(57) **ABSTRACT**

A low cost, low phase noise microwave synthesizer includes a DDS modulation circuit and a phase-locked loop. The DDS modulation circuit modulates the output of a DDS to a high frequency. The phase-locked loop downconverts the DDS output and locks the downconverted signal to a relatively low frequency, fixed reference.

### (F) BACKGROUND OF THE INVENTION

#### 1. Field of the Invention

This invention relates generally to automatic test equipment for electronics (ATE) and, more particularly, to the synthesis of low-noise, high frequency periodic signals for testing microwave and RF circuitry.

#### 2. Description of Related Art

Improvements in high-frequency electronic devices for consumer products such as cellular telephones, pagers, and wireless personal data assistants (PDAs), have given rise to a need for improved electronic testing. At the same time, pressures have been applied to product manufacturers to reduce testing costs.

An important component in the testing of high-frequency electronic devices is the microwave synthesizer. As is known, "synthesizers" are electronic instruments that generate test signals of variable frequency. The test signals are generally single frequency "tones" having low noise. Modern synthesizers include programmable electronics that afford them high frequency resolution over a wide range of frequencies. "Microwave synthesizers" are synthesizers that produce output signals in the microwave frequency band, i.e., in the vicinity of 1 Gigahertz ( $10^9$ ) or higher.

A common type of test for a high frequency device involves measuring the electronic noise that the device produces. To perform this type of test, the device under test, or "DUT," is connected to a test system, or "tester." The tester generally includes power supplies, a microwave synthesizer, and a sampling instrument. Under control of a test program, the tester activates the power supplies to apply power to the DUT, enables the synthesizer to apply an input signal to the DUT, and enables the sampling instrument to measure an output signal from the DUT. Noise on the output signal is then measured, and measured noise is compared with test limits to determine whether the DUT's noise performance is within the test limits.

For many high-frequency devices, the output signals from the DUT are generally a function of the input signals applied to the DUT. For example, if the input signal has a frequency FIN, the output generally also has the frequency FIN, or a multiple thereof. The exact input-output relationship depends upon the type of device being tested, but some numerical

2

relationship between input and output is almost always present. This being the case, any noise produced by the synthesizer may appear at the output signal. This noise creates an uncertainty in any noise measurement of the DUT, since it is not clear whether the noise being measured is produced by the DUT or injected by the synthesizer.

Therefore, the noise of the synthesizer is a most important specification. By reducing this noise, measurement uncertainties are correspondingly reduced, and the quality of testing is improved.

Because many electronic devices employ some sort of phase modulation scheme, it is particularly critical that synthesizers produce low phase noise. As is known, "phase noise" refers to variations in the phase of signals produced by a device. Phase noise can alternatively be viewed as timing jitter.

Test system developers have sought to develop microwave synthesizers with low phase noise. Their efforts have often entailed developing synthesizers consisting of multiple, adjustable phase-locked loop circuits that operate in unison.

FIG. 1 shows an example of a conventional multi-loop synthesizer **100**. The synthesizer **100** shows a synthesizer having three loops; however, it should be understood that multi-loop designs may include a greater or lesser number of loops, as the target application requires.

In the multi-loop synthesizer **100** of FIG. 1, a main phase-locked loop **102** receives a baseband input signal (Baseband In) and produces a microwave output signal (RFOUT). The main phase-locked loop **102** includes a phase comparator **110**, a loop filter/amplifier **112**, and a VCO (voltage-controlled oscillator) **114**, in its forward path, and a series of mixers **116/120** and filters/amplifiers **118/122** in its feedback path.

Additional phase-locked loops **104** and **106** are provided to generate additional high frequency signals. The phase-locked loops **104** and **106** each include a phase comparator **134/154**, a loop filter/amplifier **136/156**, a VCO **138/158**, and a feedback divider **140/160**. Input dividers **132/152** are provided to respectively divide an input signal from a clock source **130**.

The outputs of the phase-locked loops **104** and **106** are coupled to the mixers **116** and **120** in the main loop **102**. The mixers **116** and **120** successively downconvert RFOUT, to produce a much lower frequency feedback signal. The phase detector **110** compares the relatively low frequency feedback signal with Baseband In, and the operation of the loop **102** tends to force the feedback signal to a frequency that equals Baseband In.

To program a desired output frequency, RFOUT, both coarse and fine adjustments are made. The dividers **132**, **152**, **140**, and **160** of loops **104** and **106** are adjusted to establish a coarse output frequency. Baseband In is adjusted, e.g., by programming a direct digital synthesis device (DDS) to tune between the coarse frequency settings made by the dividers.

Many design features of the multi-loop synthesizer **100** promote low phase noise. For example, the clock source **130** is generally a low noise, fixed frequency reference, such as a crystal oscillator. The filters/amplifiers **136** and **156** generally have long time constants, for reducing noise injected into the mixers **116** and **120** of the main loop **102**. The main loop **102** is generally free of frequency division, which tends to reduce noise amplification.

The significant benefits of the multi-loop design **100** come at a cost, however. The component count of the circuit is high, and many filters are required. These filters are costly and occupy a large amount of space. In addition, because the

multi-loop synthesizer **100** includes multiple feedback circuits that interact, the settling time of the synthesizer **100** is sometimes difficult to predict.

What is needed is a microwave synthesizer that has low phase noise, has predictable settling characteristics, and can be built at lower cost than multi-loop designs.

#### (G) BRIEF SUMMARY OF THE INVENTION

In accordance with one embodiment of the invention, a microwave synthesizer includes a reference oscillator for generating a reference frequency, a DDS modulation circuit for generating a modulated DDS signal, and a phase-locked loop circuit, coupled to the reference oscillator and the DDS modulation circuit, for generating a variable frequency output signal. The phase-locked loop circuit includes a phase comparison circuit having a first input coupled to the reference oscillator, a second input for receiving a feedback signal, and an output. The phase-locked loop circuit further includes a controllable oscillator having a control input coupled to the output of the phase comparison circuit and an output for generating the variable frequency output signal. In addition, the phase-locked loop circuit includes a mixer circuit having a first input coupled to the DDS modulation circuit, a second input coupled to the output of the controllable oscillator, and an output coupled to the second input of the phase comparison circuit.

In accordance with another embodiment of the invention, a microwave synthesizer includes a phase comparison circuit having a first input for receiving a reference frequency, a second input for receiving a feedback signal, and an output. Also included is a controllable oscillator having a control input coupled to the output of the phase comparison circuit and an output for generating a variable frequency output signal. Further included is a programmable divider having an input coupled to the output of the controllable oscillator and an output for providing a divided signal. The microwave synthesizer still further includes a mixer circuit having a first input adapted for receiving a modulated signal, a second input coupled to the output of the programmable divider, and an output coupled to the second input of the phase comparison circuit for providing the feedback signal.

In accordance with a further embodiment of the invention, a microwave synthesizer includes a reference oscillator for generating a reference frequency. The microwave synthesizer includes a plurality of frequency multiplying units is coupled to the reference oscillator for generating respective output signals each at a different multiple of the reference frequency. Further included is a first DDS unit having a clock input coupled to the plurality of frequency multiplying units and an output for generating a first DDS signal having a programmable frequency and a first phase. In addition, the microwave synthesizer includes a second DDS unit having a clock input coupled to the plurality of frequency multiplying units and an output for generating a second DDS signal having the programmable frequency and a second phase different from the first phase. A quadrature mixer circuit has a first and second inputs respectively coupled to the outputs of the first and second DDS circuits, a third input coupled to the plurality of frequency multiplying units, and an output. The microwave synthesizer further includes a phase-locked loop circuit, having a first input coupled to the reference oscillator, a second

input coupled and to the output of the quadrature mixer circuit, and an output for providing a variable frequency output signal.

#### (H) BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWINGS

Novel features of the invention will become apparent from consideration of the ensuing description and drawings, in which—

FIG. **1** is a simplified schematic of a multi-loop microwave synthesizer according to the prior art;

FIG. **2** is a simplified schematic of a microwave synthesizer according to an embodiment of the invention;

FIG. **3** is a schematic of an embodiment of a frequency reference source, which can be used in the synthesizer of FIG. **2**;

FIG. **4** is a schematic of an embodiment of a circuit for generating a high-frequency local oscillator (LO), which can be used in the synthesizer of FIG. **2**;

FIG. **5** is a schematic of an embodiment of a DDS circuit for generating quadrature DDS signals, which can be used in the synthesizer of FIG. **2**;

FIG. **6** is a schematic of an embodiment of a single side-band upconverter, for receiving quadrature DDS signals shown in FIG. **5**;

FIG. **7** is a schematic of an embodiment of a main PLL circuit shown in FIG. **2**;

FIG. **8** is a flowchart showing a process for programming the synthesizer of FIG. **2**;

FIG. **9** is a flowchart showing a process for dithering two DDS values for outputting a frequency corresponding to a value between the two DDS values in the circuit of FIG. **2**; and

FIG. **10** is a flowchart showing a process for calibrating the synthesizer of FIG. **2**, when it is configured with the quadrature DDS shown in FIG. **5**.

#### (I) DETAILED DESCRIPTION OF THE INVENTION

As used throughout this document, the words such “comprising,” “including,” and “having” are intended to set forth certain items, steps, elements, or aspects of something in an open-ended fashion. Unless a specific statement is made to the contrary, these words do not indicate a closed list to which additional things cannot be added.

FIG. **2** shows a microwave synthesizer **200** according to an illustrative embodiment of the invention. The microwave synthesizer **200** includes a reference oscillator **210**, a DDS modulation circuit **212**, a phase-locked loop circuit **214**, an output conditioning circuit **216**, and a controller **260**. The controller **260** provides inputs to and receives outputs from the DDS modulation circuit **212**, phase-locked loop circuit **214**, and output conditioning circuit **216**, for controlling these circuits and optionally reading information back from these circuits.

The DDS modulation circuit **212** preferably includes a plurality of local oscillators **220a-220n**. Each local oscillator preferably has an input coupled to the reference oscillator **210**, and an output for providing a signal whose frequency is a multiple of the reference frequency. The output frequencies of the different local oscillators **220a-220n** are preferably different from one another. The local oscillators **220a-220n** are coupled to the inputs of a pair of selectors **222** and **224**. Each selector **222/224** preferably has “n” inputs, one for each of the “n” local oscillators. Each selector is configured to convey one of the signals at its “n” inputs to its output, under control of the controller **260**. The selector **222** has an output

5

coupled to a frequency divider **226**, which, in turn, has an output, DDS CLK, connected to the clock input of a DDS circuit **228**. The DDS circuit **228** has an output, DDS OUT, coupled to a first input of a mixer **230**. The selector **224** has an output (LO) coupled to a second input of the mixer **230**. The selectors **222** and **224** are preferably implemented with RF switches. A selectable filter **232** is optionally coupled to the output of the mixer **230**. The filter **232** is preferably configurable as either a low pass filter or a high pass filter. The output of the filter **232** conveys a modulated DDS signal, DDS MOD, to the phase-locked loop circuit **214**.

The phase-locked loop circuit **214** includes a phase comparator **240**, a loop filter **242**, and a controllable oscillator **244**. A crossover switch **238** is preferably provided at the input of the phase comparator **240**. The crossover switch has a first input coupled to the reference oscillator and a second input for receiving a feedback signal. It also has two outputs coupled to first and second inputs of the phase comparator **240**. The crossover switch **238** has two modes: a pass-through mode in which inputs are passed directly to outputs (input **1** to output **1** and input **2** to output **2**), and a crossover mode in which inputs are crossed (input **1** to output **2** and input **2** to output **1**). The crossover switch **238** maybe provided as a distinct element, or it may be integrated with the phase comparator **240**.

The crossover switch **238** allows the polarity of the phase comparator **240** to be reversed. This ability affords the synthesizer **200** with greater flexibility for locking.

The phase-locked loop circuit **214** also includes a programmable divider **246**, a mixer **248**, and a low-pass filter **250**. The programmable divider **246** has an input coupled to the output of the controllable oscillator **244**, and an output coupled to a first input of the mixer **248**. The mixer **248** has a second input coupled to the DDS modulation circuit, for receiving DDS MOD. The mixer **248** has an output coupled to the low pass filter **250**, which in turn has an output coupled to the second input of the crossover switch **238**.

The output of the phase-locked loop circuit **214**, PLL OUT, is coupled to the output conditioning circuit **216**. The output conditioning circuit includes one or more programmable dividers **252** and a filter bank **254**.

The microwave synthesizer **200** preferably operates in synchronization with the reference oscillator **210**. Within the DDS modulation circuit **212**, the local oscillators **220a-220n** each receive a reference frequency FREF from the reference oscillator **210** and produce an output signal whose frequency is a multiple of the reference frequency. The selector **222** is operated to select an output signal from one of the local oscillators **220a-220n** for input to the divider **226**. Similarly, the selector **224** is operated to select that output signal an output of one of the local oscillators for input to the mixer **230**.

With the selectors **222/224** and the divider **226** set to desired values, the DDS circuit **228** is programmed to produce DDS OUT at a desired frequency. The mixer **230** mixes DDS OUT with LO from the selector **224**. The frequency content of the mixer's output thus generally includes a carrier component, LO, and upper and lower sidebands offset from the carrier by the frequency of DDS OUT. The selectable filter **232** preferably filters the output of the mixer **230** to select either the lower sideband or the upper sideband to yield DDS MOD, which is then passed to the phase-locked loop circuit **214**.

Within the phase-locked loop circuit **214**, the output of the controllable oscillator **244**, PLL OUT, provides frequencies in the microwave range. The programmable divider **246** reduces these frequencies, and the mixer **248** downconverts

6

the output of the divider **246**. The output of the mixer **248** thus generally includes the divided PLL OUT frequency with sidebands offset by the frequency of DDS MOD. The low pass filter **250** filters the higher mixing products produced by the mixers **230** and **248**. Since the low pass filter **250** provides the feedback signal, the loop's negative feedback tends to drive the lower sideband of the mixer **248** to the reference frequency, FREF, and therefore tends to drive PLL OUT to a predetermined microwave frequency. The frequency of PLL OUT can then be divided and filtered as desired to produce arbitrarily lower frequencies.

Algebraically, DDS MOD can be represented as (LO+DDS OUT) or (LO-DDS OUT), depending on the settings of the filter **232**. If the programmable divider **246** has a division factor of D and the crossover switch **238** is configured in its pass-through mode, the sideband to which the phase comparator **240** locks has a frequency of either

$$(PLL\ OUT)/D-(LO+DDS\ OUT)\ or$$

$$(PLL\ OUT)/D-(LO-DDS\ OUT).$$

The crossover switch **238** allows the loop to maintain negative feedback and lock when the synthesizer is pre-tuned and configured to produce (PLL OUT)/D at a lower frequency than DDS MOD. By configuring the crossover switch **238** to its crossover mode, the sideband to which the phase comparator **240** locks has the following additional frequencies:

$$(LO+DDS\ OUT)-(PLL\ OUT)/D\ and$$

$$(LO-DDS\ OUT)-(PLL\ OUT)/D.$$

Since feedback forces each of the above expressions to equal the reference frequency, we can solve for PLL OUT to yield four possibilities, as follows:

$$PLL\ OUT=D*(LO+DDS\ OUT+FREF)$$

$$PLL\ OUT=D*(LO-DDS\ OUT+FREF)$$

$$PLL\ OUT=D*(LO+DDS\ OUT-FREF)\ or$$

$$PLL\ OUT=D*(LO-DDS\ OUT-FREF).$$

It is apparent that a proper selection of values for D, FREF, LO, and DDS OUT can yield a wide frequency range for PLL OUT, which translates into a wide frequency range for the microwave synthesizer **200**.

FIG. 3 shows an illustrative embodiment of the reference oscillator **210**. The oscillator includes a phase-locked loop driven from a system clock. The phase-locked loop includes a phase-frequency detector **310**, a loop filter **312**, and a controllable oscillator **314**. As is known, a phase-frequency detector is a type of phase detector that can detect a mismatch in frequency as well as phase between its input signals. The phase-frequency detector **310** has a first input that receives the system clock and a second input that provides a feedback signal from the controllable oscillator **314**. The phase-locked loop thus provides a filtered and purified version of the system clock.

The system clock is preferably a signal distributed to different equipment in an ATE system for synchronizing operation. It may be a digital clock or an analog clock. The exact frequency is not critical. The loop filter **312** preferably has a very low bandwidth for strongly filtering phase noise within the loop. The controllable oscillator **314** is preferably a voltage-controlled crystal oscillator, such as a low cost, ceramic resonator.

FIG. 4 shows an illustrative embodiment of a local oscillator (any of **220a-220n**). Only a single oscillator is shown,

but the circuit topology is representative of each of the oscillators **220a-220n**. The local oscillator receives the filtered clock signal, FREF, and produces an output signal whose frequency is a multiple of FREF. The local oscillator is constructed as a phase-locked loop; however, a sampling phase detector **410** is used in place of the conventional phase detector or phase-frequency detector. As is known, a sampling phase detector employs a step recovery diode capacitively coupled to a Schottky diode pair mixer. The step recovery diode generates harmonics of the input reference signal (here, FREF), and the Schottky diode pair acts as a phase detector. The sampling phase detector can selectively lock on a harmonic and enables the phase-locked loop to achieve frequency multiplication of the input reference without the need for a feedback divider. As is known, eliminating the feedback divider in a sampling phase detector based phase-locked loop not only avoids the noise contribution of the divider but also multiplication of the phase detector noise. Avoiding dividers in the local oscillators **220a-220n** thus improves performance. In place of the sampling phase detector **410**, a comb generator loop can be used.

FIGS. **5** and **6** show an embodiment of the DDS circuit **228** and mixer **230**. This embodiment is particularly preferred, because of its low cost, flexibility, and simplicity of integration in the synthesizer **200**. This embodiment exploits a trend in the telecommunications industry toward processing signals analytically, i.e., in quadrature. As is known, “quadrature” signals represent any frequency as a pair of ninety degree phase-shifted sinusoids. One sinusoid is in-phase, or “I,” and the other is quadrature, or

FIG. **5** shows a quadrature DDS circuit. The quadrature DDS circuit includes a pair of DDS units—one for providing an I signal and one for providing a Q signal. Each DDS unit preferably includes a phase-to-amplitude converter **514/544**, a DAC (digital-to-analog converter) **516/546**, a low pass filter **518/548**, and an output buffer **520/550**. For economy, certain elements can be shared between the DDS units and need not be replicated. For example, only a single phase register **510**, summer **512**, frequency register **540**, and accumulator **542** need be provided.

To operate the quadrature DDS circuit, the controller **260** programs the phase register **510** and frequency register **540** with values. Upon each cycle of DDS CLK, the accumulator **542** adds the contents of the frequency register **540** to its already stored value, to produce an increasing digital output value that corresponds to phase. This output is provided to the phase-to-amplitude converters **514/544**, which convert the increasing phase values to digital amplitude values. The DACs **516/546** then convert the digital amplitude values into analog levels. The filters **518/548** smooth these levels, and the buffers **520/550** output the I and Q signals. Output frequency of I and Q is varied by varying the value stored in the frequency register **540**.

The phase register **510** and summer **512** allow the phase of the I output to be offset with respect to the phase of the Q output. By programming the phase register **510** to a digital value that corresponds to 90 degrees, a phase difference of 90 degrees is established between I and Q. Similarly, by programming the phase register to minus 90 degrees, a negative 90 degree phase difference is established between I and Q.

The quadrature DDS circuit also provides a mechanism for removing errors in and between I and Q. Phase errors can be corrected by adjusting the value stored in the phase register **510**. Gain and offset errors in the DACs can be corrected using analog adjustments provided by the controller **260**. The

quadrature DDS circuit is preferably implemented with a pair of monolithic DDS chips, or with a dual core, monolithic DDS.

FIG. **6** shows the preferred implementation of the mixer **230**, in the form of a quadrature mixer. The quadrature mixer preferably includes a phase splitter **610**, first and second mixers **612** and **614**, a summer **616**, and an output buffer **618**. The phase splitter **610** receives the LO signal from the selector **224** and outputs two versions of the LO signal. Each version has the same frequency as the LO signal, but one of them is delayed 90 degrees relative to the other. The first mixer **612** mixes a non-shifted version of LO with the I signal, and the second mixer **614** mixes a shifted version of LO with the Q signal. The summer **616** combines the outputs of the mixers **612** and **614** to yield an output signal in which in-phase (I) components are summed and quadrature components (Q) are rejected. The output of the summer **616** thus has a frequency that is either the sum or difference of LO and the DDS output frequency, DDS OUT. Other mixing products are suppressed without the need for filtering. The desired sum or difference signal can be changed by reversing the phases of I and Q. Therefore, the quadrature mixer can be made to output either LO+DDS OUT or LO-DDS OUT simply by programming the phase register **510** to either plus 90 degrees or minus 90 degrees.

The quadrature mixer shown in FIG. **6** is also known as a single-sideband upconverter. Single-sideband upconverters are well known in the microwave and telecommunication arts. The advantage of using a single-sideband upconverter in this application is that it provides an easy way of selecting a desired sideband (and thus a desired frequency range) for passage to the phase-locked loop circuit **214**. It also significantly reduces the need for filtering. The selectable filter **232** from FIG. **2** can generally be eliminated when the single-sideband upconverter is used.

FIG. **7** shows an embodiment of the phase-locked loop circuit **214**. It can be seen that the phase comparator **240** has been implemented with a phase-frequency detector **740**. The controllable oscillator **244** is implemented with a YIG oscillator. The divider **246** is implemented with a programmable RF prescaler **746**. The mixer **748** and low pass filter **750** are similar to the mixer **248** and filter **250** of FIG. **2**.

The phase-frequency detector (PFD) **740** allows the phase-locked loop of FIG. **7** to acquire and lock over a relatively wide frequency range, and relaxes the need for pretuning of the YIG oscillator. The PFD is operated at a relatively low frequency (nominally 100 MHz). Inexpensive, low noise, monolithic PFDs are commercially available for use at this frequency.

The YIG oscillator **744** preferably has both coarse tune and fine tune (FM) inputs. The coarse tune inputs are preferably controlled by analog circuitry within the controller **260**, whereas the fine tune inputs are preferably coupled to loop filter/amplifier **742** for locking.

The phase-locked loop circuit of FIG. **7** preferably includes a sampling circuit for sampling the feedback signal provided to the PFD **740**. The sampling circuit includes a switch **736**, an ADC (analog-to-digital converter) **752**, a capture memory **754**, and a DFT (digital Fourier transform) unit **756**. During a calibration operation, the switch **736** is closed and the ADC **752** is made to acquire samples of the feedback signal. These samples are held in the capture memory **754**, and a discrete Fourier transform is performed on the stored samples. Results can be sent to the controller **260** for analysis. This capability allows the noise of the phase-locked loop circuit to be directly measured, and possibly adjusted.

Implementation details of the microwave synthesizer **200** described herein can be varied substantially within the scope of the invention. In the particular preferred embodiment, however, the value of FREF is nominally 100 MHz. The number “n” of local oscillators **220a-220n** is 2. The first local oscillator generates 1.8 GHz and the second local oscillator generates 2.0 GHz. For compatibility with preferred and available DDS units, the divider value M of the divider **226** is preferably 2. Therefore, the value of DDS CLK can be configured to either 900 MHz or 1.0 GHz. The DDS units are preferably tunable in a range between 100 MHz and 300 MHz, making DDS MOD variable between 1.5 GHz and 2.3 GHz, with no gaps. The YIG oscillator **744** is preferably operated over a tuning range between 6.4 and 12.8 GHz, and the programmable RF prescaler preferably provides division ratios of 4, 5, or 6. The small division ratios ensure that noise is kept low, while still satisfying the feedback requirements of the loop over the full range of DDS MOD.

Many of the components used in the synthesizer **200** are commercially available off the shelf. Suitable phase-frequency detectors are available from both Hittite Microwave of Chelmsford, Mass., and ON Semiconductor of Phoenix, Ariz. Sampling phase detectors are available from MicroMetrics of Londonderry, N.H., and Aeroflex/Metelics of Sunnyvale, Calif. Suitable DDS circuits can be obtained from Analog Devices of Norwood, Mass. Single-sideband upconverters can be purchased from Analog Devices, Maxim Integrated Products of Sunnyvale, Calif., Texas Instruments of Dallas, Tex., and Linear Technology of Milpitas, Calif.

FIG. **8** shows a process for programming the microwave synthesizer **200** to provide a desired output frequency. The steps need not be performed in the order shown. At step **810**, the synthesizer accepts a desired output frequency from a user directly or from a test program that has access to the synthesizer. At step **812**, one or more local oscillators are selected. For flexibility, local oscillators **220a-220n**, for providing DDS CLK and LO, are preferably selected independently. At step **814**, a sideband is selected from the single-sideband upconverter. This is generally accomplished by programming the phase of the phase register **510** to either plus or minus 90 degrees and configuring the crossover switch **738** to either pass-through or crossover mode. At step **816**, a prescaler divider value is selected for the programmable RF prescaler **746**. At step **818**, a DDS frequency is programmed. Output dividers and filters are configured at step **820**, and the YIG oscillator **744** is pre-tuned at step **822** to output a frequency within an expected range.

Selection of the local oscillator(s) **220a-220n**, the upper or lower sideband, and the prescaler values are made based primarily on two factors. The first factor is the ability to achieve the desired output frequency. Not all configurations can achieve all desired frequencies. The second factor is minimization of spurious noise. An advantage of the synthesizer **200** is that, in many instances, there are different configurations for achieving the same output frequency. In these instances, the configuration yielding the lowest noise, especially the lowest phase noise, is preferably selected.

The following guidelines may be used in configuring the synthesizer **200** to minimize spurious noise:

1. If the frequency of DDS OUT is close to a subharmonic of one of the LO frequencies, select an LO frequency (e.g., 900 MHz or 1 GHz) for which subharmonics are farther away;

2. If higher order mixing products from the SSB upconverter and/or mixer **248** create close-in spurs at the output of the mixer **248**, perform one of the following:
  - a) Choose a different ratio for the prescaler **246**.
  - b) Invert the polarity of the crossover switch **238**, which may move the problematic spur out of band.
  - c) If neither a) nor b) is feasible, implement a focused calibration to minimize the offending spur. Calibration is described in connection with FIG. **10**, below.
3. If multiple configurations exist (with no close-in spurs) for the same synthesizer output frequency, choose the one that has the lowest DDS output frequency.

FIG. **9** shows a process for using the microwave synthesizer **200** for generating a desired output frequency, when the output frequency cannot directly be programmed. The need for this process arises because the resolution of the DDS circuit is limited and sometimes a desired value falls between the values produced by immediately adjacent DDS levels. According to this process, two directly programmable frequency values that yield frequencies proximate to the desired frequency are dithered. The filtering action of the phase-locked loop circuit **214** averages the dithered values to produce the desired frequency value.

This process is conducted as follows. At step **910**, the synthesizer **200** is configured and the DDS circuit is programmed to produce a first frequency value from the synthesizer, proximate to the desired output frequency. After waiting a first delay interval (step **912**), the DDS circuit is programmed to produce a second frequency value from the synthesizer (step **914**). The second frequency value is also proximate to the desired output frequency, but is on the opposite side of the desired value compared with the first frequency value. After a second delay interval (step **916**), the process is repeated, with different values alternately being programmed. Due to the operation of the phase-locked loop circuit **214**, the output frequency settles upon the time weighted average of the first and second frequency values.

FIG. **10** shows a process for calibrating the microwave synthesizer **200**. As was seen in FIG. **5**, the quadrature DDS circuit includes provisions for adjusting the phase difference between the I and Q output signals, and provisions for adjusting the gain and phase of the DACs **516** and **546**. As was seen in FIG. **7**, the phase-locked loop circuit includes a sampling circuit (switch **736**, ADC **752**, capture memory **754**, and DFT unit **756**). The sampling circuit can be used for measuring noise in the feedback signal of the phase-locked loop circuit **214**. According to the calibration process, the synthesizer **200** is programmed to produce a known output frequency (step **1010**). Once the output frequency has stabilized, the switch **736** is closed and the sampling circuit is made to sample the feedback signal (step **1012**). Spurious noise is measured and examined (step **1014**). At step **1018**, the DDS circuit is adjusted in an attempt to reduce the measured spurious noise. One source of spurious noise is a phase error between I and Q. To minimize noise, the phase register **510** is adjusted (step **1018**) and measurements are repeated. The process of measuring, examining noise, and adjusting the phase is repeated until an acceptable level of noise is achieved. Gain and offset errors of the DACs **516** and **546** also contribute spurious noise. This noise may be addressed in a similar way, by adjusting the gain and/or offset of the DACs and measuring spurious noise. The DACs are then configured with the adjustments yielding acceptable (preferably minimum) levels of noise. The switch **736** is generally opened when calibration is complete.

The synthesizer **200** offers the advantages of low cost and low phase noise. The simplicity of its single-loop design

reduces the amount of hardware needed, as compared with multi-loop designs. Its use of a quadrature DDS and single-sideband upconverter suppresses unwanted sidebands without the need for complex and expensive filters. In using a quadrature DDS and single-sideband upconverter, the synthesizer **200** also exploits a current trend in the wireless telecommunications industry of supplying precise, quadrature devices at low cost. Because the synthesizer **200** requires fewer parts than many competing designs, it can be constructed in a smaller volume. In the preferred embodiment, the synthesizer **200** fits in an instrument slot less than 1.8 cm tall within an ATE system. In addition, the various settings of the synthesizer **200**, such as DDS CLK selection, LO selection, upper or lower sideband selection, YIG frequency, and prescaler values, often provide multiple choices to a user for configuring the synthesizer **200** to produce any desired output frequency. These choices enable a user to select the configuration that gives the best possible noise performance.

Having described one embodiment, numerous alternative embodiments or variations can be made. As shown and described, the DDS modulation circuit **212** receives its clock reference from the reference oscillator **210**. This is merely an example, however. Alternatively, the DDS modulation circuit can have its own clock reference, or can receive a clock reference from another source.

As shown and described, the DDS modulation circuit **212** is provided with a plurality of local oscillators. This is not strictly required. Alternatively, a single local oscillator can be used. The single local oscillator can be a fixed frequency oscillator or can provide multiple, selectable frequencies.

Those skilled in the art will therefore understand that various changes in form and detail may be made to the embodiments disclosed herein without departing from the scope of the invention.

What is claimed is:

1. A microwave synthesizer, comprising:
  - a reference oscillator for generating a reference frequency;
  - a DDS modulation circuit for generating a modulated DDS signal; and
  - a phase-locked loop circuit, coupled to the reference oscillator and the DDS modulation circuit, for generating a variable frequency output signal,
    - wherein the phase-locked loop circuit includes—
    - a phase comparison circuit having a first input coupled to the reference oscillator, a second input for receiving a feedback signal, and an output,
    - a controllable oscillator having a control input coupled to the output of the phase comparison circuit and an output for generating the variable frequency output signal, and
    - a first mixer circuit having a first input coupled to the DDS modulation circuit, a second input coupled to the output of the controllable oscillator, and an output coupled to the second input of the phase comparison circuit, and
      - wherein the DDS modulation circuit includes
        - a local oscillator circuit,
        - a DDS circuit, having a clock input coupled to the local oscillator circuit and an output for providing an output signal of programmable frequency, and
        - a second mixer circuit having a first input coupled to the output of the DDS circuit, a local oscillator input coupled to the local oscillator circuit, and an output for generating the modulated DDS signal.
2. A microwave synthesizer as recited in claim 1, further comprising a programmable divider coupled in series between the output of the controllable oscillator and the second input of the mixer circuit.

3. A microwave synthesizer as recited in claim 2, wherein the programmable divider comprises a programmable-ratio RF prescaler.

4. A microwave synthesizer as recited in claim 1, wherein the phase comparison circuit comprises a phase-frequency detector.

5. A microwave synthesizer as recited in claim 1, wherein the phase comparison circuit comprises a crossover switch coupled in series with a phase detector.

6. A microwave synthesizer as recited in claim 1, wherein the controllable oscillator comprises a YIG oscillator.

7. A microwave synthesizer as recited in claim 1, wherein the DDS circuit comprises:

a first DDS unit having a clock input coupled to the local oscillator circuit and an output for providing an output signal of programmable frequency,

a second DDS unit having a clock input coupled to the local oscillator circuit and an output for providing an output signal of programmable frequency,

wherein the second mixer circuit is a quadrature mixer circuit further having a second input coupled to the output of the second DDS unit.

8. A microwave synthesizer as recited in claim 7, wherein at least one of the first and second DDS units is adjustable for phase.

9. A method of calibrating a microwave synthesizer as recited in claim 8, comprising:

programming the first and second DDS units to produce respective output signals having the same frequency;

A) sampling the feedback signal;

B) analyzing the feedback signal to determine its spurious content;

C) adjusting the phase between the output signals of the first and second DDS units;

D) identifying a phase that yields a lower level of spurious content in the feedback signal than other phases; and

E) programming the phase between the first and second DDS units to a value substantially equal to the identified phase.

10. A microwave synthesizer as recited in claim 7, wherein the quadrature mixer circuit comprises a single-sideband upconverter.

11. A microwave synthesizer as recited in claim 7, further comprising a sampling circuit coupled to the output of the first mixer circuit, for sampling the feedback signal.

12. A microwave synthesizer as recited in claim 7, wherein at least one of the first and second DDS units is adjustable for gain.

13. A microwave synthesizer as recited in claim 7, wherein at least one of the first and second DDS units is adjustable for offset.

14. A microwave synthesizer as recited in claim 1, wherein the local oscillator circuit comprises:

a plurality of frequency multiplying units each having an input coupled to the reference oscillator and each having an output for providing an output frequency that is a multiple of the reference frequency;

a first selector having a plurality of inputs each coupled to the output of one of the plurality of frequency multiplying units and having an output coupled to the DDS circuit; and

a second selector having a plurality of inputs each coupled to the output of one of the plurality of frequency multiplying units and having an output coupled to the second mixer circuit.

13

15. A method of programming a microwave synthesizer as recited in claim 14 to achieve a desired frequency, comprising:

- A) selecting one of the frequency multiplying units for providing input to the DDS circuit;
- B) selecting one of the frequency multiplying units for providing input to the second mixer circuit; and
- C) programming the DDS circuit to produce an output frequency.

16. A method of programming a microwave synthesizer as recited in claim 1 to achieve a desired frequency, comprising:

- A) programming the DDS circuit to output a signal having a first frequency;
- B) waiting a first predetermined interval of time;
- C) programming the DDS circuit to output a signal having a second frequency;
- D) waiting a second predetermined interval of time; and
- E) repeating steps A-D,

wherein the phase-locked loop circuit has a bandwidth, and the inverse of the sum of the first predetermined interval of time and the second predetermined interval of time is greater than the bandwidth.

17. A microwave synthesizer, comprising:

a phase comparison circuit having a first input for receiving a reference frequency, a second input for receiving a feedback signal, and an output;

a controllable oscillator having a control input coupled to the output of the phase comparison circuit and an output for generating a variable frequency output signal;

a programmable divider having an input coupled to the output of the controllable oscillator and an output for providing a divided signal;

a first mixer circuit having a first input adapted for receiving a modulated signal, a second input coupled to the output of the programmable divider, and an output coupled to the second input of the phase comparison circuit for providing the feedback signal; and

a DDS modulation circuit including

a frequency multiplying circuit having an input for receiving the reference frequency,

a DDS circuit having a clock input coupled to the frequency multiplying circuit and an output for providing a programmable, periodic signal, and

a second mixer circuit having a first input coupled to the output of the DDS circuit, a second input coupled to the frequency multiplying circuit, and an output for providing the modulated signal.

18. A microwave synthesizer as recited in claim 17, wherein the phase comparison circuit comprises a phase-frequency detector having first and second inputs.

19. A microwave synthesizer as recited in claim 18, wherein the phase comparison circuit further comprises a crossover switch having first and second inputs coupled to the first and second inputs of the phase comparison circuit and first and second outputs coupled to first and second inputs of the phase-frequency detector.

20. A microwave synthesizer as recited in claim 17, wherein the frequency multiplying circuit comprises:

a plurality of frequency multiplying units each having an input for receiving the reference frequency and each having an output for providing an output frequency that is a multiple of the reference frequency; and

a selector having a plurality of inputs each coupled to the output of one of the plurality of frequency multiplying units and having an output coupled to the clock input of the DDS circuit.

14

21. A microwave synthesizer as recited in claim 20, wherein the selector is a first selector, and the frequency multiplying circuit further comprises:

a second selector having a plurality of inputs each coupled to the output of one of the plurality of frequency multiplying units and having an output coupled to the second input of the second mixer circuit.

22. A microwave synthesizer, comprising:

a reference oscillator for generating a reference frequency; a plurality of frequency multiplying units, coupled to the reference oscillator, for generating respective output signals each at a different multiple of the reference frequency;

a first DDS unit having a clock input coupled to the plurality of frequency multiplying units and an output for generating a first DDS signal having a programmable frequency and a first phase;

a second DDS unit having a clock input coupled to the plurality of frequency multiplying units and an output for generating a second DDS signal having the programmable frequency and a second phase different from the first phase;

a quadrature mixer circuit having a first and second inputs respectively coupled to the outputs of the first and second DDS circuits, a third input coupled to the plurality of frequency multiplying units, and an output; and

a phase-locked loop circuit, having a first input coupled to the reference oscillator, a second input coupled and to the output of the quadrature mixer circuit, and an output for providing a variable frequency output signal,

wherein the phase-locked loop circuit includes

a phase comparison circuit having a first input coupled to the reference oscillator, a second input for receiving a feedback signal, and an output;

a controllable oscillator having a control input coupled to the output of the phase comparison circuit and an output for generating a variable frequency output signal;

a programmable divider having an input coupled to the output of the controllable oscillator and an output for providing a divided signal; and

a mixer circuit having a first input coupled to the output of the quadrature mixer circuit, a second input coupled to the output of the programmable divider, and an output coupled to the second input of the phase comparison circuit for providing the feedback signal.

23. A microwave synthesizer as recited in claim 22, further comprising a sampling circuit coupled to the output of the mixer circuit for sampling the feedback signal.

24. A microwave synthesizer, comprising:

a phase comparator having a first input, a second input, and an output, the first input for receiving a reference frequency;

a controllable oscillator having an input and an output, the input coupled to the output of the phase comparator;

a first mixer having a first input, a second input, and an output, the second input coupled to the output of the controllable oscillator and the output coupled to the second input of the phase comparator;

a frequency multiplier having an input and an output, the input for receiving the reference frequency,

a DDS having an input and an output, the input coupled to the output of the frequency multiplier, and

a second mixer having a first input coupled to the output of the DDS, a second input coupled to the output of the frequency multiplier, and an output coupled to the first input of the first mixer.

## 15

25. A microwave synthesizer, comprising:  
 a reference oscillator for generating a reference frequency;  
 a plurality of frequency multiplying units, coupled to the  
 reference oscillator, for generating respective output sig- 5  
 nals each at a different multiple of the reference fre-  
 quency;  
 a first DDS unit having a clock input coupled to the plural-  
 ity of frequency multiplying units and an output for  
 generating a first DDS signal having a programmable  
 frequency and a first phase; 10  
 a second DDS unit having a clock input coupled to the  
 plurality of frequency multiplying units and an output  
 for generating a second DDS signal having the program-  
 mable frequency and a second phase different from the  
 first phase;

## 16

a quadrature mixer circuit having a first and second inputs  
 respectively coupled to the outputs of the first and sec-  
 ond DDS circuits, a third input coupled to the plurality of  
 frequency multiplying units, and an output; and  
 a phase-locked loop circuit including—  
 a phase comparison circuit having a first input, a second  
 input, and an output, the first input coupled to the  
 reference oscillator, and  
 a mixer having a first input coupled to the output of the  
 phase comparison circuit, a second input coupled to  
 the output of the quadrature mixer circuit, and an  
 output coupled to the second input of the phase com-  
 parison circuit.
