(54) Title: SURFACE CLEANING APPARATUS WITH DIFFERENT CLEANING CONFIGURATIONS

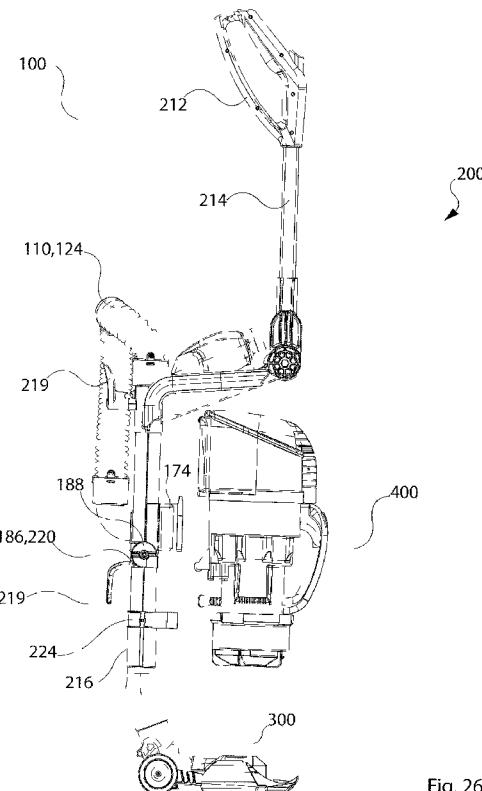

Fig. 26

(57) Abstract: An upright surface cleaning apparatus comprises an air flow path extending from a dirty air inlet to a clean air outlet, a surface cleaning head having the dirty air inlet, a support structure moveably mounted to the surface cleaning head, the support structure comprising a cleaning unit. The cleaning unit comprises a suction motor and an air treatment member positioned in the air flow path. The cleaning unit is removably mountable wherein the cleaning unit is retained on the support structure when in a storage position under the influence of gravity.

TITLE: SURFACE CLEANING APPARATUS WITH DIFFERENT CLEANING CONFIGURATIONS

FIELD

[0001] The specification relates to surface cleaning apparatus. In a 5 preferred embodiment, the surface cleaning apparatus has a portable surface cleaning unit, such as a hand vacuum, that is selectively detachable from a support structure and may be selectively connected to a surface cleaning head by an airflow conduit.

INTRODUCTION

10 [0002] The following is not an admission that anything discussed below is prior art or part of the common general knowledge of persons skilled in the art.

[0003] Various types of surface cleaning apparatus are known. Typical upright vacuum cleaners include an upper section, including an air treatment member such as one or more cyclones and/or filters, drivingly mounted to a 15 surface cleaning head. An up flow conduit is typically provided between the surface cleaning head and the upper section. In some such vacuum cleaners, a spine, casing or backbone extends between the surface cleaning head and the upper section for supporting the upper section. The air treatment member or members and/or the suction motor may be provided on the upper section.

20 [0004] Surface cleaning apparatus having a portable cleaning module that is removably mounted to an upright vacuum cleaner are known. See for example, US5,309,600. In addition surface cleaning apparatus having a removably mounted hand vacuum cleaner are also known. See for example US 4,635,315.

SUMMARY

25 [0005] The following introduction is provided to introduce the reader to the more detailed discussion to follow. The introduction is not intended to limit or define the claims.

[0006] According to one broad aspect, an upright vacuum cleaner is provided that comprises a support structure drivingly connected to a surface cleaning head. A cleaning unit is selectively detachably mounted to the support structure and may be selectively connectable in fluid communication with the surface cleaning head by an airflow conduit. A mount that permits one handed operation by a user to remove the cleaning unit from the support structure is provided. For example, the cleaning unit may be held in place by gravity when in the storage position and, optionally, also when in a floor cleaning position. Preferably, the mount permits for sliding engagement between the cleaning unit and the support structure that supports the cleaning unit. The cleaning unit is preferably vertically removable from the mount. Accordingly, the cleaning unit may seat on a mount spaced from a floor cleaning head and remain in place until lifted off even if the cleaning unit is not locked in place.

[0007] Accordingly a user may use one hand to lift the portable surface cleaning unit of the surface cleaning apparatus while still operating the surface cleaning apparatus with the user's other hand. Optionally, a lock may be provided. In such a case, the lock is preferably operated using a single hand and the portable surface cleaning unit preferably remains in position when the lock is disengaged so that a user may use the same hand to release the lock and to then remove the portable surface cleaning unit.

[0008] During operation, dirt is entrained in an air stream that is drawn into a dirty air inlet, preferably at the front of the surface cleaning head. During the operation of the surface cleaning apparatus, the cleaning unit may be removed from the mount and held by the user while still in airflow communication with the surface cleaning head (i.e. without interrupting the operation of the surface cleaning apparatus).

[0009] The cleaning unit may be slidingly received within the mount and vertically held within the mount by gravity, absent any mechanical fasteners. In this type of gravity mount, the cleaning unit is freely removable from the mount

without having to release or open any fasteners. This gravity mount configuration enables a user to quickly and easily remove the cleaning unit from the mount using a single hand.

[0010] Optionally, the cleaning unit can be detached from the surface 5 cleaning head and may receive an auxiliary cleaning tool. Accordingly, the cleaning unit may be converted to use a different cleaning tool to clean, e.g., a floor. For example, an air turbine powered brush may be selectively mounted to the cleaning unit. Alternately, or in addition, an above floor cleaning tool, e.g., an attachment that includes a flexible hose to which a cleaning tool may be mounted 10 at the end distal to the nozzle, may be used. Accordingly, the cleaning unit may be adapted for additional cleaning uses. Essentially, a removable attachment may be employed to convert an open sided nozzle to a traditional nozzle with a traditional dirty air inlet. Alternately, the nozzle may be connectable with a surface cleaning head of an upright vacuum cleaner.

15 [001 1] In one embodiment, an upright surface cleaning apparatus includes an air flow path extending from a dirty air inlet to a clean air outlet and a surface cleaning head having the dirty air inlet. The surface cleaning apparatus also includes a support structure moveably mounted to the surface cleaning head and a cleaning unit comprising a suction motor and an air treatment member. The 20 cleaning unit is positioned in the air flow path and is removably mountable. The cleaning unit is retained on the support structure when in a freely removable configuration.

[0012] In some examples, the cleaning unit and the support structure are 25 configured to retain the cleaning unit on the support structure in a storage position under the influence of gravity.

[0013] In some examples the surface cleaning apparatus also includes a lock that releasably locks the cleaning unit on the support structure. The

cleaning unit and the support structure are configured to retain the cleaning unit on the support structure when the lock is in an unlocked position.

[0014] In some examples, the cleaning unit has a bottom and the bottom is spaced from the surface cleaning head when the cleaning unit is mounted to the support structure.

[0015] In some examples, the cleaning unit is supported only by the support structure.

[0016] In some examples, the upright surface cleaning apparatus may further comprise an attachment member, the cleaning unit is removably mountable on a mount provided on the support structure, the attachment member and the mount is configured such that the cleaning unit is removable from the mount in the absence of disengaging a lock.

[0017] The cleaning unit may be removably mountable on the mount, the attachment member and mount may be configured such that the cleaning unit is removable from the mount in the absence of disengaging a lock.

[0018] In some examples, the mount has a first contact member and the attachment member has a second contact member, the second contact member is downwardly slidably engagable with the first contact member and abutment of the first and second contact members restrains movement of the cleaning unit in a forward direction of travel and a direction transverse to the forward direction of travel and the vertical.

[0019] In some examples, at least one of the contact members includes a cam surface.

[0020] In some examples, one of the contact members comprises a cam surface and the other of the contact members comprises a cam.

[0021] In some examples, one of the contact members comprises a pair of opposed spaced apart sides defining a channel between the opposed sides, at

least one of the opposed sides having an open portion, and the other of the contact members comprises an abutment member sized to be received in the channel, the abutment member having opposed sidewalls spaced apart by a distance, each sidewall facing one of the opposed sides and a distance between

5 the sidewalls and the opposed facing walls decreases from an upper end of the abutment member to a lower portion of the abutment member.

[0022] In some examples, the open portion comprises a portion of the front of the one of the contact members.

[0023] In some examples, the cleaning unit comprises an attachment member, the second contact member is provided on the attachment and the attachment member extends outwardly through the open portion.

[0024] In some examples, the attachment member is removably mounted on the cleaning unit.

[0025] In some examples, the attachment member is removably mounted on the cleaning unit using a complimentary tongue and groove connection.

[0026] In some examples, the attachment member comprises part of an air flow path from the surface cleaning head to the cleaning unit.

[0027] In some examples, a mount provided on the support structure and the attachment member are configured to retain the cleaning unit on the support structure under the influence of gravity during operation of the upright surface cleaning apparatus.

[0028] In some examples, the attachment member is vertically removable from the support structure.

[0029] In some examples, an air flow path from the surface cleaning head to the cleaning unit comprises a flexible air flow conduit.

[0030] In some examples, the upright surface cleaning apparatus has at least two operating modes comprising a first upright operating mode wherein the

upright surface cleaning apparatus is operable with the cleaning unit mounted to the support structure and forming part of the air flow path and a second operating mode wherein the cleaning unit is operable when removed from the support structure.

5 [0031] In some examples, in the second mode, the cleaning unit is operable when removed from the support structure and in air communication with the surface cleaning head.

[0032] In some examples, an air flow path from the surface cleaning head to the cleaning unit comprises a flexible air flow conduit.

10 [0033] In some examples, the cleaning unit is operable when disconnected from the surface cleaning head.

[0034] In some examples, the cleaning unit is mounted to the support structure at a midpoint of the support structure.

15 [0035] In some examples, the support structure comprises a further portion that also retains the cleaning unit on the support structure.

[0036] In some examples, the further portion is below the first contact member.

[0037] In some examples, the further portion engages a wheel of the cleaning unit.

20 [0038] In some examples, the attachment member and a mount provided on the support structure comprise a releasable securing mount and the releasable securing mount further comprises at least one magnet.

[0039] In some examples, the cleaning unit is supported on an airflow conduit of the support structure.

25 [0040] It will be appreciated that an embodiment may contain one or more of features set out in the examples.

DRAWINGS

[0041] In the detailed description, reference will be made to the following drawings, in which:

[0075] Figure 33 is an isometric view of the attachment member of Figure 32 with the shell seated on the mount and the knob in the locked position;

[0076] Figure 34 is a front elevation view of an another example of a 25 vacuum cleaner wherein the cleaning unit has been removed for hand held use; and,

[0077] Figure 35 is a top perspective view of the motor housing of the vacuum cleaner of Figure 34.

DESCRIPTION OF VARIOUS EXAMPLES

[0078] Various apparatuses or methods will be described below to provide 5 an example of each claimed invention. No example described below limits any claimed invention and any claimed invention may cover processes or apparatuses that are not described below. The claimed inventions are not limited to apparatuses or processes having all of the features of any one apparatus or process described below or to features common to multiple or all of the 10 apparatuses described below. It is possible that an apparatus or process described below is not an embodiment of any claimed invention.

[0079] The following description describes various embodiments of an upright surface cleaning apparatus, for example an upright vacuum cleaner. The upright surface cleaning apparatus generally comprises a support structure or 15 upright section that is movably connected to a surface cleaning head. In accordance with a first aspect, the support structure may be of any particular design that is flexible or bendable at a location between the upper end and the lower end of the support structure when in use. Preferably, the support structure includes a hinge that pivotally connects an upper and lower portion of the support 20 structure.

[0080] Referring to Figures 1 to 5, 15 to 19, 20 to 21 and 22 to 33, examples of an upright surface cleaning apparatus 100 are shown which exemplifies the design using a hand vacuum cleaner 400. The surface cleaning apparatus 100 is a vacuum cleaner that comprises a floor cleaning unit 200 25 comprising a surface cleaning head 300 having a support structure 210 pivotally mounted thereto and a hand vacuum cleaner 400 that is removably mounted to support structure 210. Support structure 210 may also be referred to as a handle, a backbone or an upright section. In this specification, the terms portable surface

cleaning apparatus, cleaning unit and hand vacuum are used alternately to refer to the hand vacuum cleaner 400.

[0081] It will be appreciated that in each example, the surface cleaning apparatus 400 need not be a portable cleaning unit having a dirty air inlet for 5 cleaning a surface. Instead it may be a cleaning unit that houses a suction motor and one or more air treatment members wherein the cleaning unit may be of any construction and may use any particular air treatment member (e.g., one or more cyclones comprising one or more cyclonic cleaning stages and/or one or more filters). Such a cleaning unit does not have a dirty air inlet adapted to clean a 10 floor. Instead, it is configured to receive dirty air conveyed from floor cleaning unit 300. For example, the cleaning unit may be detachable from the support structure 210 as exemplified in Figure 3a and Figure 25 but flexible hose 124 may not be removable from the cleaning head or the cleaning unit. The support structure 210 (or other elements) may also comprise cord wind members 219 (as 15 exemplified in Figures 17 and 22) for winding the power cord of the vacuum cleaner 100 when not in use.

[0082] In accordance with the first aspect, the support structure comprises first and second portions wherein the second portion is rotatable relative to the first portion about an axis that intersects a longitudinal axis of at least one of the 20 first and second portions.

[0083] As exemplified in Figures 1-5, 15-19, 20-21 and 22-33, the support structure 210 (also referred to as the handle 210) has an upper portion 214 and a lower portion 216 that are preferably pivotally connected by a hinge 218. Any type of hinge, pivot or bending mechanism known in the vacuum cleaner arts 25 may be used provided that grip 212 may be moved forwardly with respect to the upper end of lower portion 214. The handle 210 is attached to the surface cleaning head 300 and a user can move the surface cleaning head 300 along a surface to be cleaned by gripping and maneuvering the handle 210. Optionally, the lower portion 216 of the handle 210 may be moveably, e.g., hingedly or

pivottally, attached to the surface cleaning head 300, so that the lower portion 216 of the handle 210 can move relative to the surface cleaning head 300 during use. This may enable the user to move the surface cleaning head 300 beneath cabinets, furniture or other obstacles.

5 [0084] The upper portion 214 of the handle optionally includes a handgrip or grip 212 that is shaped to be gripped by a user. In the example shown, the grip 212 is at the top, or upper end of the upper portion 214 of the handle 210 and is formed in a closed loop-type shape having surfaces that are rounded to increase user comfort. In other examples, the grip 212 may be of a different 10 configuration and may be located at a different position on the upper portion 214 of the handle 210.

[0085] Alternately, or in addition, the upper portion 214 of the handle 210 optionally includes a bracket 113, as exemplified in Figures 1-5, which supports an auxiliary, or accessory or supplemental cleaning tool 112. In the example 15 shown, the bracket 113 is configured to hold a single auxiliary cleaning tool 112, but in other examples the bracket 113 may be configured to hold more than one auxiliary cleaning tool 112. Also, while shown attached to the upper portion 214, it is understood that the bracket 113 may be attached to other locations on the surface cleaning apparatus, including the lower portion 216 as exemplified in 20 Figures 17 and 20, the surface cleaning head 300 and/or the hand vacuum cleaner 400.

[0086] Optionally, the cleaning unit is not restrained within, e.g., a recess, in an outer housing or other portion of the support structure. As exemplified in Figures 1-5, 15-19, 20-21 and 22-33, an upright vacuum cleaner 100 has an 25 absence of a housing or shell that has traditionally been used with upright vacuum cleaners. For example, no molded plastic shell is provided that houses operating components of the vacuum cleaner and includes a recess for receiving the hand vacuum cleaner 400. Instead, as exemplified, one or more support rods or structural members may be used, e.g., one as exemplified in Figures 1-5, 20-

21 and 22-33 or two as exemplified in Figures 15-19, so as to define a frame to removably receive the cleaning unit. In such an embodiment, the support rods may define a frame for removably receiving the cleaning unit. As exemplified, preferably the support rods or structural members that form the upper and lower 5 portions 214, 216 have a generally cylindrical or tube-like shape. However, in other examples, the upper and lower portions 214, 216 may be any other type of relatively thin or elongated support members having suitable cross-sectional shape including square, rectangular or polygonal. In addition, the upper and lower portions 214, 216 may be solid or hollow and may be formed from any 10 suitable material, including plastic and metal. If one or both of the upper and lower portions 214, 216 are hollow, then the hollow portion may form part of the air flow path through the vacuum cleaner, as exemplified in Figures 22-33.

[0087] When the hinge 218 is in a first position, as shown in Figures 1, 2, 4, 5, 15, 16, 20, 22 and 24-26 the upper and lower portions 214, 216 of the 15 handle 210 are generally aligned with each other, e.g., they each have a longitudinal axis and the axis are generally parallel. As exemplified in Figures 15 and 21, the axis of the upper portion 214 may be located forward of the axis of the lower portion 216. The hinge 218 is preferably retained in this first position by a biasing or locking means so that the upper portion 214 of the handle 210 20 preferably remains at a fixed angular position with lower portion 216 when the lock is engaged so that forward and rearward movements applied to grip 212 of the upper portion 214 of the handle 210 can be translated to the second portion 216 as is known conventionally. In use, the hinge 218 can be unlocked, or released from the first position and upper portion 214 may be moved into one or 25 more second fixed positions, wherein the grip 212 is preferably rotated forwardly. Optionally, the lock may remain in the unlocked position such that upper portion 214 may freely rotate with respect to the lower portion 216 while it is used to move the cleaning head.

[0088] As exemplified in Figures 1, 2, 4, 5, 15, 17 and 20-23, the grip 212 preferably comprises an actuator for releasing or unlocking the releasable lock or hinge 218, for example a button or hinge release 213 that can be activated by a user during use of vacuum cleaner 100 to unlock the hinge 218. It will be
5 appreciated that the actuator may be of any type and may be located at any location and is preferably provided on the upper portion and is preferably adjacent the grip 212. When a user activates the hinge release 213, the retaining or locking means used to secure the hinge 218 in the first position is disengaged, allowing the hinge 218 to rotate or pivot, as shown in Figure 3a and 17. As the
10 hinge 218 rotates, the first portion 214 of the handle 210 can be moved into a plurality of angular positions relative to the second portion 216 handle 210. Optionally, the hinge 218 may rotate between, and lock into, one or a given number of set or indexed angular positions. Alternatively, the rotation of the hinge 218 may be continuously variable, after being initially unlocked, allowing
15 for the first portion 214 to be moved into an indefinite number of angular positions relative to the second portion 216 (e.g., freely rotatable).

[0089] The upright surface cleaning apparatus also includes a cleaning unit, for example hand vacuum cleaner 400. The cleaning unit is attached to and supported by the support structure 210. Preferably, the cleaning unit is
20 removably mounted to the support structure and it may be detachably mounted thereto. Preferably, the cleaning unit is removable from support structure 210 while still in air flow communication with the cleaning head 300. Accordingly an attachment member 120 may be used to provide both a member to removably attach the cleaning unit to support structure 210 and an air flow connection when
25 the cleaning unit is removed with the attachment member 120.

[0090] In the examples shown, the hand vacuum cleaner 400 is attached to the support structure 210 using a mount apparatus, for example mount 220. Preferably, instead of connecting directly to the hand vacuum cleaning 400, the mount apparatus is configured to receive a complimentary attachment apparatus,

for example attachment member 120, which is connected, and preferably removably connected, to the hand vacuum cleaner 400. Preferably, as exemplified in Figures 1, 2, 4, 5, 15-19, 20-21 and 22-33, the lower portion 216 comprises the mount 220 for supporting the hand vacuum cleaner 400. It will be
5 appreciated that, alternately, mount 220 may be provided on upper portion 214.

[0091] Hand vacuum cleaner 400 is preferably connected in fluid communication with the cleaning head 300 by a conduit that comprises, and may consist of, a flexible hose. In such a case, the lower portion 216 also optionally comprises a hose guide 230, as exemplified in Figures 1, 2, 4 and 5 for keeping
10 the flexible hose 124 in close proximity to the support structure 210. When the hand vacuum cleaner 400 is detached or removed from the support structure 210 the flexible hose 124 may be removed from the hose guide 230, as shown in Figure 3a. In another example, as exemplified in Figures 15-19, 20 and 22-26, a
15 hose guide may not be included when the upstream end of the flexible hose 124 is connected in air flow communication with an upper end of the lower portion 216 instead of directly to the surface cleaning head 300.

[0092] In a second aspect, which may be used by itself or with any one or more other aspects, and with or without a bendable wand, examples of the upright vacuum cleaner 100 may be operated in one or more of the following
20 three functional configurations or modes. The versatility of operating in different modes is achieved by permitting hand vacuum cleaner 400 to be removed from support structure 210 with or without attachment member 120. Alternately, or in addition, further, versatility is achieved by permitting flexible hose 124 to be disconnectable from attachment member 120 and/or the cleaning head 300.

25 [0093] In the first configuration, as exemplified in Figures 1, 2, 17 and 24, the vacuum cleaner 100 can be operated with the hand vacuum cleaner 400 mounted to the lower portion 216 of the floor cleaning unit 200. In this configuration the hand vacuum cleaner 400 is supported by the support structure 210 and the vacuum cleaner 100 can be operated as an upright vacuum cleaner.

In this configuration, the hand vacuum cleaner 400 is attached to the support structure 210 using, e.g., an attachment member 120 (examples of attachment members are described in greater detail below). In some examples, a portion of the load of the hand vacuum cleaner 400 is optionally also supported by a mount 5 bracket 224, which receives and supports another part of surface cleaning apparatus 400, such as optional rear wheel 480 of the surface cleaning apparatus 400.

[0094] In a second configuration, as exemplified in Figures 3a and 25, the surface cleaning apparatus 400 is detached from the support structure 210 but 10 remains in fluid communication with the surface cleaning head 300 via, e.g., flexible hose 124 and attachment member 120. In this configuration, the hand vacuum cleaner 400 may be carried by the user (or rested on the floor or other surface) while still serving as the vacuum or suction source for the vacuum cleaner 100.

15 [0095] In the third configuration, as exemplified in Figures 3b, 4 and 26, the surface cleaning apparatus 400 is detached from the support structure 210 and from fluid communication with surface cleaning head 300. The cleaning unit may have a nozzle and be a portable surface cleaning apparatus, such as a hand vacuum cleaner. As exemplified in Figures 4 and 26, the hand vacuum 20 cleaner 400 may be uncoupled from the attachment member 120 (which remains attached to the support structure 210) and can be used independently as a portable cleaning apparatus or a hand vacuum.

[0096] Optionally, as exemplified in Figure 3b, the surface cleaning apparatus 400 is detached from the support structure 210 and from fluid 25 communication with surface cleaning head 300 by detaching flexible hose 124 from the surface cleaning head 300. Accordingly, flexible hose 124 serves as an extended cleaning attachment for the hand vacuum cleaner 400. Optionally, one or both ends of flexible hose 124 may be disconnectable from the surface cleaning apparatus.

[0097] Accordingly, if the attachment member 120 is coupled to the hand vacuum cleaner 400, and the upstream end of the air conduit 110 (for example hose 124) is detached from the surface cleaning head 300, then the combination of the attachment member 120 and the flexible hose 124 (decoupled from the surface cleaning head 300) may serve as an auxiliary or accessory cleaning tool. The free end of the hose 124 may be maneuvered by the user to clean objects and surfaces that cannot be cleaned using the surface cleaning head 300. In some examples, the upstream end of the flexible hose 124 may be connected to the auxiliary cleaning tool 112. Alternatively, the flexible hose 124 may be removed from the attachment member 120 and the auxiliary cleaning tool 112 may be mounted directly to the air inlet 126 of the attachment member 120. It will be appreciated that tool 112 may have a plate 123 and arms 150 provided at the coupling end thereof.

[0098] Optionally, the attachment member 120 may be removed from the hand vacuum cleaner 400 and the auxiliary cleaning tool 112 may be fitted directly to the nozzle 412 (shown in Figures 6-10), without the use of a flexible hose 124 or other type intermediate air conduit. In addition to the auxiliary or accessory cleaning tool 112, the nozzle 412 may be directly connected to any one of a number of cleaning tools that have been provided with the an appropriate attachment member, including wands, brushes, crevasse tools and other hoses.

[0099] Optionally, a cleaning wand 114 may be attached to the upstream end of the flexible hose 124, as exemplified in Figure 20. The addition of the cleaning wand 114 to the end of the flexible hose 124 may enable a user to reach further (for example to the top of drapes or curtains) or to extend the airflow conduit 110 into confined spaces (for example between couch cushions or under cabinets and appliances). When assembled as shown in Figure 24, the upright vacuum cleaner configuration, the dirty air travels from the cleaning head

300 through lower portion 216 (which is the up flow duct), through hose 124 and into attachment member 120.

[00100] In some examples, the cleaning wand 114 may be shaped so that it can be received within or in air flow communication with an upper opening 286 of 5 the lower portion 216 of the support structure 210, as exemplified in Figure 22. In these examples, when the cleaning wand 114 is not in use it can be received within, and thereby stored within the lower portion 216 of the support structure 210 (not shown) or maybe mounted to upper end of lower portion 216 and form part of the support structure 210. In other examples, the cleaning wand 114 may 10 be elsewhere and flexible hose 124 may be connected directly to upper opening 286.

[00101] In any of the examples described above, the air conduit 110 (for example flexible hose 124 and/or wand 114) may still be detachable from the surface cleaning head 300 even when the cleaning unit is not detachable from 15 the support structure. Accordingly, some or all of air conduit may be detachable from the surface cleaning head 300 whether or not the hand vacuum cleaner 400 is detachable from the support structure 210 to enable a user to use the flexible hose 124 and/or the wand 114 to clean surfaces that are awkward to clean using the surface cleaning head 300, for example upholstery, drapes, stairs and other, 20 non-level, confined or elevated surfaces.

[00102] As exemplified in Figure 22, in a preferred embodiment, the lower portion 216 is hollow and forms part of the airflow passage through the vacuum cleaner. Accordingly, lower portion 216 functions as both an air flow conduit and a support structure on which surface cleaning apparatus 400 is mounted. If a 25 rigid cleaning wand 114 is not required, then the dirty air may travel from lower portion 216 directly into surface cleaning apparatus 400, e.g., via attachment member 120. Alternately, if a cleaning wand 114 is provided, then as exemplified, the dirty air may travel from the upper end of lower portion 216 into wand 114,

into flexible hose 124, through optional attachment member 120, and then into surface cleaning apparatus 400.

[00103] To provide the user with increased reach and cleaning range, the cleaning wand 114 may be more rigid than the flexible hose 124, and is 5 preferably rigid, so that the cleaning wand 114 will maintain its generally elongate configuration (that is the upstream end of the cleaning wand being separated from but generally concentric with the downstream end of the cleaning wand), even when it is only held at one end by the user. In some instances, the cleaning wand 114 may be substantially rigid so that it will not deflect or bend 10 during use. In other instances, the cleaning wand 114 may be more rigid than the flexible hose 124, but still somewhat resiliently flexible so that it can bend during use.

[00104] Optionally, the upstream end of the cleaning wand 114 can be connected to other auxiliary or accessory cleaning tools, for example an air 15 turbine powered brush 116. In some instances, the cleaning wand 114 may not be required and the flexible hose 124 may be directly connected to the brush 116 or other accessory or auxiliary tool. Some auxiliary cleaning tools, for example the brush 116 may also be described as second surface cleaning heads or auxiliary cleaning heads. In some instances, the nozzle 412 (described in detail 20 below) of the hand vacuum cleaner 400 may also be described as a second surface cleaning head, particularly when the hand vacuum cleaner 400 is configured as a hand vacuum. Optionally, the cleaning wand 114 or any other second surface cleaning head or auxiliary tool may be connected directly to the nozzle 412.

25 [00105] In accordance with a third aspect, which may be used by itself or with one or more of the other aspects, the removable cleaning unit is secured in position by gravity. This may be achieved using a mount 220 that removably receives attachment member 120. This aspect is preferably used with the second aspect but may be used with the first aspect and/or the second aspect.

[00106] Some examples of the mount 220 may be configured to removably receive a portion of the hand vacuum cleaner 400 or preferably, as exemplified, an attachment member 120 that may be removably coupled to the hand vacuum cleaner 400. Alternately, the attachment member may itself include the mount so 5 that the attachment member may be removably attached directly to the lower portion 216. This may be achieved by the attachment member and the mount being an integrated assembly wherein the attachment member and the mount are not disconnectable from each other (i.e. the hand vacuum cleaner 400 can be removed but not with the attachment member) or the attachment member and 10 the mount may be separable as exemplified in Figures 22-33, whereby the hand vacuum cleaner may be removed with or without the attachment member so as to increase the versatility of the surface cleaning apparatus.

[00107] The mount 220, as exemplified in Figures 1-5 and 15-19, is preferably configured to retain the hand vacuum cleaner 400 therein under the 15 influence of gravity. Accordingly, a mechanical lock need not be used. In particular, a user may lift the portable surface cleaning apparatus off of upright section 210 without having to press a button or otherwise release a mechanical lock. The absence of mechanical fasteners allows for simple, one-handed removal of the attachment member 120 and the hand vacuum cleaner 400 from the 20 mount 220, without the need to unlock or undo any fasteners. One-handed detachment of the hand vacuum cleaner 400 may be advantageous as it allows a user to control and maneuver the support structure 210 with one hand while simultaneously removing the hand vacuum cleaner 400 from the mount 220 with the other hand. In use, this may allow a user to frequently attach and detach the 25 hand vacuum cleaner 400 from the mount 220 in response to the user's needs, for example navigating around furniture, stairs or other obstacles on the surface to be cleaned.

[00108] Optionally, the mount 220 may be outfitted with magnets for retaining the attachment member 120. Magnets may assist in holding the hand

vacuum cleaner on the mount and still permit one-handed removal as no fastener or lock need be manually released.

[00109] Alternatively, or in addition, as exemplified in Figures 22-33 a lock, for example a rotatable locking knob may be used to releasably secure 5 adjustment member 120 and mount 220 together. In such an embodiment, it is preferred, as exemplified in the embodiment of Figures 22-33, that when the lock is disengaged, hand vacuum cleaner 400 is still held in position by gravity. Other examples of possible fasteners include clips, snaps, and straps. Magnets may alternately or in addition be used.

10 [001 10] One example of a mount 220, as exemplified in Figures 1-5, is a generally U-shaped member sized to receive a contact member on the attachment member 120, for example collar 140 or other mounting portion of the complimentary attachment member 120. The inner surface of the mount 220 comprises a corresponding contact member, for example protrusion 222 that 15 extends outward from the inner surface of the mount 220 and removably seats within the generally U-shaped channel 144 of the collar 140.

[001 11] In this example, loads placed on the mount 220 (via both the U-shaped opening and/or the mount bracket 224) are in turn transferred via the lower portion 216 of the handle 210 to the surface cleaning head 300 and 20 ultimately to the floor or other type of surface being cleaned. Another portion of the load of the hand vacuum cleaner 400 may be supported by an additional mounting bracket, such as mount bracket 224, which receives and supports optional rear wheel 480 of the hand vacuum cleaner 400. The surface of the mount bracket 224 may be complimentary to the curved shape of the optional 25 rear wheel 480 so that the optional rear wheel 480 can at least partially nest within mount bracket 224. An upward facing protrusion 222 on the inner surface of the mount 220 seats within the channel 144 of the attachment member 120 and provides a degree of lateral support, restraining the movement of the attachment member 120 (and therefore the hand vacuum cleaner 400) when the

handle 210 is moved from a vertical position to an angled position when in use. Further, protrusion 222 may comprise a cam surface to assist in guiding protrusion 222 into channel 144 as the portable surface cleaning apparatus is lowered onto mount 220. In this example the attachment member 120 and the 5 optional rear wheel 480 are preferably not held in place by clips, straps or any other type of mechanical fastening means.

[001 12] Optionally, the protrusion 222 may not have a uniform cross-section along its length. As exemplified in Figure 4, the upward facing portions of the protrusion 222 (both ends of the continuous protrusion shown in Figure 4, or the 10 upward facing portions of each saddle flange 280 described below) may taper or converge such that the upward facing portions of the protrusion 222 are narrower than the connecting central portion. When the attachment member 120 is lowered into the mount 220 by the user, the tapered upward facing portions of the protrusion 222 are generally the first portion of the protrusion 222 to engage 15 the collar 140. To adequately secure the attachment member 120 within the mount 220, the width or thickness of the central portion of the protrusion 222 is preferably substantially the same as the width of the channel 144 of the collar 140, leaving only a small clearance, if any, between the channel 144 walls and the protrusion 222. It will be appreciated that if the clearance is too tight, it may 20 be difficult to quickly place the attachment member 120 onto the mount 220.

[001 13] One advantage of the tapered upwards facing portions of the protrusion 222 may be that because the upwards facing portions have a reduced width (relative to the channel 144 width) it may be easier for a user to place the channel 144 over the ends of the upwards facing portions due to the increased 25 clearance between the channel 144 walls and the edges of the tapered upwards facing portions. After the upward facing portions have been received in the channel 144 they may act as a cam and contact the channel 144 walls or other surfaces of the collar 140 (which may function as follower or camming surfaces) and align or register the attachment member 120 within the mount 220. The

cam-like action of the protrusion 222 may create a self-aligning or self-registering connection between the attachment member 120 and the mount 220.

[001 14] As exemplified, in addition to supporting the weight of the hand vacuum cleaner 400, the attachment member 120 also preferably serves as a 5 fluid conduit establishing a fluid flow connection between the hand vacuum cleaner 400 and the airflow conduit 110, which is preferably a flexible hose 124. The mount 220 may be made from any material that can support the weight of the hand vacuum cleaner 400, including plastic and metal.

[001 15] A second example of a mount 220, as exemplified in Figures 15-19 10 comprises more than one member configured to receive the collar portion 140 of attachment member 120. As exemplified, two support rods or ribs 256 are provided, each of which holds part of mount 220.

[001 16] Split saddle mount 220 comprises a pair of generally opposing saddle flanges 280 (one on each rib and each having a contact surface) that 15 cooperate to provide a mount or a mounting location for the attachment member 120 that is connected to the hand vacuum cleaner 400. Due to the spacing of the ribs 256 and the general curvature of the hand vacuum cleaner 400, the hand vacuum cleaner 400 is preferably positioned in front of ribs 256. The attachment member 120 may extend rearward of hand vacuum cleaner 400 and may be 20 received on split saddle flanges 280. Alternately, it will be appreciated that hand vacuum cleaner 400 may be partially nested between, or be received between, the ribs 256.

[001 17] As exemplified, to supportingly engage the attachment member 120, each saddle flange 280 preferably includes a contact member, for example 25 a projection or protrusion (see Figure 18) that is received within the channel 144 of the collar 140 (as described in more detail with reference to Figures 11-14 below). The generally curved profile of the collar 140 and channel 144 may enable the attachment member 120 (and the associated hand vacuum cleaner

400) to generally self-level or self-register between the ribs 256 when the user initially places the attachment member 120 on the saddle flanges 280. Optionally, the saddle flanges 280 may include magnets or other fastening devices to secure or retain the attachment member 120.

5 [001 18] Ribs 256 are secured in position by a connecting structure at the upper and lower end of ribs 256. Any such structure may be used. As exemplified in Figures 15-19, second portion 216 may comprise a generally upside down U-shaped wishbone portion 250 to secure the upper ends of ribs 256 together.

10 [001 19] If used together with the first aspect, the wishbone 250 may be provided with a hinge 218 at the centre of an upper portion of the wishbone 250, and each prong 254 of the wishbone extends downward, and connects to a rib 256. The ribs 256 are preferably substantially parallel and cooperate to define a split saddle mount 220 for receiving the attachment member 120 and the hand 15 vacuum cleaner 400. Optionally, the ribs 256 may be integrally formed with the prongs 254 of the wishbone portion 250, or they may be separate tubes or rods fastened to the prongs 254 of the wishbone 250, as shown.

[00120] The lower ends of the ribs 256 may be attached to a bracket 260 having a generally opposite configuration than the wishbone. That is, the bracket 20 may include two, upward facing projections 262, for attaching to the ribs 256, that are connected by a cross-member 264 to provide a single downward facing coupling point 266. An advantage of providing a single, downward facing coupling point may be the fact that a single coupling point can be pivotally and rotationally connected to the surface cleaning head 300. Another advantage is 25 that a narrower rear end may be utilized for the surface cleaning head 300.

[00121] The bracket 260 also includes a housing 268, which is preferably hollow, having a lower opening 270 that is connected in flow communication with the surface cleaning head 300 (e.g. by a rigid pipe as exemplified by Figures 21-

30 or, by a flexible hose as exemplified in Figures 15-19). Housing 268 may be pivotally mounted to surface cleaning head, preferably at about the location of rear wheels 320, such as by having a portion pivotally mounted to the axle of rear wheels 320. Optionally, the connection between the lower opening 270 and the 5 surface cleaning head 300 can be a rotatable and pivotal connection. The hollow housing 268 may extend from the lower opening 270, through the cross-member 264 to define an upper collar 272.

[00122] A third example of a mount 220 and complimentary attachment member 120 is exemplified in Figures 20-21 and 22-33, specifically Figures 27-10 33. This example of the attachment member 120 exemplifies an attachment member 120 that is optionally lockably attachable to mount 220.

[00123] Mount 220 optionally comprises a contact member, for example structural member 186 that has a central opening for receiving the lower portion 216 of the support structure 210. Mount 220 may be secured to lower portion 15 216 such as by a key, a set screw, an adhesive or other locking means. In the example illustrated the central opening of structural member 186 is generally annular (to receive the generally cylindrical lower portion 216), while in other examples the central opening may have a different shape that is complimentary to the profile of its respective lower portion. In other examples, the mount 220 or 20 the structural member 186 may be integrally formed with the lower portion 216.

[00124] The mount 220 also comprises a pair of upwardly extending contact members, for example bosses 182 (not shown in Figures 20-21). The bosses 182 may be integral with structural member 186 and are sized and shaped to be received within corresponding holes 184 in shell 174 of the attachment member 25 120. Once received within their corresponding holes 184, the bosses 182 serve to register the shell 174 on the mount 220 and restrain movement of the shell 174 relative to the mount 220 in the horizontal plane (when viewed with vacuum cleaner 100 in its upright position).

[00125] Preferably, as in the example shown, each boss 182 is generally conical, or frusto-conical, in shape so that a proximate end of each boss 182 (adjacent the mount 220) is wider (i.e. has a larger diameter) than the distal end of each boss 182 (spaced apart from the proximate end). Generally, the holes 184 in the shell 174 have a width (or diameter) that corresponds to the widest portion of the bosses 182, for example the base or proximate portion of the bosses 182 in the current example. Having a width (or diameter) of a hole that corresponds to the widest portion of each boss 182 enables the entire boss 182 to be received within its corresponding hole 184. Providing a narrower distal end 10 or tip on each boss 182 may make it easier for a user to position the bosses 182 within their holes 184 when placing the shell 174 onto the mount 220 and may enable the surface of each boss 182 to act as a guide or cam engaging a corresponding guiding or cam surface on the shell (for example the inner surface of the holes 184) for guiding the shell 174 to its desired mounted position. In 15 other examples, the mount 220 may contain a greater or fewer number of bosses 182 and each boss 182 may have any desired shape (typically corresponding to the shape of the corresponding holes 184), including cubic, rectangular prism and pyramidal.

[00126] In some examples the mount 220 also includes a coupling, locking 20 or attachment means for securing the shell 174 to the mount 220, when the shell 174 is seated on the mount 220 (with bosses 182 received within corresponding holes 184). As exemplified in Figures 24-30, one example of an attachment means is locking knob 188 that is rotatably connected to the mount 220, such as on protrusion 190, and is secured thereto such as by a screw (not shown). The 25 front, or outer face of the locking knob 188 comprises a pair of tabs 191 that are sized to be graspable by a user to rotate the locking know 188 about the protrusion 190. The rear, or inner face, of the locking knob 188 comprises a channel or groove 189 that is sized to receive the locking peg 180. Operation of the locking knob 188 is described below in relation to Figures 28-30. In other

examples, the attachment means may be any suitable mechanism, including clips, snaps, magnets, latches or hook and loop type fasteners. Alternatively, the mount 220 could be free from attachment means and the shell 174 could be held in place by gravity when in use.

5 [00127] As exemplified in Figures 24-30, the groove 178 is a semi-cylindrical recess formed in shell portion 175a that is shaped to at least partially receive the lower portion 216 of the support structure 210. In other examples, the shape of the groove 178 may be any suitable, complimentary shape chosen to fit the lower portion of the support structure 210. In the example illustrated, the 10 groove 178 subtends approximately 180 degrees of arc, while in other examples the groove 178 may subtend a larger or smaller arc, for example 200 degrees or 30 degrees. Having the lower portion 216 at least partially received within or nested within the groove 178 may increase the stability of the shell 174 when placed on the mount 220, which may reduce the lateral shear loading on bosses 15 182.

[00128] Shell 174 also comprises a protrusion or locking peg 180, extending from shell 174. In the example illustrated, the locking peg 180 is located on shell portion 175a. In other examples, the locking peg 180 may be located on any suitable portion of the shell 174 and may have any shape or 20 profile that is complimentary to the groove 189 on the rear face of the locking knob 188.

[00129] Figure 31 is an illustration of the attachment member 120 when the shell 174, supporting the hand vacuum cleaner 400, is slightly separated from the mount 220, for example when the shell 174 is in the process of being placed on, 25 or removed from, the mount 220. As shown in this figure, the lower portion 216 is partially received within the groove 178 which may serve to stabilize the shell 174 and may also serve as a locating or positioning means, which may help a user to horizontally align the holes 184 in the shell 174 with the bosses 182 on

the mount 220. When the shell 174 is spaced apart from the mount 220 the knob 188 is rotated to its open or unlocked position, as shown.

[00130] When the shell 174 is lowered onto the mount 220, as shown in Figure 28, the shell 174 (and hand vacuum cleaner 400) are supported by an 5 upper face of the mount 220 and the bosses 182. The locking knob 188 is rotated to the unlocked position.

[00131] As shown in Figure 33, to secure the shell 174 to the mount 220, the knob 188 is rotated into its closed or locked position (clockwise as illustrated in Figures 28-30), thereby retaining locking peg 180 and restraining vertical 10 movement of the shell 174 relative to the mount 220. As described above, horizontal movement (i.e. in the horizontal plane) of the shell 174 relative to the mount 220 is restrained by the combination of the groove 178 and the bosses 182 received in holes 184. Accordingly, with the knob 188 in the locked position (as shown in Figure 30) the shell 174 is fixed relative to the mount 220.

15 [00132] Optionally, as exemplified in Figures 20-21, the mount 220 may be configured to operate only as a gravity mount (free from fasteners) and may not include a locking knob 188 or locking peg 180.

[00133] In operation, the cleaning unit may not be lifted vertically off of attachment member 120 if the lock is engaged. If the lock is not engaged, then 20 the attachment member may be lifted off of the mount 220 and the cleaning unit removed while still in air flow communication with hose 124.

[00134] In each example of the surface cleaning apparatus 100, the mount 220 may be located in a variety of locations along the length of the second portion 216. Preferably, the mount 220 is positioned at approximately the waist 25 height of the intended user (e.g., 2.5 - 3.5 feet above the floor) so that the user can attach or detach the hand vacuum cleaner 400 from the support structure 210 without bending over. This may decrease the stress and strain experienced

by the user when the user removes the hand vacuum cleaner 400 from the support structure 210.

[00135] In other examples, the mount may be any type of supporting apparatus, connected to the support structure of the surface cleaning apparatus, 5 that is configured to detachably support the cleaning unit, for example the hand vacuum cleaner 400 that includes both the dirt collection chamber and the suction motor. Preferably, as described above, the mount is configured to stably support the cleaning unit and retain the cleaning unit in the mounted position in the absence of a locking mechanism or when a locking mechanism is in the 10 unlocked position. This configuration can provide both stability and quick, easy access for a user wishing to remove the cleaning unit.

[00136] For example, as exemplified in Figure 34 and 35, a pod or hand carriable cleaning unit 400 may have a motor housing 500 having a mount 502. Mount 502 has an opening 504 that is slideably mounted on to tube 506. As 15 exemplified, tube 506 is a part of air flow conduit 110 and is provided on cleaning head 300 and, preferably rotatably mounted thereon. When mount 502 is slid downwardly on to tube 506, pod 400 is positioned on cleaning head 300 and will remain in place until lifted off. It will be appreciated that a similar mounting means may be used to mount pod higher up on a support shaft provided on or in lieu of 20 tube 506. In an alternate embodiment, a lock may be provided to secure pod 400 in place.

[00137] In some examples, the mount can include a supporting platform that is connected to, and extends from the support structure. The supporting platform can be sized and shaped to correspond to the lower end of the cleaning 25 unit, for example the rear portion 410 of the hand vacuum 400. In this example the supporting platform is substantially co-extensive with the bottom of the suction motor housing, thereby underlying the centre of gravity of the cleaning unit, which enables the cleaning unit to remain seated on the supporting platform, even in the absence of a locking member. The supporting platform can be a

solid plate or, can be provided with a plurality of apertures or openings to allow the air to flow through the platform (for example to accommodate cleaning unit exhaust air flow or provide a cooling air flow).

[00138] Optionally, the supporting platform can include a recess or cavity 5 for receiving a least a portion of the cleaning unit, which can allow the supporting platform to positively engage or retain the cleaning unit thereby inhibiting the cleaning unit from tipping over or falling off the platform when the surface cleaning apparatus is in use.

[00139] Optionally, the supporting platform can be pivotally mounted to the 10 support structure, and biased toward the support structure, so that the support platform will automatically fold toward the support structure when the cleaning unit is removed. In such a configuration, the distance by which the support structure protrudes from the front of the support structure may be reduced, which can preserve the advantage of the floor cleaning head being able to be 15 maneuvered beneath furniture and into other narrow spaces, as described above.

[00140] In another example, the mount may be a lip or ledge that is substantially smaller than the bottom surface of the cleaning unit, for example having an area that is less than 50% of the area of the bottom of the cleaning 20 unit. In this example, the cleaning unit may not consistently balance when resting on the ledge, depending on the orientation of the support structure. To ensure the cleaning unit remains stable on the ledge in the absence of a latching or locking member, the ledge may include a protrusion, or more than one protrusion, that is slidably received within a corresponding slot or aperture on the 25 cleaning unit.

[00141] The protrusions can be generally elongated members extending from the ledge. The protrusions can be generally thin or plate like in nature or can be formed as thicker, three dimensional members, including, for example,

cylinders and polygonal prisms. In some examples, a user may wish to remove the cleaning unit from the mount by lifting the cleaning unit in a generally upward or vertical direction. In these examples, the protrusions and corresponding slots in the cleaning unit may be oriented in a generally vertical direction. In other 5 examples, the protrusions can extend from the ledge at an angle. In further examples, the protrusions can extend in the generally horizontal direction and the cleaning unit can include a generally horizontal slot. In such examples, a user can mount and remove the cleaning unit by translating the cleaning unit horizontally relative to the support structure.

10 [00142] The protrusions can be formed from any suitable material having the necessary mechanical properties to support the weight of the cleaning unit. Potentially suitable materials include plastic and metal. Alternatively, or in addition, the protrusions may be formed to have a cross-sectional shape that contributes to the structural stiffness or rigidity of the protrusion, including, for 15 example C-channel, I-beam, and tubular cross-sectional shapes.

[00143] Protrusions extending from the ledge can include a single protrusion configured to support cleaning unit, or a plurality of protrusions, arranged in a pattern, that cooperate to support the weight of the cleaning unit and to resist bending and torsion loads exerted by the cleaning unit when the 20 surface cleaning unit is in a stored position or an in use position.

[00144] The surface cleaning head 300 serves as a base portion of the vacuum cleaner 100 and is preferably in rolling contact with the surface to be cleaned. When the vacuum cleaner is 100 in an upright position (as exemplified in Figures 1, 2, 4, 5, 15, 16 and 20-23) the surface cleaning head 300 is 25 supported by optional main or rear wheels 320 and/or optional front wheels (not shown). Any surface cleaning head may be used.

[00145] In some examples, as exemplified in Figure 3a, the vacuum cleaner 100 may comprise an additional support wheel 321 that is provided on

the support structure 210 to provide additional rolling support when the vacuum cleaner 100 is moved into an angled position during use. In other examples, the surface cleaning head 300 may include a greater or fewer number of wheels. Preferably, lower portion 216 is rotatably mounted to the cleaning head.

5 Accordingly, a user may rotate grip 212 clockwise or counterclockwise to assist in steering the cleaning head.

[00146] The surface cleaning head 300 also comprises a dirty air inlet 310 that is connected in fluid communication with a dirty air outlet 312 by one or more dirty air conduits (not shown). Preferably, the dirty air inlet is an air flow chamber 10 10 wherein at least a portion of the lower side is open.

[00147] The dirty air outlet 312 may be coupled, optionally removably coupled, to the upstream end of the conduit, preferably via a flexible hose 124, that extends from the dirty air outlet 312 of the surface cleaning head 300 to the upright section, such as the attachment member air inlet 126. The fluid pathway 15 may continue through the attachment member passageway 129, which terminates in attachment member air outlet 127, and through attachment member air outlet 127 which mates with the opening 438 of the portable cleaning apparatus 400.

[00148] In some examples, as exemplified in Figures 15-19, the surface 20 cleaning head 300 includes a hollow conduit member 330 and a second air conduit 334. As exemplified in Figures 17-19, one example of the second air conduit 334 is a second flexible hose 335. In the preferred arrangement shown, the dirty air outlet 312 of the surface cleaning head 300 is connected to the second or upstream flexible hose 335 and the second flexible hose 335 extends 25 from the dirty air outlet 312, through the hollow conduit member 330, through the hollow housing 268 to the upper collar 272. The downstream end of the second flexible hose 335 may be fixedly connected to the upper collar 272, or it may have a fitting that seats upon a surface of the upper collar 272 preventing the second flexible hose 335 from retracting within the hollow housing 268 while

leaving the downstream end of the second flexible hose 335 free to extend upward, away from the upper collar 272.

[00149] The second flexible hose 335 forms part of the continuous airflow passageway that connects the dirty air outlet 312 of the surface cleaning head 300 to the opening 438 on the hand vacuum cleaner 400. In accordance with a fourth aspect that may be used by itself or with any other aspect, to establish the continuous airflow passageway, the downstream end of the second upstream flexible hose 335 may be connected to the upstream end of the downstream flexible hose 124. The connection between the flexible hose 124 and the downstream end of the second flexible hose 335 is preferably a detachable connection so that the flexible hose 124 can be detached from the surface cleaning head 300 as described above.

[00150] Optionally, in a fifth aspect, which may be used by itself or with any one or more other aspects, the second flexible hose 335 is also an extensible, or stretchable, hose that can extend when pulled on by the user. In some examples, the second flexible hose 335 is a stretch hose and may have a stretched length to non-stretched length ratio of between 2:1 - 6:1. In examples where the second flexible hose 335 is not stretchable, when a user removes the hand vacuum cleaner 400 from its mount during use, the maximum distance that the hand vacuum cleaner 400 can be separated from the support structure 210 and the surface cleaning head 300 is determined by the length of the flexible hose 124. However, in some instances, a user may wish to move the hand vacuum cleaner 400 a greater distance from the support structure 210, for example to pass the surface cleaning head 300 under a bed or other large piece of furniture. When a stretchable second flexible hose 335 is used, the downstream end of the second flexible hose 335 can unseat from the upper collar 272 and extend away from the bracket 260, whereby some of hose 335 may pass through housing 268 thereby lengthening the airflow conduit connecting the hand vacuum cleaner 400 to the surface cleaning head 300 and

allowing the hand vacuum cleaner 400 to be moved further from the support structure 210 in use. Accordingly, it will be appreciated that some or all of the conduit that may be extended to provide additional length for an air flow passage may be stored on the surface cleaning head 300.

5 [00151] It will be appreciated that lower section 216 may be rotatably mounted on cleaning head 300 without hose 335 extending through a housing 268. Further, a housing 268 may be used even if lower section 216 is not rotatably mounted to cleaning head 300. Such a housing need not be pivotally mounted to surface cleaning head.

10 [00152] Preferably, the second flexible hose 335 is also resilient so that it will return to its original, un-stretched length when it is released by the user. The resilience of the second flexible hose 335 may tend to retract the second flexible hose 335 through the hollow housing 268 and the hollow conduit member 330 and may serve to re-seat the downstream end of the second flexible hose 335 on 15 the upper collar 272. In this example, the second flexible hose 335 functions as a variable length air conduit and may reduce the need for a user to add extra hoses or conduit members to the vacuum 100 during use.

[00153] To allow for easy and repeated extension of the second flexible hose 335, the second flexible hose 335 may be sized to freely pass through both 20 the hollow conduit member 330 of the surface cleaning head 300 and the hollow housing 268 of the bracket 260.

[00154] In the example shown in Figure 15-19, the hollow housing 268 is integral the bracket 260 and also serves as the coupling means that connects the lower portion 216 to the surface cleaning head 300. As shown, the coupling 25 between the lower portion 216 and the surface cleaning head 300 may be the telescoping or overlapping engagement of the lower opening 270 over the surface cleaning head 300 hollow conduit member 330. In other examples, the coupling or attachment between the lower portion 216 and the surface cleaning

head 300 may be any type of connection including a threaded connection, clamps or tabs. The connection between the lower portion 216 and the surface cleaning head 300 may be fixed or selectively releasable. An advantage of providing a single, downward facing coupling point 266 may be the fact that a 5 single coupling point 266 can be pivotally and rotationally connected to the surface cleaning head 300. Further, the hollow conduit member 330 may be pivotally connected to the surface cleaning head 300, as exemplified in Figures 15-19, and in other examples, the hollow conduit member 330 may be fixedly connected to the surface cleaning head 300, or integrally formed therewith.

10 [00155] As shown, the hollow housing 268 may be integral with the bracket 260 and provide both a hollow passageway and an attachment point. However, in other examples, the hollow housing 268 may be external the bracket 260 and may be formed from a separate conduit. Similarly, the air flow conduit 110 connecting the attachment member 120 to the second flexible hose 335 may be 15 the flexible hose 124 or any other suitable conduit, including flexible conduits, rigid conduits, conduits integral with the handle and conduits external the handle.

[00156] Optionally, the ribs 256 (or another portion of the second portion 216) may be surrounded by a housing or shell. The housing may provide structural strength to the second portion 216 or it may merely provide an 20 improved aesthetic appearance of the vacuum 100, or both. If a housing is formed around a section of the second portion 216 (or any other section of the handle 210 or support structure 210) the mount for supporting the hand vacuum (for example the mount 220 or the saddle flanges 280) may be within a recess in the housing. Providing a recess in the housing for receiving the hand vacuum 25 may create a more integrated or seamless visual appearance when the hand vacuum is mounted to the support structure 210; it may also improve the rigidity of the support structure 210.

[00157] In a sixth aspect, which may be used by itself or with any one or more other aspects when hand vacuum cleaner 400 is mounted to the backbone,

the centre of gravity of the backbone and hand vacuum cleaner 400 combined is preferably below a plane P extending from the axle of rear wheel 320 to the upper end of upper portion 214 (as exemplified in Figure 17), thereby improving maneuverability of surface cleaning head 300. As exemplified, this may be

5 achieved by wishbone portion 250 extending forwardly to provide a mount for upper portion 214 (i.e. the handle) at a forward point of the backbone and passageway 268 extending rearwardly. It will be appreciated that other constructions, such as those exemplified in Figures 1-5 or Figures 20-30, may be used to position the centre of gravity behind the plane. For example, as best

10 shown in Figure 5, one example of the lower portion 216 includes an upper end that is connected to the hinge 218 such that the upper portion 214 is drivingly connected to the surface cleaning head 300. In this construction the lower end includes a step-back or kinked-back portion 215. The step-back portion 215 enables the mount 220 to be positioned sufficiently behind the rear wheels 320

15 such that the centre of gravity of the combination of the support structure 210 and the hand vacuum cleaner 400 is below the plane P. As a result of this configuration, the surface cleaning apparatus 100 may be more stable when rotated and maneuvered by the user, especially when upper portion 214 is rotated about hinge 218. Specifically, locating the centre of gravity of the

20 combination of the hand vacuum cleaner 400 and the support structure 210 below the plane P may tend to reduce the over rotation of the support structure 210 or over-steer of the vacuum 100 in use, and may reduce the strain on a user's arm and wrist.

[00158] It will be appreciated that the dual hose construction (i.e. the

25 flexible hose 124 and the second flexible hose 335 of Figure 15-19) may be used in combination with any example disclosed herein or by itself in a surface cleaning apparatus. Similarly, the positioning of a removably mounted portable surface cleaning apparatus with a low centre of gravity may be used in

combination with any example disclosed herein or by itself in a surface cleaning apparatus.

[00159] Preferably, the cleaning unit is a portable surface cleaning apparatus, and more preferably a hand vacuum cleaner, wherein the portable surface cleaning apparatus optionally has a nozzle having an open sided air flow chamber. It will be appreciated that the cleaning unit may be of any construction and may use any particular air treatment member (e.g., one or more cyclones comprising one or more cyclonic cleaning stages and/or one or more filters). Further, the cleaning unit may alternately, or in addition, selectively receive an auxiliary cleaning tool.

[00160] Referring now to Figures 6-14, examples a hand vacuum cleaner 400 and the attachment member 120 of the vacuum 100 are shown in more detail.

[00161] In some examples, the cleaning unit can be a hand vacuum cleaner 400 that can be operated as the vacuum suction supply for the vacuum 100 and it can be operated as a stand alone hand vacuum cleaner, that is movable along a surface to be cleaned by gripping and maneuvering handle 402, when it is removed from, or detached from the support structure 210. The hand vacuum cleaner 400 includes an upper portion 404, a lower portion 406, a front 408, and a rear 410. In the example shown, maneuvering handle 402 is provided at the upper portion 404. In alternate examples, maneuvering handle 402 may be provided elsewhere on the vacuum cleaner 400, for example at the rear 410.

[00162] In the example shown, the hand vacuum cleaner 400 comprises a nozzle 412 and a cyclone unit 414, which together preferably form a cleaning head portion 416 of the hand vacuum cleaner 400. In the example shown, the cleaning head portion 416 is provided at the front 408 of the hand vacuum cleaner 400.

[00163] Nozzle 412 comprises a dirty air inlet 418, through which dirty air is drawn into the portable cleaning apparatus 400, and when used as a hand vacuum cleaner the nozzle 412 directly engages a surface to be cleaned. An airflow passage extends from the dirty air inlet 418 to a clean air outlet 420 of the hand vacuum cleaner 400. In the example shown, clean air outlet 420 is at the rear 410 of the hand vacuum cleaner 400. It will be appreciated that clean air outlet may optionally be connected to a fluid conduit provided in the floor cleaning unit.

[00164] Cyclone unit 414 is provided in the airflow passage, downstream of the dirty air inlet 418. In the example shown, the cyclone unit 414 comprises one cyclone 422, and one dirt chamber 424. In alternate examples, the cyclone unit 410 may include more than one cyclone, and more than one dirt chamber. Further, the cyclones may be arranged in stages, and may be provided in parallel or in sequence. Alternately, or in addition, one or more filters or other dirt separation members may be used.

[00165] In the example shown, the nozzle 412 is positioned at the lower portion 406 of the portable cleaning apparatus 400. More preferably, as in the example shown, nozzle 412 is positioned at the bottom of the portable cleaning apparatus 400, and is preferably beneath the cyclone unit 414 when used as a hand vacuum cleaner and is between the cyclone unit 414 and the mount 220 when attached to the support structure 210. Further, as in the example shown, the nozzle 412 is preferably fixedly positioned at the lower portion 406 of the portable cleaning apparatus 400. That is, the nozzle 412 is not movable with respect to the remainder of the portable cleaning apparatus 400, and is fixed at the lower portion 406 of the portable cleaning apparatus 400. As shown in Figures 7 and 8, nozzle 412 has a width W_N and, as shown in Figure 11, coupling plate 123 has a width W_p that is generally the same as width W_N .

[00166] Nozzle 412 exemplifies a particular design for an open sided nozzle. Open sided nozzle 412 has an open side that faces the surface to be

cleaned when the nozzle is placed against a surface to be cleaned. Accordingly, nozzle 412 defines an air flow chamber that has an open lower side. In operation, air will flow longitudinally through the air flow chamber to an air exit. It will be appreciated that only part of the nozzle may have an open lower side.

5 Alternately, all of the nozzle, from an air inlet end to the air outlet, may have an open lower side. It will be appreciated that various other design may be used. An advantage of using an open sided nozzle is that the nozzle may be the member that is used to mount hand vacuum cleaner 400 to attachment member 120.

[00167] Referring now to Figures 8-14, nozzle 412 comprises an upper 10 nozzle wall 426. In the example shown, the upper nozzle wall 426 comprises a portion 419 of a wall 415 of the cyclone unit. Nozzle 412 further preferably comprises a depending wall 428 extending downwardly from the upper nozzle wall 426. The depending wall 428 is generally U-shaped. The height of the depending wall may vary. The open end of the U-shape defines an open side 15 wall 430 of the nozzle 412, and forms the dirty air inlet 418 of the portable cleaning apparatus 400. In the example shown, the open side wall 430 is provided at the front of the nozzle 412 and forms a portion of a flow passage that is in communication with the opening 438. When in use as a hand vacuum, optional wheels 435 are in contact with a surface and the open side wall 430 sits 20 above and is adjacent a hard surface to be cleaned. It will be appreciated that depending wall 428 may be positioned only rearward of opening 438. Alternately, or in addition, depending wall 428 may be provided adjacent the lateral sides of opening 438. The depending walls may be discrete walls or they may be joined together as exemplified. The walls may be continuous or discontinuous.

25 [00168] In the example shown, the lower end 432 of the depending wall 428 defines an open lower end 434 of the nozzle 412. The open lower end 434 extends to the front 408 of the hand vacuum cleaner 400, and merges with the open side 430. In use, the open lower end 434 faces a surface to be cleaned. In the example shown, a plurality of wheels 435 are mounted to the depending wall

428, and extend below the lower end 432 of the depending wall 428. Accordingly, when in use as a hand vacuum, when wheels 435 are in contact with a surface, the lower end 432 of the depending wall 428 is spaced from a surface to be cleaned, and the space between the lower end of the depending 5 wall 428 and the surface to be cleaned form a secondary dirty air inlet to the portable cleaning apparatus 400 when used as a hand vacuum.

[00169] The upper nozzle wall 426, depending wall 428, and open lower end 434 of the nozzle 412 define an airflow chamber 436 of the nozzle. An opening 438 is preferably provided in the upper nozzle wall 426, and is in 10 communication with the airflow chamber 436. When in use as a hand vacuum, the wheels 435 are in contact with a surface, the opening 438 faces a surface to be cleaned, air enters the dirty air inlet 418, passes horizontally through the airflow chamber 436, and passes into the opening 438. Opening 438 is in communication with a cyclone inlet passage 439, which is in communication with 15 a cyclone air inlet 440 of cyclone 422. In some embodiments, opening 438 need not be in upper wall 426.

[00170] Nozzle 412 and attachment member 120 are configured such that attachment member 120 may form part of the air flow conduit to opening 438 when attachment member 120 is mounted to hand vacuum cleaner 400. For 20 example, when the portable cleaning apparatus 400 is used in combination with the support structure 210 and the surface cleaning head 300, the opening 438 in the nozzle 412 is in sealed, fluid communication with the air outlet 127 of the attachment member 120. By way of this connection, a continuous fluid pathway is established between the dirty air input 310 of the surface cleaning head 300 25 and the opening 438.

[00171] It will be appreciated that examples of the attachment member 120 may be removably mounted to nozzle 412 by any engagement means known in the connecting arts. For example, pivoting arms may be used, see for example Figure 14, or sliding engagement may be used, see for example Figure 25.

Further, attachment member 120 may be of any configuration. Attachment member 120 may be part of, or may be connected to, an accessory cleaning tool by any means, such as a flexible hose. The flexible hose may be hose 124 if hose 124 is removably mounted to the floor cleaning unit.

5 [00172] As exemplified in Figures 1-19, one example of the attachment member 120 is removably engaged with nozzle 412 by the engagement of pivoting arms in slots provided on nozzle 412. Accordingly, for example, nozzle 412 may also include a slot 490 defining a recess in the depending wall 428 that is adjacent the upper nozzle wall 426. The slot 490 preferably extends 10 continuously along the U-shaped portion of the nozzle depending wall 428 and may be bounded at each end by corners 492. The attachment member 120 includes two arms 150 each having a shoulder 154 and being pivotally connected to the coupling plate 123 using pins 156 (alternatively, the arms 150 could be resilient). Figure 14 is a partially exploded view of the attachment member 120, 15 illustrating one example of the rotational connection between the coupling 142 and the collar 140. In the example shown, the coupling 142 comprises a cylindrical body wall that passes through an opening in the collar 140. Once the coupling 142 had been inserted into the collar 140 it is retained using fastening clip 143. The combination of the coupling plate 123 and the arms 150 may also 20 be described as connecting portion, mounting portion or nozzle mounting portion of the attachment member 120.

[00173] In order to assemble the mount on nozzle 412, coupling plate 123 may be slid into the open end of airflow chamber 436. Accordingly, when the coupling plate 123 of the attachment member 120 is slid into the airflow chamber 25 436, the arms 150 are pressed together by the nozzle 412 walls until the point when arms 150 are aligned with slot 490 (i.e. when the shoulders 154 are advanced past the corners 492). When the arms 150 are aligned with the slot 490, the attachment member 120 is "clicked-in" or locked in place when the arms 150 spread apart and the shoulders 154 of the arms 150 become lodged behind

the corners 492 of slot 490. The arms 150 may be manually separated or the attachment member may include a biasing means (not shown) that biases the arms 150 apart. With the arms 150 in the spread configuration the attachment member 120 cannot be slidably removed from the nozzle 412. When a user 5 wishes to detach the attachment means 120 from the nozzle 412 the user may squeeze upstanding tabs 152 together thereby allowing the shoulders 154 to slide past the corners 492. The mount may alternately be inserted by squeezing upstanding tabs 152 together so that plate 123 may be inserted in chamber 436.

[00174] When the hand vacuum cleaner 400 is coupled to the attachment 10 member 120 the airflow chamber 436 may receive, and be partially filled with the coupling plate 123 (as exemplified in Figures 1-5, 15-19, 20-21 or 22-33) of the attachment member 120. The coupling plate 123 is preferably shaped to be slidably received within the airflow chamber 436.

[00175] Insertion of the coupling plate 123 into the airflow chamber 436 15 serves to register the air outlet 127 with the nozzle opening 438. As shown, the air outlet 127 has a width W_0 and a length L_0 that are preferably the same as the width W_0 and a length L_0 of the opening 438. A sealing gasket 123 may be provided at the juncture of the openings.

[00176] In some examples, as exemplified in Figure 21, the hand vacuum 20 cleaner 400 may be connected to the attachment member 120 using a complimentary tongue and groove connection, instead of or in addition to the arms 150 and slot 490 described above. As exemplified in Figure 21, the nozzle 412 of the may contain a slot or groove 494. Optionally, the grooves 494 on each side of the nozzle 412 may be separate, or they may be different portions of 25 a single continuous groove 494 (like the continuous slot 490). The grooves 494 are sized to receive corresponding tongues 170 extending from a surface of the attachment member 120. When the tongues 170 are slidably received within the grooves 494 movement of the portable surface cleaning apparatus 400 is

restrained in the sideways and forward-backward directions relative to the backbone 200. A sealing gasket may optionally be provided.

[00177] The nesting of the tongues 170 into the grooves 494 can provide sufficient stability and support for the portable surface cleaning apparatus 400 that additional fasteners are not necessary. When the surface cleaning apparatus 100 is in use, the gravitation forces acting on the portable surface cleaning apparatus 400 are sufficient to keep it seated on the attachment member 120. The grooves 494 may have downward facing open ends that can engage the tongues 170 when the portable surface cleaning apparatus 400 is lowered onto the attachment member by the user in a vertical movement. To detach the portable surface cleaning apparatus 400 from the attachment member 120 the user may lift or slide the portable surface cleaning apparatus 400 upward to a disengaged position where the tongues 170 are removed from the grooves 494.

15 [00178] The attachment member 120 and the nozzle 412 may alternately, or in addition also include a plurality of magnets 158 that magnetically couple the attachment member 120 to the nozzle 412 to improve the connection between them and ensure that air outlet 127 is properly registered with opening 438. It will be appreciated that, in an alternate embodiment, only magnets maybe used.

20 Other mounting means may be used. For example, a plurality of latches may be used or air outlet 127 may extend into opening 438.

[00179] As exemplified in Figures 26-29, the cleaning unit may be secured in position by sliding engagement. As exemplified, a coupling plate 123 is configured to be slidingly received within a portion of the nozzle of the surface cleaning apparatus, and is sized so that the air outlet 127 is registered with the air inlet of the hand vacuum cleaner 400 when coupled. As exemplified, hand vacuum cleaner 400 may be held on the coupling plate 123 using only gravitational forces once it is slid into position. As with the embodiment of Figure

21, coupling plate 123 may be formed as or with one or more tongues that are received in mating grooves of the hand vacuum cleaner 400.

[00180] Clean air outlet 420 is provided downstream of the cyclone unit 414, suction motor and optional post-motor filter contained optionally within the 5 cleaner body 460. Clean air outlet 420 may comprise a plurality of apertures formed in housing 461. The cleaner body 460 may also contain one or more of a separation plate, a dirt chamber a pre-motor filter and a plurality of connecting fluid conduits or passageways.

[00181] In the examples shown, cleaner body 460 is removably mounted to 10 head portion 416. For example, cleaner body 460 may be entirely removable from head portion 416, or pivotally mounted to head portion 416. Accordingly, cleaner body 460 and head portion 416 may be separated in order to provide access to the interior of cleaner body 460 or head portion 416. This may allow a pre-motor filter to be cleaned, changed, or serviced, or the motor to be cleaned, 15 changed or serviced. Alternately, head portion 416 may be cleaned or serviced. For example, any dirt stuck in the enclosed passages portable cleaning apparatus 400 may be removed. Alternately, a replacement cleaner body 460 or head portion 416 may be provided, and may be mounted to an existing head portion 416 or cleaner body 460, respectively.

20 [00182] One or more additional rear wheels 480 may be mounted to housing 461 at lower portion 406, and may be used in conjunction with wheels 435 when the portable cleaning apparatus 400 is used as a hand vacuum. When the portable cleaning apparatus 400 is attached to the support structure 210 the additional wheel 480 preferably engages with the mount bracket 224 and partially 25 supports the portable cleaning apparatus 400 on the handle 210 as described above.

[00183] Preferably, as exemplified in Figures 11 and 28, in accordance with a seventh aspect that may be used by itself or with one or more other aspects,

the portion of the attachment member 120 that is used to mount the attachment member to the backbone may also comprise part of the air flow path from surface cleaning head 300 to hand vacuum cleaner 400. For example, as exemplified in Figure 11, the attachment member 120 may include a mounting portion or collar 5 140 that includes a coupling 142 and defines a channel 144. The collar 140 is connected to the airflow passageway 128, or alternatively may be connected directly to the air conduit 110. Optionally, the coupling 142 is a rotatable coupling that allows the airflow passageway 128 to rotate relative to the collar 140.

[00184] In another example, as exemplified in Figure 29, the attachment 10 member 120 comprises a shell 174 having two complimentary shell portions 175a and 175c, which cooperate to define the outer surfaces of the shell 174. Shell portion 175a comprises a coupling 176 for joining the attachment member airflow passage way 128 to the shell 174 and a groove 178 for receiving a portion of the lower portion 216.

15 [00185] The coupling 176 may be any type of suitable coupling including a rigid coupling, a fixed coupling, a releasable coupling and a rotatable coupling. The coupling 176 comprises a central opening or aperture that forms part of the continuous airflow conduit or passage way between the air inlet 126 and the air outlet 127 formed in coupling plate 123 (which, in the example illustrated is 20 formed from complimentary portions 123a, 123b and internal members 177). The coupling 176 and the air outlet 127 are connected in fluid communication by internal shell conduit 175c (shown comprising two portions, but optionally formed from more than two portions or a single member). Therefore, in the present example, as best illustrated in Figure 26, dirty air from the surface cleaning head 25 300 travels into air inlet 126, through airflow passageway 128, through shell portion 175a, through internal shell conduit 175c and exits via air outlet 127 formed through shell portion 175b and the integral coupling plate 123. In the example shown, airflow passageway 128 is connected to flexible hose 124 using

an annular insert 179 that comprises clips 160. In other examples, the clips 160 may be integral the airflow passageway 128.

[00186] The upstream end of the airflow passageway 128 defines the air inlet 126. In operation, the air inlet 126 is preferably coupled to the airflow conduit 110 that extends to the surface cleaning head 300 (the flexible air hose 124 in the example shown). As exemplified in Figures 10-14, the air inlet 126 is releasably coupled to the flexible air hose by clips 160. Downstream of the coupling 142 an enclosed airflow passage connects the airflow passage 128 to the air outlet 127. It will be appreciated that the attachment member 120 need not comprise part of the air flow passage. For example, coupling 142 may be located out of the flow path defined by passageway 128. Alternately, plate 123 need not have opening 127. Accordingly, attachment member may have a first part that is secured to hand vacuum cleaner 400 and a second distinct part that completes that air flow passage from surface cleaning head 300 to opening 438.

15 [00187] The airflow passageway 128 may be flexible or rigid and may be generally straight or may have a curved shape, as shown. Preferably, the curved airflow passageway 128 subtends fewer than 45 degrees.

[00188] It will be appreciated that the removable cleaning unit or hand vacuum cleaner and the bendable wand may be used by themselves or with any other feature disclosed herein. In addition, any of the features disclosed herein may be used by themselves, or with any other feature, and may include the removable cleaning unit and the bendable wand. It will be appreciated that the removable cleaning unit may comprise the operating components of the surface cleaning apparatus (the motor and cyclones/filters) or only some of them and is preferably capable of being used as a self contained portable cleaning apparatus if removed from physical contact with and air flow communication with the upright vacuum cleaner.

[00189] It will be appreciated that the gravity mount construction may be used by itself or with any other feature disclosed herein.

[00190] It will be further appreciated that any construction of an upright structure for a surface cleaning apparatus may be used by itself or with any other
5 feature disclosed herein.

[00191] In addition, any of the features disclosed herein may be used by themselves, or with any other feature.

[00192] What has been described above has been intended to be illustrative of the invention and non-limiting and it will be understood by persons
10 skilled in the art that other variants and modifications may be made without departing from the scope of the invention as defined in the claims appended hereto.

CLAIMS:

1. An upright surface cleaning apparatus comprising:
 - (a) an air flow path extending from a dirty air inlet to a clean air outlet;
 - (b) a surface cleaning head having the dirty air inlet;
 - 5 (c) a support structure moveably mounted to the surface cleaning head; and,
 - (d) a cleaning unit comprising a suction motor and an air treatment member, and the cleaning unit is positioned in the air flow path and removably mountable wherein the cleaning unit is retained on the support structure when in a freely removable configuration.

10

2. The upright surface cleaning apparatus of claim 1 wherein the cleaning unit and the support structure are configured to retain the cleaning unit on the support structure in a storage position under the influence of gravity.

15 3. The upright surface cleaning apparatus of claim 1 further comprising a lock releasably locking the cleaning unit on the support structure and the cleaning unit and the support structure are configured to retain the cleaning unit on the support structure when the lock is in an unlocked position.

20 4. The upright surface cleaning apparatus of claim 1 wherein the cleaning unit has a bottom and the bottom is spaced from the surface cleaning head when the cleaning unit is mounted to the support structure.

25 5. The upright surface cleaning apparatus of claim 1 wherein the cleaning unit is supported only by the support structure.

6. The upright surface cleaning apparatus of claim 2 further comprising an attachment member, the cleaning unit is removably mountable on a mount provided on the support structure, the attachment member and the mount is

configured such that the cleaning unit is removable from the mount in the absence of disengaging a lock.

7. The upright surface cleaning apparatus of claim 6 wherein the mount has a
5 first contact member and the attachment member has a second contact member, the second contact member is downwardly slidably engagable with the first contact member and abutment of the first and second contact members restrains movement of the cleaning unit in a forward direction of travel and a direction transverse to the forward direction of travel and the
10 vertical.
8. The upright surface cleaning apparatus of claim 7 wherein at least one of the contact members includes a cam surface.
- 15 9. The upright surface cleaning apparatus of any of claims 7-8 wherein one of the contact members comprises a cam surface and the other of the contact members comprises a cam.
10. The upright surface cleaning apparatus of any of claims 7-9 wherein one of
20 the contact members comprises a pair of opposed spaced apart sides defining a channel between the opposed sides, at least one of the opposed sides having an open portion, and the other of the contact members comprises an abutment member sized to be received in the channel, the abutment member having opposed sidewalls spaced apart by a distance,
25 each sidewall facing one of the opposed sides and a distance between the sidewalls and the opposed facing walls decreases from an upper end of the abutment member to a lower portion of the abutment member.

11. The upright surface cleaning apparatus of claim 10 wherein the open portion comprises a portion of the front of the one of the contact members.
12. The upright surface cleaning apparatus of claim 11 wherein the cleaning unit 5 comprises an attachment member, the second contact member is provided on the attachment and the attachment member extends outwardly through the open portion.
13. The upright surface cleaning apparatus of claim 12 wherein the attachment 10 member is removably mounted on the cleaning unit.
14. The upright surface cleaning apparatus of claim 13 wherein the attachment member is removably mounted on the cleaning unit using a complimentary tongue and groove connection.

15

15. The upright surface cleaning apparatus of any of claims 12-13 wherein the attachment member comprises part of an air flow path from the surface cleaning head to the cleaning unit.

20

16. The upright surface cleaning apparatus of any of claims 2 and 6-15 wherein a mount provided on the support structure and the attachment member are configured to retain the cleaning unit on the support structure under the influence of gravity during operation of the upright surface cleaning apparatus.

25

17. The upright surface cleaning apparatus of any of claims 1-16 wherein the attachment member is vertically removable from the support structure.

18. The upright surface cleaning apparatus of any of claims 1-17 wherein an air flow path from the surface cleaning head to the cleaning unit comprises a flexible air flow conduit.

5 19. The upright surface cleaning apparatus of any of claims 1-18 wherein the upright surface cleaning apparatus has at least two operating modes comprising:

10 (i) a first upright operating mode wherein the upright surface cleaning apparatus is operable with the cleaning unit mounted to the support structure and forming part of the air flow path; and,

(ii) a second operating mode wherein the cleaning unit is operable when removed from the support structure.

15 20. The upright surface cleaning apparatus of claim 19 wherein, in the second operating mode, the cleaning unit is operable when removed from the support structure and in air communication with the surface cleaning head.

20 21. The upright surface cleaning apparatus of claim 20 wherein an air flow path from the surface cleaning head to the cleaning unit comprises a flexible air flow conduit.

22. The upright surface cleaning apparatus of claim 21 wherein the cleaning unit is operable when disconnected from the surface cleaning head.

25 23. The upright surface cleaning apparatus of any of claims 1-22 wherein the cleaning unit is mounted to the support structure at a midpoint of the support structure.

24. The upright surface cleaning apparatus of any of claims 1-23 wherein the support structure comprises a further portion that also retains the cleaning unit on the support structure.

5 25. The upright surface cleaning apparatus of claim 24 wherein the further portion is below the first contact member.

26. The upright surface cleaning apparatus of any of claims 24-25 wherein the further portion engages a wheel of the cleaning unit.

10

27. The upright surface cleaning apparatus of any of claims 6-15 wherein the attachment member and a mount on the support structure comprise a releasable securing mount and the releasable securing mount further comprises at least one magnet.

15

28. The upright surface cleaning apparatus of claim 1 wherein the cleaning unit is supported on an airflow conduit of the support structure.

Box No. II Observations where certain claims were found unsearchable (Continuation of item 2 of the first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons

1 Claim Nos

because they relate to subject matter not required to be searched by this Authority, namely

2 Claim Nos 10 to 15

because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically

These claims could not be searched due to the inclusion of the feature "at least one of the opposed sides [of one of the contact members] having an open portion" in claim 10. The meaning of the term "open portion" could not be determined. As claims 11 to 15 either also include this feature or ultimately depend on claim 10, claims 10 to 15 were found to be unclear and unsearchable

3 Claim Nos

because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6 4(a)

Box No. III Observations where unity of invention is lacking (Continuation of item 3 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows

1 As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims

2 As all searchable claims could be searched without effort justifying additional fees, this Authority did not invite payment of additional fees

3 As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claim Nos

4 No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims, it is covered by claim Nos

Remark on Protest The additional search fees were accompanied by the applicant's protest and, where applicable, the payment of a protest fee

The additional search fees were accompanied by the applicant's protest but the applicable protest fee was not paid within the time limit specified in the invitation

No protest accompanied the payment of additional search fees
