(54) Title: COMMUNICATION SYSTEM AND COMMUNICATION CONTROLLING METHOD

(57) Abrégé/Abstract:

A communication method in LIPA/ SIPTO architecture is provided which, when a user equipment (UE) is to connect from a serving area to an external network, allows re-selection of an optimal gateway. The communication method allows selecting a gateway apparatus physically or topologically close to a site, where the user equipment is attached.

ABSTRACT

A communication method in LIPA/ SIPTO architecture is provided which, when a user equipment (UE) is to connect from a serving area to an external network, allows re-selection of an optimal gateway. The communication method allows selecting a gateway apparatus physically or topologically close to a site, where the user equipment is attached.

1

DESCRIPTION

COMMUNICATION SYSTEM AND COMMUNICATION CONTROLLING METHOD

This is a divisional application of Canadian National Phase application from International Application No. PCT/JP2010/066211, filed on 17th September, 5 2010.

TECHNICAL FIELD

[0001]

This invention relates to a mobile communication system and, more particularly, to a system optimal for re-selection of a gateway that connects a terminal 10 to a packet data network. This invention also relates to a communication controlling method.

BACKGROUND ART

[0002]

In EPC (Evolved Packet Core), bearer management is performed based 15 on an 'Always On' concept in such a manner that a PGW (PDN (Packet Data Network) Gateway), initially selected when a UE (User Equipment or 'terminal') has attached the EPC, is fixedly used as anchor until the UE detaches. By this manner of operation, it is possible for a service network (a packet data network) to provide services premised on permanent connection. It is because the IP information driven 20 out by the PGW is unchanged even if the UE moves repeatedly within the EPC.

[0003]

When a UE moves within the EPC, an SGW (Serving Gateway) is re-selected in accompaniment with the movement of the UE. Each time the SGW is re-selected, a bearer between the SGW and the PGW is updated by disconnection and 25 re-establishment to ensure connectivity from the UE to the PGW.

78792-13E

2

[0004]

In general, in selecting a PGW, such a PGW is selected which is close to the SGW physically or from the perspective of network topology.

[0005]

5 However, in case the UE performs repeated movement over long distances or has stayed in a far-away place after such long-distance movement, the PGW, initially selected, may be far away from a SGW in terms of a distance(a physical or network topological distance). As a result, network efficiency is deteriorated to present problems such as transmission delay of user data or
10 inefficient consumption of network resources within the EPC.

[0006]

For example, when a passenger to Japan from abroad enters at Narita International Airport, he/she may usually power-up the mobile phone apparatus at the International Airport to attach to EPC. Hence, a PGW located close to Narita
15 International Airport is selected. However, after entrance to Japan, he/she may move to e.g., Tokyo, Osaka, Sapporo or Fukuoka. Hence, after each such movement, the PGW close to the Narita International Airport is no longer the most efficient PGW.

SUMMARY OF THE INVENTION

[0007]

20 The following is an analysis by the present inventors. In the EPC network, a default bearer, established at the time of attachment, is not deleted/ re-established until the time of detachment under the 'Always On' principle. If the bearer is to be switched due to UE's movement, the PGW, selected at the time of attachment, remains fixed as anchor.

25 [0008]

78792-13EPPH

3

Consequently, such a problem is raised that, when a UE moves over a long distance, maintaining connection to the PGW selected at the time of the attachment may be efficient from the perspective of EPC network.

[0009]

5 Such a system is thus desired that, when a UE moves over a long distance, and the UE is to connect from a serving area in which the UE resides to an external network (service network), allows re-selecting an optimal PGW (result of analysis by the present inventors).

[0010]

10 According to an aspect of the present invention, there is provided a communication method for Local IP Access (LIPA) or Selected IP Traffic Offload (SIPTO) architecture, the method comprising: a mobility management entity (MME) paging a user equipment, on a case where the MME decides that it is necessary to relocate a gateway apparatus; the user equipment transmitting a service request signal to the MME; the MME
15 sending a deactivate bearer request to a base station for requesting the relocation; the base station transmitting a radio resource control (RRC) connection reconfiguration to the user equipment on receipt of the deactivate bearer request; the user equipment transmitting a notification of completion of the RRC connection reconfiguration to the base station; the base station transmitting a deactivate bearer response to the MME on receipt of the notification; the
20 user equipment initiating a UE requested packet data network (PDN) connectivity procedure; and a new packet data network gateway apparatus (PGW) being selected in the UE requested PDN connectivity procedure.

 According to another aspect of the present invention, there is provided a communication system for a Local IP Access (LIPA) or Selected IP Traffic Offload (SIPTO)
25 architecture, the system comprising: a user equipment; a mobility management entity (MME) for managing a mobility of the user equipment; and a base station for connecting to the user equipment; wherein the MME pages the user equipment, on a case where the MME decides that it is necessary to relocate a gateway apparatus, the user equipment transmits a service

78792-13EPPH

4

request signal to the MME, the MME sends a deactivate bearer request to the base station for requesting the relocation, the base station, on receipt of the deactivate bearer request, transmits a radio resource control (RRC) connection reconfiguration to the user equipment, the user equipment transmits a notification of completion of the RRC connection

- 5 reconfiguration to the base station, the base station transmits a deactivate bearer response to the MME, and the user equipment initiates a UE requested packet data network (PDN) connectivity procedure, a new packet data network gateway apparatus (PGW) being selected in the UE requested PDN connectivity procedure.

- According to another aspect of the present invention, there is provided a user
 10 equipment for Local IP Access (LIPA) or Selected IP Traffic Offload (SIPTO) architecture, the user equipment comprising: means for transmitting a service request signal to a mobility management entity (MME), in response to paging from the MME; and means for sending, on receipt of a radio resource control (RRC) connection reconfiguration from a base station, a notification of completion of the RRC connection reconfiguration to the base station to initiate
 15 a UE requested packet data network (PDN) connectivity procedure, wherein a new packet data network gateway apparatus (PGW) is selected in the UE requested PDN connectivity procedure.

- According to another aspect, there is provided a communication method in Local IP Access (LIPA)/ Selected IP Traffic Offload (SIPTO) architecture, the method
 20 comprising: a mobility management entity (MME) sending a deactivate bearer request for requesting re-selection, to a base station, when the MME decides that it is necessary to re-select a gateway apparatus; the base station transmitting an RRC connection reconfiguration to a user equipment; the user equipment transmitting a notification of completion of an RRC connection reconfiguration to the base station; the base station transmitting a deactivate bearer
 25 response to the MME; and the user equipment initiating a UE requested PDN connectivity (UE requested PDN connectivity) procedure, the gateway apparatus being re-selected.

According to another aspect, there is provided a communication system in Local IP Access (LIPA)/ Selected IP Traffic Offload (SIPTO) architecture, the system comprising: a mobility management entity (MME); a base station; and a user equipment,

78792-13EPPH

4a

wherein the MME sends a deactivate bearer request (Deactivate Bearer request) for requesting re-selection to the base station, when the mobility management entity (MME) decides that it is necessary to re-select a gateway apparatus, the base station transmits an RRC connection reconfiguration to the user equipment, the user equipment transmits a notification of completion of
5 the RRC connection reconfiguration to the base station, and the base station transmits a deactivate bearer response to the MME, and the user equipment initiates a UE requested PDN connectivity procedure, the gateway apparatus being re-selected.

According to another aspect, there is provided a user equipment in a communication system by Local IP Access (LIPA)/ Selected IP Traffic Offload (SIPTO) architecture, wherein on
10 receipt of an RRC connection reconfiguration from a base station, a user equipment sends a notification of completion of RRC connection reconfiguration to the base station to initiate a UE requested PDN connectivity procedure to cause re-selection of a gateway apparatus to be performed.

Some embodiments may provide a system and a method, which make it possible to re-select an optimal gateway node, when a terminal (UE) is to connect from a serving area to an
15 external network.

[0011]

In another aspect, there is provided a communication method in Local IP Access (LIPA)/ Selected IP Traffic Offload (SIPTO) architecture, wherein a gateway apparatus physically or topologically close to a site, where the user equipment is attached, is selected according to
20 movement of the user equipment.

[0012]

In another aspect, there is provided a communication system in Local IP Access (LIPA)/ Selected IP Traffic Offload (SIPTO) architecture, wherein a gateway apparatus physically or topologically close to a site, where the user equipment is attached, is selected according to
25 movement of the user equipment.

[0013]

78792-13E

5

According to another aspect, there is provided user equipment in a communication system by Local IP Access (LIPA)/ Selected IP Traffic Offload (SIPTO) architecture, wherein a gateway apparatus physically or topologically close to a site, where the user equipment is attached, is selected according to movement of
5 the user equipment.

[0014]

In another aspect, there is provided a communication method in Local IP Access (LIPA)/ Selected IP Traffic Offload (SIPTO) architecture, wherein, in case a mobility management entity (MME) decides that it is necessary to re-select a gateway
10 apparatus, the MME sends a first signal for setting re-attachment to a user equipment, the user equipment on receipt of the first signal transmitting a second signal for re-attachment to the MME and the MME re-selecting the gateway apparatus.

[0015]

15 According to another aspect, there is provided a communication system in Local IP Access (LIPA)/ Selected IP Traffic Offload (SIPTO) architecture, comprising a mobility management entity (MME) and a user equipment, wherein the MME sends a first signal for setting re-attachment when the MME decides that it is necessary to re-select a gateway apparatus, the user equipment sends a second
20 signal for re-attachment to the MME on receipt of the first signal, and the MME re-selects the gateway apparatus.

[0016]

According to another aspect, there is provided a user equipment in a communication system by Local IP Access (LIPA)/ Selected IP Traffic Offload
25 (SIPTO) architecture, wherein the user equipment receives a first signal that sets re-attachment from a mobility management entity (MME) to send a second signal for re-

78792-13EPPH

6

attachment to the MME to cause re-selection of a gateway apparatus to be performed.

[0017]

In another aspect, there is provided a communication method in Local
5 IP Access (LIPA)/ Selected IP Traffic Offload (SIPTO) architecture, wherein the method comprises:

the MME sending a deactivate bearer request (Deactivate Bearer request), requesting re-selection, to a base station, when a mobility management entity (MME) decides that it is necessary to re-select a gateway apparatus;

10 the base station sending an RRC connection reconfiguration (RRC connection reconfiguration) to a user equipment; and

the user equipment sending a notification of completion of an RRC connection reconfiguration (RRC connection reconfiguration) to the base station;

the base station sending a deactivate bearer response (Deactivate
15 Bearer response) to the MME; and

the user equipment initiating a UE requested PDN connectivity (UE requested PDN connectivity) procedure,

as a result, re-selection of a gateway apparatus being performed.

[0018]

20 According to another aspect, there is provided a communication system in Local IP Access (LIPA)/ Selected IP Traffic Offload (SIPTO) architecture, comprising:

78792-13E

6a

a mobility management entity (MME);

a base station; and

a user equipment, wherein when the MME decides that it is necessary to re-select a gateway apparatus, the MME sends a deactivate bearer request
5 (Deactivate Bearer request), requesting re-selection, to the base station,

the base station sends an RRC connection reconfiguration (RRC connection reconfiguration) to the user equipment,

the user equipment sends a notification of completion of the RRC connection reconfiguration (RRC connection reconfiguration) to the base station,

10 the base station sends a deactivate bearer response (Deactivate Bearer response) to the MME,

the user equipment initiates a UE requested PDN connectivity (UE requested PDN connectivity) procedure to cause re-selection of a gateway apparatus to be performed.

15 [0019]

According to another aspect, there is provided a user equipment in a communication system by Local IP Access (LIPA)/ Selected IP Traffic Offload (SIPTO) architecture, wherein, in case of receiving an RRC connection reconfiguration from the base station, the user equipment sends a notification of
20 completion of RRC connection reconfiguration to the base station to initiate a UE requested PDN connectivity procedure to cause re-selection of a gateway apparatus to be performed.

[0020]

78792-13E

6b

According to some embodiments, it is possible to re-select an optimal gateway node at a time when a user equipment is to connect from a serving area to an external network (service network).

[0022]

The following describes exemplary embodiments of the present invention will now be described. A system according to one of modes of the present invention re-selects a PGW (PDN gateway) in EPC in keeping with movement of a user equipment (UE) and re-establishes a default bearer, thereby realizing improvement of transmission delay and efficiency of network resources in the EPC.

[0023]

In current 3GPP standardization, such techniques, termed LIPA (Local IP Access) or SIPTO (Selected IP Traffic Offload), are under study. In these techniques, user traffic is not taken into EPC and is made to have direct access to an external packet network from a radio access network, in which a UE resides. In case the present invention is adapted to cooperate with the LIPA/ SIPTO architecture, it becomes possible to realize efficient utilization of network resource more effectively.

[0024]

In a system according to an exemplary embodiment of the present invention, a PGW is re-selected for a UE which is being attached to the EPC.

[0025]

An EPC bearer usually uses in a fixed manner, a PGW which is initially selected when a UE is attached (registered) to the EPC network, as an anchor, until the UE is detached (deleted from registration). However, in case the UE moves over a long distance, it may occur frequently that the PGW initially selected ceases to be a most efficient gateway apparatus for the external network.

[0026]

In one of modes of the present invention, a path (bearer) between a UE and a PGW may be optimized by re-selecting and modifying the PGW, such as when the UE is in an idle state.

[0027]

In one of modes of the present invention, a default bearer is re-established, with the re-selection of as the PGW, when the UE is

not involved in packet communication, i.e., when the UE is in idle mode. By so doing, network resources between UE and PGW may be optimized without detracting from the user experience.

[0028]

5 The following describes the operation in case the UE moved astride an SGW. Fig.2 shows, as Comparative Example, a case where the present invention is not applied. Referring to Fig.2, since the UE is attached to an SGW 61 on the left side of Fig.2, a PGW 71, which is closer to the left side SGW 61 in a physical distance or a
10 network-topological distance, is initially selected, and a connection path 1 is set. When the UE is moved a long distance, the UE continues to use the left-side PGW 71. Hence, the UE and the PGW are connected by an inefficient connection path 2.

[0029]

15 In contrast, Fig.3 shows a case where the UE moves astride the SGW, as the present invention is applied. Referring to Fig.3, since the UE is attached to the SGW 61 on the left side of Fig.3, the PGW 71, closer to the left side SGW 61 in a physical distance or a network-topological distance, is initially selected, and a connection
20 path 3 is set. The EPC then re-examines the connectivity between the UE and the external network (service network), using the UE's movement over the large distance as a trigger. As a result of the re-check, the EPC gives a decision that a right-side PGW2 provides a more efficient connection (UE-PGW path) than the left-side PGW 71.
25 Hence, the path between the UE and the PGW is changed over from the connection path 3 to the connection path 4, thus assuring more efficient connection. The present invention will now be described with reference to exemplary embodiments.

[0030]

30 <Exemplary Embodiment 1>

Fig.1 shows the arrangement of a network system according of the present exemplary embodiment. The basic arrangement itself of the network remains unchanged from a hitherto-used EPC network arrangement.

78792-13E PPH

[0031]

Referring to Fig.1, UE1 to UE3 are mobile phones. In Fig.1, eNodeB (evolved Node B) are base stations of LTE (Long Term Evolution), while NodeB 21 and RNC (Radio Network Controller) 31 are apparatuses for radio access adopted in the UMTS (Universal Mobile Telecommunication System).

[0032]

An MME (Mobility Management Entity) 41 is an apparatus for mobility management as introduced by EPC.

10 [0033]

An SGSN (Serving GPRS (General Packet Radio Service) Support Node) 51 is a serving apparatus, used for UMTS, and may or may not handle a user plane processing, depending on a connection modes.

15 [0034]

In case the SGSN does not handle a user plane, the user plane is set between the SGW (Serving Gateway) and the RNC.

[0035]

SGWs 61 and 62 are serving apparatuses that may handle the user plane. PGW 71 and 72 are gateway apparatuses that connect an external network (a service network 81 in the drawing) and RNC.

[0036]

The following describes the operation of the present exemplary embodiment. Initially, an update procedure of a tracking area (TA Update Procedure) will be described with reference to a Comparative Example to which the present invention is not applied.

[0037]

Fig.4 shows a case of TA update accompanied by SGW change (Comparative Example). It is noted that, when a UE is in idle condition, that is, in a no-connection state, it is managed to which tracking area (position registration area) the UE belongs, however, it is not managed in which cell the UE resides.

[0038]

MME receives a TA update request (TA Update Request) from

the UE and, if it is determined that SGW needs to be changed, a create session request (Create Session Request) is sent to an SGW (2) which is a change-target SGW.

[0039]

5 The SGW(2) sends a modify bearer request (Modify Bearer Request) to the PGW (1) to notify the PGW (1) of the fact that the SGW as destination of connection is changed.

[0040]

10 On completion of update of the bearer context information, the PGW (1) sends a response to the modify bearer request (Modify Bearer Response) to the SGW (2).

[0041]

15 On receipt of the response to the modify bearer request (Modify Bearer Response) from the PGW (1), the SGW (2) sends a create session response (Create Session Response) to the MME.

[0042]

 On receipt of the create session response (normal response) from the SGW (2), the MME sends a delete session request (Delete Session Request) to the SGW (1), which is a change-source SGW.

20 [0043]

 After deletion of the bearer context, the SGW (1) sends a delete session response (Delete Session Response) to the MME.

[0044]

25 On receipt of the delete session response (Delete Session Response) from the SGW (1), the MME sends a TA (Tracking Access) accept (TA accept) to the UE.

[0045]

30 In contrast to the Comparative Example, shown in Fig.4, the sequence operation shown in Fig.5 is carried out in an exemplary embodiment of the present invention. The following describes the sequence of the present exemplary embodiment with reference to Fig.5.

[0046]

 The MME receives a TA update request (TA Update Request)

from the UE. In case the MME decides that the SGW is to be changed, the MME sends a create session request (Create Session Request) to the SWG (2) which is a change-target SGW.

[0047]

5 In case the MME decides that PGW re-arrangement is necessary, the MME selects a PGW (2) that can be efficiently connected to the external network (service network), and sets address information that identifies the PGW, in the create session request (Create Session Request).

10 [0048]

The SGW (2), on receipt of the new PGW address, sends a create session request (Create Session Request) to the PGW (2).

[0049]

15 The PGW (2), responsive to the create session request (Create Session Request) sent from the SGW (2), creates a bearer context. The PGW (2) also assigns a new IP address for the user to the UE. After completion of assignment of the new IP address for the user and creation of the bearer context, the PGW (2) sends a create session response (Create Session Response) to the SGW (2).

20 [0050]

The SGW (2), responsive to the create session response (Create Session Response) from the PGW (2), sends a delete session request (Delete Session Request) to the PGW (1).

[0051]

25 The PGW (1) deletes the bearer context and sends a delete session response (Delete Session Response) to the SGW (2).

[0052]

30 The SGW (2), responsive to the delete session response (Delete Session Response) from the PGW (1), sends a create session response (Create Session Response) to the MME.

[0053]

The MME, responsive to a normal response from the SGW (2), sends a delete session request (Delete Session Request) to the SGW (1), which is the change-source SGW.

[0054]

After deleting bearer context, the SGW (1) sends a delete session response (Delete Session Response) to the MME.

[0055]

- 5 On receipt of the response, the MME sends a TA update accept (TA Update Accept) to the user. The IP information, newly assigned to the user, is set in the TA Update Accept and notified to the UE.

[0056]

- 10 In the foregoing, such a case has been explained in which GTPv2 protocol (GPRS (General Packet Radio Service) Tunneling Protocol v2) is used between SGW and PGW. Similar functions may be implemented for such a case where PMIPv6 (Proxy Mobile IPv6) is used.

[0057]

- 15 In case of using PMIPv6 between the SGW and the PGW, Proxy Binding Update is used in place of Create Session Request/ Delete Session Request. Also, Proxy Binding Acknowledgement is used in place of Create Session Response/ Delete Session Response.

[0058]

- 20 The sequence to re-select a PGW is as shown in Fig.5. To implement the above functions, it is necessary for an MME to re-select a PGW at an appropriate timing.

[0059]

- 25 If, during when a UE is performing packet communication, a PGW connected to a service network is changed, the information such as IP address is changed for a communication counterpart of the UE. As a result, the packet communication by the UE is disconnected. Thus, in the operation shown in Fig.5, it is necessary to re-select a PGW, during when the UE is not performing packet communication, 30 that is, during ECM (EPS Connection Management)- IDLE time).

[0060]

Fig.5 shows the operation when an SGW is changed. However, even in case an SGW is not changed, the basic operation is the same. The message sequence, shown in Fig.5, is explained using message

names for a case where the communication between an SGW and a PGW is implemented in accordance with GTP protocol. However, similar effects may also be obtained in case the communication between the SGW and the PGW is implemented in accordance with PMIP (Proxy Mobile IP) protocol.

[0061]

If, in Fig.5, an SGSN is substituted for an MME, the operation is that of PGW re-selection in case an access network is UMTS.

[0062]

In the present exemplary embodiment, described above, the following operation and advantageous effect may be obtained.

[0063]

The selection of PGW based on the position in which a UE resides becomes possible. Since a PGW which is of a physically short distance from the UE or network-topologically close to the UE is selected and connected to the UE, network resources may be optimized by efficient connection.

[0064]

User data transmission delay may be reduced by efficient path connection between the UE and the PGW.

[0065]

Cooperated with the LIPA/ SIPTO architecture, it becomes possible to provide packet communication services without user data being taken into the EPC. Hence, it becomes possible for a mobile communication operator to reduce a load of an EPC network apparatus.

[0066]

<Exemplary Embodiment 2>

The following describes a second exemplary embodiment of the present invention with reference to Fig.6. On receipt of a TA update request (TA Update Request), sent from a terminal (UE), MME examines whether or not a PGW, to which the UE is connected, is appropriate.

[0067]

Fig.6 shows a status in which a UE is connected to a PGW (1)

(an EPS bearer established between the UE and the PGW (1): EPS bearer originally established).

[0068]

In case the MME decides that re-selection of another suitable PGW is necessary, the MME sets a cause value that urges re-attach in a TA update request (TA Update Request) to send a TA update reject (TA Update Reject) to the UE.

[0069]

In response to the TA update reject (TA Update Reject) from the MME, the UE sends an attach (ATTACH) signal to the MME. On receipt of the TA update reject (TA Update Reject), the MME is able to newly start up a logic for selecting a PGW, as a result of which an optimal PGW is re-selected.

[0070]

In the example of Fig.6, such a case is shown in which a PGW (2) is re-selected to perform a connection procedure to the PGW (2). That is, a create session request (Create Session Request) from the MME is sent to the SGW (2) and the create session request (Create Session Request) is sent from the SGW (2) to the PGW (2). On receipt of a create session response (Create Session Response) from the PGW (2), the SGW (2) sends the create session response to the MME. MME sends a delete session request (Delete Session Request) to the SGW (1). The SGW (1) returns a delete session response (Delete Session Response) to the MME. On receipt of the delete session response, the MME returns TA Update Accept which indicates the completion of TA update, to the terminal (UE).

[0071]

In the present exemplary embodiment, the following operation and advantageous effect may be obtained.

[0072]

In the present exemplary embodiment 2, no impact is imposed on a UE in the first exemplary embodiment, while minimum changes may suffice insofar as the EPC is concerned.

[0073]

<Exemplary Embodiment 3>

The following describes a third exemplary embodiment of the present invention with reference to Fig.7. In the present exemplary embodiment, the usual TA update procedure is slightly changed.

5 [0074]

The sequence shown in Fig.7 is a normal TA update procedure. As a point of change in the present exemplary embodiment, completion of the TA update procedure is notified from an MME to a UE.

[0075]

10 Referring to Fig.7, on receipt of a TA update request (TA Update Request) from the UE, the MME sends a create session request (Create Session Request) to the SGW (2). A modify bearer request (Modify Bearer Request) is sent from the SGW (2) to the PGW (1). On receipt of a create session response (Create Session Response) from the SGW
15 (2), the MME sends a delete session request (Delete Session Request) to the SGW (1). On receipt of the delete session response (Delete Session Response) from the SGW (1), the MME sends a TA update accept (TA Update Accept (PDN)).

[0076]

20 In the present exemplary embodiment, new information, that is, PDN of the TA Update Accept (PDN) in Fig. 7, is added to a TA Update Accept signal to urge re-connection of the packet data network (PDN) which is currently in a connected state.

[0077]

25 On receipt of the TA update accept (TA Update Accept) signal, added by the new information (PDN), the UE recognizes the PDN (packet data network) for re-connection, based on the information specified. It is noted that a plurality of PDNs may sometimes be so added. For the PDN, the UE starts up a UE requested PDN
30 Disconnection processing (processing of disconnection of the PDN as requested by the UE) or a UE requested PDN connectivity processing (processing of connection of the PDN as requested by the UE) to re-connect the packet data network (PDN).

[0078]

In this re-connection of the packet data network (PDN), it is possible for the MME to newly start up the PGW selection logic. As a result, it is necessary to re-select an optimum PGW.

[0079]

5 Fig.7 shows the operation for the case where the SGW is changed. However, even when the SGW is not changed, the basic operation remains the same.

[0080]

The present exemplary embodiment has the following operation and meritorious effect:

[0081]

According to the present exemplary embodiment, PGW re-connection may be made without starting up ATTACH processing (re-attach).

15 [0082]

Starting up ATACH processing means that, if there are a plurality of PDN connections, processing for PGW re-selection is started up for the entire PDN connections, and hence the processing of a relatively large scale is invoked.

20 [0083]

With the present exemplary embodiment, in contrast, only the re-selection of the PGW needed may be made by EPC startup.

[0084]

<Exemplary Embodiment 4>

25 The following described a fourth exemplary embodiment of the present invention with reference to Fig.8. In the fourth exemplary embodiment of the present invention, PGW re-selection, which may be started up by the EPC (MME) at an optional timing, is made in a manner not dependent upon the TA update procedure carried out by the
30 UE. If, when the MME is in a connected state, PGW re-selection is decided to be necessary, a Page signal is sent to the UE and the connection with the UE is tried.

[0085]

It is noted that the cause information (reason information) is

added as an option to the Page signal. See Page (cause) of Fig.8. The UE is allowed to neglect this Page signal (Page signal with the cause information). This is a measure taken in order to avoid battery consumption in the UE caused by iterative execution of this processing.

[0086]

Inherently, the Page signal is a signal used for notification of an incoming call. In contrast, the Page signal, sent in case PGW re-selection is needed, is for enhancing the efficiency of the connection path in the EPC, such that it may not be said to be an indispensable operation. On receipt of this Page signal, the UE sends a service request (Service request) signal to the MME for communication therewith. The MME sends a deactivate bearer request (Deactivate Bearer request) from the MME to the eNodeB. The eNodeB sends an RRC connection reconfiguration. On receipt of a notification of completion of the RRC connection reconfiguration from the UE, the eNodeB sends a deactivate bearer response (Deactivate Bearer Response) to the MME.

[0087]

The MME then disconnects the connection of the packet data network (PDN), for which PGW re-selection is necessary, to induce the procedure of UE requested packet data network connection from the UE (UE requested PDN connectivity).

[0088]

By carrying out this procedure, it becomes possible for the MME to newly start up the PGW selection logic. Thus, as a result, re-selection of suitable PGW becomes necessary. For this procedure, the EPC (MME) is able to start up PGW re-connection at an optional timing. In this case, O&M (Operation and Maintenance), LIPA or SIPTO connection/ disconnection may be used as a trigger.

[0089]

In the present exemplary embodiment, such operation and meritorious effect may be obtained that the MME may re-select PGW at an optional timing.

78792-13EPH

18

[0090]

<Exemplary Embodiment 5>

The following describes a utilization example of the present invention to a LIPA or SIPTO architecture. Figs.9 and 10 show the arrangement of the present exemplary embodiment.

[0091]

Referring to Fig.9, UE1 to UE3 are mobile phone apparatuses. eNodeB 11 and 12 are LTE base stations. NodeB 21 and RNC 31 are apparatuses for radio access (Radio Access) adopted by the UMTS system. An MME 41 is an apparatus introduced by EPC to manage the mobility. An SGSN 51 is a serving apparatus used for the UMTS, and may or may not handle a user plane depending upon connection configurations. In case the SGSN does not handle a user plane, the user plane is set between the SGW and the RNC.

15 [0092]

SGWs 61 and 62 are apparatuses inside the service range that handle the user plane. The PGW 71 and 72 are gateway apparatuses that interconnect the external network (service network 81 in Fig.9) and the EPC. LPGW (Local PGW 91 and 92) are gateway apparatuses that share certain portions in common with the eNodeB or that are located extremely close to the eNodeB and to allow connection to the service network 81.

[0093]

In Fig.10, UE1 and UE2 are mobile phone apparatuses. NodeB 21 and 22 and RNC 31 and 32 are apparatuses for radio access adopted in the UMTS system. SGSNs 61 and 62 are serving apparatuses and may or may not handle the user plane depending upon connection configurations. In case the SGSN does not handle a user plane, the user plane is set between the GGSN and RNC. It is noted that the configuration in which the user plane is set between the GGSN and RNC is called the 'direct tunnel connection'.

[0094]

GGSNs 71 and 72 are gateway apparatuses that interconnect the external network (service network 81 in Fig.10) and GPRS (General

78792-13EPH

19

Packet Radio Service) network.

[0095]

LGGSNs (Local GGSNs (Gateway GPRS Support Nodes)) 101 and 102 are gateway apparatuses that share certain portions in common with or are located extremely close to the RNCs (Radio Network Controllers) and that allow for connection to the service network 81.

[0096]

The following describes the operation of the fifth exemplary embodiment shown in Fig.9, with reference to the sequence diagram shown in Fig.11.

[0097]

The MME receives a TA update request (TA Update Request) from the UE. In case the architecture is that of LIPA or SIPTO, the TA update request (TA Update Request) signal from the eNodeB to the MME is encapsulated in the S1-AP message for transmission.

[0098]

At this time, the eNodeB notifies the MME on the S1-AP message of the fact that PDN connection may be set by the LIPA/SIPTO architecture.

20 [0099]

In case the MME decides that the SGW needs to be changed, it sends a create session request (Create Session Request) to the SGW (2) which is a change-target SGW.

[0100]

25 In case the MME decides that re-arrangement to LPGW is necessary, the MME selects an LPGW that may efficiently be connected to the external network (service network 81), and sets address information that designates the PGW, in the create session request (Create Session Request). It is noted that the above mentioned notification on the S1-AP message that PDN connection may be set by the LIPA/SIPTO architecture is by way of illustration only such that it is also possible for the MME to decide on the necessity for re-selection based on some other information.

30

[0101]

On receipt of a new PGW address, the SGW (2) sends a create session request (Create Session Request) to the LPGW. On receipt of the create session request (Create Session Request), the LPGW creates
5 a bearer context (Bearer Context).

[0102]

The LPGW assigns a new IP address for the user to the UE.

[0103]

On completion of assignment of the new IP address for the user
10 and creation of the bearer context (Bearer Context), the LPGW sends a create session response (Create Session Response) to the SGW (2).

[0104]

On receipt of the create session response (Create Session Response), the SGW (2) sends a delete session request (Delete Session
15 Request) to the PGW(1).

[0105]

The PGW (1) deletes the bearer context (Bearer Context) and sends a delete session response (Delete Session Response) to the SGW
(2).

20 [0106]

On receipt of the delete session response (Delete Session Response), the SGW (2) sends a create session response (Create Session Response) to the MME.

[0107]

25 On receipt of the normal response from the LPGW, the MME sends a delete session request (Delete Session Request) to the SGW (1), a change-source SGW.

[0108]

After deleting the bearer context (Bearer Context), the SGW (1)
30 sends a delete session response (Delete Session Response) to the MME.

[0109]

On receipt of the delete session response (Delete Session Response), the MME sends TA accept (TA Accept) to the UE. In this

TA accept (TA Accept), IP address information, newly assigned to the user, is set and notified of the UE.

[0110]

The foregoing description is for the case of using GTPv2
5 protocol between the SGW and the PGW. Similar functions may, however, be implemented using PMIPv6.

[0111]

In this case, Proxy Binding Update is used in place of the create session request (Create Session Request)/ delete session request
10 (Delete Session Request). Also, proxy binding acknowledgement (Proxy Binding Acknowledgement) is used in place of the create session response (Create Session Response)/ delete session response (Delete Session Response).

[0112]

15 The sequence for LPGW re-selection is shown in Fig.11. However, if the above function is to be implemented, it is necessary for the MME to re-select the PGW at an appropriate timing.

[0113]

If, when the UE is engaged in packet communication, it is tried
20 to change the PGW connected to the service network, the information such as the IP address is changed for the UE's counterpart of communication. As a result, the packet communication by the UE is disconnected. Thus, in the sequence operation shown in Fig.11, it is necessary to re-select the PGW when the UE is not engaged in packet
25 communication. That is, PGW re-selection is to be made during the ECM-IDLE time.

[0114]

Fig.11 shows the operation when the SGW is changed. However, even in case the SGW is not changed, the basic operation is
30 the same. The message sequence, shown in Fig.11, is explained in terms of message names for a case where the communication between the SGW and the PGW is implemented using GTP protocol. However, similar effects may also be obtained in case the communication between the SGW and the PGW is implemented using PMIP protocol.

[0115]

If, in Fig.11, the MME is substituted by the SGSN, and the eNodeB is substituted by RNC, the operation is that of PGW re-selection in case the access network is the UMTS.

5 [0116]

In the present exemplary embodiment, as described above, packet communication services may be extended by LPGW re-selection as no user traffic is taken into the EPC. Hence, a mobile communication operator is able to reduce a load of an EPC network apparatus.

[0117]

<Exemplary Embodiment 6>

Following describes a sixth exemplary embodiment of the present invention will now be described. The configuration of the present exemplary embodiment is that as shown Fig.9. The following describes the operation of the present exemplary embodiment will now be set out with reference to Fig. 12.

[0118]

The MME receives a TA update request (TA Update Request) from the UE. In the case of the LIPA/ SIPTO architecture, a TA update request (TA Update Request) signal is encapsulated in the S1-AP message for communication from the eNodeB to the ME. The eNodeB sends to the MME a notification on the S1-AP message to the effect that PDN connection may be set based on the LIPA/ SIPTO architecture.

[0119]

The MME examines whether or not the PGW, the UE in question is connected to, is appropriate. It is noted that the above mentioned notification on the S1-AP message that setting of PDN connection by the LIPA/ SIPTO architecture is possible is by way of illustration only such that it is also possible for the MME to decide on the necessity for re-selection of a new PGW based on some other information.

[0120]

Fig.12 shows a state in which the UE is connected to PGW (1) (EPS bearer originally established from the UE to the PGW (1)). In case the MME decides that LPGW re-selection is necessary, it sets a cause value that urges re-attach (ATTACH) in the TA update request (TA Update Request) and returns a TA update reject (TA Update Reject) to the UE.

[0121]

The UE is induced by the TA update reject (TA Update Reject) to send the ATTACH signal to the MME. This ATTACH signal is also encapsulated in the S1-AP message for transmission. The eNodeB sends to the MME a notification on the S1-AP message to the effect that PDN connection may be set based on the LIPA/ SIPTO architecture.

[0122]

It is now possible for the MME to newly start up the PGW selection logic. As a result, it becomes necessary to re-select LPGW.

[0123]

Fig.12 shows an example connection processing to LPGW re-selected. A create session request (Create Session Request) from the MME to the SGW (2) and LPGW, a create session response (Create Session Response) from the LPGW to the SGW (2) and MME, a delete session request (Delete Session Request) from the MME to the SGW (1), a delete session response (Delete Session Response) from the SGW (1) to the MME and a TA update accept from the MME to the UE, are sent.

[0124]

In the present exemplary embodiment, as described above, packet communication services may be extended by LPGW re-selection as no user traffic is taken into EPC. Hence, a mobile communication operator is able to reduce a load of an EPC network apparatus.

[0125]

<Exemplary Embodiment 7>

The following describes a seventh exemplary embodiment of the present invention will now be described. The configuration of the

present exemplary embodiment is that as shown Fig.9. The operation of the present exemplary embodiment will now be described with reference to Fig.13. In the present exemplary embodiment, the regular TA update procedure is changed.

5 [0126]

The MME receives a TA update request (TA Update Request) from the UE. It is noted that, in the case of the LIPA/ SIPTO architecture, the TA update request (TA Update Request) signal from the eNodeB to the MME is encapsulated in the S1-AP message for
10 transmission.

[0127]

At this time, a notification is sent on the S1-AP message to the MME to the effect that PDN connection may be set based on the LIPA/ SIPTO architecture. It is noted however that the notification sent on
15 the S1-AP message to the effect that PDN connection may be set based on the LIPA/ SIPTO architecture is by way of illustration only such that it is also possible for the MME to decide on the necessity for re-selection of a new PGW based on some other information.

[0128]

20 The TA update accept (TA Update Accept) signal that notifies the completion of the TA update procedure from the MME to the UE is added by new information (PDN in Fig.13) to urge re-connection of the packet data network (PDN) which is currently in a connected state. On receipt of the TA update accept (TA Update Accept) signal added
25 by the new information (PDN), the UE recognizes the PDN (packet data network) for re-connection, based on the information specified. It is noted that a plurality of PDNs may sometimes be so added. For the PDN in question, the UE starts up the conventional UE requested PDN connection processing or the UE requested PDN connectivity
30 processing to re-connect the packet data network (PDN).

[0129]

In this re-connection of the packet data network (PDN), it is possible for the MME to newly start up the PGW selection logic, as a result of which it becomes necessary to re-select an optimum PGW.

78792-13EPPH

25

[0130]

The operation for the case where the SGW is to be changed has been explained with reference to Fig.13. However, even when the SGW is not changed, the basic operation remains the same.

5 [0131]

In the present exemplary embodiment, as described above, packet communication services may be extended by LPGW re-selection as no user traffic is taken into EPC. Hence, mobile communication operator is able to reduce a load of an EPC network apparatus.

10 [0132]

<Exemplary Embodiment 8>

The following describes an eighth exemplary embodiment of the present invention. The configuration of the present exemplary embodiment is that as shown Fig.10. The operation of the present
15 exemplary embodiment will now be described with reference to Fig.14.

[0133]

The SGSN (Serving GPRS Support Node) receives an RA (Routing Area) update request (RA Update Request) from the UE. In
20 the case of the LIPA/ SIPTO architecture, the RA update request signal from the NodeB to the SGSN is encapsulated in a RANUP (Radio Access Network Access Part) message for transmission. The RRC sends to the SGSN a notification on the RANAP message to the effect that PDN connection may be set based on the LIPA/ SIPTO
25 architecture.

[0134]

The SGSN examines whether or not the GGSN (Gateway GPRS Support Node), the UE in question is connected to, is appropriate. It is noted that the above mentioned notification on the RANAP message
30 that PDN connection setting by the LIPA/ SIPTO architecture is possible is only by way of illustration. That is, it is also possible for the MME to decide on the necessity for re-selection of a new PGW based on some other information.

[0135]

Fig.14 shows a state in which the UE is connected to GGSN (GTP tunnel connection is established between UE and GGSN: see 'GTP Tunneling originally established' of Fig.14).

[0136]

5 In case the SGSN decides that LGGSN re-selection is necessary, the SGSN sets a reason value (cause value) that urges re-attach (ATTACH) in the RA update request (RA Update Request) to send back an RA update reject (RA Update Reject) signal to the UE.

[0137]

10 The UE is caused by the RA update reject (RA Update Reject) signal to send the ATTACH signal to the SGSN to try to re-attach (ATTACH) to the GPRS network. The SGSN sends an RA update request (RA Update Request) to an HLR (Home Location Register). An insert subscriber data (Insert Subscriber data) is sent from the HLR
15 to the GGSN. The GGSN sends back an insert subscriber data acknowledge (Insert Subscriber data ack) response to the HLR. On receipt of the ack response (ack), the HLR sends back an RA update response (RA Update Response) to the SGSN. The SGSN sends back an ATTACH accept (ATTACH Accept) to the UE.

20 [0138]

The UE then sends a request for activating PDP context (Activate PDP context request), requesting PDP (Packet Data Protocol) connection, to the SGSN.

[0139]

25 On receipt of the request for activating PDP context (Activate PDP context request), the SGSN decides whether or not the connection to LGGSN is appropriate. When the SGSN decides that the connection to LGGSN is appropriate, the SGSN performs creation of a GTP (GPRS Tunneling Protocol) tunnel to the LGGSN (Create PDP
30 context request). The Create PDP context request is sent back from the LGGSN to the SGSN, and a PDP context activate response (Activate PDP context response) is sent back from SGSN to the UE to enable connection between UE and LGGSN.

[0140]

In the present exemplary embodiment, as described above, packet communication services may be extended by LPGW re-selection as no user traffic is taken into the EPC. Hence, a mobile communication operator is able to reduce a load of a GPRS network apparatus.

[0141]

The particular exemplary embodiments or examples may be changed or adjusted within the gamut of the entire disclosure of the present invention, inclusive of claims, based on the fundamental technical concept of the invention. Further, variegated combinations or selection of elements disclosed herein may be made within the framework of the claims. That is, the present invention may encompass various modifications or corrections that may occur to those skilled in the art in accordance with and within the gamut of the entire disclosure of the present invention, inclusive of claim and the technical concept of the present invention.

CLAIMS:

1. A communication method for Local IP Access (LIPA) or Selected IP Traffic Offload (SIPTO) architecture, the method comprising:

5 a mobility management entity (MME) paging a user equipment, on a case where the MME decides that it is necessary to relocate a gateway apparatus;

the user equipment transmitting a service request signal to the MME;

the MME sending a deactivate bearer request to a base station for requesting the relocation;

10 the base station transmitting a radio resource control (RRC) connection reconfiguration to the user equipment on receipt of the deactivate bearer request;

the user equipment transmitting a notification of completion of the RRC connection reconfiguration to the base station;

the base station transmitting a deactivate bearer response to the MME on receipt of the notification;

15 the user equipment initiating a UE requested packet data network (PDN) connectivity procedure; and

a new packet data network gateway apparatus (PGW) being selected in the UE requested PDN connectivity procedure.

2. The communication method according to claim 1, wherein a new serving gateway apparatus (SGW) is further selected in the UE requested PDN connectivity procedure.

3. A communication system for a Local IP Access (LIPA) or Selected IP Traffic Offload (SIPTO) architecture, the system comprising:

a user equipment;

78792-13EPPH

29

a mobility management entity (MME) for managing a mobility of the user equipment; and

a base station for connecting to the user equipment;

wherein

5 the MME pages the user equipment, on a case where the MME decides that it is necessary to relocate a gateway apparatus,

the user equipment transmits a service request signal to the MME,

the MME sends a deactivate bearer request to the base station for requesting the relocation,

10 the base station, on receipt of the deactivate bearer request, transmits a radio resource control (RRC) connection reconfiguration to the user equipment,

the user equipment transmits a notification of completion of the RRC connection reconfiguration to the base station,

the base station transmits a deactivate bearer response to the MME, and

15 the user equipment initiates a UE requested packet data network (PDN) connectivity procedure,

a new packet data network gateway apparatus (PGW) being selected in the UE requested PDN connectivity procedure.

4. The communication system according to claim 3, wherein a new serving
20 gateway apparatus (SGW) is further selected in the UE requested PDN connectivity procedure.

5. A user equipment for Local IP Access (LIPA) or Selected IP Traffic Offload (SIPTO) architecture, the user equipment comprising:

78792-13EPPH

30

means for transmitting a service request signal to a mobility management entity (MME), in response to paging from the MME; and

means for sending, on receipt of a radio resource control (RRC) connection reconfiguration from a base station, a notification of completion of the RRC connection
5 reconfiguration to the base station to initiate a UE requested packet data network (PDN) connectivity procedure,

wherein a new packet data network gateway apparatus (PGW) is selected in the UE requested PDN connectivity procedure.

6. The user equipment according to claim 5, wherein a new serving gateway
10 apparatus (SGW) is further selected in the UE requested PDN connectivity procedure.
