ABSTRACT

The invention generally relates to methods of treating a male subject with a prostate condition, for example, benign prostate hyperplasia (BPH). In certain embodiments, the invention provides methods of treating a male subject with a prostate condition, which include administering a MetAP2 inhibitor at a dose that does not substantially modulate angiogenesis.

METHODS OF TREATING A SUBJECT WITH BENIGN PROSTATE HYPERPLASIA

REFERENCE TO RELATED APPLICATIONS

This application is a national stage filing under 35 U.S.C. 371 of PCT/US2011/020515, filed Jan. 7, 2011, which claims priority to U.S. Ser. No. 61/293,320 filed Jan. 8, 2010, all of which are incorporated by reference in their entirety.

BACKGROUND

Benign Prostate Hyperplasia (BPH), also called prostate enlargement, occurs in almost all men as they age. About half of the men in their 60s have at least some symptoms of BPH. The prostate is the semen-producing gland that surrounds the urethra, the tube that carries urine from the bladder out to the body. Symptoms of BPH result when the prostate gland grows to the extent that it blocks the flow of urine through the urethra. This blockage may cause urinary problems, including an inability to completely empty the bladder, a frequent urge to urinate, a weak urine stream, nocturia, and hematuria. In some cases, these urinary problems lead to more serious complications, including urinary tract infections; bladder damage, stones, or infection; and kidney damage.

Medications used to control prostate growth include alpha blockers and 5-alpha reductase inhibitors. Alpha blockers may act by relaxing the muscles around the bladder neck, which makes urination easier. Alpha blockers approved by the Food and Drug Administration to treat BPH are terazosin (Hytrin®), doxazosin (Cardura®), tamsulosin (Flomax®) and alfuzosin (Uroxatral®). The long-term effects of alpha-blockers are unknown and side effects include infections with drugs taken to treat impotence and dizziness and light-headedness upon standing. 5-alpha reductase inhibitors, such as finasteride (Proscar®) and dutasteride (Avodart®) act by shrinking the prostate. 5-alpha reductase drugs may only be effective in subjects with BPH and not in subjects with moderately-enlarged or normal-sized prostates. In addition, 5-alpha reductase drugs may take up to a year to produce therapeutic effects, may decrease libido, and may interfere with accurate reading of PSA tests, which are used to diagnose prostate cancer.

Non-invasive procedures used to treat BPH include transurethral microwave therapy (TUMT), transurethral needle ablation (TUNA), interstitial laser therapy (ILT), and prostatic stents. TUMT, TUNA, and ILT involve the use of heat produced by microwaves, radio waves, and lasers, respectively, to destroy prostate tissue blocking the urethra. TUMT, TUNA, and ILT may be less effective for large prostates, and the long-term effectiveness of these procedures is unknown. Prostatic stents are metal coils used to prop open the urethra. Stents are typically used in subjects unwilling or unable to take medications and/or have surgery, and are typically not considered to be a long-term treatment option.

Surgery to treat BPH include transurethral resection of the prostate (TURP), transurethral incision of the prostate (TUIP), laser surgery, and open prostatectomy. In TURP, a narrow instrument is inserted into the urethra and used to scrape away prostate tissue surrounding the urethra. TUIP is performed similarly to TURP, but only one or two cuts in the prostate are made to relieve the pressure on the urethra. Laser surgery, such as photoselective vaporization of the prostate (PVP) and holmium laser enucleation of the prostate (HoLEP) involve the use of lasers to destroy prostate tissue. In an open prostatectomy, the prostate is accessed through an incision is made in a subject's lower abdomen (rather than through the urethra), and the inner portion of the prostate is removed. A subject who undergoes surgery to treat BPH may require additional surgeries if the prostate grows back. Side effects, such as impotence, incontinence, infection and scarring, may occur.

Medications, non-invasive procedures and surgeries known in the art for treating BPH may not be as effective as desired and often produce side effects. Methods of treating subjects with BPH that are more effective than current therapies, e.g., surgery, are clearly needed.

SUMMARY

At least in part, this disclosure provides for a method for treating benign prostatic hypertrophy (BPH) and related disorders, in a male subject in need thereof, comprising administering (e.g. parenterally, intravenously, subcutaneously, orally), a therapeutically effective amount of a MetAP-2. Such methods may result in reduction in the rate of growth of the subject's prostate, for example, such methods may provide for a decrease in the prostate of said male subject by at least 25% within 30 days.

Provided methods may provide that at least one of sperm viability, motility, quantity, and rate of production are not substantially. Contemplated MetAP-2 inhibitors include famagillin-based compounds.

Provided methods, may, in some embodiments, further comprise administering an additional therapeutic agent, for example, an alpha blocker (e.g. terazosin, doxazosin, tamsulosin and alfuzosin), a 5 alpha reductase inhibitor (e.g. finasteride and dutasteride), saw palmetto, beta-sitosterol, and pygeum. In another embodiment, contemplated methods may further comprise administering a non-invasive procedure, such as transurethral microwave therapy (TUMT), transurethral needle ablation (TUNA), interstitial laser therapy (ILT), prostatic stents, and/or may further comprise administering a surgical treatment, such as transurethral resection of the prostate (TURP), transurethral incision of the prostate (TUIP), laser surgery, or open prostatectomy.

Exemplary MetAP-2 inhibitors may be, for example, represented by Compound 1:

```
O
\_/ \_/ \\
H H
O
```

or a pharmaceutically acceptable salt thereof.

MetAP-2 inhibitors may be administered at a dose of about 0.01 mg/kg to about 10 mg/kg, or about 0.04 mg/kg to about 1.0 mg/kg.

Also provided herein is a method for reducing the prostate gland in a male subject in need thereof, comprising administering a therapeutically effective amount of a MetAP-2 inhibitor to the male subject.
Overview

The disclosure relates at least in part to methods for treating a prostate condition, such as BPH, which include administering a MetAP2 inhibitor. MetAP2 encodes a protein that functions at least in part by enzymatically removing the amino terminal methionine residue from certain newly synthesized proteins. Increased expression of the MetAP2 gene has been historically associated with various forms of cancer. Molecules inhibiting the enzymatic activity of MetAP2 have been identified and have been explored for their utility in the treatment of various tumor types (Wang et al. (2003) Cancer Res. 63:7861) and infectious diseases such as microsporidiosis, leishmaniasis, and malaria (Zhang et al. (2002) J. Biomed. Sci. 9:34). While BPH is not a form of cancer, it has been found that MetAP2 inhibitors can effectively treat subjects with BPH. Disclosed herein are methods relating to administering a MetAP-2 inhibitor to treat a prostate condition, e.g., BPH.

BPH may be diagnosed based on an evaluation of a subject’s reported symptoms and family history, as well as by the results of one or more tests including a digital rectal exam, urine test, blood test, transrectal ultrasound (TRUS), urodynamic pressure-flow studies, cystoscopy, intravenous pyelogram or CT urogram, prostate-specific antigen (PSA) blood test, urinary flow test, and postvoid residual volume test.

MetAP2 inhibitors

MetAP2 inhibitors refer to a class of molecules that inhibit the activity of MetAP2, e.g., the ability of MetAP2 to cleave the N-terminal methionine residue of newly synthesized proteins to produce the active form of the protein, or the ability of MetAP2 to regulate protein synthesis by protecting the subunit of eukaryotic initiation factor 2 (eIF2) from phosphorylation.

Exemplary MetAP2 inhibitors may include irreversible inhibitors that covalently bind to MetAP2. For example, such irreversible inhibitors include fumagillin, fumagilloid, and fumagillin ketone.

Derivatives and analogs of fumagillin, and pharmaceutically acceptable salts thereof are contemplated herein as irreversible MetAP2 inhibitors, such as O-(4-dimethylaminoethoxy)aminomethyl) fumagilloid (CKD-732, also referred to herein as Compound A), O-(3,4,5-trimethoxycinnamoyl) fumagilloid, O-(3-chloroaminomethyl) fumagilloid; O-(4-aminoaminomethyl) fumagilloid; O-(3,4-dimethoxycinnamoyl) fumagilloid; O-(4-hydroxycinnamoyl) fumagilloid; O-(3,4,5-trimethoxycinnamoyl) fumagilloid; O-(3,4,5-trimethoxycinnamoyl) fumagilloid; O-(4-nitroaminomethyl) fumagilloid; O-(3,4-dimethoxy-6-nitroaminomethyl) fumagilloid; O-(4-acetoxy-3,5-dimethoxycinnamoyl) fumagilloid; O-(4-ethoxycinnamoyl) fumagilloid; O-(4-ethylnitroaminomethyl) fumagilloid; O-(3-dimethylaminomethyl-4-hydroxycinnamoyl) fumagilloid; O-(3,4-dimethylaminomethyl-6-nitroaminomethyl) fumagilloid; O-(4-acetoxyaminomethyl) fumagilloid; O-(4-cyanocinnamoyl) fumagilloid; O-(4-methoxycinnamoyl)oxy-2-(1,2-epoxy-1,5-dimethyl-4-hexenyl)-3-methoxy-1-chloromethyl-1-cyclohexanol; O-(3,4,5-trimethoxycinnamoyl) fumagilloid; O-(4-dimethoxyaminomethyl) fumagilloid; O-(3,4,5-trimethoxycinnamoyl)oxy-2-(1,2-epoxy-1,5-dimethyl-4-hexenyl)-3-methoxy-1-chloromethyl-1-cyclohexanol; O-(4-dimethoxycinnamoyl)oxy-2-(1,2-epoxy-1,5-dimethyl-4-hexenyl)-3-methoxy-1-chloromethyl-1-cyclohexanol; and O-(3,4,5-trimethoxycinnamoyl)oxy-2-(1,2-epoxy-1,5-dimethyl-4-hexenyl)-3-methoxy-1-chloromethyl-1-cyclohexanol.

Fumagillin, and some derivatives thereof, have a carboxylic acid moiety and can be administered in the form of the free acid. Alternatively, contemplated herein are pharmaceutically acceptable salts of fumagillin, fumagilloid, and derivatives thereof. Pharmaceutically acceptable salts illustratively include those that can be made using the following bases: ammonia, L-arginine, benzenethione, betaine, bismuth, calcium hydroxide, choline, deanol, diethanolamine, diethylyamine, 2-diethylylaminoethanol, ethylenediamine, N-methylglucamine, hydramine, 11-imidazole, lysine, magnesium hydroxide, 4-(2-hydroxyethyl) morpholine, pipеразин, potassium hydroxide, 1-(2-hydroxyethyl) pyrrolidine, sodium hydroxide, triethanolamine, zinc hydroxide, dicyclocexlamine, or any other electron pair donor (as described in Handbook of Pharmaceutical Salts, Stan & Werum, VHCA and Wiley, Uchsenfrit-Hoestadt Germany, 2002). Contemplated pharmaceutically acceptable salts may include hydrochloric acid, bromic acid, sulfuric acid, phosphoric acid, nitric acid, formic acid, acetic acid, trifluoroacetic acid, oxalic acid, fumaric acid, tartaric acid, maleic acid, methanesulfonic acid, benzenesulfonic acid or para-toluene-sulfonic acid.

Esters of the present invention may be prepared by reacting fumagillin or fumagilloid with the appropriate acid under standard esterification conditions described in the literature (Houben-Weyl 4th Ed. 1952, Methods of Organic, Synthesis). Suitable fumagillin esters include ethyl methanoate, ethyl ethanoate, ethyl propanoate, propyl methanoate, propyl ethanoate, and methyl butanoate.

In another embodiment, contemplated irreversible inhibitors of MetAP2 may include siRNA, shRNA, an antibody or an antisense compound of MetAP2.

For example, contemplated MetAP2 inhibitors may include:

Methods

A method of treating a condition affecting the prostate, e.g., benign prostate hyperplasia (BPH), in a subject in need thereof is provided herein, comprising parenterally or non-parenterally administering a therapeutically effective amount of a MetAP2 inhibitor to said subject. In some embodiments, a contemplated therapeutically effective amount of a MetAP2 as described below, does not substantially modulate or suppress angiogenesis, but is still effective as MetAP2 inhibitor. The term "angiogenesis" is known to persons skilled in the art, and refers to the process of new blood vessel formation, and is essential for the exponential growth of solid tumors and tumor metastasis. For example, provided herein is a method of treating a condition affecting the prostate in a subject in need thereof, comprising administering a therapeutically effective amount of a MetAP2 inhibitor to said subject, wherein substantially no loss of new blood vessels in the prostate or other tissue compartments occur as compared to a subject being treated for a prostate condition with, e.g., surgery.

In some embodiments, disclosed methods, upon administration of said MetAP2 inhibitor e.g. daily or weekly, for about 3, 4, 5 or 6 months or more may result in a reduction in the rate of prostate growth in a male subject of at least a 5%, 10%, 20%, or 30%, or more based on the prostate's original rate of growth. In some embodiments, disclosed methods, upon administration of said MetAP2 inhibitor e.g. daily or weekly, for about 3, 4, 5 or 6 months or more may result in a reduction in the size of a prostate of at least a 5%, 10%, 20%, or 30%, or more based on the original size of the prostate. In an embodiment, reduction in size of the prostate following treatment with therapeutically effective doses of MetAP2 inhibitors may substantially cease once a subject attains a
desired prostate size, i.e., a size that reduces and/or eliminates symptoms, e.g., urinary symptoms, of a prostate condition, e.g., BPH.

Some methods disclosed herein may involve co-administration of another BPH treatment, such as a therapeutic agent. Therapeutic agents include but are not limited to alpha blockers, e.g., terazosin (Hytrin®), doxazosin (Cardura®), tamsulosin (Flomax®) and alfuzosin (Uroxatral®), 5-alpha reductase inhibitors, e.g., finasteride (Proscar®) and dutasteride (Avodart®), saw palmetto, beta-sitosterol, and pygeum. In some embodiments, contemplated methods include co-administration of a non-invasive procedure, e.g., transurethral microwave therapy (TUMT), transurethral needle ablation (TUNA), interstitial laser therapy (ILT), and prostatic stents. Further embodiments include co-administering a surgical treatment, e.g., transurethral resection of the prostate (TURP), transurethral incision of the prostate (TUIP), laser surgery, and open prostatectomy.

In some embodiments, co-administration of a MetAP-2 inhibitor and another BPH treatment occur at the same time. In other embodiments, administration of a MetAP-2 inhibitor occurs immediately prior to or immediately after another BPH treatment. In yet another embodiment, a period of time may elapse between administration of a MetAP-2 inhibitor and another BPH treatment. For example, a male subject may be administered prostate surgery to reduce the size of the prostate, followed by a recovery period of, e.g., 1 week, 2 weeks, 3 weeks, 4 weeks, 2 months, or 6 months or longer, after which the male subject is administered a MetAP-2 inhibitor to reduce the rate of re-growth of the prostate.

Administration and Formulation

Contemplated herein are formulations suitable for parenteral or non-parenteral administration of MetAP2 inhibitors. In certain embodiments, a subject may have a lower systemic exposure (e.g., at least about 2, 3, 5, 10, 20, or at least about 50% less systemic exposure) to the non-parenterally (e.g., orally) administered a MetAP2 inhibitor as compared to a subject parenterally (e.g., subcutaneously) administered the same dose of the MetAP2 inhibitor. For example, non-parenterally (e.g., orally) administered MetAP2 inhibitors may bind less to MetAP2 as compared to parenterally (e.g., subcutaneously) administered MetAP2 inhibitors.

Contemplated non-parenteral administration includes oral, buccal, transdermal (e.g. by a dermal patch), topical, inhalation, sublingual, ocular, pulmonary, nasal, or rectal administration.

Contemplated parenteral administration includes intravenous and subcutaneous administration, as well as administration at a site of a minimally-invasive procedure or a surgery.

In another embodiment, provided herein are effective dosages, e.g., a daily dosage of a MetAP2 inhibitor, that may not substantially modulate or suppress angiogenesis. For example, provided here are methods that include administering doses of MetAP2 inhibitors that are effective for reducing the rate of growth of the prostate, but are significantly smaller doses than that necessary to modulate and/or suppress angiogenesis (which may typically require about 12.5 mg/kg to about 50 mg/kg or more). For example, contemplated dosage of a MetAP2 inhibitor in the methods described herein may include administering about 25 mg/day, about 10 mg/day, about 5 mg/day, about 3 mg/day, about 2 mg/day, about 1 mg/day, about 0.75 mg/day, about 0.5 mg/day, about 0.1 mg/day, about 0.05 mg/day, or about 0.01 mg/day.

For example, an effective amount of the drug for reducing the rate of prostate growth in a male subject may be about 0.0001 mg/kg to about 25 mg/kg of body weight per day. For example, a contemplated dosage may from about 0.001 to 10 mg/kg of body weight per day, about 0.001 mg/kg to 1 mg/kg of body weight per day, about 0.01 mg/kg to 0.1 mg/kg of body weight per day or about 0.005 to about 0.045 mg/kg of body weight a day. In an embodiment a MetAP2 inhibitor such as disclosed herein (e.g. O-(4-dimethylaminophenoxycinnamoyl)lumigilol); may be administered about 0.005 to about 1 mg/kg, or to about 5 mg/kg, or about 0.005 to about 0.1 mg/kg of a subject.

For example, provided herein is a method for treating a prostate condition in a male subject in need thereof, comprising administering, parenterally (e.g. intravenously) or non-parenterally, about 0.005 to about 0.04 mg/kg of a MetAP2 inhibitor selected from O-dimethylaminophenoxycinnamoyl) famagilol and pharmaceutically acceptable salts thereof (for example, an oxalate salt), to said subject. Such a method, upon administration of said MetAP2 inhibitor e.g. daily or weekly, for about 3, 4, 5 or 6 months or more may result in at least a 10%, 20%, 30%, or 40% or more reduction in the rate of growth of the prostate.

Contemplated methods include administration of a composition comprising a MetAP2 inhibitor, for example, hourly, twice hourly, every three to four hours, hourly, twice daily, 1, 2, 3 or 4 times a week, every three to four days, every week, or once every two weeks depending on half-life and clearance rate of the particular composition or inhibitor.

Treatment can be continued for as long or as short a period as desired. The compositions may be administered on a regimen of, for example, one to four or more times per day. A suitable treatment period may be, for example, at least about one week, at least about two weeks, at least about one month, at least about six months, at least about one year, or indefinitely. A treatment period may terminate when a desired result, for example desired prostate size, is achieved. For example, treatment may terminate when reduction of about 20% of the prostate, about 30% of the prostate or more has been achieved. A treatment regimen may include a corrective phase, during which a MetAP2 inhibitor dose sufficient to provide reduction of prostate size is administered, followed by a maintenance phase, during which a lower MetAP2 inhibitor dose sufficient to reduce or prevent growth is administered.

For pulmonary (e.g., intrabronchial) administration, MetAP2 inhibitors may be formulated with conventional excipients to prepare an inhalable composition in the form of a fine powder or atomizable liquid. For ocular administration, MetAP2 inhibitors may be formulated with conventional excipients, for example, in the form of eye drops or an ocular implant. Among excipients useful in eye drops are viscosity-increasing or gelling agents, to minimize loss by lacrimation through improved retention in the eye.

Liquid dosage forms for oral or other administration include, but are not limited to, pharmaceutically acceptable emulsions, microemulsions, solutions, suspensions, syrups and elixirs. In addition to the active agent(s), the liquid dosage forms may contain inert diluents commonly used in the art such as, for example, water or other solvents, solubilizing agents and emulsifiers such as ethyl alcohol, isopropyl alcohol, ethyl carbonate, ethyl acetate, benzig alcohol, benzyl benzoate, propylene glycol, 1,3-butanediol glycol, dimethylformamide, oils (in particular, cottonseed, groundnut, corn, germ, olive, castor, and sesame oils), glycerol, tetrahydrofurfuryl alcohol, polyethylene glycols and fatty acid esters of sorbitan, and mixtures thereof. Besides inert diluents, the ocular, oral, or other systemically-delivered compositions can also include adjuvants such as wetting agents, and emulsifying and suspending agents.
Dosage forms for topical or transdermal administration of an inventive pharmaceutical composition may include ointments, pastes, creams, lotions, gels, powders, solutions, sprays, inhalants, or patches. The active agent is admixed under sterile conditions with a pharmaceutically acceptable carrier and any needed preservatives or buffers as may be required. For example, cutaneous routes of administration are achieved with aqueous drops, a mist, an emulsion, or a cream.

Transdermal patches may have the added advantage of providing controlled delivery of the active ingredients to the body. Such dosage forms can be made by dissolving or dispersing the compound in the proper medium. Absorption enhancers can also be used to increase the flux of the compound across the skin. The rate can be controlled by either providing a rate controlling membrane or by dispersing the compound in a polymer matrix or gel.

When administered in lower doses, injectable preparations are also contemplated herein, for example, sterile injectable aqueous or oleaginous suspensions may be formulated according to the known art using suitable dispersing or wetting agents and suspending agents.

Compositions for rectal administration may be suppositories which can be prepared by mixing a MetAP2 inhibitor with suitable non-irritating excipients or carriers such as cocoa butter, polyethylene glycol, or a suppository wax which are solid at ambient temperature but liquid at body temperature and therefore melt in the rectum and release the active agent(s). Alternatively, contemplated formulations can be administered by release from a lumen of an endoscope after the endoscope has been inserted into a rectum of a subject.

Oral dosage forms, such as capsules, tablets, pills, powders, and granules, may be prepared using any suitable process known to the art. For example, a MetAP2 inhibitor may be mixed with enteric materials and compressed into tablets.

Alternatively, formulations of the invention are incorporated into chewable tablets, crushable tablets, tablets that dissolve rapidly within the mouth, or mouth wash.

EXAMPLE

This example is not intended in any way to limit the scope of this invention but is provided to illustrate aspects of the disclosed methods. Many other embodiments of this invention will be apparent to one skilled in the art.

Example 1

Administration of a MetAP-2 Inhibitor to Reduce Prostate Size

Male rats were divided into a control group and three test groups with 20 animals per group. Animals were administered the MetAP-2 inhibitor Compound I, represented by the formula:

![Compound I](image)

Compound I was prepared in a 5% mannitol solution was administered once daily for four weeks by a fifteen-minute intravenous infusion according to Table I.

**Significantly different from the control group at 0.01 using Dunnett's test.

Administration of a MetAP-2 inhibitor at all doses causes a reduction in the weight of the prostate gland in male animals.

INCORPORATION BY REFERENCE

References and citations to other documents, such as patents, patent applications, patent publications, journals, books, papers, web content, have been made throughout this disclosure. All such documents are hereby incorporated herein by reference in their entirety for all purposes.

EQUIVALENTS

Various modifications of the invention and many further embodiments thereof, in addition to those shown and
described herein, will become apparent to those skilled in the art from the full contents of this document, including references to the scientific and patent literature cited herein. The subject matter herein contains important information, exemplification and guidance that can be adapted to the practice of this invention in its various embodiments and equivalents thereof.

What is claimed is:

1. A method for treating benign prostatic hypertrophy (BPH) in a male subject in need thereof, comprising administering a therapeutically effective amount of a MetAP-2 inhibitor to said male subject.

2. The method of claim 1, wherein the MetAP-2 inhibitor is a fumagillin-based compound.

3. The method of claim 1, wherein the method results in a reduction in the rate of growth of the subject's prostate.

4. The method of claim 1, wherein upon administration, the prostate of said male subject decreases by at least 25% within 30 days.

5. The method of claim 1, wherein administration occurs parenterally.

6. The method of claim 1, wherein administration is intravenous or subcutaneous.

7. The method of claim 1, wherein at least one of sperm viability, motility, quantity, and rate of production are not substantially decreased after administration of said MetAP-2 inhibitor.

8. The method of claim 1, further comprising administering an additional therapeutic agent.

9. The method of claim 8, wherein the additional therapeutic agent is selected from the group consisting of an alpha blocker, a 5 alpha reductase inhibitor, saw palmetto, boasterol, and pygeum.

10. The method of claim 9, wherein the alpha blocker is selected from the group consisting of terazosin, doxazosin, tamsulosin and alfuzosin.

11. The method of claim 9, wherein the 5 alpha reductase inhibitor is selected from the group consisting of finasteride and dutasteride.

12. The method of claim 1, further comprising administering a non-invasive procedure.

13. The method of claim 12, wherein the non-invasive procedure is selected from the group consisting of transurethral microwave therapy (TUMT), transurethral needle ablation (TUNA), interstitial laser therapy (ILT), and prostatic stents.

14. The method of claim 1, further comprising administering a surgical treatment.

15. The method of claim 14, wherein the surgical treatment is selected from the group consisting of transurethral resection of the prostate (TURP), transurethral incision of the prostate (TUIP), laser surgery, and open prostatectomy.

16. A method for treating benign prostatic hypertrophy (BPH) in a male subject in need thereof, comprising administering a therapeutically effective amount of Compound I, represented by:

17. The method of claim 1, wherein the MetAP-2 inhibitor is administered at a dose of about 0.01 mg/kg to about 10 mg/kg.

18. The method of claim 1, wherein the MetAP-2 inhibitor is administered at a dose of about 0.04 mg/kg to about 1.0 mg/kg.

19. A method for reducing the prostate gland in a male subject in need thereof, comprising administering a therapeutically effective amount of a MetAP-2 inhibitor to a male subject in need thereof.

20. A method for reducing the prostate gland in a male subject in need thereof, comprising administering a therapeutically effective amount of a Compound I, represented by:
