof as described herein. These vector and/or host cell may contain additional cellular constituents such as cellular proteins, baculovirus proteins, lipids, carbohydrates etc.

One particular bacterial expression system for polypeptide production is the *E. coli* pET expression system (Novagen, Inc., Madison, Wis). According to this expression system,
15 DNA encoding a polypeptide is inserted into a pET vector in an orientation designed to allow expression. Since the gene encoding such a polypeptide is under the control of the T7 regulatory signals, expression of the polypeptide is achieved by inducing the expression of T7 RNA polymerase in the host cell. This is typically achieved using host strains that express T7 RNA polymerase in response to IPTG induction. Once produced, a recombinant
20 polypeptide is then isolated according to standard methods known in the art, for example, those described herein.

Another bacterial expression system for polypeptide production is the pGEX expression system (Pharmacia). This system employs a GST gene fusion system that is designed for high-level expression of genes or gene fragments as fusion proteins with rapid
25 purification and recovery of functional gene products. The protein of interest is fused to the carboxyl terminus of the glutathione S-transferase protein from *Schistosoma japonicum* and is readily purified from bacterial lysates by affinity chromatography using Glutathione Sepharose 4B. Fusion proteins can be recovered under mild conditions by elution with glutathione. Cleavage of the glutathione S-transferase domain from the fusion protein is
30 facilitated by the presence of recognition sites for site-specific proteases upstream of this domain. For example, proteins expressed in pGEX-2T plasmids may be cleaved with thrombin; those expressed in pGEX-3X may be cleaved with factor Xa.

Once a recombinant polypeptide of the invention is expressed, it is isolated, e.g., using affinity chromatography. In one example, an antibody (e.g., produced as described

herein) raised against a polypeptide of the invention may be attached to a column and used to isolate the recombinant polypeptide. Lysis and fractionation of polypeptide-harboring cells prior to affinity chromatography may be performed by standard methods (see, e.g., Ausubel et al., supra).

5 Once isolated, the recombinant protein can, if desired, be further purified, e.g., by high performance liquid chromatography (see, e.g., Fisher, Laboratory Techniques In Biochemistry and Molecular Biology, eds., Work and Burdon, Elsevier, 1980). Polypeptides of the invention, particularly short peptide fragments, can also be produced by chemical synthesis (e.g., by the methods described in Solid Phase Peptide Synthesis, 2nd ed., 1984 The
10 Pierce Chemical Co., Rockford, Ill.). These general techniques of polypeptide expression and purification can also be used to produce and isolate useful peptide fragments or analogs (described herein).

Alphavirus and Flavivirus Polypeptides and Analogs

15 The invention provides VLPs comprising one or more alphavirus, CHIKV, WEEV, EEEV, VEEV, Ross River virus, Barmah Forest virus, or flavivirus polypeptides. Also included in the invention are VLPs comprising one or more alphavirus, CHIKV, WEEV, EEEV, VEEV, Ross River virus, Barmah Forest virus, or flavivirus polypeptides or
20 fragments thereof that are modified in ways that enhance or do not inhibit their ability to modulate an immune response. In one embodiment, the invention provides methods for optimizing an alphavirus, CHIKV, WEEV, EEEV, VEEV, Ross River virus, Barmah Forest virus, or flavivirus amino acid sequence or nucleic acid sequence by producing an alteration. Such alterations may include certain mutations, deletions, insertions, or post-translational modifications. The invention further includes analogs of any naturally-occurring polypeptide
25 of the invention. Analogs can differ from the naturally-occurring the polypeptide of the invention by amino acid sequence differences, by post-translational modifications, or by both. Analogs of the invention will generally exhibit at least 85%, more preferably 90%, and most preferably 95% or even 99% identity with all or part of a naturally-occurring amino, acid
30 sequence of the invention. The length of sequence comparison is at least 10, 13, 15 amino acid residues, preferably at least 25 amino acid residues, and more preferably more than 35 amino acid residues.

Alterations of an alphavirus, CHIKV, WEEV, EEEV, VEEV, Ross River virus, Barmah Forest virus, or flavivirus polypeptide include but are not limited to site-directed, random point mutagenesis, homologous recombination (DNA shuffling), mutagenesis using

uracil containing templates, oligonucleotide-directed mutagenesis, phosphorothioate-modified DNA mutagenesis, mutagenesis using gapped duplex DNA or the like. Additional suitable methods include point mismatch repair, mutagenesis using repair-deficient host strains, restriction-selection and restriction-purification, deletion mutagenesis, mutagenesis by total gene synthesis, double-strand break repair, and the like. Mutagenesis, e.g., involving chimeric constructs, is also included in the present invention. In one embodiment, mutagenesis can be guided by known information of the naturally occurring molecule or altered or mutated naturally occurring molecule, e.g., sequence, sequence comparisons, physical properties, crystal structure or the like.

In one embodiment, the invention provides polypeptide variants that differ from a reference polypeptide. The term “variant” refers to an amino acid sequence that is altered by one or more amino acids with respect to a reference sequence. The variant can have “conservative” changes, wherein a substituted amino acid has similar structural or chemical properties, e.g., replacement of leucine with isoleucine. Alternatively, a variant can have “nonconservative” changes, e.g., replacement of a glycine with a tryptophan. Analogous minor variations can also include amino acid deletion or insertion, or both. Guidance in determining which amino acid residues can be substituted, inserted, or deleted without eliminating biological or immunological activity can be found using computer programs well known in the art, for example, DNASTAR software. Desirably, variants show substantial biological activity. In one embodiment, a protein variant forms a VLP and elicits an antibody response when administered to a subject.

Natural variants can occur due to mutations in the proteins. These mutations may lead to antigenic variability within individual groups of infectious agents. Thus, a person infected with a particular strain develops antibody against that virus, as newer virus strains appear, the antibodies against the older strains no longer recognize the newer virus and reinfection can occur. The invention encompasses all antigenic and genetic variability of proteins from infectious agents for making VLPs.

Again, in an exemplary approach to determining the degree of identity, a BLAST program may be used, with a probability score between e^{-3} and e^{-100} indicating a closely related sequence. Modifications include *in vivo* and *in vitro* chemical derivatization of polypeptides, e.g., acetylation, carboxylation, phosphorylation, or glycosylation; such modifications may occur during polypeptide synthesis or processing or following treatment with isolated modifying enzymes. Analogs can also differ from the naturally-occurring polypeptides of the invention by alterations in primary sequence. These include genetic

variants, both natural and induced (for example, resulting from random mutagenesis by irradiation or exposure to ethanemethylsulfate or by site-specific mutagenesis as described in Sambrook, Fritsch and Maniatis, Molecular Cloning: A Laboratory Manual (2d ed.), CSH Press, 1989, or Ausubel et al., supra). Also included are cyclized peptides, molecules, and
5 analogs which contain residues other than L-amino acids, e.g., D-amino acids or non-naturally occurring or synthetic amino acids, e.g., .beta. or .gamma. amino acids.

In addition to full-length polypeptides, the invention also includes fragments of any one of the polypeptides of the invention. As used herein, the term "a fragment" means at least 5, 10, 13, or 15. In other embodiments a fragment is at least 20 contiguous amino acids,
10 at least 30 contiguous amino acids, or at least 50 contiguous amino acids, and in other embodiments at least 60 to 80 or more contiguous amino acids. Fragments of the invention can be generated by methods known to those skilled in the art or may result from normal protein processing (e.g., removal of amino acids from the nascent polypeptide that are not required for biological activity or removal of amino acids by alternative mRNA splicing or
15 alternative protein processing events).

Non-protein analogs having a chemical structure designed to mimic alphavirus, CHIKV, WEEV, EEEV, VEEV, Ross River virus, Barmah Forest virus, or flavivirus VLPs or one or more alphavirus, CHIKV, WEEV, EEEV, VEEV, Ross River virus, Barmah Forest virus, or flavivirus polypeptides functional activity can be administered according to methods
20 of the invention. Alphavirus, CHIKV, WEEV, EEEV, VEEV, Ross River virus, Barmah Forest virus, or flavivirus analogs may exceed the physiological activity of native alphavirus, CHIKV, WEEV, EEEV, VEEV, Ross River virus, Barmah Forest virus, or flavivirus.

Methods of analog design are well known in the art, and synthesis of analogs can be carried out according to such methods by modifying the chemical structures such that the resultant
25 analogs exhibit the immunomodulatory activity of a native alphavirus, CHIKV, WEEV, EEEV, VEEV, Ross River virus, Barmah Forest virus, or flavivirus polypeptide. These chemical modifications include, but are not limited to, substituting alternative R groups and varying the degree of saturation at specific carbon atoms of the native alphavirus, CHIKV, WEEV, EEEV, VEEV, Ross River virus, Barmah Forest virus, or flavivirus molecule.

30 Preferably, the analogs are relatively resistant to *in vivo* degradation, resulting in a more prolonged therapeutic effect upon administration. Assays for measuring functional activity include, but are not limited to, those described in the Examples below.

Alphavirus and Flavivirus VLP Production

The invention also provides constructs and methods for producing a VLP comprising alphavirus or flavivirus polypeptides, or fragments thereof, as well as compositions and methods that increase the efficiency of VLP production. In embodiments, inclusion of an
5 alphavirus E2 protein or a flavivirus envelope protein having a non-lysine residue (e.g., asparagine) at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein results in enhanced VLP production. In embodiments, inclusion of an alphavirus E2 protein having a modification at the amino acid position corresponding to amino acid 251 in the CHIKV E2 protein that destabilizes the E2 protein during viral budding results in
10 enhanced VLP production. In a related embodiment, VLP are exposed to high pH, basic, or non-acidic conditions during VLP production (e.g., in cell culture, during purification). In specific embodiments, the pH is at least about 7.2 (pH 7.2, 7.3, 7.4, 7.5, 7.6, 7.7, 7.8, 7.9, 8.0, 8.1, 8.2, 8.3, 8.4, 8.5, 8.6, 8.7, 8.8, or higher). In certain embodiments, the addition of leader sequences to the alphavirus capsid, E3, E2, 6K, E1, or portions thereof, or to flavivirus capsid,
15 envelope, or portions thereof, can improve the efficiency of protein transporting within the cell. In another example, a heterologous signal sequence can be fused to the alphavirus capsid, E3, E2, 6K, E1, or portions thereof, or to flavivirus capsid, envelope, or portions thereof. In one embodiment, the signal sequence can be derived from the gene of an insect cell. Another method to increase efficiency of VLP production is to codon optimize the
20 nucleotides that encode alphavirus capsid, E3, E2, 6K, E1, or portions thereof, or flavivirus capsid, envelope, or portions thereof for a specific cell type.

In various embodiments, one or more charged residues in the nuclear localization sequence of an alphavirus (CHIKV, WEEV, EEEV, VEEV, Ross River virus, Barmah Forest virus) capsid protein are altered. In particular embodiments, the charged residues in the
25 alphavirus capsid protein NLS are lysine and arginine. In specific embodiments, lysine and arginine in the alphavirus capsid protein NLS are replaced with an alanine or asparagine. In related embodiments, one or more alterations in an alphavirus capsid protein Nuclear Localization Signal (NLS) provides or increases the expression of alphavirus VLPs and increased alphavirus VLP yields. In specific embodiments, the alphavirus capsid protein is a
30 WEEV CBA87 strain capsid protein having one or more of the alterations K67N, K68N, and/or K69N. In certain embodiments, the alphavirus capsid protein is a VEEV TC83 strain capsid protein having one or more of the alterations K64N, K65A, K65N, K67A, and/or K67N. In some embodiments, the alphavirus capsid protein is a EEEV PE-6 strain capsid protein having an alteration K67N. In particular embodiments, the alphavirus capsid protein

is a CHIKV(Strain 37997) strain capsid protein having one or more of the alterations R62A, R63A, R65A, K66A, K68A, and/or K69A. In specific embodiments, the alphavirus capsid protein is a Ross River Virus capsid protein having one or more of the alterations R71N, K72N, K73N, and/or K74N. In specific embodiments, the alphavirus capsid protein is a
5 Barmah Forest Virus capsid protein having one or more of the alterations K64A, K64N, K65A, K65N, K67A, K67N, K68A, and/or K68N.

Methods of cloning said proteins are known in the art. For example, the gene encoding a specific alphavirus protein can be isolated by RT-PCR from polyadenylated mRNA extracted from cells which had been infected with said virus. The resulting gene can
10 be cloned as a DNA insert into a vector. The term “vector” refers to the means by which a nucleic acid can be propagated and/or transferred between organisms, cells, or cellular components. Vectors include plasmids, viruses, bacteriophages, pro-viruses, phagemids, transposons, artificial chromosomes, and the like, that replicate autonomously or can integrate into a chromosome of a host cell. A vector can also be a naked RNA polynucleotide,
15 a naked DNA polynucleotide, a polynucleotide composed of both DNA and RNA within the same strand, a poly-lysine-conjugated DNA or RNA, a peptide-conjugated DNA or RNA, a liposome-conjugated DNA, or the like, that is not autonomously replicating. In many, but not all, common embodiments, the vectors of the present invention are plasmids or bacmids.

Thus, the invention comprises nucleotides that encode proteins, including chimeric
20 molecules, cloned into an expression vector that can be expressed in a cell that induces the formation of VLPs of the invention. An “expression vector” is a vector, such as a plasmid that is capable of promoting expression, as well as replication of a nucleic acid incorporated therein. Typically, the nucleic acid to be expressed is “operably linked” to a promoter and/or enhancer, and is subject to transcription regulatory control by the promoter and/or enhancer.
25 In embodiments, the VLP comprises an alphavirus E2 envelope protein having a non-lysine residue (e.g., asparagine) at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein, and in particular a CHIKV or WEEV E2 protein. In embodiments, the VLP comprises an alphavirus E2 envelope protein having a modification at the amino acid position corresponding to amino acid 251 in the CHIKV E2 protein that destabilizes the E2
30 protein during viral budding. In another embodiment, the VLP further comprises one or more additional envelope proteins selected from the group consisting of E3, 6K and E1. In another embodiment, the VLP comprises an alphavirus capsid protein. In related embodiments, the CHIKV or WEEV capsid protein is used. In another embodiment, the VLPs are comprised of E3, E2, 6K and E1. In still another embodiment, the VLPs are comprised of capsid, E3, E2,

6K and E1. In embodiments, the VLP comprises a flavivirus envelope protein having a non-lysine residue (e.g., asparagine) at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein. In another embodiment, the VLP comprises a flavivirus capsid protein. In another embodiment, the expression vector is a baculovirus vector.

5 The invention also provides methods of producing a VLP comprising alphavirus or flavivirus polypeptides, or fragments thereof, including an alphavirus E2 polypeptide or a flavivirus envelope polypeptide that has a non-lysine residue (e.g., asparagine) at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein. In embodiments, the alphavirus E2 polypeptide has a modification at the amino acid position corresponding to
10 amino acid 251 in the CHIKV E2 protein that destabilizes the E2 protein during viral budding. In one example, the method involves expressing in a cell a polynucleotide encoding an alphavirus polypeptide, such as an CHIKV or WEEV polypeptide, or a flavivirus polypeptide and culturing said cell, thereby producing VLPs. In one embodiment, a cell (e.g., human cell) is infected with a DNA vaccine, where the DNA vaccine is a DNA vector, comprising a
15 nucleic acid segment encoding an alphavirus capsid protein or one or more alphavirus envelope proteins, or fragments thereof to produce an alphavirus VLP. In particular, the alphavirus is CHIKV or WEEV. In another embodiment, a cell (e.g., human cell) is infected with a DNA vaccine, where the DNA vaccine is a DNA vector, comprising a nucleic acid segment encoding an flavivirus capsid protein or one or more flavivirus envelope proteins, or
20 fragments thereof to produce a flavivirus VLP.

 Depending on the expression system and host cell selected, the VLPs are produced by growing host cells transformed by an expression vector under conditions whereby the recombinant proteins are expressed and VLPs are formed. In one embodiment, the invention comprises a method of producing a VLP, that involves transfecting vectors encoding at least
25 one alphavirus protein into a suitable host cell and expressing said alphavirus protein under conditions that allow VLP formation. In another embodiment, the eukaryotic cell is selected from the group consisting of, yeast, insect, amphibian, avian or mammalian cells. The selection of the appropriate growth conditions is within the skill or a person with skill of one of ordinary skill in the art.

30 Methods to grow cells that produce VLPs of the invention include, but are not limited to, batch, batch-fed, continuous and perfusion cell culture techniques. In one embodiment, a cell comprising an alphavirus polynucleotide, such as a CHIKV or WEEV polynucleotide, or a flavivirus polynucleotide, is grown in a bioreactor or fermentation chamber where cells propagate and express protein (e.g., recombinant proteins) for purification and isolation.

Typically, cell culture is performed under sterile, controlled temperature and atmospheric conditions. A bioreactor is a chamber used to culture cells in which environmental conditions such as temperature, atmosphere, agitation and/or pH can be monitored. In one embodiment, the bioreactor is a stainless steel chamber. In another embodiment, said
5 bioreactor is a pre-sterilized plastic bag (e.g., Cellbag.RTM., Wave Biotech, Bridgewater, N.J.). In other embodiment, said pre-sterilized plastic bags are about 50 L to 1000 L bags.

The VLPs are isolated using methods that preserve the integrity thereof, such as by gradient centrifugation, e.g., cesium chloride, sucrose and iodixanol, as well as standard purification techniques including, e.g., ion exchange and gel filtration chromatography.

10 The following is an example of how VLPs of the invention can be made, isolated and purified. A person of skill in the art appreciates that there are additional methods that can be used to make and purify VLPs. Accordingly, the invention is not limited to the methods described herein.

In general, production of VLPs of the invention is accomplished by seeding a
15 mammalian cell (e.g., human embryonic kidney (293T) cells) or Sf9 cells (non-infected) into shaker flasks, allowing the cells to expand and scaling up as the cells grow and multiply (for example from a 125-ml flask to a 50 L Wave bag). The medium used to grow the cells is formulated for the appropriate cell line (preferably serum free media, e.g., insect medium ExCell-420, JRH). Next, the cells are transfected or infected with an appropriate vector (e.g.,
20 mammalian expression vector or for SF(cells recombinant baculovirus at the most efficient multiplicity of infection (e.g., from about 1 to about 3 plaque forming units per cell). The polynucleotides, or portions thereof, are expressed in the cells where they self assemble into VLPs and are secreted from the cells approximately 24 to 72 hours post infection. Usually, transfection or infection is most efficient when the cells are in mid-log phase of growth (4-
25 8×10^6 cells/ml) and are at least about 90% viable. Additionally, the transfected cells may be exposed to high pH conditions in cell culture (pH > 7.2, e.g., pH 7.2, 7.3, 7.4, 7.5, 7.6, 7.7, 7.8, 7.9, 8.0, 8.1, 8.2, 8.3, 8.4, 8.5, 8.6, 8.7, 8.8, or higher) to increase VLP production.

VLPs of the invention are harvested approximately 48 to 120 hours post infection, when the levels of VLPs in the cell culture medium are near the maximum but before
30 extensive cell lysis. The cell density and viability at the time of harvest can be about 0.5×10^6 cells/ml to about 1.5×10^6 cells/ml with at least 20% viability, as shown by dye exclusion assay. Next, the medium is removed and clarified. NaCl can be added to the medium to a concentration of about 0.4 to about 1.0 M, preferably to about 0.5 M, to avoid VLP aggregation. The removal of cell and cellular debris from the cell culture medium containing

VLPs of the invention can be accomplished by tangential flow filtration (TFF) with a single use, pre-sterilized hollow fiber 0.5 or 1.00 μ m filter cartridge or a similar device.

Additionally, the VLPs may be exposed to high pH conditions during purification (pH > 7.2, e.g., pH 7.2, 7.3, 7.4, 7.5, 7.6, 7.7, 7.8, 7.9, 8.0, 8.1, 8.2, 8.3, 8.4, 8.5, 8.6, 8.7, 8.8, or higher) to increase VLP production.

Next, VLPs in the clarified culture medium are concentrated by ultrafiltration using a disposable, pre-sterilized 500,000 molecular weight cut off hollow fiber cartridge. The concentrated VLPs can be diafiltrated against 10 volumes pH 7.0 to 8.0 phosphate-buffered saline (PBS) containing 0.5 M NaCl to remove residual medium components.

The concentrated, diafiltered VLPs can be further purified on a 20% to 60% discontinuous sucrose gradient in pH 7.2 PBS buffer with 0.5 M NaCl by centrifugation at 6,500 x g for 18 hours at about 4 C to about 10 C. Usually VLPs will form a distinctive visible band between about 30% to about 40% sucrose or at the interface (in a 20% and 60% step gradient) that can be collected from the gradient and stored. This product can be diluted to comprise 200 mM of NaCl in preparation for the next step in the purification process. This product contains VLPs and may contain intact baculovirus particles.

Further purification of VLPs can be achieved by anion exchange chromatography, or 44% isopycnic sucrose cushion centrifugation. In anion exchange chromatography, the sample from the sucrose gradient (see above) is loaded into column containing a medium with an anion (e.g., Matrix Fractogel EMD TMAE) and eluted via a salt gradient (from about 0.2 M to about 1.0 M of NaCl) that can separate the VLP from other contaminants (e.g., baculovirus and DNA/RNA). In the sucrose cushion method, the sample comprising the VLPs is added to a 44% sucrose cushion and centrifuged for about 18 hours at 30,000 g. VLPs form a band at the top of 44% sucrose, while baculovirus precipitates at the bottom and other contaminating proteins stay in the 0% sucrose layer at the top. The VLP peak or band is collected.

The intact baculovirus can be inactivated, if desired. Inactivation can be accomplished by chemical methods, for example, formalin or .beta.-propiolactone (BPL). Removal and/or inactivation of intact baculovirus can also be largely accomplished by using selective precipitation and chromatographic methods known in the art, as exemplified above. Methods of inactivation comprise incubating the sample containing the VLPs in 0.2% of BPL for 3 hours at about 25° C to about 27° C. The baculovirus can also be inactivated by incubating the sample containing the VLPs at 0.05% BPL at 4° C for 3 days, then at 37° C for one hour.

After the inactivation/removal step, the product comprising VLPs can be run through another diafiltration step to remove any reagent from the inactivation step and/or any residual sucrose, and to place the VLPs into the desired buffer (e.g., PBS). The solution comprising VLPs can be sterilized by methods known in the art (e.g., sterile filtration) and stored in the refrigerator or freezer.

The above techniques can be practiced across a variety of scales. For example, T-flasks, shake-flasks, spinner bottles, up to industrial sized bioreactors. The bioreactors can comprise either a stainless steel tank or a pre-sterilized plastic bag (for example, the system sold by Wave Biotech, Bridgewater, N.J.). A person with skill in the art will know what is most desirable for their purposes.

As described herein, upon administration to a desired host, the VLPs of the present invention are taken up by cells normally infected by the particular virus. When the VLP contains/packages a target agent, the agent is internalized into the cell upon VLP entry. This property facilitates the use of the VLPs described herein as delivery vehicles because they enable the delivery of a target agent(s) into a desired cell.

Thus, in certain embodiments, a DNA vaccine or VLP comprises an agent(s), such as a therapeutic or diagnostic agent(s) that needs to be delivered to a subject, e.g., imaging agent, nucleic acid sequence (including siRNA and microRNA), radionuclide, hormone, peptide, antiviral agent, antitumor/chemotherapeutic agent, cell growth modulating agent, cell growth inhibitor, cytokine, antigen, adjuvant, toxin, etc. The agent encapsulated should not adversely affect the VLP, or VLP stability. This may be determined by producing VLP containing the desired agent and assessing its effects, if any, on VLP stability.

Accordingly, the present invention provides methods for introducing an agent into a cell. In embodiments, the agent is packaged into a VLP as described herein, producing a packed VLP. In related embodiments, the packed VLP is contacted with a cell. In related embodiments, the packed VLP is allowed to enter the cell, thereby resulting in delivery of the agent into the cell.

In embodiments, the invention provides methods of treating viral diseases and/or disorders or symptoms thereof which comprise administering a therapeutically effective amount of a pharmaceutical composition comprising a VLP or DNA of the formulae herein to a subject (e.g., a mammal such as a human). Thus, one embodiment is a method of treating a subject suffering from or susceptible to a viral infection, viral disease or disorder or symptom thereof. The method includes the step of administering to the mammal a therapeutic or prophylactic amount of an amount of a compound herein sufficient to treat the disease or

disorder or symptom thereof, under conditions such that the disease or disorder is prevented or treated.

The methods herein include administering to the subject (including a subject identified as in need of such treatment) an effective amount of a compound described herein, or a composition described herein to produce such effect. Identifying a subject in need of such treatment can be in the judgment of a subject or a health care professional and can be subjective (e.g., opinion) or objective (e.g., measurable by a test or diagnostic method).

As used herein, the terms “treat,” “treating,” “treatment,” and the like refer to reducing or ameliorating a disorder and/or symptoms associated therewith. It will be appreciated that, although not precluded, treating a disorder or condition does not require that the disorder, condition or symptoms associated therewith be completely eliminated.

As used herein, the terms “prevent,” “preventing,” “prevention,” “prophylactic treatment” and the like refer to reducing the probability of developing a disorder or condition in a subject, who does not have, but is at risk of or susceptible to developing a disorder or condition.

The therapeutic methods of the invention (which include prophylactic treatment) in general comprise administration of a therapeutically effective amount of the agents herein, such as a VLP or DNA of a formulae herein to a subject (e.g., animal, human) in need thereof, including a mammal, particularly a human. Such treatment will be suitably administered to subjects, particularly humans, suffering from, having, susceptible to, or at risk for a disease, disorder, or symptom thereof. Determination of those subjects “at risk” can be made by any objective or subjective determination by a diagnostic test or opinion of a subject or health care provider (e.g., genetic test, enzyme or protein marker, Marker (as defined herein), family history, and the like). The agents herein may be also used in the treatment of any other disorders in which an alphavirus may be implicated.

In one embodiment, the invention provides a method of monitoring treatment progress. The method includes the step of determining a level of diagnostic marker (Marker) (e.g., any target delineated herein modulated by a compound herein, a protein or indicator thereof, etc.) or diagnostic measurement (e.g., screen, assay) in a subject suffering from or susceptible to a disorder or symptoms thereof associated with an alphavirus, in which the subject has been administered a therapeutic amount of a compound herein sufficient to treat the disease or symptoms thereof. The level of Marker determined in the method can be compared to known levels of Marker in either healthy normal controls or in other afflicted patients to establish the subject’s disease status. In preferred embodiments, a second level of

Marker in the subject is determined at a time point later than the determination of the first level, and the two levels are compared to monitor the course of disease or the efficacy of the therapy. In certain preferred embodiments, a pre-treatment level of Marker in the subject is determined prior to beginning treatment according to this invention; this pre-treatment level of Marker can then be compared to the level of Marker in the subject after the treatment commences, to determine the efficacy of the treatment.

Immunogenic Compositions

The invention provides compositions and methods for inducing an immunological response in a subject, particularly a human, which involves inoculating the subject with a VLP as described herein in a suitable carrier for the purpose of inducing or enhancing an immune response. In one embodiment, an immune response protects the subject from an alphavirus infection, such as a CHIKV, WEEV, EEEV, VEEV, Ross River virus, or Barmah Forest virus infection, a flavivirus infection, or inflammatory consequences thereof (e.g., arthritis). The administration of this immunological composition may be used either therapeutically in subjects already experiencing an alphavirus infection, such as a CHIKV or WEEV infection, or may be used prophylactically to prevent an alphavirus infection. The administration of this immunological composition may also be used either therapeutically in subjects already experiencing a flavivirus infection or prophylactically to prevent a flavivirus infection.

In certain embodiments, the alphavirus candidate vaccines were developed by comparing the immunogenicity of gene products derived from two disparate strains, the 37997 strain from West Africa and the latest outbreak strain, OPY-1, of the East/Central/South African genotype. These strains share ~95% amino acid sequence similarity but have distinct biological differences, particularly related to their host range. In particular, the presence of a non-lysine residue (e.g., asparagine) at amino acid 234 in the CHIKV E2 protein resulted in enhanced VLP production. The introduction of a non-lysine residue (e.g., asparagine) into other alphaviruses at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein also resulted in enhanced VLP production of other alphaviruses. In addition, modification of the amino acid position corresponding to amino acid 251 in the CHIKV E2 protein further destabilized the E2 protein during viral budding, resulting in enhanced VLP production.

VLPs of the invention are useful for preparing vaccines and immunogenic compositions. One important feature of VLPs is the ability to express surface proteins so that

the immune system of a vertebrate induces an immune response against said protein. However, not all proteins can be expressed on the surface of VLPs. There may be many reasons why certain proteins are not expressed, or be poorly expressed, on the surface of VLPs. One reason is that said protein is not directed to the membrane of a host cell or that
5 said protein does not have a transmembrane domain.

The preparation of immunogenic compositions and vaccines is known to one skilled in the art. The immunogenic composition or vaccine includes a VLP comprising one or more alphavirus polypeptides, one or more flavivirus polypeptides, or fragments thereof, where the VLP has one or more alterations in an alphavirus E2 protein and/or an alphavirus capsid protein
10 Nuclear Localization Signal (NLS). The immunogenic composition or vaccine may include a VLP comprising an alphavirus E2 polypeptide or a flavivirus envelope polypeptide that has a non-lysine residue (e.g., asparagine) at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein. The alphavirus E2 polypeptide may have a modification at the amino acid position corresponding to amino acid 251 in the CHIKV E2 protein that
15 destabilizes the E2 protein during viral budding. The immunogenic composition or vaccine may include a VLP comprising an alphavirus (CHIKV, WEEV, EEEV, VEEV, Ross River virus, Barmah Forest virus) capsid protein in which the nuclear localization sequence is altered. The alphavirus capsid protein nuclear localization sequence is altered in a charged residue (e.g., lysine or arginine), which is replaced with a non-charged residue (e.g., alanine
20 or asparagine). In specific embodiments, the alphavirus capsid protein is a WEEV CBA87 strain capsid protein having one or more of the alterations K67N, K68N, and/or K69N. In certain embodiments, the alphavirus capsid protein is a VEEV TC83 strain capsid protein having one or more of the alterations K64N, K65A, K65N, K67A, and/or K67N. In some embodiments, the alphavirus capsid protein is a EEEV PE-6 strain capsid protein having an
25 alteration K67N. In particular embodiments, the alphavirus capsid protein is a CHIKV (Strain 37997) strain capsid protein having one or more of the alterations R62A, R63A, R65A, K66A, K68A, and/or K69A. In specific embodiments, the alphavirus capsid protein is a Ross River Virus capsid protein having one or more of the alterations R71N, K72N, K73N, and/or K74N. . In specific embodiments, the alphavirus capsid protein is a Barmah Forest Virus
30 capsid protein having one or more of the alterations K64A, K64N, K65A, K65N, K67A, K67N, K68A and/or K68N.

The invention also provides expression vectors encoding one or more alphavirus polypeptides, flavivirus polypeptides, or fragments thereof or variants thereof, including an alphavirus E2 polypeptide or a flavivirus envelope polypeptide that has a non-lysine residue

(e.g., asparagine) at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein. The alphavirus E2 polypeptide may have a modification at the amino acid position corresponding to amino acid 251 in the CHIKV E2 protein that destabilizes the E2 protein during viral budding. Such an immunogenic composition is delivered *in vivo* in order to induce or enhance an immunological response in a subject, such as a humoral response.

For example, a VLP comprising one or more CHIKV or WEEV polypeptides or fragments or variants thereof, including a CHIKV or WEEV E2 polypeptide that has a non-lysine residue (e.g., asparagine) at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein and/or a modification at the amino acid position corresponding to amino acid 251 in the CHIKV E2 protein that destabilizes the E2 protein during viral budding, are delivered *in vivo* in order to induce an immune response.

Typically vaccines are prepared in an injectable form, either as a liquid solution or as a suspension. Solid forms suitable for injection may also be prepared as emulsions, or with the polypeptides encapsulated in liposomes. Vaccine antigens are usually combined with a pharmaceutically acceptable carrier, which includes any carrier that does not induce the production of antibodies harmful to the subject receiving the carrier. Suitable carriers typically comprise large macromolecules that are slowly metabolized, such as proteins, polysaccharides, polylactic acids, polyglycolic acids, polymeric amino acids, amino acid copolymers, lipid aggregates, and inactive virus particles. Such carriers are well known to those skilled in the art. These carriers may also function as adjuvants.

The VLPs described herein may be administered in combination with an adjuvant (e.g., Ribi). Adjuvants are immunostimulating agents that enhance vaccine effectiveness. If desired, the VLP comprising one or more alphavirus polypeptides or fragments or variants thereof are administered in combination with an adjuvant that enhances the effectiveness of the immune response generated against the antigen of interest. Effective adjuvants include, but are not limited to, aluminum salts such as aluminum hydroxide and aluminum phosphate, muramyl peptides, bacterial cell wall components, saponin adjuvants, and other substances that act as immunostimulating agents to enhance the effectiveness of the composition.

Immunogenic compositions, i.e., the VLPs described herein, pharmaceutically acceptable carrier and adjuvant, also typically contain diluents, such as water, saline, glycerol, ethanol. Auxiliary substances may also be present, such as wetting or emulsifying agents, pH buffering substances, and the like. Proteins may be formulated into the vaccine as neutral or salt forms. The immunogenic compositions are typically administered parenterally, by injection; such injection may be either subcutaneously or intramuscularly.

Additional formulations are suitable for other forms of administration, such as by suppository or orally. Oral compositions may be administered as a solution, suspension, tablet, pill, capsule, or sustained release formulation.

Immunogenic compositions are administered in a manner compatible with the dose formulation. The immunogenic composition comprises an immunologically effective amount of the VLP described herein and other previously mentioned components. By an immunologically effective amount is meant a single dose, or a composition administered in a multiple dose schedule, that is effective for the treatment or prevention of an infection. The dose administered will vary, depending on the subject to be treated, the subject's health and physical condition, the capacity of the subject's immune system to produce antibodies, the degree of protection desired, and other relevant factors. Precise amounts of the active ingredient required will depend on the judgement of the practitioner, but typically range between 5 μ g to 250 μ g of antigen per dose.

The invention provides a VLP for use in treating or preventing an alphavirus infection (e.g., CHIKV or WEEV infection). The invention also provides a VLP for use in treating or preventing a flavivirus infection.

Pharmaceutical Compositions and Administration

The invention features pharmaceutical compositions that comprise VLPs as described herein. The pharmaceutical compositions useful herein contain a pharmaceutically acceptable carrier, including any suitable diluent or excipient, which includes any pharmaceutical agent that does not itself induce the production of an immune response harmful to the vertebrate receiving the composition, and which may be administered without undue toxicity and a VLP of the invention. As used herein, the term "pharmaceutically acceptable" means being approved by a regulatory agency of the Federal or a state government or listed in the U.S. Pharmacopia, European Pharmacopia or other generally recognized pharmacopia for use in mammals, and more particularly in humans. These compositions can be useful as a vaccine and/or antigenic compositions for inducing a protective immune response in a vertebrate.

In particular embodiments, the invention encompasses an antigenic formulation comprising VLPs which comprises at least one viral protein, for example one alphavirus protein or one flavivirus protein. The alphavirus may be selected from the group consisting of, but not limited to, EEEV, WEEV, VEEV, SFV, CHIKV, Ross River virus, Barmah Forest virus, O'nyong-nyong virus, Sindbis virus, Mayaro virus, and Ockelbo virus.

In certain embodiments, the pharmaceutical compositions comprise alphavirus or flavivirus VLPs and a pharmaceutically acceptable carrier. In certain preferred embodiments, the pharmaceutical composition comprises VLPs of CHIKV, WEEV, EEEV, VEEV, Ross River virus, or Barmah Forest virus, and a pharmaceutically acceptable carrier. In other
5 certain preferred embodiments, the pharmaceutical composition comprises VLPs of CHIKV, WEEV, EEEV, VEEV, Ross River virus, or Barmah Forest virus, an adjuvant, and a pharmaceutically acceptable carrier.

In embodiments, the VLPs comprise an alphavirus (CHIKV, WEEV, EEEV, VEEV, Ross River virus, Barmah Forest virus) VLP having one or more alterations in an E2 protein
10 and/or an alphavirus capsid protein Nuclear Localization Signal (NLS). In embodiments, the VLPs are comprised of CHIKV, WEEV, EEEV, VEEV, Ross River virus, Barmah Forest virus envelope proteins, including a CHIKV or WEEV E2 envelope protein having a non-lysine residue (e.g., asparagine) at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein and/or a modification at the amino acid position corresponding to
15 amino acid 251 in the CHIKV E2 protein that destabilizes the E2 protein during viral budding. In embodiments, the VLPs comprise additional CHIKV or WEEV envelope proteins selected from the group consisting of CHIKV or WEEV E3, 6K, and E1 envelope proteins. In another embodiment, the pharmaceutical composition further comprises a CHIKV or WEEV capsid protein. In certain examples, the VLPs are comprised of E3, E2, 6K and E1. In other
20 examples, the VLPs are comprised of capsid, E3, E2, 6K and E1. In various embodiments, the VLP comprises an alphavirus (CHIKV, WEEV, EEEV, VEEV, Ross River virus, Barmah Forest virus) capsid protein in which the nuclear localization sequence is altered. The alphavirus capsid protein nuclear localization sequence is altered in a charged residue (e.g., lysine or arginine), which is replaced with a non-charged residue (e.g., alanine or asparagine).
25 In specific embodiments, the alphavirus capsid protein is a WEEV CBA87 strain capsid protein having one or more of the alterations K67N, K68N, and/or K69N. In certain embodiments, the alphavirus capsid protein is a VEEV TC83 strain capsid protein having one or more of the alterations K64N, K65A, K65N, K67A, and/or K67N. In some embodiments, the alphavirus capsid protein is a EEEV PE-6 strain capsid protein having an alteration K67N.
30 In particular embodiments, the alphavirus capsid protein is a CHIKV (Strain 37997) strain capsid protein having one or more of the alterations R62A, R63A, R65A, K66A, K68A, and/or K69A. In specific embodiments, the alphavirus capsid protein is a Ross River Virus capsid protein having one or more of the alterations R71N, K72N, K73N, and/or K74N. In specific embodiments, the alphavirus capsid protein is a Barmah Forest Virus capsid protein

having one or more of the alterations K64A, K64N, K65A, K65N, K67A, K67N, K68A and/or K68N.

The invention also encompasses a vaccine formulation comprising VLPs that comprise at least one viral protein, an alphavirus E2 protein or a flavivirus envelope protein having a non-lysine residue (e.g., asparagine) at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein. The alphavirus E2 protein may have a modification at the amino acid position corresponding to amino acid 251 in the CHIKV E2 protein that destabilizes the E2 protein during viral budding. The alphavirus may be selected from the group consisting of, but not limited to, EEEV, WEEV, VEEV, SFV, CHIKV, O'nyong-nyong virus, Sindbis virus, Mayaro virus, Ross River virus, Barmah Forest virus, and Ockelbo virus.

In certain preferred embodiments, the vaccine composition comprises VLPs of CHIKV or WEEV, and a pharmaceutically acceptable carrier. In other certain preferred embodiments, the vaccine composition comprises VLPs of CHIKV or WEEV, an adjuvant, and a pharmaceutically acceptable carrier. In one embodiment, the vaccine comprises VLPs that contain a CHIKV or WEEV E2 alphavirus that has a non-lysine residue (e.g., asparagine) at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein and/or a modification at the amino acid position corresponding to amino acid 251 in the CHIKV E2 protein that destabilizes the E2 protein during viral budding. In another embodiment, the vaccine composition comprises VLPs containing additional CHIKV or WEEV envelope proteins, for example, the envelope proteins can be selected from the group consisting of E3, 6K, and E1. In another embodiment, the vaccine composition further comprises a CHIKV or WEEV capsid protein and a pharmaceutically acceptable carrier or excipient. In certain examples, the VLPs are comprised of E3, E2, 6K and E1. In other examples, the VLPs are comprised of capsid, E3, E2, 6K and E1.

Pharmaceutically acceptable carriers include but are not limited to saline, buffered saline, dextrose, water, glycerol, sterile isotonic aqueous buffer, and combinations thereof. A thorough discussion of pharmaceutically acceptable carriers, diluents, and other excipients is presented in Remington's Pharmaceutical Sciences (Mack Pub. Co. N.J. current edition). The formulation should suit the mode of administration. In a preferred embodiment, the formulation is suitable for administration to humans, preferably is sterile, non-particulate and/or non-pyrogenic.

The composition, if desired, can also contain minor amounts of wetting or emulsifying agents, or pH buffering agents. The composition can be a solid form, such as a

lyophilized powder suitable for reconstitution, a liquid solution, suspension, emulsion, tablet, pill, capsule, sustained release formulation, or powder. Oral formulation can include standard carriers such as pharmaceutical grades of mannitol, lactose, starch, magnesium stearate, sodium saccharine, cellulose, magnesium carbonate, etc.

5 In certain embodiments, the VLP composition is supplied in liquid form, for example in a sealed container indicating the quantity and concentration of the VLP composition. Preferably, the liquid form of the VLP composition is supplied in a hermetically sealed container at least about 50 µg/ml, more preferably at least about 100 µg/ml, at least about 200 µg/ml, at least 500 µg/ml, or at least 1 mg/ml.

10 Generally, VLPs or DNA vaccines of the invention are administered in an effective amount or quantity (as described herein) sufficient to stimulate an immune response against one or more strains of a virus as described here, for example an alphavirus, e.g., CHIKV or WEEV, or a flavivirus. Preferably, administration of the VLP of the invention elicits immunity against a virus, for example an alphavirus, in particular example CHIKV or WEEV,
15 or a flavivirus. Typically, the dose can be adjusted within this range based on, e.g., age, physical condition, body weight, sex, diet, time of administration, and other clinical factors. The prophylactic vaccine formulation is systemically administered, e.g., by subcutaneous or intramuscular injection using a needle and syringe, or a needle-less injection device. Alternatively, the vaccine formulation is administered intranasally, either by drops, large
20 particle aerosol (greater than about 10 microns), or spray into the upper respiratory tract or small particle aerosol (less than 10 microns) or spray into the lower respiratory tract. While any of the above routes of delivery results in an immune response, intranasal administration confers the added benefit of eliciting mucosal immunity at the site of entry of many viruses, including alphaviruses, for example CHIKV or WEEV, or flaviviruses.

25 Thus, the invention also comprises a method of formulating a vaccine or antigenic composition that induces immunity to an infection or at least one symptom thereof to a mammal, comprising adding to said formulation an effective dose of VLPs, e.g., alphavirus (e.g., CHIKV or WEEV) or flavivirus VLPs. In one embodiment, the infection is an alphavirus infection, for example, but not limited to, EEEV, WEEV, VEEV, SFV, CHIKV,
30 O'nyong-nyong virus, Sindbis virus, Mayaro virus, Ross River virus, Barmah Forest virus, and Ockelbo virus. In another embodiment, the infection is a flavivirus infection.

In certain cases, stimulation of immunity with a single dose is preferred, however additional dosages can also be administered, by the same or different route, to achieve the desired effect. In neonates and infants, for example, multiple administrations may be required

to elicit sufficient levels of immunity. Administration can continue at intervals throughout childhood, as necessary to maintain sufficient levels of protection against infections. Similarly, adults who are particularly susceptible to repeated or serious infections, such as, for example, health care workers, day care workers, family members of young children, the elderly, and individuals with compromised cardiopulmonary function or immune systems may require multiple immunizations to establish and/or maintain protective immune responses. Levels of induced immunity can be monitored, for example, by measuring amounts of neutralizing secretory and serum antibodies, and dosages adjusted or vaccinations repeated as necessary to elicit and maintain desired levels of protection.

Prime Boost

The present methods also include a variety of prime-boost regimens. In these methods, one or more priming immunizations is followed by one or more boosting immunizations. The actual immunogenic composition can be the same or different for each immunization and the type of immunogenic composition (e.g., containing protein or expression vector), the route, and formulation of the immunogens can also be varied.

For example, in one embodiment, the prime comprises administering a DNA or gene-based vaccine as described herein and the boost comprises administering a VLP as described herein. In another embodiment, the prime comprises administering a VLP as described herein and the boost comprises administering a DNA or other gene-based vaccine as described herein.

One useful prime-boost regimen provides for two priming immunizations, four weeks apart, followed by two boosting immunizations at 4 and 8 weeks after the last priming immunization. It should also be readily apparent to one of skill in the art that there are several permutations and combinations that are encompassed using the DNA, bacterial and viral expression vectors of the invention to provide priming and boosting regimens.

Methods of administering a composition comprising VLPs and/or DNA vaccines (vaccine and/or antigenic formulations) include, but are not limited to, parenteral administration (e.g., intradermal, intramuscular, intravenous and subcutaneous), epidural, and mucosal (e.g., intranasal and oral or pulmonary routes or by suppositories). In a specific embodiment, compositions of the present invention are administered intramuscularly, intravenously, subcutaneously, transdermally or intradermally. The compositions may be administered by any convenient route, for example by infusion or bolus injection, by absorption through epithelial or mucocutaneous linings (e.g., oral mucous, colon, conjunctiva,

nasopharynx, oropharynx, vagina, urethra, urinary bladder and intestinal mucosa, etc.) and may be administered together with other biologically active agents. In some embodiments, intranasal or other mucosal routes of administration of a composition comprising VLPs of the invention may induce an antibody or other immune response that is substantially higher than other routes of administration. In another embodiment, intranasal or other mucosal routes of administration of a composition comprising VLPs of the invention may induce an antibody or other immune response that will induce cross protection against other strains of the virus. Administration can be intramuscular, subdermal, intraperitoneal. In one preferred embodiment, the administration is intramuscular.

In yet another embodiment, the vaccine and/or antigenic formulation is administered in such a manner as to target mucosal tissues in order to elicit an immune response at the site of immunization. For example, mucosal tissues such as gut associated lymphoid tissue (GALT) can be targeted for immunization by using oral administration of compositions which contain adjuvants with particular mucosal targeting properties. Additional mucosal tissues can also be targeted, such as nasopharyngeal lymphoid tissue (NALT) and bronchial-associated lymphoid tissue (BALT).

Vaccines and/or antigenic formulations of the invention may also be administered on a dosage schedule, for example, an initial administration of the vaccine composition with subsequent booster administrations. In particular embodiments, a second dose of the composition is administered anywhere from two weeks to one year, preferably from about 1, about 2, about 3, about 4, about 5 to about 6 months, after the initial administration. Additionally, a third dose may be administered after the second dose and from about three months to about two years, or even longer, preferably about 4, about 5, or about 6 months, or about 7 months to about one year after the initial administration. The third dose may be optionally administered when no or low levels of specific immunoglobulins are detected in the serum and/or urine or mucosal secretions of the subject after the second dose. In a preferred embodiment, a second dose is administered about one month after the first administration and a third dose is administered about six months after the first administration. In another embodiment, the second dose is administered about six months after the first administration. In another embodiment, said VLPs of the invention can be administered as part of a combination therapy. For example, VLPs of the invention can be formulated with other immunogenic compositions, antivirals and/or antibiotics. A VLP may be administered concurrently, subsequent to, or sequentially with another immunogenic composition, antiviral,

antibiotic, or any other agent that prevents or treats an alphavirus infection (e.g., CHIKV or WEEV infection).

The dosage of the pharmaceutical formulation can be determined readily by the skilled artisan, for example, by first identifying doses effective to elicit a prophylactic or therapeutic immune response, e.g., by measuring the serum titer of virus specific immunoglobulins or by measuring the inhibitory ratio of antibodies in serum samples, or urine samples, or mucosal secretions. Said dosages can be determined from animal studies. A non-limiting list of animals used to study the efficacy of vaccines include the guinea pig, hamster, ferrets, chinchilla, mouse and cotton rat, and non-human primates. Most animals are not natural hosts to infectious agents but can still serve in studies of various aspects of the disease. For example, any of the above animals can be dosed with a vaccine candidate, e.g., VLPs of the invention, to partially characterize the immune response induced, and/or to determine if any neutralizing antibodies have been produced. For example, many studies have been conducted in the mouse model because mice are small size and their low cost allows researchers to conduct studies on a larger scale.

In addition, human clinical studies can be performed to determine the preferred effective dose for humans by a skilled artisan. Such clinical studies are routine and well known in the art. The precise dose to be employed will also depend on the route of administration. Effective doses may be extrapolated from dose-response curves derived from in vitro or animal test systems.

As also well known in the art, the immunogenicity of a particular composition can be enhanced by the use of non-specific stimulators of the immune response, known as adjuvants. Adjuvants have been used experimentally to promote a generalized increase in immunity against unknown antigens (e.g., U.S. Pat. No. 4,877,611). Immunization protocols have used adjuvants to stimulate responses for many years, and as such, adjuvants are well known to one of ordinary skill in the art. Some adjuvants affect the way in which antigens are presented. For example, the immune response is increased when protein antigens are precipitated by alum. Emulsification of antigens also prolongs the duration of antigen presentation. The inclusion of any adjuvant described in Vogel et al., "A Compendium of Vaccine Adjuvants and Excipients (2nd Edition)," herein incorporated by reference in its entirety for all purposes, is envisioned within the scope of this invention.

Exemplary adjuvants include complete Freund's adjuvant (a non-specific stimulator of the immune response containing killed *Mycobacterium tuberculosis*), incomplete Freund's adjuvants and aluminum hydroxide adjuvant. Other adjuvants comprise GMCSF, BCG,

aluminum hydroxide, MDP compounds, such as thur-MDP and nor-MDP, CGP (MTP-PE), lipid A, and monophosphoryl lipid A (MPL). RIBI, which contains three components extracted from bacteria, MPL, trehalose dimycolate (TDM) and cell wall skeleton (CWS) in a 2% squalene/Tween-80 emulsion also is contemplated. MF-59, Novasomes.RTM., MHC
5 antigens may also be used.

The VLPs of the invention can also be formulated with "immune stimulators." These are the body's own chemical messengers (cytokines) to increase the immune system's response. Immune stimulators include, but not limited to, various cytokines, lymphokines and chemokines with immunostimulatory, immunopotentiating, and pro-inflammatory
10 activities, such as interleukins (e.g., IL-1, IL-2, IL-3, IL-4, IL-12, IL-13); growth factors (e.g., granulocyte-macrophage (GM)-colony stimulating factor (CSF)); and other immunostimulatory molecules, such as macrophage inflammatory factor, Flt3 ligand, B7.1; B7.2, etc. The immunostimulatory molecules can be administered in the same formulation as the VLPs, or can be administered separately. Either the protein or an expression vector
15 encoding the protein can be administered to produce an immunostimulatory effect. Thus in one embodiment, the invention comprises antigenic and vaccine formulations comprising an adjuvant and/or an immune stimulator.

Methods of Delivery

The VLPs of the invention are useful for preparing compositions that stimulate an immune response. Such compositions are useful for the treatment or prevention or an alphavirus infection (e.g., a CHIKV, WEEV, EEEV, VEEV, Ross River virus, or Barmah
20 Forest virus infection) or a flavivirus. Both mucosal and cellular immunity may contribute to immunity to infectious agents and disease. In one embodiment, the invention encompasses a method of inducing immunity to an alphavirus infection, for example CHIKV, WEEV, EEEV, VEEV, Ross River virus, or Barmah Forest virus infection in a subject, by administering to
25 the subject a CHIKV, WEEV, EEEV, VEEV, Ross River virus, or Barmah Forest virus VLP or a DNA vaccine. In another embodiment, the invention encompasses a method of inducing immunity to a flavivirus infection by administering to the subject a flavivirus VLP or a DNA
30 vaccine.

The invention also provides a method to induce immunity to viral infection or at least one symptom thereof in a subject, comprising administering at least one effective dose of a VLP or DNA vaccine as described herein, for example a VLP comprising one or more viral proteins, for example one or more alphavirus or flavivirus virus envelope proteins, or a DNA

vaccine comprising a nucleic acid segment encoding one or more alphavirus or flavivirus envelope proteins, or fragments thereof. In certain cases, the VLP further comprises an alphavirus or flavivirus capsid protein. In another embodiment, the method comprises inducing immunity to a viral infection, e.g., alphavirus or flavivirus infection, or at least one symptom thereof by administering said formulation in multiple doses.

VLPs of the invention can induce substantial immunity in a vertebrate (e.g., a human) when administered to said vertebrate. The substantial immunity results from an immune response against VLPs of the invention that protects or ameliorates infection or at least reduces a symptom of infection in said vertebrate. In some instances, if the said vertebrate is infected, said infection will be asymptomatic. The response may not be a fully protective response. In this case, if said vertebrate is infected with an infectious agent, the vertebrate will experience reduced symptoms or a shorter duration of symptoms compared to a non-immunized vertebrate.

In one embodiment, the invention comprises a method of inducing substantial immunity to alphavirus infection or at least one symptom thereof in a subject, comprising administering at least one effective dose of a VLP and /or a DNA vaccine comprising a nucleic acid segment encoding an alphavirus or flavivirus capsid protein or one or more alphavirus or flavivirus envelope proteins or fragments thereof, where the VLP has one or more alterations in an E2 protein and/or a alphavirus capsid protein Nuclear Localization Signal (NLS). In various embodiments, the VLP includes an envelope protein having a non-lysine residue (e.g., asparagine) at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein and/or a modification at the amino acid position corresponding to amino acid 251 in the CHIKV E2 protein that destabilizes the E2 protein during viral budding. In particular embodiments, the infection is CHIKV or WEEV and the VLP comprises one or more CHIKV or WEEV envelope proteins as described herein. In another embodiment, the invention comprises a method of vaccinating a mammal against an alphavirus comprising administering to said mammal a protection-inducing amount of VLPs or DNA vaccines comprising at least one alphavirus protein. In one embodiment, said method comprises administering DNA vaccines comprising alphavirus capsid, E3, E2, 6K and E1. In another embodiment, said method comprises administering DNA vaccines comprising alphavirus E3, E2, 6K and E1. In another embodiment, said method comprises administering DNA vaccines comprising C-Env₃₇₉₉₇. In another embodiment, said method comprises administering DNA vaccines comprising Env₃₇₉₉₇. In another embodiment, said method comprises administering DNA vaccines comprising CMV/R CHIKV C-E3-E2-6K-E1 (strain OPY1) E2 K234N. In

another embodiment, said method comprises administering DNA vaccines comprising CMV/R WEEV C-E3-E2-6K-E1 (strain 71V-1658) E2 K235N. In another embodiment, said method comprises administering DNA vaccines comprising VLPC-E2(37997). In another embodiment, said method comprises administering DNA vaccines comprising VLPOPY-1 E2(37997). In one embodiment, said method comprises administering VLPs comprising alphavirus capsid, E3, E2, 6K, and E1. In another embodiment, said method comprises administering VLPs comprising alphavirus E3, E2, 6K, and E1. In one embodiment, said method comprises administering VLPs comprised of CHIKV or WEEV envelope proteins. In various embodiments, the VLP comprises an alphavirus (CHIKV, WEEV, EEEV, VEEV, Ross River virus, Barmah Forest virus) capsid protein in which the nuclear localization sequence is altered. The alphavirus capsid protein nuclear localization sequence is altered in a charged residue (e.g., lysine or arginine), which is replaced with a non-charged residue (e.g., alanine or asparagine). In specific embodiments, the alphavirus capsid protein is a WEEV CBA87 strain capsid protein having one or more of the alterations K67N, K68N, and/or K69N. In certain embodiments, the alphavirus capsid protein is a VEEV TC83 strain capsid protein having one or more of the alterations K64N, K65A, K65N, K67A, and/or K67N. In some embodiments, the alphavirus capsid protein is a EEEV PE-6 strain capsid protein having an alteration K67N. In particular embodiments, the alphavirus capsid protein is a CHIKV(Strain 37997) strain capsid protein having one or more of the alterations R62A, R63A, R65A, K66A, K68A, and/or K69A. In specific embodiments, the alphavirus capsid protein is a Ross River Virus capsid protein having one or more of the alterations R71N, K72N, K73N, and/or K74N. In specific embodiments, the alphavirus capsid protein is a Barmah Forest Virus capsid protein having one or more of the alterations K64A, K64N, K65A, K65N, K67A, K67N, K68A and/or K68N.

In another embodiment, the invention comprises a method of vaccinating a mammal against a flavivirus comprising administering to said mammal a protection-inducing amount of VLPs or DNA vaccines comprising at least one flavivirus protein. In another embodiment, said method comprises administering VLPs comprising flavivirus envelope protein. In another embodiment, said method comprises administering VLPs comprising flavivirus capsid protein.

In another embodiment, the invention comprises a method of inducing a protective cellular response to a viral infection or at least one symptom thereof in a subject, comprising administering at least one effective dose of a DNA vaccine or a VLP.

As mentioned above, the VLPs of the invention prevent or reduce at least one symptom of an infection in a subject. A reduction in a symptom may be determined subjectively or objectively, e.g., self assessment by a subject, by a clinician's assessment or by conducting an appropriate assay or measurement (e.g., body temperature), including, e.g., a quality of life assessment, a slowed progression of viral infection or additional symptoms, a reduced severity of viral symptoms or a suitable assays (e.g., antibody titer and/or T-cell activation assay). The objective assessment comprises both animal and human assessments.

The invention also provides assays to identify inhibitors of viral entry comprising, in at least one embodiment, genetically modified target cells expressing at least one alphavirus (e.g., CHIKV or WEEV) or flavivirus viral receptor, together with any co-receptors which might be required for infection or entry. These cells are genetically modified in the sense that they express a reporter gene, such as an affinity tag, a fluorogenic protein or an enzyme able to convert substrates into fluorogenic, chromogenic or luminometric products. Coupling this type of reporter signal to an inhibition of viral infection is accomplished by arranging the expression of the reporter gene to be strongly decreased (downregulated) upon infection with the virus of interest. In principle, this can be ensured by any suitable means, but especially preferred are:

The reporter gene product itself is fused to a cellular protein which, upon infection with the virus of interest is itself downregulated. For example, the reporter gene product can be fused to the corresponding viral receptor, which in many cases is downregulated upon infection.

Thus in one aspect a compound library may be screened for the ability to inhibit the infection of cells with alphavirus (e.g., CHIKV, WEEV, EEEV, VEEV, Ross River virus, or Barmah Forest virus) or flavivirus. An appropriate indicator cell line is generated that stably expresses a reporter gene. In one example, these cells are seeded in microtiter plates and incubated with alphavirus (e.g., CHIKV, WEEV, EEEV, VEEV, Ross River virus, or Barmah Forest virus) or flavivirus particles in the presence of different compounds, e.g., antibodies, in each well. Upon infection, the fusion protein is downregulated due to the expression of the viral genes. Consequently, only cells that have not been infected with CHIKV will express the reporter gene. Thus, wells that exhibit a positive reporter signal contain compounds that inhibit infection. Variations and modifications of these assays will be apparent from the relevant sections of the description which explain individual parts of the assay in more detail. Specifically, in one embodiment, the reporter gene can be expressed when infection occurs rather than the reporter gene being downregulated upon infection. In further embodiments,

the viral particles are pseudotyped viral particles comprising one or more envelope protein and, optionally, the capsid protein from alphavirus (e.g., CHIKV, WEEV, EEEV, VEEV, Ross River virus, or Barmah Forest virus) or flavivirus.

In another embodiment, the invention provides methods for identifying inhibitors of viral entry using a reporter gene system as exemplified herein. Briefly, the invention provides recombinant lentiviral vectors expressing a reporter gene. Cells are incubated and co-transfected with an expression vector, e.g., Env_{OPY-1}, and a reporter plasmid using a standard techniques.

Cells are plated into one day prior to infection. Alphavirus or flavivirus Env-pseudotyped lentiviral vectors encoding the reporter gene are first titrated by serial dilution. Similar amounts of pseudotyped vectors are then incubated with the candidate inhibitors prior to adding the virus. Cells are then lysed using cell lysis buffer and the reporter gene activity is measured. Inhibitors of viral entry are identified based on the expression of the reporter gene.

Kits

The invention also provides for a pharmaceutical pack or kit comprising one or more containers filled with one or more of the ingredients of the vaccine formulations of the invention. In a preferred embodiment, the kit comprises two containers, one containing VLPs and the other containing an adjuvant. Associated with such container(s) can be a notice in the form prescribed by a governmental agency regulating the manufacture, use or sale of pharmaceuticals or biological products, which notice reflects approval by the agency of manufacture, use or sale for human administration.

The invention also provides that the VLP formulation be packaged in a hermetically sealed container such as an ampoule or sachette indicating the quantity of composition. In one embodiment, the VLP composition is supplied as a liquid, in another embodiment, as a dry sterilized lyophilized powder or water free concentrate in a hermetically sealed container and can be reconstituted, e.g., with water or saline to the appropriate concentration for administration to a subject.

The invention also features a kit comprising a VLP as described herein. The invention also features kits comprising a DNA vaccine as described herein and instructions for use.

The invention also features a kit comprising a VLP in a first container and a DNA vaccine in a second container, and instructions for use in a prime boost immunization.

The following examples are offered by way of illustration, not by way of limitation. While specific examples have been provided, the above description is illustrative and not restrictive. Any one or more of the features of the previously described embodiments can be combined in any manner with one or more features of any other embodiments in the present invention. Furthermore, many variations of the invention will become apparent to those skilled in the art upon review of the specification. The scope of the invention should, therefore, be determined not with reference to the above description, but instead should be determined with reference to the appended claims along with their full scope of equivalents.

The practice of the present invention employs, unless otherwise indicated, conventional techniques of molecular biology (including recombinant techniques), microbiology, cell biology, biochemistry and immunology, which are well within the purview of the skilled artisan. Such techniques are explained fully in the literature, such as, "Molecular Cloning: A Laboratory Manual", second edition (Sambrook, 1989); "Oligonucleotide Synthesis" (Gait, 1984); "Animal Cell Culture" (Freshney, 1987); "Methods in Enzymology" "Handbook of Experimental Immunology" (Weir, 1996); "Gene Transfer Vectors for Mammalian Cells" (Miller and Calos, 1987); "Current Protocols in Molecular Biology" (Ausubel, 1987); "PCR: The Polymerase Chain Reaction", (Mullis, 1994); "Current Protocols in Immunology" (Coligan, 1991). These techniques are applicable to the production of the polynucleotides and polypeptides of the invention, and, as such, may be considered in making and practicing the invention. Particularly useful techniques for particular embodiments will be discussed in the sections that follow.

The following examples are put forth so as to provide those of ordinary skill in the art with a complete disclosure and description of how to make and use the assay, screening, and therapeutic methods of the invention, and are not intended to limit the scope of what the inventors regard as their invention.

EXAMPLES

Example 1: Lentiviral vectors pseudotyped with CHIKV envelope mediated entry through the same mechanism as wild type virus

To examine the mechanism and specificity of CHIKV cell entry, lentiviral vector reporters were pseudotyped with glycoproteins from different CHIKV strains that mediate entry into permissive cells. The CHIKV spike on the virion surface is formed by three E1-E2 heterodimers, where E1 glycoproteins mediate fusion and E2 glycoproteins interact with the

host receptor. CHIKV E genes expressing the native polypeptide, E3-E2-6K-E1 polyprotein, for the 37997 and for LR2006 OPY-1 strains were inserted into an expression vector (E37997 and EOPY-1) (Figure 1A, Figures 6, 7A, 7B, and 8A-8C). The incorporation of the two CHIKV Es into the pseudotyped lentiviral vectors was verified by buoyant density gradient sedimentation of the virus. Both CHIKV E and HIV-1 Gag had the same buoyant density as lentivirus particles (Figure 5). The 37997 and LR2006 OPY-1 CHIKV pseudotyped lentiviral vectors infected several permissive cell lines (Sourisseau *et al.*, *PLoS. Pathog.* 3, e89 (2007)) as measured by luciferase reporter activity, while a control devoid of CHIKV envelope proteins did not infect these cell lines (Figure 1B, left), and infectivity was dose-dependent (Figure 1B, right).

To determine whether entry occurred through the same mechanism as native virus, the pH and endosome dependence of entry was analyzed as described previously (Yang *et al.*, *J. Virol.* 78, 5642 (2004)). CHIKV infects cells through a process of pH-dependent cell fusion. Thus, addition of ammonium chloride or chloroquine, which prevents acidification of the endosome, caused a dose-dependent reduction in CHIKV pseudotyped vector entry (Figure 1C). Similar inhibition of entry was observed with VSV- G, known to enter in this fashion, but not with amphotropic murine leukemia virus (MuLV) glycoprotein 70, which enters in a pH-independent fashion. These findings demonstrated that lentiviral vectors pseudotyped with CHIKV envelope mediated entry through the same mechanism as wild type virus. Sera from mice injected with a CHIKV strain were next examined. Incubation of immune sera with the CHIKV pseudotyped lentiviral vector but not VSV-G pseudotyped vector inhibited entry (Figure 1D). The specificity and potency of neutralizing antibodies could therefore be quantified without exposure to infectious virus.

Example 2: VLPs have morphology of wild type virus

CHIKV encodes 4 nonstructural proteins, NS1, NS2, NS3 and NS4, which are involved in virus replication, and 5 structural proteins, which consist of capsid (C) and envelope proteins (E; E1, E2, E3 and 6K) that are synthesized as polyproteins and are cleaved by capsid autoprotease and signalases (Strauss, *Microbiol. Rev.* 58, 491 (1994)).

Eukaryotic expression vectors encoding C-E3-E2-6K-E1 from strains 37997 and LR2006 OPY-1 (C-E37997 and C-EOPY-1) were analyzed for their ability to give rise to VLP. The plasmids C-E37997 or C-EOPY-1 or the expression vectors described above, E37997 or EOPY-1 (Figure 2A, upper panel), were transfected into human embryonic kidney (293T) cells, and expression was confirmed by Western blotting (Figure 2A, lower panel). C and

E1/E2 proteins were detected in the supernatant after transfection of the C-E37997 or C-EOPY-1 vector, suggesting that CHIKV VLPs had been generated. VLPs were purified by buoyant density gradient sedimentation. The yield of VLPs from strain 37797 was 10-20 mg/L, approximately 100 times higher than that from strain LR2006 OPY-1; strain 37997 was therefore chosen for further VLP characterization and development. Fractionation of clarified supernatant showed peak incorporation of E1/E2 at a density of 1.2 g/ml (Figure 2B, left), comparable to the density of wild type CHIKV. Examination of the purified fraction from strain 37997 by electron microscopy revealed VLPs with the same morphologic appearance as wild type virus (Figure 2B, right).

Cryoelectron microscopy and three dimensional image reconstruction assuming icosahedral symmetry showed that the VLPs had an external diameter of 65 nm and a core diameter of 40 nm (Figure 2C, left). The potent immunogenic E1/E2 glycoproteins are organized into 240 heterodimers, assembled into 80 glycoprotein spikes arranged with T=4 quasi symmetry on the surface of the VLPs (Figure 2C, left), closely similar to the structure of Sindbis virus (Figure 2C, right). In addition, the organization of the nucleocapsid core is also remarkably similar to that of other alphaviruses.

Example 3: VLPs induced a more potent neutralizing antibody response to CHIKV than DNA vaccines

The immunogenicity of DNA and VLP vaccines was determined in mice immunized with DNA vaccines encoding C-E or E (strains 37997 and LR2006 OPY-1) or VLPs from strain 37997 (VLP37997) in the presence or absence of Ribi adjuvant. Mice injected with VLPs with adjuvant generated the highest titer neutralizing responses against both the homologous strain 37997 (Figure 3A, right panel; IC₅₀, 1:10,703) and the heterologous strain LR2006 OPY-1 (Figure 3B, right panel; IC₅₀, 1:54,600). While immunization with the plasmids encoding C-E and E from both strains elicited neutralizing responses, these responses were 100-fold lower than the VLP- immunized mice (Figure 3A, B; left panel). These results indicate that VLPs elicited a more potent neutralizing antibody response than DNA vaccines.

To characterize VLP-induced immune responses in a model with strong predictive value for humans, rhesus macaques were immunized with VLPs. Monkeys were injected with VLP37997 or PBS alone as a control. Sera from immunized and control monkeys were tested against CHIKV strain 37997 and LR2006 OPY-1 pseudotyped lentiviral vectors. All non-human primates (NHP) immunized with VLPs developed substantial neutralizing

activity to both homologous and heterologous strains after primary immunization that increased after boosting (Figure 3C; left panel: strain 37997, right panel: strain LR2006 OPY-1). To confirm that these antibodies neutralized infectious virus, a plaque reduction neutralization test (PRNT) was performed against the CHIKV LR2006 OPY-1. The antisera from the immunized monkeys elicited neutralizing antibody responses against LR2006 OPY-1 at titers that exceeded 1:40,000 (Figure 3D). These data suggested that neutralizing antibodies using pseudotyped lentiviral vectors correlated with the PRNT assay, and that all immunized monkeys generated potent neutralizing antibody responses against CHIKV.

Example 4: Primate VLP immunization protected against viremia and inflammatory consequences of CHIKV infection

The ability of the VLP vaccine to protect against infection was determined by intravenous challenge of monkeys immunized with VLPs or controls using a high titer LR2006 OPY-1 virus stock 15 weeks after the final immunization. Similar to humans, infection in the NHP resulted in non-lethal viremia and a pro-inflammatory response as measured by an increase in monocyte counts. The control monkeys showed viremia beginning at 6 hours and lasting until 72 hours after challenge, while all of the immunized monkeys controlled the challenge virus completely (Figure 4A). Similarly, the monocyte counts in control monkeys increased markedly relative to vaccinated monkeys by 4 days after challenge (Figure 4B, Control vs. VLPs; $p = 0.0036$). These data indicated that immunization protected against viremia as well as the inflammatory consequences of infection. To define the mechanism of protection in these animals, the question of whether immune IgG could protect against lethal challenge was examined using an adoptive transfer model.

Example 5: Humoral immune responses induced by CHIKV VLPs conferred protection against CHIKV infection

Previous studies have shown that immunodeficient mice with defective type-I IFN signaling developed severe infection, displaying symptoms and tissue tropism analogous to humans, and providing a model to evaluate immune mechanisms of protection. Purified total IgG from immune or control monkeys was passively transferred into these mice. The recipient mice were challenged intradermally 24 hours after IgG transfer with a lethal dose of LR2006 OPY-1. Recipients of purified CHIKV immune IgG demonstrated no detectable viremia after infection and were completely protected from lethality (Figures 4C, D). In contrast, all mice that received purified IgG from control monkeys showed severe infection

and viremia, and all died. These results indicate that humoral immune responses induced by CHIKV VLPs conferred protection against CHIKV infection.

Example 6: Importance of amino acid 234 in the E2 protein of CHIKV in VLP production

Although the two strains are highly related, with 95% amino acid similarity between the sequences of the structural genes, VLPs are produced efficiently by the CHIKV 37997 strain, but yields of VLPs from the OPY-1 strain are very low. In order to understand the mechanism underlying the difference in VLP production between the CHIKV strains, genes between the 37997 and the OPY-1 strains were swapped and VLP production was assessed. Specifically, using the C-E3-E2-6K-E1 expression vector, either capsid (C) alone, C-E3, C-E3-E2, or C-E3-E2-6K regions from CHIKV₃₇₉₉₇ was inserted into the expression vector using an overlap extension PCR method.

The chimeric genes between 37997 and OPY-1 strains were amplified using the primers shown in Table 1.

Briefly, two fragments of the chimeric genes were amplified with 40 to 51 base pairs of primers that overlapped by 20 oligonucleotides and either of CHIKV 37997 F, CHIKV 37997 R, CHIKV OPY-1 F, or CHIKV OPY-1 R primers. These two fragments were assembled in the overlapping region and amplified again with CHIKV 37997 F, CHIKV 37997 R, CHIKV OPY-1 F, or CHIKV OPY-1 R primers. The PCR products were cloned into the C-EOPY-1 expression vector after confirming the sequence. Chimeric CHIKV were made using the PCR-based Quickchange (Stratagene, La Jolla, CA) method according to the manufacturer's instructions with sense and anti-sense primers shown in Table 1. The OPY-1 genes of either the capsid alone, the capsid to E3, the capsid to E2 or the capsid to 6K were replaced with the corresponding genes from 37997 ($VLP_{C(37997)}$, $VLP_{C-E3(37997)}$, $VLP_{C-E2(37997)}$ or $VLP_{C-6K(37997)}$). Each mutant was confirmed by sequencing, and the chimeric CHIKV expression vectors are depicted in Figure 6A.

293F cells were transfected with these plasmids and the expression of CHIKV structural proteins and yield of VLPs in the supernatant and cell lysate were determined using Western blot analysis (Figure 6B). Expression of capsid and E1/E2 in cell lysates was similar for all of the plasmids, but VLP release in supernatants was significantly different (Figure

6B). Notably, the yield of OPY-1 VLP increased when the 37997 strain E2 region was included in the vector (Figure 6B, lane 4, upper panel). To determine which region was responsible for this increase, the different polypeptide regions of 37997 were inserted into the OPY-1 expression vector. This analysis revealed that the E2 region alone was responsible for increased VLP production. Replacement of E2 enhanced VLP as determined by Comma-
5 blue staining of sucrose density sedimentation purified particles (Figure 6C, lane 13). To map the subregion responsible for this effect, chimeras that further subdivided E2 were prepared. The NH₂-terminal E2 domain (E2 1-290 a.a.) or the COOH-terminal E2 domain (E2 291-423 a.a.) was replaced in the VLP_{OPY-1} expression vector. VLP production in
10 transfected cells revealed that the NH₂-terminal region (1-290 a.a.) was necessary and sufficient for efficient VLP synthesis (Figure 6C, lane 14).

The sequences of 37997 and OPY-1 differed in this region by twelve amino acids (Figure 7A). To determine which amino acids were critical for VLP generation, site-specific mutations were introduced individually at these sites. Eleven of the twelve mutants
15 synthesized VLPs at levels similar to the NH₂-terminal chimeric E2 expression vector (WT) (Figure 7B). In contrast, the N234K mutation from OPY-1 abolished VLP release (Figure 7B, lane 11), indicating that this amino acid residue played a critical role in the regulation of VLP synthesis.

To determine whether modification of amino acid residue 234 from strain 37997 could
20 improve VLP yield, this site was mutated from K to N in the OPY-1 expression vector (VLP_{OPY-1} K234N). Though expression of envelope from VLP_{OPY-1} K234N on the cell surface was similar to that of VLP_{OPY-1} (Figure 8A), VLP release was increased by 86-fold compared to the parental OPY-1 expression vector (Figure 8B). It was hypothesized that VLP_{OPY-1} has a role in pH-dependent VLP yield, and that the VLP_{OPY-1} K234N mutant is
25 insensitive to pH. To test this hypothesis, the yield of VLP mutants was compared at pH 7.0 (wt), 7.3, 7.5, and 7.8. VLP_{OPY-1} yield increased at pH 7.3, 7.5, and 7.8, while the VLP_{OPY-1} K234N mutant yield did not increase at high pH (Figure 8C).

That alphaviruses conserve lysine (K) at position 234 (Voss *et al.*, *Nature* 468:709-712 (2010)), indicates that 234K plays important roles for the virus life cycle. Based on
30 recent structure determination of CHIKV OPY-1 E2 protein, E2 234K is in an acid sensitive region (ASR) that was disordered in the alphavirus E2-E1 structure at low pH (Voss *et al.*, *Nature* 468:709-712; Li L, 2010 *nature* p705). This region initiates a conformational change in E1/E2 virus spikes in acidic pH conditions. The conformational changes allow the hydrophobic fusion peptide loop of E1 to interact with the cellular membrane and initiate

fusion. The exposure of different pH conditions to Semliki Forest virus (SFV) particle changed the conformation of E1/E2 (Wu, SR, 2007, J of Biological chemistry, p6752). The pH condition is also important for the budding process. The budding of SFV became efficient when the infected cells were incubated at a pH above 7.5 than at a pH below 7.0 (J of Virology. 2001, p8329-8339, Lu et al.).

Therefore, it was examined whether pH conditions in the medium increase the yield of VLP_{OPY-1}. The VLP yield was significantly increased in higher pH conditions (Figure 57A). GFP expression as an expression indicator was similar level in different pH condition, suggesting that there was no protein expression effect in pH condition. Without being bound to a particular theory, it was hypothesized that K234N mutant might decrease the activity of the pH sensor amino acids and result in the increase of VLP yield. Histidine amino acids in E1/E2 play important roles for the pH dependent conformational change, as the pK is in the same range as the pH of the conformational transition (Voss et al., Nature 468:709-712). Without being bound to a particular theory, it was hypothesized that 232H might play an important role as a pH sensor because 234K and 232H are in close proximity with one another based on the structure model (Figure 57B). To test this hypothesis, it was examined whether additional alternation of this specific region of E2 also affected VLP production (Figure 57C). Although several point mutations in 232H were introduced to be insensitive to pH, none of the mutants produced the VLPs, possibly due to destabilization by the mutations. It was found that K233N or H256Q in ASR region mutants increased the yield of VLPs (Figure 57C, lane 6, 9, 11 and 14). Because K233N mutant is next to 232H, it might have the same effect as the K234N mutant. In addition, mutation E2 H170M was also introduced into the OPY-1 strain, as these amino acids interact strongly with a salt bridge and one hydrogen bond between E2 and E1 (Voss et al., Nature 468:709-712). The mutant E2 H170M increased the yield of OPY-1 VLPs (Figure 57C, lane 7 and 12). These mutants suggesting that inactivation of amino acids that play important roles in E1/E2 conformational change increased VLP synthesis.

Thus, specific sequences in the E2 region responsible for robust CHIKV VLP generation were identified, and this mechanism was related to pH dependent E1/E2 conformational change. It has been shown that alphavirus assembly and budding efficiency is related to several factors, such as pH condition (J of Virology. 2001, p8329-8339, Lu et al), the COOH-terminal of E1 and E2 palmitylation (Ivanova et al., J. Virol. 67:2546-2551; Ryan et al., Virology 249:62-67), interactions between E1 and E2 (Yao et al., J. Virol. 72:1418-1423; Yao et al., J. Virol. 70:7910-7920), interactions between the cytoplasmic domain of E2

and capsid proteins (Kong et al., J Virol 77:12764-12772; Wilkinson et al., Biochemistry 44:2800-2810; Zhao et al., EMBO J. 13:4204-4211) or the requirement for cholesterol in the cell membrane (Lu et al., J. Virol. 73:4272-4278; Marquardt et al., J. Cell. Biol. 123:57-65; Vashishtha et al. J. Cell. Biol. 140:91-99); however, no studies have shown a correlation of budding efficiency with the E2 ASR. This observation suggests that correct conformation of the E1/E2 is important for budding efficiency and several amino acids in ASR play an important role for E1/E2 conformational change for budding and entry. Although further studies are needed to develop the vaccine against alphaviruses, since VLP vaccines are known to have advantages, such as a good safety profile and their ability to induce high levels of immunogenicity (Bachmann et al., Science 262:1448-1451; Chackerian, Vaccines 6:381-390). (Akahata 2010), VLP vaccine strategy may prove to be optimal and this results described here furthers developments of alphavirus vaccines.

Example 7: Importance of amino acid 234 in the E2 protein of other alphaviruses in VLP production

To determine the role of the amino acid corresponding to amino acid 234 of CHIKV in other alphaviruses, the sequences of the E2 protein for Aura virus, Una virus, Mayaro virus, Middelburg virus, O'nyong-nyong virus (strain SG650), Ndumu virus, Barmah Forest virus, Seal louse virus, Salmon pancreas disease virus (SPDV), Whataroa virus, Sindbis virus, Western equine encephalomyelitis virus (WEEV), Venezuelan equine encephalitis virus (VEEV), Ross river virus (strain NB5092), Bebaru virus, Semliki forest virus, Alphavirus M1, Fort Morgan virus, and Eastern equine encephalitis virus (EEEV) were aligned using the NCBI database. Examination of these sequences revealed that the K at the position corresponding to amino acid 234 of CHIKV was highly conserved. Similarly, the generation of VLP from expression vectors encoding the structural genes of these viruses is typically low. A representative sequence alignment showing the sequences of the E2 protein from CHIKV 37997, CHIKV OPY-1, Ross River, Sindbis, WEEV, EEEV, and WEEV is shown in Figure 9A.

To evaluate the effect of this residue in WEEV, an expression vector encoding WEEV E2 with the K235N mutation was prepared. Mutation of K235N in the WEEV expression vector increased VLP yield by >7-fold in transfected 293F cells compared to the wild type WEEV expression vector (Figure 9B). These VLPs were immunogenic in mice. Neutralizing antibody responses in BALB/c mice were measured using a pseudotyped lentiviral vector system (see Akahata *et al.*, *Nat. Med.* 16:334-338 (2010)) after immunization

with WEEV VLPs, alone, or in an equal mixture with CHIKV VLPs. Mice immunized with WEEV or WEEV and CHIKV VLPs generated similarly high titers of neutralizing antibodies to WEEV (Figure 9C). This result indicated that the WEEV VLPs were effective immunogens and that combination with CHIKV did not diminish their immunogenicity. To determine whether these immune responses are protective, immunized mice can be challenged with a lethal dose of a heterologous WEEV, the Fleming strain, a highly virulent strain isolated from a human patient. If the immune responses are protective, mice immunized with WEEV VLPs will be able to control the challenge virus.

Example 8: Alterations in alphavirus capsid protein NLS increase VLP yield.

The ability to produce large quantities of VLPs is important to their use as vaccines. The yield of VLPs from CHIKV strain 37997 was 100 times greater than that of the OPY-1 strain, although the amino acid profiles of the two strains are more than 95% identical. Other alphaviruses showed varying but lower yields of VLPs or no VLP expression. Based on these observations, an analysis of the structure of CHIKV and other alphaviruses was undertaken to determine which regions are responsible for this difference in VLP yields.

Different mutations were made to the EEEV capsid protein and subsequently tested to determine their effect on cellular toxicity, as well as their ability to improve VLP yields when expressed in mammalian cells. Several mutants were made to the acid sensitive region (ASR) region of EEEV capsid protein, but this did not improve EEEV VLP expression. Interestingly, there was no capsid expression in the supernatant. For example, in EEEV VLP constructs expressing the EEEV E2 envelope variant R239N EEEV capsid protein was undetectable by Western Blot in fractions collected from density gradient centrifugation (Figure 35B). Additionally, EEEV capsid protein was observed in the nucleus at early time points after EEEV infection, although it was exported into the cytoplasm in the late stage of replication. Eastern Equine Encephalitis Virus (EEEV) capsid has also been reported as toxic to cells (Aguilar et al. 2007, Journal of Virology 81(8):3866-76 at page 3866).

The Eastern Equine Encephalitis (EEEV) capsid protein has a predicted nuclear localization signal (NLS) at amino acid (a.a.) positions 67-70 (Figure 35A). Targeted mutations to the nuclear localization signal (NLS) motif (KRKK) of EEEV capsid protein were created that changed lysine (K) to asparagine (N) at amino acids 67 (K67N), 68 (K68N) and 69 (K69N). The lysine (K) to asparagine (N) mutation was designed to diminish the inhibition of VLP production by the NLS. The structure and properties of the proposed modifications to the nuclear localization signal (NLS) were analyzed using PredictProtein

software (<http://www.predictprotein.org>). Maps and sequences of exemplary EEEV PE-6 strain capsid protein K67N expression vectors are shown at Figures 47A-47D and 48A-48D.

Modification of the EEEV capsid protein NLS resulted in improved yields of EEEV VLPs when expressed in mammalian cells. The K67N mutation was tested alone, in
 5 combination with K68N, or in combination with K68N and K69N. All 3 groups of EEEV capsid protein mutations showed a substantially increased level of VLP expression when compared to the wild type version of the EEEV capsid protein. For example, in EEEV VLP constructs expressing an EEEV E2 envelope variant R239N and an EEEV variant capsid protein K67N, abundant EEEV VLPs having were readily detectable by Western blot of
 10 density gradient centrifugation fractions (Figure 35B). In contrast, in EEEV VLP constructs expressing an EEEV E2 envelope variant R239N and wild-type EEEV capsid protein, EEEV VLPs and EEEV capsid proteins were undetectable by Western Blot in corresponding density gradient centrifugation fractions (Figure 35B). Thus, an alteration in a EEEV capsid protein NLS provided EEEV VLP expression and increased EEEV VLP yield.

15 Alphavirus capsid proteins have amino acid sequences that can act as nuclear localization signals. Additional alphavirus capsid protein NLS sequences were identified as above. The Western Equine Encephalitis Virus (WEEV) capsid protein has a predicted nuclear localization signal (NLS) at amino acid (a.a.) positions 67-70 (Figure 36A). The Venezuelan Equine Encephalitis Virus (VEEV) capsid protein has a predicted NLS at amino
 20 acid positions 64-68 (Figure 37A). The Chikungunya (CHIKV) capsid protein has a predicted nuclear localization signal (NLS) at amino acid (a.a.) positions 62-69. The Ross River virus capsid protein has a predicted nuclear localization signal (NLS) at amino acid (a.a.) positions 71-74. The Barmah Forest virus capsid protein has a predicted nuclear localization signal (NLS) at amino acid (a.a.) positions 64-68.

25 Mutations to the alphavirus capsid protein have also been applied to Western equine encephalitis virus (WEEV) (Figure 36B) and Venezuelan Equine Encephalitis Virus (VEEV) (Figure 37B), which are similar to EEEV in sequence, and, like EEEV, are termed “new world” alphaviruses. Mutations to the alphavirus capsid protein have also been applied to Chikungunya (CHIKV) (Figure 39) and Ross River viruses, which are termed “old world”
 30 alphaviruses. Maps and sequences of exemplary WEEV CBA87 strain capsid protein expression vectors having one or more of the alterations K67N, K68N, and/or K69N are shown at Figures 40A-40D, 41A-41D, and 42A-42D. Maps and sequences of exemplary VEEV TC83 strain capsid protein expression vectors having one or more of the alterations K64N, K65A, K65N, K67A, and/or K67N are shown at Figures 43A-43D, 44A-44D, 45A-

45D, and 46A-46D. Maps and sequences of exemplary CHIKV(Strain 37997) strain capsid protein expression vectors having one or more of the alterations R62A, R63A, R65A, K66A, K68A, and/or K69A are shown at Figures 50A-50D, 51A-51D, and 52A-52D. Maps and sequences of exemplary Ross River Virus capsid protein expression vectors having one or more of the alterations R71N, K72N, K73N, and/or K74N are shown at Figures 53A-53D, 54A-54D, 55A-55D, and 56A-56D. Maps and sequences of exemplary Barmah Forest Virus capsid protein expression vectors having an alteration at K64A is shown at Figures 59A-59E.

As with EEEV VLPs, WEEV VLPs having a wild-type capsid protein were unable to be expressed. The introduction of alterations to the WEEV capsid protein NLS provided WEEV VLP expression and increased WEEV VLP yield (Figure 36B). The introduction of alterations to the VEEV capsid protein NLS increased VEEV VLP expression by more than 100-fold compared to the wild type VEEV and increased EEEV VLP yield (Figures 37B and 38B).

It has been discovered that mutating an NLS in an alphavirus capsid protein improves or allows expression of alphavirus VLPs in mammalian cells. Without being bound to a particular theory, the nuclear localization signal motif of the alphavirus capsid protein accumulates alphavirus capsid protein into the nucleus and prevents the secretion of alphavirus VLPs. Improvement in yields of alphavirus VLPs allows for their use as immunogenic compositions or vaccines, including a pan-alphavirus vaccine.

Example 9: High pH mediates efficient virus-like particle formation

As shown for CHIKV, it was examined whether pH conditions in the medium increase the yield of other VLPs. The VLP yield of EEEV was significantly increased under higher pH conditions, e.g., at pH 7.9 compared to at pH 7.1 (Figure 60). The yield of EEV VLP was shown to increase with increasing pH (Figure 61). Additionally, the pH dependent effect on yield was also observed when Tris-HCl buffer was added to cells after transfection with expression vectors for EEEV67N VLP (Figure 62) or VLP_{OPY-1} (Figures 63A and B).

Additional mutations in the pH sensitive region of CHIKV OPY-1 (K233N, H170M, K200L, and H256Q) were constructed and studied. The mutations in the pH sensitive region resulted in VLPs being stable longer than 3-4 days after transfection compared to wild-type VLP which was present at a lower level at 3 days and nearly undetectable at 4 days (Figure 64).

Example 10: Multivalent Virus-Like Particle Vaccine Against Eastern, Western and Venezuelan Equine Encephalitis Virus Protected Mice Against Infection

A multivalent virus-like particle (VLP) vaccine was developed against WEEV, EEEV and VEEV using VLPs that have the mutations that allowed WEEV, EEEV and VEEV to express VLPs. To evaluate the effect of the NLS signals, expression vectors were constructed encoding WEEV, EEEV and VEEV containing NLS signal mutations (Figures 65A and 65B). These mutations increased VLP yield by >100-fold compared to the wild type expression vector. The resulting VLPs were purified by buoyant density gradient sedimentation. Fractionation of clarified supernatant showed that the greatest incorporation of E1/E2 into the VLPs occurred at a density of 1.2 g/ml, and was comparable to the density of the wild type VLPs. Cryoelectron microscopy and three dimensional image reconstruction, assuming icosahedral symmetry, showed that the VLPs had an external diameter of 65 nm and a core diameter of 40 nm with T=4 quasi symmetry. These specifications were very similar to the structure of CHIKV VLPs and other WT alphaviruses previously described.

To evaluate the immunogenicity of these VLPs, BALB/c mice were injected intramuscularly with VLPs from an individual alphavirus VLPs or all the combinations of WEEV, EEEV and VEEV VLPs. While the immunized mice did not generate cross neutralizing antibodies to different viruses, they all produced high titer neutralizing responses against the virus with which they were immunized (Figure 2A; IC₅₀, 1:36586, 1:17284, 1:2263 against VEEV, EEEV and WEEV, respectively). The mice vaccinated with multivalent VLPs showed high levels of neutralizing antibodies against all of the viruses (Figure 66A: IC₅₀, 1:23492, 1:10796, 1:1091, against VEEV, EEEV, WEEV, respectively). This result indicated that the multivalent VLP vaccine was effective in eliciting a multivalent immune response and that combination with other alphavirus VLPs did not diminish immunogenicity against the individual viruses.

To determine whether these immune responses were protective, immunized mice were challenged with a lethal dose of a heterologous WEEV, the Fleming strain, which is a highly virulent strain isolated from a human patient. High viremia was observed in the control, VEEV VLP and EEEV VLP groups but not in the WEEV VLPs and the trivalent groups (Figure 66B). Mice immunized with WEEV VLPs controlled the challenge virus, while all control mice developed severe infections and died (Figure 66C). These data demonstrate that the WEEV VLP vaccine, alone or in combination with VLP of another alphavirus, confers protection.

To characterize VLP-induced immune responses in a model with stronger predictive value for humans, rhesus macaques were immunized with VLPs. Monkeys were injected intramuscularly with WEEV VLPs alone, a multivalent WEEV/EEEV/VEEV VLP vaccine or PBS alone as a control. Sera from immunized and control monkeys are tested using
 5 pseudotyped lentiviral vectors and monkeys are challenged to measure protection from disease.

Although there have been several reports of progress in development of alphavirus vaccines, including a DNA vaccine (Nagata, L. P, 2005. Vaccine 23:2280-2283, Dupuy L, 2009, vaccine), a recombinant Ad5 vaccine (Barabe, N. D. 2007. Vaccine 25:6271-6276.,
 10 Phillpotts 2005, vaccine 1615-1623), a live attenuated vaccine (Pittman PR, 1996;14(4) p337-43), and an inactivated vaccine (Coke F, Applied Microbiology, 1974, p150-, Edelman R, Journal of infectious disease, 1979, Vol 140 p708-), no candidates have been licensed to date. A live attenuated VEEV vaccine, TC-83, caused fever, headache and malaise in 25% and no response in 20% of vaccinated people (Pittman PR, 1996;14(4) p337-43). In addition,
 15 sequential administration of live attenuated alphavirus vaccines in human trials revealed an immunologic interference between the viruses and induced poor immunogenicity (McClain, D. J, 1998, J Infect Dis 177:634-641). A formalin-killed VEEV, EEEV and WEEV required multiple injections and even then, resulted in low levels of immunogenicity (Jahrling 1984, 19(3) p429-31). Global climate, trade, and frequent travel has caused the spread of
 20 mosquitoes, the carrier of these viruses, to new geographic areas, which may pose a threat of other *alphavirus* outbreaks. In this study, an effective multivalent alphavirus VLP vaccine was developed, suggesting the potential for creating a more global pan-alphavirus VLP vaccine using this approach. The safety and efficiency of VLP vaccines combined with their relatively less complicated production requirements make them promising candidates in the
 25 future of vaccine field.

Example 9: Additional embodiments

Additional embodiments are disclosed in the attached appendix, which is hereby incorporated by reference.

30 In this study, specific sequences in the E2 region were identified as responsible for robust CHIKV VLP generation. This strategy was then adapted to enhance the expression of a different alphavirus, WEEV. CHIKV is an enveloped positive-strand RNA virus, member of the alphavirus genus. Its structural proteins consist of one capsid (C) and an envelope (E) polyprotein that is processed to form E1/E2 heterodimers. The structural proteins are

synthesized as polyproteins and are cleaved by capsid autoprotease between the capsid and envelopes. The capsid protein assembles into a core particle, which is transported to the plasma membrane. After cleavage of the capsid protein, the PE2 (the precursor to the E3-E2 proteins)-6K-E1 envelope polyprotein is recognized by a signal sequence in the E3 protein domain to direct translocation into the endoplasmic reticulum (ER) membrane and transported to the cell surface through the Golgi network. PE2 is cleaved by furin, and E3 dissociates from E2. E1 and E2 then form a heterodimer (E1/E2). Capsid proteins associate with envelope on the cell surface and are encased within a lipid bilayer containing viral envelope proteins that initiate the budding of viral particles.

It has been shown that alphavirus assembly and budding efficiency is related to several factors, such as the COOH-terminal of E1 and E2 palmitoylation, interactions between E1 and E2, interactions between the cytoplasmic domain of E2 and capsid proteins or the requirement for cholesterol in the cell membrane; however, no studies have shown a correlation of budding efficiency with the E2 and E3 binding domains. Interestingly, several mutants that block the furin cleavage site between E2 and E3 have been characterized, and most of these rescue mutants contain modifications in residues associated with the E2 and E3 binding domain. This observation suggests that destabilization of the E3/E2 binding domain is important for restoring infectivity, and that conformational changes due to the destabilization might help increase virus replication, including the maturation and fusion processes.

WEEV transmitted by mosquitoes has caused encephalitis in birds, horses and humans in the USA, Canada and South America. Because of these reports of illness and the potential bioterrorism threat through aerosol transmission, WEEV vaccine development is important. Although there have been several reports of progress in WEEV vaccine development, including a DNA vaccine and a recombinant Ad5 vaccine, no candidates have been licensed to date. Since VLP vaccines are known to have advantages, such as a good safety profile and their ability to induce high levels of immunogenicity, this vaccine strategy may prove to be optimal.

Previous human trials revealed immunologic interference from sequential administration of live attenuated vaccines against heterologous alphaviruses using CHIKV and Venezuelan equine encephalitis virus. In this study, the combination of CHIKV and WEEV VLPs in a vaccine did not decrease the immune responses against both viruses, suggesting that a pan-alphavirus VLP vaccine that could include other pathogenic alphaviruses, such as Eastern equine encephalitis virus, Venezuelan equine encephalitis virus

Ross River virus, or Barmah Forest virus might be possible. The results described here furthers our understanding of the mechanism of VLP budding and vaccine development in alphaviruses.

VLPs are known to be highly immunogenic and elicit higher titer neutralizing antibody responses than subunit vaccines based on individual proteins. Such VLPs authentically present viral spikes and other surface components in a repetitive array that effectively elicits recognition by B-cells to stimulate antibody secretion. This recognition leads to B cell signaling and MHC class II up-regulation that facilitates the generation of high titer specific antibodies. VLPs from other viruses, including hepatitis B virus (HBV) and human papillomavirus (HPV), elicit high titer neutralizing antibody responses that contribute to protective immunity in humans. Similarly, alphavirus VLPs have been found to confer protection against alphavirus infection in a non-human primate model of infection.

Accordingly, VLPs are a viable vaccine strategy for treating alphavirus and flavivirus infection. As reported herein, alphavirus VLPs can be modified at the amino acid positions corresponding to amino acids 234 and 251 in the CHIKV E2 protein to enhance the production of VLPs. The methods described herein provide an attractive approach to developing and producing vaccines for alphaviruses and flaviviruses.

The results reported herein were obtained using the following methods and materials.

Vector construction

Plasmids encoding the structural polyproteins C, E1, E2, E3 and 6K (strains 37997 and LR2006 OPY-1, GenBank EU224270)(Figure 24)and EU224268 (Figure 23), respectively) were synthesized as previously described (Yang *et al.*, *Science* **317**, 825 (2007)) (GeneArt, Regensburg, Germany). Plasmids encoding the polyproteins E3, E2, 6K, and E1 were amplified by PCR using the following primers:

sense primer 5' GCTCTAGACACCATGAGCCTCGCCCTCCCGGTCTTG 3' and antisense primer 5' TGGATCCTCATTAGTGCCTGCTAAACGACA 3' (37997); and sense primer 5' GCTCTAGACACCATGAGTCTTGCCATCCCAGTTATG 3' and antisense primer 5' TGGATCCTCATTAGTGCCTGCTGAACGACA 3' (LR2006 OPY-1).

XbaI and BamHI sites were inserted for cloning. Each fragment was digested with XbaI/BamHI and inserted into a eukaryotic expression vector under the control of a

cytomegalovirus enhancer/promoter, CMV/R (Yang *et al.*, *Science* **317**, 825 (2007)) (C-E37997, C-EOPY-1, E37997^{and} EOPY-1). To confirm expression of CHIKV C and E proteins, 293T cells were transfected using a FuGENE™ 6 Transfection Reagent kit (Roche Diagnostics GmbH, Germany) with 3 µg of the plasmid DNAs, following the manufacturer's recommendations.

The chimeric CHIKV and WEEV expression vectors VLP_{C(37997)}, VLP_{C-E3(37997)}, VLP_{C-E2(37997)}, VLP_{C-6K(37997)}, VLP_{OPY-1 E2(37997)}, VLP_{OPY-1 5'-E2(37997)}, and VLP_{OPY-1 3'-E2(37997)} were constructed using an overlap extension PCR method described previously in Kong *et al.*, *J. Virol.* **77**, 12764 (2003). The chimeric genes between 37997 and OPY-1 strains were amplified using the primers shown in Table 1 (see above). Briefly, two fragments of the chimeric genes were amplified with 40 to 51 base pairs of primers that overlapped by 20 oligonucleotides and either of CHIKV 37997 F, CHIKV 37997 R, CHIKV OPY-1 F or CHIKV OPY-1 R primers. These two fragments were assembled in the overlapping region and amplified again with CHIKV 37997 F, CHIKV 37997 R, CHIKV OPY-1 F or CHIKV OPY-1 R primers. The PCR products were cloned into the VLP_{OPY-1} expression vector after confirming of sequence. A vector encoding the Western Equine Encephalitis virus (WEEV) structural polyproteins C-E3-E2-6K-E1 (strain 71V-1658, GenBank AF214040) was synthesized as previously described in Akahata *et al.*, *Nat. Med.* **16**, 334 (2010). CHIKV and WEEV mutants were made using the PCR-based Quickchange (Stratagene, La Jolla, CA) method according to the manufacturer's instructions with sense and anti-sense primers shown in Table 1 (see above). Each mutant was confirmed by sequencing. Other sequences and maps useful to the invention include those shown at Figures 10A-10C, 11A-11C, 12A, 12B, 13A, 13B, 14A, 14B, 15A, 15B, 16A, 16B, 17A, 17B, 18A, 18B, 19A, 19B, 20A, 20B, 21A, 21B, 22A, 22B, 23A, 23B, 24A, 24B, 25A, 25B, 26A, 26B, 27, 28, 29A, 29B, 30A-30C, 32A-32C, 33A-33C, 34A and 34B, 38A, 58A-58E, and 59A-59E.

Cell culture

293T and 293A (human embryonic kidney cells), Vero (African green monkey kidney epithelial cells), HeLa (human cervical adenocarcinoma), A549 (human lung carcinoma) and BHK (baby hamster kidney cells) were cultured in Dulbecco's modified Eagle's medium (DMEM; GIBCO BRL, Carlsbad, CA) containing 10% heat-inactivated fetal bovine serum (FBS) (GIBCO BRL, Carlsbad, CA).

Production of pseudotyped lentiviral vectors

Lentiviral vectors expressing glycoproteins from different CHIKV strains were created. The recombinant lentiviral vectors expressing a luciferase reporter gene were produced as previously described (Naldini et al., *Proc. Natl. Acad. Sci. USA* **93**, 11382 (1996), Yang et al., *Science* **317**, 825 (2007)). Briefly, 293T cells were co-transfected with 500 ng CHIKV E plasmid from either strain (_{E37997} or EOPY-1), 7 µg of a transducing vector encoding a luciferase reporter gene (pHR⁺CMV-luciferase plasmid), and 7 µg of a packaging plasmid expressing human immunodeficiency virus-1 (HIV-1) structural proteins (pCMV⁺ΔR8.2). 2 µg of vesicular stomatitis virus glycoprotein (VSV-G), 2 µg of pNGVL-4070A amphotropic MuLV gp70 expression vector or 500 ng of empty vector served as positive and negative controls for these pseudotyped reporters respectively. After a calcium phosphate transfection (Invitrogen, Carlsbad, CA) overnight, the culture media was replenished with fresh media. 48 hours later, supernatants were harvested, filtered through a 0.45 µm syringe filter, stored in aliquots, and frozen at -80° C. The viruses were standardized by the amount of HIV-1 Gag p24. CHIKV pseudotyped lentiviral vectors harvested 72 hours after transfection were normalized according to HIV-1 Gag p24 levels before infection, as previously described (Yang et al., *Science* **317**, 825 (2007)).

When the 293-derived suspension cell line 293F (Invitrogen, Carlsbad, CA) was used, the 293F cells were cultured in FreeStyleTM 293 Expression medium (Invitrogen, Carlsbad, CA). 293F cells (3×10^7) (Invitrogen) were transfected with 293fectin transfection reagent (Invitrogen, Carlsbad, CA) and 30 µg of each VLP plasmid following the manufacturer's recommendations

Buoyant density gradient sedimentation analysis and purification of VLPs

Buoyant density gradient analysis and purification of VLPs was performed as described previously in Akahata et al., *J. Virol.* **79**, 626 (2005) and Akahata et al., *Nat. Med.* **16**, 334 (2010). Briefly, a 293-derived suspension cell line, 293F (2.5×10^8 cells) (Invitrogen, Carlsbad, CA) was transfected with 293fectin transfection reagent (Invitrogen, Carlsbad, CA) and 125 µg of C-_{E37997} plasmid following the manufacturer's recommendations. The supernatants were harvested 72 hours after transfection and filtered through a 0.45 µm pore size filter, then layered onto a 60% Optiprep (Iodixanol) medium (Invitrogen, Carlsbad, CA) and centrifuged at 50,000 x g for 1.5 hours with a Surespin 630 rotor (Sorvall). The supernatants were removed to leave 4 ml above the virus band and mixed to a 20% final concentration of OptiPrep. A density gradient was formed by centrifugation at 360,000 x g for 3.5 hours

with an NVT100 rotor (Beckman). 500 µl of each fraction was collected, weighed, and the densities of the fractions were plotted. 20 µl of each fraction was separated on a 4%-15% SDS-PAGE gel, and then stained using a Coomassie staining kit (InstantBlue, expedeon) following the manufacturer's recommendations or transferred onto an Immobilon-P membrane, and blotted with antisera reactive to the respective alphavirus (EEEV, WEEV, VEEV, CHIKV) as a primary antibody (e.g., sera from mice injected with the CHIKV strain S-27 (ATCC, VR-1241AF), CHIKV VLPs (strain 37997), or WEEV immune ascitic fluid (ATCC, VR-1251AF)) and goat anti-mouse immunoglobulins linked to horseradish peroxidase as a secondary antibody (Santa Cruz Biotechnology, Santa Cruz, CA).

Production and purification of anti-CHIKV mouse monoclonal antibodies

Monoclonal antibodies against CHIKV E2 were developed based on methods described previously in Yang *et al.*, *Science* **317**, 825 (2007). Briefly, female BALB/c mice were immunized with CHIKV VLPs three times. Injections with 20 µg CHIKV VLPs were administered every 4 weeks for a total of 3 injections. Three days after the final boost, spleens from the mice were harvested and used to produce hybridoma cells. Hybrids producing the antibody of interest were screened by ELISA using plates coated with CHIKV VLPs, and also using a neutralizing assay employing CHIKV pseudotyped viral vectors as previously mentioned in Akahata *et. al.*, *Nat. Med.* **16**, 334 (2010). Two clones, m10-18 and m242, showed strong neutralization and were purified as described previously in Yang *et al.*, *Science* **317**, 825 (2007).

Neutralization of CHIKV E pseudotyped lentiviral vectors by mouse and monkey antisera

The neutralization assay was performed as described previously (Yang *et al.*, *Science* **317**, 825 (2007)). A total of 10^4 293A cells were plated into each well of a 96-well dish one day prior to infection. CHIKV E-pseudotyped lentiviral vectors encoding luciferase were first titrated by serial dilution. Similar amounts of pseudotyped lentiviral vectors (with p24 levels of approximately 50 ng/ml) were then incubated with the indicated dilutions of mouse antisera for 60 minutes at room temperature prior to adding the virus: sera solution to 293A cells (10^4 cells/well in a 96-well dish, 50 µl/well, in triplicate). Sera from non-immune mice or monkeys were used as a negative control. After a 24 hour incubation, cells were lysed using cell lysis buffer (Cell Signal) and the luciferase activity was measured using Microbeta[®] JET (PerkinElmer, Turku, Finland) following incubation with "Luciferase assay reagent"

(Promega, Madison, WI), according to the manufacturer's protocol. Inhibition values were calculated as follows: inhibition (%) = $[1 - (\text{luciferase activity (cps) in pseudotyped lentiviral vector infected cells incubated with the indicated dilutions of mouse antisera}) / (\text{luciferase activity (cps) in pseudotyped lentiviral vector infected cells incubated with the same dilutions of non-immune mouse serum})] \times 100$. The IC_{50} was calculated with Prism software (version 5).

Electron microscopy

The morphology of the VLPs was examined by the Image Analysis Laboratory at the National Cancer Institute. VLPs were purified by Optiprep density centrifugation and were then fixed in 4% formaldehyde in PBS. Negative-stain electron microscopy for viral diagnosis has been described previously (Palmer and Martin, *Electron Microscopy in Viral Diagnosis* (CRC Press, Boca Raton, FL, 1988)). Briefly, 1.0 μ l of the sample was placed onto a carbon-coated Formvar-filmed copper grid (Tousimis Research Corp., Rockville, MD) and VLPs were allowed to attach. The VLPs were negatively stained by addition of 2 μ l of 1% PTA solution (phosphotungstic acid, pH 7.0) (Fisher Scientific Co., Fairlawn, NJ). The grid was then examined by electron microscope (Hitachi H7000, Tokyo, Japan) operated at 75 kV. Digital images were taken by a CCD camera (AMT, Danvers, MA).

Cryo-electron microscopy and image analysis

CHIKV VLPs were flash-frozen on holey grids in liquid ethane. Images were recorded at 47K magnification with a CM300 FEG microscope with electron dose levels of approximately $20 \text{ e}^-/\text{\AA}^2$. All micrographs were digitized at $6.35 \mu\text{m pixel}^{-1}$ using a Nikon scanner. Individual particle images were boxed using the program e2boxer in the EMAN2 package (Tang *et al.*, *J Struct. Biol.* **157**, 38 (2007)). CTF parameters were determined and phases were flipped using the CTFIT program from the EMAN package (Ludtke *et al.*, *J Struct. Biol.* **128**, 82 (1999)). An initial model was constructed in EMAN using assigned 2-, 3-, and 5-fold views and was refined in EMAN assuming icosahedral symmetry. The number of particles incorporated into the final reconstruction was 1489, giving a final resolution of 18 $\text{\AA}$ based on a 0.5 Fourier shell correlation threshold.

Immunizations and challenge of mouse and monkeys

19 μ g of VLPs (equivalent to approximately 10 μ g of E1/E2) in 60 μ l normal saline were mixed with 60 μ l of Ribi solution (Sigma Adjuvant system, Sigma-Aldrich) per

mouse following the manufacturer's recommendations. Female 6- to 8-week-old BALB/c mice were injected in the right and left quadriceps muscles with VLPs in normal saline or Ribi in 120 µl total volume, two times at weeks 2 and 6. For DNA vaccination groups, the mice were injected in the right and left quadriceps muscles with a total of 15 µg of purified
5 plasmid C-E₃₇₉₉₇, E₃₇₉₉₇, C-EOPY-1, or EOPY-1 suspended in 100 µl of normal saline three times at weeks 0, 3, and 6. Five mice/group were injected. 10 days after the last injection, sera and spleen were collected.

In the monkey experiments, rhesus macaques (*Macaca mulatta*) weighing 3-4 kg were injected intramuscularly in the anterior quadriceps with either twenty µg of VLPs in 1 ml PBS
10 (VLP group) or 1 ml PBS alone (control group) at weeks 0, 4 and 24. Six monkeys/group were injected. Blood was collected to measure antibody titers on days -14, 0, 10, 28, 38, 56, 70, 161 and 178. The monkeys (n=3 per group, randomly selected from each group) were challenged with 10¹⁰ PFU of CHIKV (strain LR2006 OPY-1) by intravenous injection. Blood was collected to measure viremia at 0, 6, 24, 48, 72, 96, 120 and 168 hours. The
15 monkeys were sacrificed at 168 hours after challenge. The whole blood cells were measured using a hematology analyzer (IDEXX Laboratories, Inc., Westbrook, Maine). Bleeds were EDTA-anticoagulated using 20-22 gauge needles and either syringes or vacuum tubes. The maximum blood volume removed did not exceed 20% (12 ml/kg) per month, with no more than 15% (9 ml/kg) removed during any single draw.

20 All animal experiments were reviewed and approved by the Animal Care and Use Committee, Vaccine Research Center (VRC), National Institute of Allergy and Infectious Diseases (<http://www.niaid.nih.gov/vrc>) and performed in accordance with all relevant federal and National Institutes of Health guidelines and regulations.

25 Virus preparation

CHIKV (strain LR2006 OPY-1) was prepared and the virus titers were determined as previously described (Tsetsarkin et al., PLoS. Pathog. 3, e201 (2007) and Pastorino *et al.*, *J Virol. Methods* **124**, 65 (2005)). Briefly, viral RNA transcribed from plasmid CHIK-LR ic was transfected into BHK-21 cells by electroporation. The supernatants from the
30 transfected cells were aliquotted and the stock virus was titrated and tissue culture infectious dose 50% (TCID₅₀) endpoint titers were determined using Vero cells. To produce virus for vertebrate challenge, C6/36 (*Aedes albopictus*) cells grown to confluence in T150 flasks were infected with stock virus at a multiplicity of infection of 0.03. Supernatants were harvested

at 48 hours post-infection, aliquotted and titrated to determine TCID₅₀ endpoint titers on Vero cells.

Plaque assay

Serum samples were tested for CHIKV neutralizing antibody by a standard plaque reduction neutralization test (PRNT). Briefly, monkey sera were heat inactivated at 56°C for 30 minutes and diluted in virus diluent (PBS/5% BSA). Diluted serum samples were mixed with an equal volume of 40 PFU CHIKV (strain LR2006 OPY-1) and incubated for 1 hour at 37°C. Six-well plates of confluent Vero cells were inoculated with 200 µl of the serum-virus mixtures in duplicate and incubated at 37°C for 1 hour. Plates were overlaid with 3 ml of medium containing 0.9% agarose (Lonza Rockland, Rockland, ME) and incubated at 37°C in a 5% CO₂ incubator for 2 days. A second overlay medium containing neutral red and 1% agarose was then added and the plates were incubated overnight before plaques were visualized and counted. The viremia in the monkeys after challenge was measured by plaque assay. Six-well plates of confluent Vero cells were inoculated with 200 µl of the serum-PBS mixtures in duplicate. The serum dilutions were 1:200, 1:400, 1:800, 1:1000, 1:10,000 and 1:100,000, since at lower dilutions toxicities were observed in the cells (detection limit 1:200 dilution = 1000 PFU/ml).

Passive transfer of immunoglobulin and challenge in IFN α / β R^{-/-} mice

IFN α / β R^{-/-} mice were kindly given by Robert Seder and Daniel D. Pinschewer. IgG was purified from the serum in monkeys immunized with CHIKV VLPs or injected with PBS (control) using a HiTrapTM Protein G HP column (GE Healthcare) following the manufacturer's recommendations. IgG was further purified using a Melon Gel IgG Purification Kit (Pierce) following the manufacturer's recommendations. Purified IgG was dialyzed 3 times against PBS. 2 mg of purified IgG (from approximately 200 µl of serum) was administered intravenously into each recipient IFN α / β R^{-/-} mouse by tail vein injection 24 hours before challenge. The mice were challenged with 30 PFU of CHIKV (strain LR2006 OPY-1) by intradermal injection.

Detection of CHIKV RNA by quantitative RT-PCR

For RNA isolation, serum samples were spun down at 10,000 x g for 1 hour, liquid poured off and 1 ml of RNA-STAT 60 (Isotex Diagnostics, Friendswood, TX) added. Samples were then incubated at RT for 5 min and resuspended in 250 µl of chloroform by

vortexing. The samples were spun down at 10,000 x g for 1 hour, the aqueous top-layer removed, 0.5 ml isopropanol and 10 µl tRNA (10 µg/ml) added and precipitated overnight at -20°C. Samples were spun down for 1 hour, washed with cold 75% ethanol and spun again for another hour. RNA was resuspended in 30 µl RNase-free water. For RT-PCR, 10% RNA was added to TaqMan reagents (Applied Biosystems, Foster City, CA) along with primers and probe (listed below) and amplified in a 7700 Sequence Detection System (Applied Biosystems). Briefly, the sample was reverse-transcribed at 48°C for 30 min., held at 95°C for 10 min, then run for 40 cycles of 95°C for 30 s and 60°C for 1 min. The signal was compared to a standard curve of known concentrations of plasmid containing the LR2006 OPY-1 sequence starting at 10⁷ down to 1 copy/mL and multiplied by 10, giving a detection range from 40-10⁸ copies/mL. All samples were performed in triplicate. The primers and probe were designed to bind to a highly conserved region on the E1 structural protein gene.

Primer sequences:

CHIK-F 5' AAGCTCCGCGTCCTTTACCAAG 3' and CHIK-R 5' CCAAATTGTCCTGGTCTTCCT3'.

Probe sequence: CHICK-P FAM-CCAATGTCTTCAGCCTGGACACCTTT-TAMRA as described previously in Huang *et al.*, *J. Virol.* **78**, 12557 (2004) and Pastorino *et al.*, *J Virol. Methods* **124**, 65 (2005)).

Structural models for analysis of CHIKV E1/E2 and surface area calculations

The CHIKV E1/E2 (OPY-1 strain) was modeled from PDB accession number 3N40-44 and displayed using Pymol (www.pymol.org). The electrostatic potential of the E1/E2 surface was calculated using APBS (www.poissonboltzmann.org/apbs/) and visualized with Pymol using blue and red to represent positive and negative charges, respectively.

Alignment of alphaviruses E2 protein

The representative alphavirus E2 glycoproteins were aligned in the NCBI database (<http://www.ncbi.nlm.nih.gov/Structure/cdd/cddsrv.cgi?uid=pfam00943>) to a panel that included Aura virus, Una virus, Mayaro virus, Middelburg virus, O'nyong-nyong virus (strain SG650), Ndumu virus, Barmah Forest virus, Seal louse virus, Salmon pancreas disease virus (SPDV), Whataroa virus, Sindbis virus, Western equine encephalomyelitis virus (WEEV), Venezuelan equine encephalitis virus (VEEV), Ross river virus (strain NB5092), Barmah

Forest virus, Bebaru virus, Semliki forest virus, Alphavirus M1, Fort Morgan virus, and Eastern equine encephalitis virus (EEEV). CHIKV strains were aligned using the NCBI protein blast tool (<http://blast.ncbi.nlm.nih.gov/Blast.cgi>).

5 Flow cytometry

CHIKV envelope expression on transfected cell membranes was measured by flow cytometry as described previously in Wu *et al.*, *J. Virol.* **83**, 5077 (2009), with the CHIKV E2 monoclonal antibody m10-18 or a control mouse monoclonal antibody as a primary antibody and goat anti-mouse immunoglobulins linked to Phycoerythrin as a secondary antibody
10 (Sigma). The data was analyzed and displayed with FlowJo 8.8.6 software (Tree Star).

Other Embodiments

From the foregoing description, it will be apparent that variations and modifications may be made to the invention described herein to adopt it to various usages and conditions.
15 Such embodiments are also within the scope of the following claims.

The recitation of a listing of elements in any definition of a variable herein includes definitions of that variable as any single element or combination (or subcombination) of listed elements. The recitation of an embodiment herein includes that embodiment as any single embodiment or in combination with any other embodiments or portions thereof.

20 All patents and publications mentioned in this specification are herein incorporated by reference to the same extent as if each independent patent and publication was specifically and individually indicated to be incorporated by reference.

What is claimed is:

1. A virus-like particle (VLP) comprising one or more alterations that enhance VLP production, wherein the alteration is in an E2 protein or an alphavirus capsid protein Nuclear
5 Localization Signal (NLS).

2. The virus-like particle (VLP) of claim comprising an alphavirus E2 protein comprising at least one alteration that enhances VLP production, wherein the alteration is at an amino acid position corresponding to amino acid 233, amino acid 234, or amino acid 251
10 in a Chikungunya virus (CHIKV) E2 protein.

3. The VLP of claim 2, wherein the VLP further comprises an alphavirus capsid (C) protein.

4. The VLP of claim 2 or 3, wherein the VLP further comprises an alphavirus envelop protein selected from the group consisting of E3, 6K, and E1.
15

5. The VLP of any one of claims 2-4, wherein the VLP comprises an alphavirus polyprotein comprising C-E3-E2-6K-E1.
20

6. The VLP of any one of claims 2-5, wherein the alphavirus is selected from the group consisting of Eastern equine encephalitis virus (EEEV), Western equine encephalitis virus (WEEV), Venezuelan equine encephalitis virus (VEEV), Semliki Forest virus (SFV), Chikungunya virus (CHIKV), O'nyong-nyong virus, Sindbis virus, Mayaro virus, Ross River
25 virus, Barmah Forest virus, or Ockelbo virus.

7. The VLP of any one of claims 2-6, wherein the alphavirus E2 protein or the alphavirus capsid protein is a CHIKV or WEEV protein.

8. The VLP of any one of claims 2-7, wherein the alphavirus E2 protein(s) or the alphavirus capsid protein is derived from CHIKV strain 37997.
30

9. The VLP of any one of claims 2-7, wherein the alphavirus E2 protein(s) or the alphavirus capsid protein is derived from WEEV strain 71V-1658.

10. The VLP of any one of claims 2-9, wherein the alphavirus E2 protein has an asparagine residue at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein.

5

11. The VLP of any one of claims 2-9, wherein the alphavirus E2 protein has a modification at the amino acid position corresponding to amino acid 251 in the CHIKV E2 protein that destabilizes the E2 protein during VLP budding.

10 12. The VLP of any one of claims 2-11, wherein the alphavirus E2 protein comprises at least alterations at an amino acid corresponding to amino acid 233, amino acid 234, and at amino acid 251 in a Chikungunya virus (CHIKV) E2 protein.

13. A VLP comprising a Chikungunya virus (CHIKV) E2 protein comprising an
15 alteration at amino acid 233, amino acid 234, and/or at amino acid 251.

14. A VLP comprising a WEEV E2 protein, wherein the WEEV E2 protein has an alteration at amino acid position 235.

20 15. A virus-like particle (VLP) comprising a flavivirus envelop protein comprising an alteration at an amino acid position corresponding to amino acid 233 or amino acid 234 in a Chikungunya virus (CHIKV) E2 protein.

16. The VLP of claim 15, wherein the VLP further comprises a flavivirus capsid protein.
25

17. The VLP of claim 15, wherein the flavivirus envelope protein or the flavivirus capsid protein is a Yellow Fever Virus (YFV), Dengue Virus (DENV), Japanese Encephalitis Virus (JEV), Tick-Borne Encephalitis Virus (TBEV), or West Nile Virus (WNV) protein.

30 18. The VLP of any of claims 2-17, wherein the VLP comprises a protein or polynucleotide of interest for delivery to a cell.

19. The VLP of claim 18, wherein the protein or polynucleotide of interest is derived from a virus, bacteria, or fungus.

20. An isolated polynucleotide encoding the VLP of any one of claims 2-19.

21. An expression vector comprising the isolated polynucleotide of claim 18.

5

22. The expression vector of claim 19, wherein the expression vector is capable of expression in a prokaryotic or eukaryotic cell.

23. The expression vector of claim 19, wherein the vector comprises the CMV/R promoter.

10

24. A prokaryotic or eukaryotic cell comprising the expression vector of any one of claims 20-23.

25. An immunogenic composition comprising an effective amount of the VLP of any one of claims 2-19.

15

26. An immunogenic composition comprising an effective amount of the expression vector of any one of claims 20-23, wherein administration of the immunogenic composition to a subject results in production of a VLP.

20

27. The immunogenic composition of claim 25 or 26, wherein the VLP induces an immune response in the subject.

28. The immunogenic composition of claim 27, wherein the immune response treats or prevents a virus infection in the subject.

25

29. The immunogenic composition of any one of claims 25-28, wherein the VLP induces antibodies against homologous or heterologous strains of alphavirus or flavivirus.

30

30. The immunogenic composition of any one of claims 25-28, wherein the immunogenic composition further comprises an adjuvant.

31. An immunogenic composition comprising at least two VLPs selected from the group consisting of Eastern equine encephalitis virus (EEEV), Western equine encephalitis virus (WEEV), Venezuelan equine encephalitis virus (VEEV), Semliki Forest virus (SFV), Chikungunya virus (CHIKV), O'nyong-nyong virus, Sindbis virus, Mayaro virus, Ross River virus, Barmah Forest virus, or Ockelbo virus.

32. An immunogenic composition comprising at least two VLPs selected from the group consisting of Yellow Fever Virus (YFV), Dengue Virus (DENV), Japanese Encephalitis Virus (JEV), Tick-Borne Encephalitis Virus (TBEV), or West Nile Virus (WNV).

33. A method of inducing an immune response against a virus in a subject, comprising administering to the subject an effective amount of the immunogenic composition of any one of claims 24-31.

34. The method of claim 32, wherein the method induces neutralizing antibodies in the subject.

35. A vaccine comprising an effective amount of a VLP of any of claims 1-19.

36. A vaccine comprising a polynucleotide encoding the VLP of any one of claims 1-19.

37. The vaccine of claim 36, wherein the vaccine is a DNA vaccine.

38. A method for treating or preventing an a virus infection in a subject, comprising administering to the subject an effective amount of the immunogenic composition of any one of claims 25-32 or the vaccine of any one of claims 35-37.

39. The method of claim 38, wherein the vaccine or immunogenic composition is administered in one or more doses.

40. The method of claim 39, wherein the vaccine or immunogenic composition is administered in one or more priming immunizations and one or more boosting immunizations.

41. The method of claim 40, wherein the priming immunizations are administered at one, two, three, four, five, six, seven, or eight week intervals.

42. The method of claim 40, wherein the boosting immunizations are administered two weeks, one month, two months, or three months after the priming immunization.

43. The method of claim 38, wherein the administration of the vaccine or immunogenic composition protects the subject against viremia or the inflammatory consequences of an alphavirus or flavivirus infection.

44. The method of claim 38, wherein the administration of the vaccine or immunogenic composition protects the subject from lethality.

45. A method for producing a VLP, the method comprising expressing an alphavirus structural protein in a cell, thereby resulting in self-assembly of the VLP, wherein the cell expresses an alphavirus E2 protein that has i) an asparagine residue at the amino acid position corresponding to amino acid 233 in a CHIKV E2 protein, ii) an asparagine residue at the amino acid position corresponding to amino acid 234 in a CHIKV E2 protein, or iii) a modification at the amino acid position corresponding to amino acid 251 in the CHIKV E2 protein, and wherein the modification destabilizes the the alphavirus E2 protein during VLP budding.

46. The method of claim 45, wherein the cell further expresses an alphavirus capsid (C) or an alphavirus envelope protein selected from the group consisting of E3, 6K, and E1.

47. The method of claim 46, wherein the cell expresses an alphavirus polypeptide comprising C-E3-E2-6K-E1.

48. The method of claim 45, wherein the alphavirus envelope protein(s) or the alphavirus capsid protein is derived from EEEV, WEEV, VEEV, SFV, CHIKV, O'nyong-nyong virus, Sindbis virus, Mayaro virus, Ross River virus, Barmah Forest virus, or Ockelbo virus.

49. A method for producing a VLP, wherein the method comprises expressing a flavivirus structural protein in a cell, thereby resulting in self-assembly of the VLP, wherein the cell

expresses a flavivirus envelope protein that has i) an asparagine residue at the amino acid position corresponding to amino acid 233 in a CHIKV E2 protein, or ii) an asparagine residue at the amino acid position corresponding to amino acid 234 in a CHIKV E2 protein.

5 50. The method of claim 49, wherein the cell further expresses a flavivirus capsid protein.

51. The method of claim 49, wherein the flavivirus envelope protein or flavivirus capsid protein is derived from YFV, DENV, JEV, TBEV, or WNV.

10 52. A method for enhancing VLP production in a cell comprising:

a. altering an amino acid residue in an alphavirus E2 protein that corresponds to amino acid 233, amino acid 234, and/or amino acid 251 in a CHIKV E2 protein; and

b. expressing the alphavirus E2 protein in a cell;

15 thereby resulting in self-assembly of the VLP.

53. The method of claim 52, wherein the method further comprises expressing an alphavirus capsid (C) or an alphavirus envelope protein selected from the group consisting of E3, 6K, and E1 in the cell.

20

54. The method of claim 52, wherein the method comprises expressing an alphavirus polyprotein comprising C-E3-E2-6K-E1 in the cell.

25 55. The method of any one of claims 52-54, wherein the alphavirus E2 protein comprises an asparagine residue at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein.

30 56. The method of any one of claims 52-54, wherein the alphavirus E2 protein is altered at the amino acid position corresponding to amino acid 251 in the CHIKV E2 protein such that the alteration destabilizes the alphavirus E2 protein during VLP budding.

57. A method for enhancing VLP production in a cell comprising:

- a. altering an amino acid residue in a flavivirus envelope protein that corresponds to amino acid 233 and/or amino acid 234 in a CHIKV E2 protein; and
 - b. expressing the flavivirus envelope protein in a cell;
- 5 thereby resulting in self-assembly of the VLP.

58. The method of claim 57, wherein the method further comprises expressing an flavivirus capsid protein in the cell.

10 59. The method of claims 57 or 58, wherein the flavivirus envelope protein is altered such that it has an asparagine residue at the amino acid position corresponding to amino acid 234 in the CHIKV E2 protein.

15 60. The method of any one of claims 57-59, wherein the flavivirus envelope protein is altered such that it has an asparagine residue at the amino acid position corresponding to amino acid 233 in the CHIKV E2 protein.

20 61. The method of claim 52 or 57, wherein the method further comprises isolating the VLP.

62. The method of claims 49-61, comprising exposing the VLP or VLP expressing cell to a pH of about 7.2 or higher.

25 63. A VLP produced by the method of any one of claims 52-62.

64. A kit comprising the VLP of any one of claims 2-19 or 63, and directions for the use of said VLP to generate an immune response in a subject.

65. A method for introducing an agent into a cell comprising:

- 30 a. packaging the agent into the VLP of any one of claims 2-19 or 63
- b. contacting a cell with the packed VLP; and
- c. allowing the packed VLP to enter the cell, thereby introducing the agent into the cell.

66. The method of claim 65, wherein the agent is selected from the group consisting of a small molecule chemical compound, an antibody, a nucleic acid molecule, a polypeptide, or fragments thereof.

67. The VLP of any one of claims 2-9, wherein the alphavirus E2 protein has an asparagine residue at the amino acid position corresponding to amino acid 233 in the CHIKV E2 protein.

68. The method of any one of claims 52-54, wherein the alphavirus E2 protein comprises an asparagine residue at the amino acid position corresponding to amino acid 233 in the CHIKV E2 protein.

69. The VLP of claim 1, wherein the alphavirus is selected from the group consisting of Eastern equine encephalitis virus (EEEV), Western equine encephalitis virus (WEEV), Venezuelan equine encephalitis virus (VEEV), Chikungunya virus (CHIKV), Ross River virus, Barmah Forest virus (BFV), Semliki Forest virus (SFV), O'nyong-nyong virus, Sindbis virus, Mayaro virus, or Ockelbo virus.

70. The VLP of claim 1, wherein the alphavirus capsid protein is an EEEV, WEEV, VEEV, CHIKV Ross River virus, or Barmah Forest virus capsid protein.

71. The VLP of claim 1, wherein the one or more alterations is in an NLS at an amino acid position selected from the group consisting of:

At amino acids 67-70 of an EEEV capsid protein;

At amino acids 67-70 of an WEEV capsid protein;

At amino acids 64-68 of an VEEV capsid protein;

At amino acids 62-69 of a CHIKV capsid protein;

At amino acids 71-74 of a Ross River virus capsid protein; and

At amino acids 64-68 of a Barmah Forest virus capsid protein.

72. The VLP of claim 71, wherein the alteration is a substitution in a charged amino acid of the NLS.

73. The VLP of claim 72, wherein the charged amino acid is lysine or arginine.

74. The VLP of claim 73, wherein the lysine or arginine is substituted with asparagine or alanine.

5 75. The VLP of claim 73, wherein the EEEV virus capsid protein NLS is altered at amino acid 67.

76. The VLP of claim 73, wherein the EEEV virus capsid protein NLS comprises K67N.

10 77. The VLP of claim 73, wherein the WEEV virus capsid protein NLS is altered at one or more of amino acids 67, 68, and 69.

78. The VLP of claim 77, wherein the WEEV capsid protein NLS comprises K67N, K68N, and/or K69N.

15

79. The VLP of claim 73, wherein the VEEV virus capsid protein NLS is altered at one or more of amino acids acid 64, 65, and 67.

80. The VLP of claim 79, wherein the VEEV virus capsid protein NLS comprises K64N, K65A or K65N, and/or K67A or K67N.

20

81. The VLP of claim 73, wherein the Chikungunya virus capsid protein NLS is altered at one or more of amino acids 62, 63, 65, 66, 68, and 69.

25 82. The VLP of claim 81, wherein the Chikungunya virus capsid protein NLS comprises R62A, R63A, R65A, R66A, R68A and/or R69A.

83. The VLP of claim 73, wherein the Ross River virus capsid protein NLS is altered at one or more of amino acids 71, 72, 73, and 74.

30

84. The VLP of claim 82, wherein the Ross River virus capsid protein NLS comprises R71N, R72N, R73N, and/or R74N.

85. The VLP of claim 73, wherein the Barmah Forest virus capsid protein NLS is altered at one or more of amino acids 64, 65, 67 and 68.

86. The VLP of claim 82, wherein the Barmah Forest virus capsid protein NLS comprises K64A, K65A or K65N, K67A, K67N, K68A and/or K68N.

87. The VLP of any of claims 1 and 71-86, wherein the VLP comprises a protein or polynucleotide of interest for delivery to a cell.

88. The VLP of claim 87, wherein the protein or polynucleotide of interest is derived from a pathogen.

89. The VLP of claim 88, wherein the pathogen is a virus, bacteria, fungus.

90. An isolated polynucleotide encoding the VLP of any one of claims 1 and 71-89.

91. An expression vector comprising the isolated polynucleotide of claim 90.

92. The expression vector of claim 91, wherein the expression vector is E37997, EOPY-1, CMV/R WEEV CBA87 strain capsid K67N VLP, CMV/R WEEV CBA87 strain capsid K67N K68N VLP, CMV/R WEEV CBA87 strain capsid K67N K68N K69N VLP, CMV/R VEEV TC83 strain K64N VLP, CMV/R VEEV TC83 strain K64N K65N VLP, CMV/R VEEV TC83 strain K65N K67N VLP, CMV/R VEEV TC83 strain K65A K67A VLP, CMV/R EEEV PE-6 strain capsid K67N VLP, CMV/R EEEV PE-6 strain capsid K67N E2 R239N VLP, CMV/R CHIKV(Strain 37997) Capsid R62A, CMV/R CHIKV(Strain 37997) Capsid R62A R63A, CMV/R CHIKV(Strain 37997) Capsid R62A R63A R65A K66A K68A K69A, CMV/R CHIKV(Strain 37997) Capsid R65A, CMV/R Ross River Virus T48 capsid R71N, CMV/R Ross River Virus T48 capsid R71N K72N, CMV/R Ross River Virus T48 capsid R71N K72N K73N, CMV/R Ross River Virus T48 capsid R71N K72N K73N K74N, or CMV/R BFV VLP K64A..

93. The expression vector of claim 92, wherein the expression vector is capable of expression in a eukaryotic cell.

94. The expression vector of claim 92, wherein the vector comprises the CMV/R promoter.

95. An immunogenic composition comprising an effective amount of the VLP of any one of claims 1 and 71-89 or the expression vector of claims 23-25.

96. A pan-alphavirus immunogenic composition comprising virus-like particles (VLPs) derived from two or more alphaviruses selected from the group consisting of a EEEV, WEEV, VEEV, CHIKV Ross River virus, or Barmah Forest virus, wherein the VLPs comprise one or more alterations that enhance VLP production, wherein the alteration is in an E2 protein or an alphavirus capsid protein Nuclear Localization Signal (NLS).

97. A method of inducing an immune response against one or more alphaviruses selected from the group consisting of a EEEV, WEEV, VEEV, CHIKV Ross River virus, or Barmah Forest virus in a subject, the method comprising administering to the subject an effective amount of the immunogenic composition of claim 95 or 96.

98. The method of claim 97, wherein the method protects the subject against infection by said alphavirus or protects the subject against viremia or an inflammatory consequence of infection with said virus.

99. A method for producing a VLP, the method comprising expressing an alphavirus capsid protein comprising an alteration in an NLS in a eukaryotic cell, and isolating said VLP.

100. A method for enhancing VLP production in a cell, the method comprising: expressing an alphavirus capsid protein comprising an alteration in an NLS in a eukaryotic cell under conditions that provide for self-assembly of the VLP.

101. A VLP produced by the method of claim 99 or 100.

102. A kit comprising the VLP of any one of claims 1 and 71-89 or the expression vector of claims 92-94, and directions for the use of said VLP or expression vector to generate an immune response in a subject.

103. A method for introducing a protein or polynucleotide of interest into a cell, the method comprising contacting the cell with a VLP of claim 84, thereby introducing the agent into the cell.

Figure 60

EEEV VLPs were purified at pH7.9 and yield compared to yields at pH 7.1

Figure 61

Yield of EEEV VLPs is pH dependent

1. EEEV Capsid K67N without changing medium (final pH7.1)
2. Adding Sodium Acetate buffer pH5.5 (1M, final 20mM and pH6.9)
3. Adding KH_2PO_4 buffer pH6.2 (1M, final 20mM and pH6.7)
4. Adding HEPES buffer pH7.5 (1M, final 20mM and pH7.26)
5. Adding Tris-HCl buffer pH8.0 (1M, final 20mM and pH7.5)
6. Adding Tris-HCl buffer pH7.5 (1M, final 20mM and pH7.2)
7. Adding Tris-HCl buffer pH8.8 (2M, final 20mM and pH8.0)

Figure 62

Addition of Tris-HCl buffer 24 after transfection of EEV 67N

Figure 63

A

Adding Tris-HCl buffer to maintain higher pH
24h after transfection of CHIKV OPY-1

1. CHIKV OPY-1 without changing medium (final pH7.1)
2. Adding Tris-HCl buffer pH8.8 (2M, final 20mM and pH7.9)
3. Adding Tris-HCl buffer pH8.0 (1M, final 20mM and pH7.5)
4. Adding Tris-HCl buffer pH7.5 (1M, final 20mM and pH7.2)

B

Figure 64

Adding mutation to the pH sensitive ASR region of CHIKV OPY-1

3 and 4 days after transfection mutations are expressed at similar levels but WT CHIKV OPY-1 is almost gone

Figure 65

Figure 66
