FIELD OF THE INVENTION

The present invention also provides methods for treating inflammation, pain and fever; for treating and/or improving the gastrointestinal properties of COX-2 inhibitors; for facilitating wound healing; for treating and/or preventing renal toxicity; and for treating and/or preventing other disorders resulting from elevated levels of cyclooxygenase-2.

BACKGROUND OF THE INVENTION

Nonsteroidal anti-inflammatory compounds (NSAIDs) are widely used for the treatment of pain, inflammation, and acute and chronic inflammatory disorders such as osteoarthritis and rheumatoid arthritis. These compounds inhibit the activity of the enzyme cyclooxygenase (COX), also known as prostaglandin G/H synthase, which is the enzyme that converts arachidonic acid into prostanoids. The NSAIDs also inhibit the production of other prostaglandins, especially prostaglandin G₂, prostaglandin H₂ and prostaglandin E₂, thereby reducing the prostaglandin-induced pain and swelling associated with the inflammation process. The chronic use of NSAIDs has been associated with adverse effects, such as gastrointestinal ulceration and renal toxicity. The undesirable side effects are also due to the inhibition of prostaglandin in the affected organ.

Recently two isoforms of cyclooxygenase, encoded by two distinct genes (Kujubu et al, J. Biol. Chem., 266, 12866-12872 (1991)), have been identified – a
constitutive form, cyclooxygenase-1 (COX-1), and an inductive form, cyclooxygenase-2 (COX-2). It is thought that the antiinflammatory effects of NSAIDs are mediated by the inhibition of COX-2, whereas the side effects seem to be caused by the inhibition of COX-1. The NSAIDs currently on the market either inhibit both isoforms of COX with little selectivity for either isoform or are COX-1 selective. Recently compounds that are selective COX-2 inhibitors have been developed and marketed. These selective COX-2 inhibitors have the desired therapeutic profile of an antiinflammatory drug without the adverse effects commonly associated with the inhibition of COX-1. However, these compounds can result in dyspepsia and can cause gastropathy (Mohammed et al, N. Engl. J. Med., 340(25) 2005 (1999)).

There is still a need in the art for COX-2 inhibitor compounds that have gastroprotective properties, facilitate wound healing, decreased renal toxicity and dyspepsia, and that can be used at low dosages. The present invention is directed to these, as well as other, important ends.

**SUMMARY OF THE INVENTION**

The present invention provides novel nitrosated and/or nitrosylated COX-2 inhibitors, which are COX-2 inhibitors linked to at least one nitrogen monoxide group (NO), and/or at least one nitrogen dioxide group (NO₂) (i.e., nitrosylated and/or nitrosated group, respectively). The resulting compounds are potent analgesics, have antiinflammatory properties and have an unexpected potential for facilitating wound healing. The novel compounds also have unexpected properties in the treatment and/or prevention of renal toxicity. The COX-2 inhibitors can be nitrosated and/or nitrosylated through one or more sites, such as oxygen.
(hydroxyl condensation), sulfur (sulfhydryl condensation) and/or nitrogen. The COX-2 inhibitor can be, for example, a sulfonamide containing 1,5-diarylpypyrazole derivative, such as, for example, CELEBREX® (4-(5-(4-methylphenyl)-3-(trifluoromethyl)-1H-pyrazol-1-yl)benzenesulfonamide, Celecoxib). The COX-2 inhibitor can also be, for example, a methylsulfonylphenyl-furanone derivative, such as, for example, Rofecoxib (VIOXX®, 4-(4′-methylsulfonylphenyl)-3-phenyl-2-(5H)-furanone). The present invention also provides compositions comprising such compounds in a pharmaceutically acceptable carrier.

The present invention is also based on the discovery that administering at least one nitrosated and/or nitrosylated COX-2 inhibitor and at least one nitric oxide donor reduces the gastrointestinal distress induced by COX-2 inhibitors. A nitric oxide donor is a compound that contains a nitric oxide moiety and which releases or chemically transfers nitric oxide to another molecule. Nitric oxide donors include, for example, S-nitrosothiols, nitrites, nitrates, N-oxo-N-nitrosamines, and substrates of the various isozymes of nitric oxide synthase. Thus, another aspect of the invention provides compositions comprising at least one COX-2 inhibitor that is substituted with at least one NO and/or NO₂ group (i.e., nitrosylated and/or nitrosated), and at least one compound that donates, transfers or releases nitric oxide as a charged species, i.e., nitrosonium (NO⁺) or nitroxy (NO⁻), or as the neutral species, nitric oxide (NO•), and/or stimulates endogenous production of nitric oxide or EDRF in vivo and/or is a substrate for nitric oxide synthase.

Yet another aspect of the invention provides compositions comprising at least one COX-2 inhibitor that is substituted with at least one NO and/or NO₂ group (i.e., nitrosylated and/or nitrosated), and, optionally, at least one compound that donates, transfers or releases nitric oxide as a charged species, i.e., nitrosonium (NO⁺) or nitroxy (NO⁻), or as the neutral species, nitric oxide (NO•), and/or stimulates endogenous production of nitric oxide or EDRF in vivo and/or is a substrate for nitric oxide synthase, and, optionally, at least one therapeutic agent, including but not limited to, steroids, nonsteroidal antiinflammatory compounds (NSAID), 5-lipoxygenase (5-LO) inhibitors, leukotriene B₄ (LTB₄) receptor antagonists, leukotriene A₄ (LTA₄) hydrolase inhibitors, 5-HT agonists, HMG CoA inhibitors, H₂ antagonists, antineoplastic agents, antiplatelet agents, decongestants,

Yet another aspect of the present invention provides methods for treating and/or preventing inflammation, pain and fever; for treating and/or improving gastrointestinal properties of COX-2 inhibitors; for facilitating wound healing; for treating and/or preventing renal toxicity; and for treating and/or preventing COX-2 mediated disorders (i.e., disorders resulting from elevated levels of COX-2) in a patient in need thereof which comprises administering to the patient a therapeutically effective amount of at least one nitrosated and/or nitrosylated COX-2 inhibitor compound, and, optionally, at least one compound that donates, transfers or releases nitric oxide as a charged species, i.e., nitrosonium (NO⁺) or nitroxy (NO⁻), or as the neutral species, nitric oxide (NO•), and/or stimulates endogenous production of nitric oxide or EDRF *in vivo* and/or is a substrate for nitric oxide synthase and/or stimulates endogenous production of NO or EDRF *in vivo* and/or is a substrate for nitric oxide synthase (i.e., NO donors). The method can optionally further comprise the administration of at least one therapeutic agent, such as, for example, steroids, nonsteroidal antiinflammatory compounds (NSAID), 5-lipoxygenase (5-LO) inhibitors, leukotriene B₄ (LTB₄) receptor antagonists,

Compounds that donate, transfer or release nitric oxide species in vivo have been recognized as having a wide spectrum of advantages and applications. The present invention is based on the unexpected discovery of the effects of such compounds alone and together with one or more COX-2 inhibitors directly or indirectly linked with one or more nitric oxide moieties. Treatment or prevention of inflammation, pain and fever; treatment and/or improvement of the gastrointestinal properties of COX-2 inhibitors; facilitation of wound healing; and treatment and/or prevention of renal toxicity and cyclooxygenase-2 mediated disorders can be obtained by the use of the nitrosated and/or nitrosylated COX-2 inhibitors of the present invention; or by the use of the nitrosated and/or nitrosylated COX-2 inhibitors in conjunction with one or more compounds that donate, release or transfer nitric oxide and/or stimulate endogenous production of NO and/or EDRF in vivo and/or is a substrate for nitric oxide synthase, and, optionally, with one or more therapeutic agents.

In one embodiment, the present invention describes nitrosated and/or nitrosylated COX-2 inhibitors of Formula (I):

Another aspect of the present invention provides processes for making the
novel compounds of the invention and to the intermediates useful in such
processes. The reactions are performed in solvents appropriate to the reagents and
materials used are suitable for the transformations being effected. It is understood
by one skilled in the art of organic synthesis that the functionality present in the
molecule must be consistent with the chemical transformation proposed. This will,
on occasion, necessitate judgment by the routinier as to the order of synthetic
steps, protecting groups required, and deprotection conditions. Substituents on the
starting materials may be incompatible with some of the reaction conditions
required in some of the methods described, but alternative methods and
substituents compatible with the reaction conditions will be readily apparent to one
skilled in the art. The use of sulfur and oxygen protecting groups is well known for
protecting thiol and alcohol groups against undesirable reactions during a
synthetic procedure and many such protecting groups are known and described
by, for example, Greene and Wuts, *Protective Groups in Organic Synthesis*, Third

The chemical reactions described herein are generally disclosed in terms of
their broadest application to the preparation of the compounds of this invention.
Occasionally, the reactions may not be applicable as described to each compound
included within the disclosed scope. The compounds for which this occurs will be
readily recognized by one skilled in the art. In all such cases, either the reactions
can be successfully performed by conventional modifications known to one skilled
in the art, e.g., by appropriate protection of interfering groups, by changing to
alternative conventional reagents, by routine modification of reaction conditions,
and the like, or other reactions disclosed herein or otherwise conventional, will be
applicable to the preparation of the corresponding compounds of this invention. In
all preparative methods, all starting materials are known or readily prepared from
known starting materials.

The parent COX-2 inhibitor compounds can then be nitrosated and/or nitrosylated through one or more sites such as oxygen, sulfur and/or nitrogen using the methods described in the examples herein and using conventional methods known to one skilled in the art. For example, known methods for nitrosating and nitrosylating compounds are described in U.S. Patent Nos. 5,380,758 and 5,703,073; WO 97/27749; WO 98/19672; and Oae et al, *Org. Prep. Proc. Int.*, 15(3):165-198 (1983), the disclosures of each of which are incorporated by reference herein in their entirety. The methods of nitrosating and/or nitrosylating the compounds described in the examples herein and in these references can be applied by one skilled in the art to produce any of the nitrosated and/or nitrosylated COX-2 inhibitors described herein.

The compounds of the present invention include the parent COX-2 inhibitors, including those described herein, which have been nitrosated and/or nitrosylated through one or more sites such as oxygen (hydroxyl condensation), sulfur (sulphydryl condensation) and/or nitrogen. The nitrosated and/or nitrosylated COX-2 inhibitors of the present invention donate, transfer or release a biologically active form of nitrogen monoxide (i.e., nitric oxide).

Nitrogen monoxide can exist in three forms: NO- (nitroxyll), NO• (uncharged nitric oxide) and NO+ (nitrosonium). NO• is a highly reactive short-lived species that is potentially toxic to cells. This is critical because the pharmacological efficacy of NO depends upon the form in which it is delivered. In contrast to the nitric oxide radical (NO•), nitrosonium (NO+) does not react with O2 or O2• species, and functionalities capable of transferring and/or releasing NO+ and
NO- are also resistant to decomposition in the presence of many redox metals. Consequently, administration of charged NO equivalents (positive and/or negative) is a more effective means of delivering a biologically active NO to the desired site of action.

Compounds contemplated for use in the present invention (e.g., nitrosated and/or nitrosylated COX-2 inhibitors) are, optionally, used in combination with nitric oxide and compounds that release nitric oxide or otherwise directly or indirectly deliver or transfer a biologically active form of nitrogen monoxide to a site of its intended activity, such as on a cell membrane in vivo.

The term "nitric oxide" encompasses uncharged nitric oxide (NO•) and charged nitrogen monoxide species, preferably charged nitrogen monoxide species, such as nitrosonium ion (NO⁺) and nitroxyl ion (NO⁻). The reactive form of nitric oxide can be provided by gaseous nitric oxide. The nitrogen monoxide releasing, delivering or transferring compounds have the structure F-NO, wherein F is a nitrogen monoxide releasing, delivering or transferring moiety, and include any and all such compounds which provide nitrogen monoxide to its intended site of action in a form active for its intended purpose. The term "NO adducts" encompasses any nitrogen monoxide releasing, delivering or transferring compounds, including, for example, S-nitrosothiols, nitrites, nitrates, S-nitrothiols, sydnonimines, 2-hydroxy-2-nitrosohydrazines, (NONOates), (E)-alkyl-2-[(E)-hydroxyimino]-5-nitro-3-hexene amines or amides, nitrosoamines, furoxans as well as substrates for the endogenous enzymes which synthesize nitric oxide. The "NO adducts" can be mono-nitrosylated, poly-nitrosylated, mono-nitrosated and/or poly-nitrosated at a variety of naturally susceptible or artificially provided binding sites for biologically active forms of nitrogen monoxide.

One group of NO adducts is the S-nitrosothiols, which are compounds that include at least one -S-NO group. These compounds include S-nitroso-polypeptides (the term "polypeptide" includes proteins and polyamino acids that do not possess an ascertained biological function, and derivatives thereof); S-nitrosylated amino acids (including natural and synthetic amino acids and their stereoisomers and racemic mixtures and derivatives thereof); S-nitrosylated sugars; S-nitrosylated, modified and unmodified, oligonucleotides (preferably of at least 5, and more preferably 5-200 nucleotides); straight or branched, saturated or
unsaturated, aliphatic or aromatic, substituted or unsubstituted S-nitrosylated hydrocarbons; and S-nitroso heterocyclic compounds. S-nitrosothiols and methods for preparing them are described in U.S. Patent Nos. 5,380,758 and 5,703,073; WO 97/27749; WO 98/19672; and Oae et al, *Org. Prep. Proc. Int.*, 15(3):165-198 (1983), the disclosures of each of which are incorporated by reference herein in their entirety.

Another embodiment of the present invention is S-nitroso amino acids where the nitroso group is linked to a sulfur group of a sulfur-containing amino acid or derivative thereof. Such compounds include, for example, S-nitroso-N-acetylcysteine, S-nitroso-captopril, S-nitroso-N-acetylpenicillamine, S-nitroso-homocysteine, S-nitroso-cysteine, S-nitroso-glutathione, S-nitroso-cysteiny1-glycine, and the like.

Suitable S-nitrosylated proteins include thiol-containing proteins (where the NO group is attached to one or more sulfur groups on an amino acid or amino acid derivative thereof) from various functional classes including enzymes, such as tissue-type plasminogen activator (TPA) and cathepsin B; transport proteins, such as lipoproteins; heme proteins, such as hemoglobin and serum albumin; and biologically protective proteins, such as immunoglobulins, antibodies and cytokines. Such nitrosylated proteins are described in WO 93/09806, the disclosure of which is incorporated by reference herein in its entirety. Examples include polynitrosylated albumin where one or more thiol or other nucleophilic centers in the protein are modified.

Other examples of suitable S-nitrosothiols include:

(i) \( \text{HS}(\text{C}(R_x)(R_y))_{m\text{SNO}} \);  
(ii) \( \text{ONS}(\text{C}(R_x)(R_y))_{n\text{SNO}} \); and

In cases where R_ and R_ are a heterocyclic ring or taken together R_ and R_ are a heterocyclic ring, then R_ can be a substituent on any disubstituted nitrogen contained within the radical wherein R_ is as defined herein.

Nitrosothiols can be prepared by various methods of synthesis. In general, the thiol precursor is prepared first, then converted to the S-nitrosothiol derivative by nitrosation of the thiol group with NaNO_2 under acidic conditions (pH is about 2.5) which yields the S-nitroso derivative. Acids which can be used for this purpose include aqueous sulfuric, acetic and hydrochloric acids. The thiol precursor can also be nitrosylated by reaction with an organic nitrite such as tert-butyl nitrite, or a nitrosonium salt such as nitrosonium tetrafluoroborate in an inert solvent.

NO$_2$ compounds that are polypeptides or hydrocarbons with a pair or pairs of
thiols that are sufficiently structurally proximate, i.e., vicinal, that the pair of thiols
will be reduced to a disulfide. Compounds which form disulfide species release
nitroxyl ion (NO$^-$) and uncharged nitric oxide (NO$^\bullet$). Compounds where the thiol
groups are not sufficiently close to form disulfide bridges generally provide nitric
oxide as the NO$^-$ form and not as the uncharged NO$^\bullet$ form.

Another group of NO adducts are N-oxo-N-nitrosoamines that donate,
transfer or release nitric oxide and are represented by the formula: $\text{R}^1\text{R}^2-(\text{O-M})-$
NO, where $\text{R}^1$ and $\text{R}^2$ are each independently a polypeptide, an amino acid, a sugar,
a modified or unmodified oligonucleotide, a straight or branched, saturated or unsaturated, aliphatic or aromatic, substituted or unsubstituted hydrocarbon, or a heterocyclic group, and where M⁺ is an organic or inorganic cation, such as, for example, an alkyl substituted ammonium cation or a Group I metal cation.

The present invention is also directed to compounds that stimulate endogenous NO or elevate levels of endogenous endothelium-derived relaxing factor (EDRF) in vivo or are substrates for nitric oxide synthase. Such compounds include, for example, L-arginine, L-homoarginine, and N-hydroxy-L-arginine, including their nitrosated and nitrosylated analogs (e.g., nitrosated L-arginine, nitrosylated L-arginine, nitrosated N-hydroxy-L-arginine, nitrosylated N-hydroxy-L-arginine, nitrosated L-homoarginine and nitrosylated L-homoarginine), precursors of L-arginine and/or physiologically acceptable salts thereof, including, for example, citrulline, ornithine or glutamine, inhibitors of the enzyme arginase (e.g., N-hydroxy-L-arginine and 2(S)-amino-6-boronoheptanoic acid) and the substrates for nitric oxide synthase, cytokines, adenosin, bradykinin, calreticulin, bisacodil, and phenolphthalein. EDRF is a vascular relaxing factor secreted by the endothelium, and has been identified as nitric oxide (NO) or a closely related derivative thereof (Palmer et al, Nature, 327:524-526 (1987); Ignarro et al, Proc. Natl. Acad. Sci. USA, 84:9265-9269 (1987)).

Another embodiment of the present invention provides compositions comprising at least one parent COX-2 inhibitor and at least one compound that donates, transfers or releases nitric oxide, or elevates levels of endogenous EDRF or nitric oxide, or is a substrate for nitric oxide synthase. The parent COX-2 inhibitors includes any of those described in the prior art, including those described in the patents and publications cited herein, as well as the novel compounds described herein.

The compounds and compositions of the present invention can be administered by any available and effective delivery system including, but not limited to, orally, bucally, parenterally, by inhalation spray, by topical application, by injection, transdermally, or rectally (e.g., by the use of suppositories) in dosage unit formulations containing conventional nontoxic pharmaceutically acceptable carriers, adjuvants, and vehicles, as desired. Parenteral includes subcutaneous injections, intravenous, intramuscular, intrasternal injection, or infusion techniques.

Transdermal compound administration, which is known to one skilled in the art, involves the delivery of pharmaceutical compounds via percutaneous passage of the compound into the systemic circulation of the patient. Topical administration can also involve the use of transdermal administration such as transdermal patches or iontophoresis devices. Other components can be incorporated into the transdermal patches as well. For example, compositions and/or transdermal patches can be formulated with one or more preservatives or bacteriostatic agents including, but not limited to, methyl hydroxybenzoate, propyl hydroxybenzoate, chlorocresol, benzalkonium chloride, and the like. Dosage forms for topical administration of the compounds and compositions can include creams, sprays, lotions, gels, ointments, eye drops, nose drops, ear drops, and the like. In such dosage forms, the compositions of the invention can be mixed to form white, smooth, homogeneous, opaque cream or lotion with, for example, benzyl alcohol 1% or 2% (wt/wt) as a preservative, emulsifying wax, glycerin, isopropyl palmitate, lactic acid, purified water and sorbitol solution. In addition, the compositions can contain polyethylene glycol 400. They can be mixed to form ointments with, for example, benzyl alcohol 2% (wt/wt) as preservative, white petrolatum, emulsifying wax, and tenox II (butylated hydroxyanisole, propyl gallate, citric acid, propylene glycol). Woven pads or rolls of bandaging material, e.g., gauze, can be impregnated with the compositions in solution, lotion, cream, ointment or other such form can also be used for topical application. The compositions can also be applied topically using a transdermal system, such as one of an acrylic-based polymer adhesive with a resinous crosslinking agent impregnated with the composition and laminated to an impermeable backing.

Solid dosage forms for oral administration can include capsules, tablets, effervescent tablets, chewable tablets, pills, powders, sachets, granules and gels. In
such solid dosage forms, the active compounds can be admixed with at least one
inert diluent such as sucrose, lactose or starch. Such dosage forms can also
comprise, as in normal practice, additional substances other than inert diluents,
e.g., lubricating agents such as magnesium stearate. In the case of capsules, tablets,
effervescent tablets, and pills, the dosage forms can also comprise buffering agents.
Soft gelatin capsules can be prepared to contain a mixture of the active compounds
or compositions of the present invention and vegetable oil. Hard gelatin capsules
can contain granules of the active compound in combination with a solid,
pulverulent carrier such as lactose, saccharose, sorbitol, mannitol, potato starch,
corn starch, amylopectin, cellulose derivatives of gelatin. Tablets and pills can be
prepared with enteric coatings.

Liquid dosage forms for oral administration can include pharmaceutically
acceptable emulsions, solutions, suspensions, syrups, and elixirs containing inert
diluents commonly used in the art, such as water. Such compositions can also

and sweetening, flavoring, and perfuming agents.

Suppositories for vaginal or rectal administration of the compounds and
compositions of the invention, such as for treating pediatric fever and the like, can
be prepared by mixing the compounds or compositions with a suitable
nonirritating excipient such as cocoa butter and polyethylene glycols which are
solid at room temperature but liquid at rectal temperature, such that they will melt
in the rectum and release the drug.

Injectable preparations, for example, sterile injectable aqueous or oleaginous
suspending agents, wetting agents and/or suspending agents. The sterile injectable
preparation can also be a sterile injectable solution or suspension in a nontoxic
parenterally acceptable diluent or solvent, for example, as a solution in 1,3-
butanediol. Among the acceptable vehicles and solvents that can be used are
water, Ringer’s solution, and isotonic sodium chloride solution. Sterile fixed oils
are also conventionally used as a solvent or suspending medium.

The compositions of this invention can further include conventional
excipients, i.e., pharmaceutically acceptable organic or inorganic carrier substances
suitable for parenteral application which do not deleteriously react with the active
compounds. Suitable pharmaceutically acceptable carriers include, for example, water, salt solutions, alcohol, vegetable oils, polyethylene glycols, gelatin, lactose, amylose, magnesium stearate, talc, surfactants, silicic acid, viscous paraffin, perfume oil, fatty acid monoglycerides and diglycerides, petroethral fatty acid esters, hydroxymethyl-cellulose, polyvinylpyrrolidone, and the like. The pharmaceutical preparations can be sterilized and if desired, mixed with auxiliary agents, e.g., lubricants, preservatives, stabilizers, wetting agents, emulsifiers, salts for influencing osmotic pressure, buffers, colorings, flavoring and/or aromatic substances and the like which do not deleteriously react with the active compounds. For parenteral application, particularly suitable vehicles consist of solutions, preferably oily or aqueous solutions, as well as suspensions, emulsions, or implants. Aqueous suspensions may contain substances which increase the viscosity of the suspension and include, for example, sodium carboxymethyl cellulose, sorbitol and/or dextran. Optionally, the suspension may also contain stabilizers.

The composition, if desired, can also contain minor amounts of wetting agents, emulsifying agents and/or pH buffering agents. The composition can be a liquid solution, suspension, emulsion, tablet, pill, capsule, sustained release formulation, or powder. The composition can be formulated as a suppository, with traditional binders and carriers such as triglycerides. Oral formulations can include standard carriers such as pharmaceutical grades of mannitol, lactose, starch, magnesium stearate, sodium saccharine, cellulose, magnesium carbonate, and the like.

Various delivery systems are known and can be used to administer the compounds or compositions of the present invention, including, for example, encapsulation in liposomes, microbubbles, emulsions, microparticles, microcapsules and the like. The required dosage can be administered as a single unit or in a sustained release form.

The bioavailability of the compositions can be enhanced by micronization of the formulations using conventional techniques such as grinding, milling, spray drying and the like in the presence of suitable excipients or agents such as phospholipids or surfactants.

nitrosylated COX-2 inhibitor compositions or the parent COX-2 inhibitor for the
treatment of gastrointestinal disorders are orally, bucally or by inhalation. The
preferred methods of administration for the treatment of inflammation and
microbial infections are orally, bucally, topically, transdermally or by inhalation.

The compounds and compositions of the present invention can be
formulated as pharmaceutically acceptable salt forms. Pharmaceutically acceptable
salts include, for example, alkali metal salts and addition salts of free acids or free
bases. The nature of the salt is not critical, provided that it is pharmaceutically-
acceptable. Suitable pharmaceutically-acceptable acid addition salts may be
prepared from an inorganic acid or from an organic acid. Examples of such
inorganic acids include, but are not limited to, hydrochloric, hydrobromic,
hydroiodic, nitric, carbonic, sulfuric and phosphoric acid and the like. Appropriate
organic acids include, but are not limited to, aliphatic, cycloaliphatic, aromatic,
heterocyclic, carboxylic and sulfonic classes of organic acids, such as, for example,
formic, acetic, propionic, succinic, glycolic, gluconic, lactic, malic, tartaric, citric,
ascorbic, glucuronic, maleic, fumaric, pyruvic, aspartic, glutamic, benzoic,
anthranilic, mesylic, salicylic, p-hydroxybenzoic, phenylacetic, mandelic, embonic

from the corresponding compound by reacting, for example, the appropriate acid
or base with the compound.

While individual needs may vary, determination of optimal ranges for
effective amounts of the compounds and/or compositions is within the skill of the
art. Generally, the dosage required to provide an effective amount of the
compounds and compositions, which can be adjusted by one of ordinary skill in the
art, will vary depending on the age, health, physical condition, sex, diet, weight,
extent of the dysfunction of the recipient, frequency of treatment and the nature and scope of the dysfunction or disease, medical condition of the patient, the route of administration, pharmacological considerations such as the activity, efficacy, pharmacokinetic and toxicology profiles of the particular compound used, whether a drug delivery system is used, and whether the compound is administered as part of a drug combination.

The amount of a given nitrosated and/or nitrosylated COX-2 inhibitor or the parent COX-2 inhibitor which will be effective in the treatment of a particular disorder or condition will depend on the nature of the disorder or condition, and can be determined by standard clinical techniques, including reference to Goodman and Gilman, supra; The Physician’s Desk Reference, Medical Economics Company, Inc., Oradell, N.J., 1995; and Drug Facts and Comparisons, Inc., St. Louis, MO, 1993. The precise dose to be used in the formulation will also depend on the route of administration, and the seriousness of the disease or disorder, and should be decided by the physician and the patient’s circumstances.

The amount of nitric oxide donor in a pharmaceutical composition can be in amounts of about 0.1 to about 10 times the molar equivalent of the COX-2 inhibitor. The usual daily doses of nitrosated and/or nitrosylated COX-2 inhibitors are about 0.001 mg to about 140 mg/kg of body weight per day, preferably 0.005 mg to 30 mg/kg per day, or alternatively about 0.5 mg to about 7 g per patient per day. For example, inflammations may be effectively treated by the administration of from about 0.01 mg to 50 mg of the compound per kilogram of body weight per day, or alternatively about 0.5 mg to about 3.5 g per patient per day. The compounds may be administered on a regimen of up to 6 times per day, preferably 1 to 4 times per day, and most preferably once per day. Effective doses may be extrapolated from dose-response curves derived from in vitro or animal model test systems and are in the same ranges or less than as described for the commercially available compounds in the Physician’s Desk Reference, supra.

The present invention also provides pharmaceutical kits comprising one or more containers filled with one or more of the ingredients of the pharmaceutical compounds and/or compositions of the present invention, including, at least, one or more of the COX-2 inhibitors optionally substituted with at least one NO and/or NO₃ group, described herein and one or more of the NO donors described herein.
Associated with such kits can be additional therapeutic agents or compositions (e.g., steroids, NSAIDs, 5-lipoxygenase (5-LO) inhibitors, leukotriene B₄ (LTB₄) receptor antagonists and leukotriene A₄ (LTA₄) hydrolase inhibitors, 5-HT agonists, HMG-CoA inhibitors, H₂ antagonists, antineoplastic agents, antiplatelet agents, decongestants, diuretics, sedating or non-sedating anti-histamines, inducible nitric oxide synthase inhibitors, opioids, analgesics, Helicobacter pylori inhibitors, proton pump inhibitors, isoprostane inhibitors, and the like), devices for administering the compositions, and notices in the form prescribed by a governmental agency regulating the manufacture, use or sale of pharmaceuticals or biological products which reflects approval by the agency of manufacture, use or sale for humans.

Fuming HNO₃ (0.76 mL, 18 mmol) was added to Ac₂O (2.7 mL, 28.8 mmol) at 0 °C via syringe and stirred for 5 min at 0 °C. The mixture was then transferred with a pasteur pipette to a stirred suspension of the product of Example 20d (1.2 g, 3.6 mmol) in EtOAc (40 mL) at room temperature and the mixture was stirred for 45 minutes at room temperature. Cold saturated NaHCO₃ (40 mL) was added and shaken well in a separatory funnel. The organic layer was separated and dried over Na₂SO₄. The solvent was evaporated under reduced pressure to afford a viscous oil which was dissolved in CH₂Cl₂ (5 mL) and hexane (25 mL). The resulting clear solution was left in a freezer at -10 °C for 4 hours to give title compound (1.05 g, 77%) as a yellow solid. mp 104 °C. ¹H-NMR (300 MHz, CDCl₃) δ 8.05 (d, J = 8.4 Hz, 2H), 7.55 (d, J = 8.4 Hz, 2H), 6.39 (s, 1H), 5.50 (s, 2H), 3.95–4.10 (mult, 1H), 3.13 (s, 3H), 1.60–2.10 (mult, 7H), 1.15–1.30 (mult, 3H); ¹³C-NMR (75 MHz, CDCl₃) δ 143.1, 142.1, 140.7, 136.0, 129.8, 127.9, 107.3, 68.6, 58.6, 44.4, 33.3, 25.5, 25.0; mass spectrum (API-TIS), m/z 380 (MH⁺). Example 21: Assay for Ovine COX-1 and COX-2 activity

The ovine COX-1 and COX-2 activities and the measurement of the prostaglandin products synthesized were performed using the COX Inhibitor Screening Assay (Cayman Chemical, Ann Arbor, MI, which also contained the Prostaglandin Screening EIA Kit, used for prostaglandin quantification). The test compounds were dissolved at 50 times the highest final reaction concentration in DMSO or any other suitable solvent as stock solutions. These stock solutions were then diluted in the same solvent. Eight glass test tubes (13 x 100 mm) were placed
in a 37°C water bath. To each test tube was added 950 μL of reaction buffer (0.1 M Tris-HCl, pH 8.0, containing 5 mM EDTA, and 2 mM phenol), 10 μL of 100 M heme solution, and 10 μL (5 units) of either ovine COX-1 or COX-2 and the resulting mixture was incubated with the enzyme for 2 minutes. Twenty μL of the solvent was added to one tube (100% initial activity or solvent control) and 20 μL of each dilution of the test compound was added to one tube each. Each tube was vortexed immediately after the addition. The enzyme was incubated with the inhibitor for 3.5 minutes at 37°C. The enzymatic reaction was then initiated by the addition of 10 μL of freshly prepared 10 mM arachidonic acid (neutralized with KOH), vortexed and then incubated for 2 minutes at 37°C. The reaction was terminated by the addition of 50 μL of 1 M HCl, vortexed and placed at room temperature. One hundred microliters of a saturated stannous chloride solution (50 mg/mL of 0.1 M HCl) was added and the reaction mixture was allowed to stand at room temperature for at least 5 minutes.

The prostaglandins (PG) produced in the reactions were assayed, after a 2,000-fold dilution, using the Prostaglandin Screening EIA Kit (Cayman Chemical, Ann Arbor, MI). The assay contains an antibody with broad specificity for all the prostaglandin families (PGF, PGE, PGD, and thromboxane B-type) synthesized in the COX-1/COX-2 reactions. The synthesized prostaglandin competes with a PG-tagged acetylcholine esterase tracer for binding to the PG antibody. Binding of synthesized PG lowers the colorimetric development of the Ellman's Reagent (computed as %B/B₀). The actual amount of synthesized PG was interpolated from a standard curve using known amounts of supplied prostaglandin E2 (PGE₂) concentration vs. %B/B₀). The data generated were the mean ± standard deviation of triplicate wells in the EIA for a single reaction at a given inhibitor concentration. A plot of % of control (i.e., the solvent control without inhibitor) vs. test compound inhibitor concentration for both isoenzymes was used to determine the IC₅₀'s for COX-1 and COX-2 for that test compound. The IC₅₀ for the compounds are given in Table 1.

The NSAID, indomethacin, did not show selectivity for either COX-1 or COX-2. Celecoxib, a selective COX-2 inhibitor, used as a control, was selective for COX-2. The results show that the nitrosated compounds (i.e., Examples 1b, 2b and 5b) have similar COX-2 selectivity as their parent non-nitrosated compound (i.e., Example 1a, 2a and 5a respectively). Hence, nitrosation did not effect the COX-2 inhibition properties. The results show that the nitrosylated compound (i.e., Example 3g) was not as potent as the parent non-nitrosylated compound (i.e., Example 3e). The nitrosylation of the sulfonamide group on the parent COX-2 inhibitor probably effected the COX-2 inhibition properties of the nitrosylated compound.

Example 22: Assay for Human COX-1 and COX-2 activity

The human COX-1 and COX-2 activities and the measurement of the prostaglandin products synthesized were performed using the COX Inhibitor Screening Assay (Cayman Chemical, Ann Arbor, MI, which also contained the Prostaglandin Screening EIA Kit, used for prostaglandin quantification). The test compounds were dissolved at 50 times the highest final reaction concentration in DMSO or any other suitable solvent as stock solutions. Twenty μL of the solvent was added to one tube (100% initial activity or solvent control) and 20 μL of each dilution of the test compound was added to one tube each. Each tube was vortexed immediately after the addition. The enzyme was incubated with the inhibitor for 20 minutes at 25 °C. The enzymatic reaction was then initiated by the addition of 10 μL of freshly prepared 10 mM arachidonic acid (neutralized with KOH), vortexed and then incubated for 2 minutes (or, in some cases as indicated, 30 seconds) at 37 °C. The reaction was terminated by the addition of 50 μL of 1 M HCl, vortexed and placed at room temperature. One hundred microliters of a saturated stannous chloride solution (50 mg/mL of 0.1 M HCl) was added and the reaction mixture was allowed to stand at room temperature for at least 5 min.

The data generated were the mean ± standard deviation of triplicate wells in the EIA for a single reaction at a given inhibitor concentration. A plot of % of control (i.e., the solvent control without inhibitor) vs. test compound inhibitor concentration for both isoenzymes was used to determine the IC50’s for COX-1 and COX-2 for that test compound, when IC50’s were calculated. The % inhibition for selected concentrations of inhibitors tested are given in Table 2.

<sup>a</sup> = Ovine COX-1

The results show that the nitrosated compounds (i.e., Examples 2b, 5b, 19e and 20e) have similar or slightly improved COX-2 selectivity compared to their parent non-nitrosated compound (i.e., Example 2a, 4a, 19d and 20d, respectively). Hence, nitrosation did not effect the COX-2 inhibition properties and might improve the COX-2 inhibition properties.

Example 23: Preparation of rat aortic smooth muscle rings

Male Sprague-Dawley rats (Charles River Laboratories (Wilmington, MA) were euthanized by intraperitoneal injection of a high dose of sodium pentobarbitone (80-100 mg/kg). The thoracic aorta was rapidly excised and immediately placed in a Petri dish containing warm (37 °C) oxygenated (95% O<sub>2</sub> and 5% CO<sub>2</sub>) Kreb’s buffer (composition per millimolar: NaCl (119); KCl (4.69); CaCl<sub>2</sub>·H<sub>2</sub>O (2.52); MgSO<sub>4</sub>·7H<sub>2</sub>O (0.57); NaHCO<sub>3</sub> (25); NaH<sub>2</sub>PO<sub>4</sub>·H<sub>2</sub>O (1.01) and glucose (11.1). Under a stereoscopic dissecting microscope, the aorta was cleaned, freed from adhering fat and connective tissues. The tissue was cut into ring segments, each approximately 2-3 mm in length.

For experiments to measure relaxation of the tissue under various conditions, a stainless steel tissue holder and an U-shaped stainless steel wire were inserted into the lumen of the aortic ring. The tissue holder anchored the ring at
the bottom of the organ bath whereas the end of the U-shaped steel wire was tied with fine silk thread so that it connected to the FT-202 transducer. The tissue holder and the steel wire along with the aortic ring were then suspended in a 5-mL double-jacketed temperature-controlled glass organ bath (Radnoti Glass Technology, Inc., Monrovia, CA) filled with fresh Kreb's buffer. A mixture of 95% O₂ and 5% CO₂ was bubbled through a porous sintered disc at the bottom of the bath. The rings were given an initial resting tension of 1.5 g and the preparation was allowed to equilibrate at the initial tension for about 90 minutes. During this equilibration period, the bath fluid was changed every 15 minutes and replaced with fresh prewarmed (37 °C) Kreb's buffer. The isometric tension of the aortic muscle at rest and its response to different stimuli were recorded on a Power Macintosh 6100 computer via a MacLab 8/S computer interface (CB Sciences, Inc, Milford, MA) after an initial amplification through a low-noise ETH-400 bioamplifier (CB Sciences, Inc, Milford, MA). Contractile responsiveness of the tissue strips was established with 10 μM phenylephrine, and the strips were incubated with the drug for 20 minutes to establish a steady level of contraction. To test the relaxation effects, test compounds were added to the phenylephrine-precontracted strips in the tissue bath at cumulative concentrations of 0.1 μM to 0.1 mM. Concentration of test compounds was increased only after relaxation at the previous concentration had reached a plateau level.

**Example 24: Relaxation of aortic smooth muscle ring by Example 1**

The tissue was prepared according to Example 23. The percent contraction of phenylephrine-contracted aortic smooth muscle rings induced by isosorbide dinitrate (ISDN), Example 1a and Example 1b (nitrate) was measured. Fig. 1 shows that the parent non-nitrosated compound, Example 1a, did not relax the aortic ring. The nitrosated compound, Example 1b, induced the relaxation of the aortic ring. The observed relaxation was more potent than that obtained by the nitrate compound, isosorbide dinitrate.

**Example 25: Relaxation of aortic smooth muscle ring by Example 2**

The tissue was prepared according to Example 23. The percent contraction of phenylephrine-contracted aortic smooth muscle rings induced by isosorbide dinitrate (ISDN), Example 2a and Example 2b (nitrate) was measured. Fig. 2 shows that the parent non-nitrosated compound, Example 2a, did not relax the
aortic ring. The nitrosated compound, Example 2b, induced the relaxation of the aortic ring. The observed relaxation was similar to that obtained by the nitrate compound, isosorbide dinitrate.

**Example 26: Relaxation of aortic smooth muscle ring by Example 3**

The tissue was prepared according to Example 23. The percent contraction of phenylephrine-contracted aortic smooth muscle rings induced by S-nitrosoglutathione (GSNO), Example 3e and Example 3h (nitrosothiol) was measured. Fig. 3 shows that the parent non-nitrosylated compound, Example 3e, did not relax the aortic ring. The nitrosylated compound, Example 3h, induced the relaxation of the aortic ring. The observed relaxation was similar to that obtained by the nitrosothiol compound, S-nitrosoglutathione.

**Example 27: Relaxation of aortic smooth muscle ring by Example 20**

The tissue was prepared according to Example 23. The percent contraction of phenylephrine-contracted aortic smooth muscle rings induced by isosorbide dinitrate (ISDN), Example 20d and Example 20e (nitrate) was measured. Fig. 4 shows that the parent non-nitrosylated compound, Example 20d, did not relax the aortic ring. The nitrosated compound, Example 20e, induced the relaxation of the aortic ring. The observed relaxation was similar to that obtained by the nitrate compound, isosorbide dinitrate.

**Example 28: Anti-inflammatory paw edema test for Example 2**

The carrageenan-induced rat paw edema test was used to measure anti-inflammatory activity. The paw edema test was performed according to the method of Winter et al, *Proc. Soc. Exp. Biol. Med.* 111: 544-547, 1962. Male Sprague-Dawley rats (200-250 g) were fasted for 24 hours with water *ad libitum*. The rats were dosed intragastrically with test compounds in a volume of 5 mL/kg. One hour after dosing the paw volume was measured. Then each rat received a subplantar injection of 50 μl of 1% suspension of carrageenan. Three hours later, the paw volume was measured and compared with the initial volume measured immediately after carrageenan injection. The increase in paw volume is presented as the mean ± SEM for 5 rats per group. Data were analyzed by performing an ANOVA test followed by a Student-Keuls post hoc test.

**Figure 5** shows that the parent non-nitrosated compound Example 2a, the nitrosated compound Example 2b and Celecoxib all reduced the paw volume and,
hence, these compounds have antiinflammatory activity. Thus, nitrosation did not 
effect the COX-2 inhibition properties of the compounds.

Box I Observations where certain claims were found unsearchable (Continuation of Item 1 of first sheet)

This international report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. □ Claim Nos.:
   because they relate to subject matter not required to be searched by this Authority, namely:

2. □ Claim Nos.:
   because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

3. □ Claim Nos.:
   because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of Item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

Please See Continuation Sheet

1. □ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.

2. □ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.

3. ☒ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.: 1-66 (in part) i.e., compounds of formula II and VII

4. □ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.: 

Remark on Protest □ The additional search fees were accompanied by the applicant’s protest.
☒ No protest accompanied the payment of additional search fees.
