Abstract:
An energy exchanger is provided. The exchanger includes a housing having a front and a back. A plurality of panels forming desiccant channels extend from the front to the back of the housing. Air channels are formed between adjacent panels. The air channels are configured to direct an air stream in a direction from the front of the housing to the back of the housing. A desiccant inlet is provided in flow communication with the desiccant channels. A desiccant outlet is provided in flow communication with the desiccant channels. The desiccant channels are configured to channel desiccant from the desiccant inlet to the desiccant outlet in at least one of a counter-flow or cross-flow direction with respect to the direction of the air stream.
CROSS-REFERENCE TO RELATED APPLICATIONS

BACKGROUND OF THE INVENTION

[0002] The subject matter described herein relates generally to an energy exchange system for conditioning air in an enclosed structure, and more particularly, to a liquid-to-air membrane energy exchanger (LAMEE).

[0003] Enclosed structures, such as occupied buildings, factories and animal barns, generally include an HVAC system for conditioning ventilated and/or recirculated air in the structure. The HVAC system includes a supply air flow path and an exhaust air flow path. The supply air flow path receives pre-conditioned air, for example outside air or outside air mixed with re-circulated air, and channels and distributes the air into the enclosed structure. The pre-conditioned air is conditioned by the HVAC system to provide a desired temperature and humidity of supply air discharged into the enclosed structure. The exhaust air flow path discharges air back to the environment outside the structure. Without energy recovery, conditioning the supply air typically requires a significant amount of auxiliary energy. This is especially true in environments having extreme outside air conditions that are much different than the required supply air temperature and humidity. Accordingly, energy exchange or recovery systems are typically used to recover energy from the exhaust air flow path. Energy recovered from air in the exhaust flow path is utilized to reduce the energy required to condition the supply air.

[0004] Conventional energy exchange systems may utilize energy recovery devices (e.g. energy wheels and permeable plate exchangers) or heat exchange devices
(e.g. heat wheels, plate exchangers, heat-pipe exchangers and run-around heat exchangers) positioned in both the supply air flow path and the return air flow path. LAMEEs are fluidly coupled so that a desiccant liquid flows between the LAMEEs in a run-around loop, similar to run-around heat exchangers that typically use aqueous glycol as a coupling fluid. When the only auxiliary energy used for such a loop is for desiccant liquid circulation pumps and external air-flow fans, the run-around system is referred to as a passive run-around membrane energy exchange (RAMEE) system, otherwise it is an active RAMEE system with controlled auxiliary heat and/or water inputs or extractions.

[0005] For the passive RAMEE system with one or more LAMEEs in each of the exhaust and supply air ducts, energy in the form of heat and water vapor is transferred between the LAMEEs in the supply and exhaust ducts, which is interpreted as the transfer of sensible and latent energy between the exhaust air and the supply air. For example, the exhaust air LAMEE may recover heat and moisture from the exhaust air to transfer the heat and moisture to the supply air during winter conditions to heat and humidify the supply air. Conversely, during summer conditions, the supply air LAMEE may transfer heat and moisture from the supply air to the exhaust air to cool and dehumidify the supply air.

[0006] Laboratory prototype LAMEEs have been constructed and tested in passive RAMEE loops to utilize both cross-flow and counter-flow arrangements for each LAMEE. In a counter-flow configuration, the desiccant liquid flows in a direction 180° away from the air flow direction in the adjacent air flow channel (i.e. counter-flow with respect to the air flow direction for each pair of flow channels) and heat and water vapor are transferred through the semi-permeable, energy exchange, membrane of each LAMEE. In the cross-flow arrangement, the liquid desiccant in the LAMEE flows at 90° or perpendicular to the air flow direction through each pair of channels in the LAMEE energy exchange membrane area.

[0007] Both counter-flow and cross-flow LAMEE devices can be used to recover energy from exhaust air-flows. This energy can be used to condition the supply air using another LAMEE device. Cross-flow LAMEEs are not without disadvantages.
In certain circumstances, cross-flow exchangers generally have lower energy transfer effectiveness in comparison to counter-flow exchangers of the same energy exchange membrane area and inlet operating conditions. Accordingly, it may be desirable to have an energy exchange system that utilizes counter-flow LAMEEs. However, counter-flow LAMEEs are generally more difficult and expensive to construct. In particular, counter-flow LAMEEs require headers positioned on each end of the LAMEE and require tighter design specifications. Accordingly, conventional counter-flow LAMEEs may be impractical for some applications but, where higher performance factors are needed, they may be cost effective for other applications.

[0008] Cross-flow and counter-flow LAMEE devices have been constructed and tested in laboratory RAMEE system loops. The laboratory test prototypes for LAMEE devices have not performed as expected. In particular, the test systems have not reached steady-state operating conditions during a reasonable test period. Moreover, the internal geometric configurations of the air and liquid flow channels are known to be far from the simple geometric configurations with uniform, equally distributed mass flow conditions assumed in the reported theoretical models.

[0009] Several key problems exist with the past research and development efforts for LAMEE devices. First, simple theoretical models of RAMEE or HVAC systems containing LAMEE devices, with overly simplified internal geometries and physics, fail to model what is physically occurring within the system. For example, each fluid flow will self adjust in a few seconds to distribute its local mass flux to minimize the pressure drop across the exchanger as a whole unit for each type of fluid, flow channel geometry, Reynolds number, Rayleigh number, and total mass flow rate. Within a fluid, both viscous flow forces and buoyancy forces can alter the flow streamlines. For example, buoyancy forces, caused by fluid density gradients, may result in unstable mal-distributed flow when the fluid density increases with height (i.e. counter to gravity) and the viscous forces are not sufficient to cause a uniform flow and so avoid a mal-distribution of flow within an exchanger. With some flow configurations in an exchanger, such flow conditions are likely to occur for laminar liquid flows but not the
air flows. The enhanced performance of stable flows with enhancing buoyancy effects that self correct mal-distributions of flow are not exploited in existing systems.

[0010] When the self-adjusted flow is steady, the rate of entropy generation due to viscous (laminar or turbulent) flow will be a minimum for each flow channel and collectively for all the channels for each fluid (air or liquid desiccant) in the LAMEE. Due to small geometric variations and destabilizing buoyancy effects in each channel and among all the flow channels for each fluid, the self-adjusted flow distribution will not, in general, be such that the fluid mass flux is equally distributed among all channels or is uniformly distributed in each channel for heat and mass transfer through the semi-permeable membrane surfaces in a LAMEE. In order to minimize the declination of performance of each LAMEE due to the non-uniformities of flow distribution, the design specifications must be very complete for each and all independent performance influencing factors. When the uneven flow distribution leads to unequal flows among channels and/or poor non-uniform area integrated or locally averaged heat and water vapor transfer rates, the flow is mal-distributed in the exchanger for energy exchange. Mal-distribution of flows in any LAMEE in a RAMEE system will cause the performance of the system to be sub-optimal. Mal-distribution of flow will be especially prevalent for laminar flows with destabilizing buoyancy effects within each liquid channel and among the many liquid flow channels of a LAMEE. However, mal-distribution can also occur with transition and turbulent flows. Local flow instabilities, due to channel flow surface geometry when the flow is above threshold Reynolds numbers, will induce local turbulent mixing that can reduce mal-distributed flow in each channel and will increase both the pressure drop and convection coefficients. Exploiting fluid flow turbulence instabilities for enhanced convection coefficients and reduction of flow mal-distribution in exchangers has not been fully recognized or exploited in HVAC exchanger designs.

[0011] Further, LAMEE devices constructed with very flexible membranes need more detailed design and construction specifications for each local flow region in flow channels than more rigid flat-plate heat exchangers if they are to exceed the performance factors required for buildings (i.e. ASHRAE Std. 90.1 and 189.1) when
tested using an accepted international standard {i.e. ASHRAE Std. 84} and/or approach the theoretical performance factors put forward by modelers. There is no indication that previous researchers and inventors have fully understood the complexities of the physical problems or were aware of the large number of independent design factors that influence the performance of the exchangers.

[0012] The key problems with existing RAMEE type energy recovery systems and HVAC systems having one or more LAMEE type devices for air conditioning supply air for buildings are closely related to the research and development problems set forth above. Typically, the factors that impact on the performance are not considered as a complete set if they are considered at all.

[0013] The steady-state performance of a passive RAMEE system is not characterized by a single factor as are some simple systems (e.g. pumps and motors). Rather, the performance may be characterized by a set of six dimensionless performance factors (i.e. four system effectiveness values for the measured fraction of the maximum possible steady-state sensible and latent energy transfer under summer and winter standard test conditions and two RER values for the measured fraction of auxiliary energy used with respect to the total energy transferred between the supply and exhaust air streams for the summer and winter test conditions). The set of performance factors, Pf, can be referred to as the dependent objective dimensionless ratios determined by analyzing the data from two standard steady-state tests for a passive RAMEE system.

[0014] The set of dimensionless ratios or factors that cause changes to the values in Pf are independent factors, If, because each one, or collectively several or all, will, if changed significantly, change one or more of the factors in the set, Pf. Mathematically, the relationship is expressed such that the dependent dimensionless set Pf is only a function of a predetermined dimensionless set, If, the operating conditions for the inlet air temperature and humidity (i.e. one standard test condition for winter and another for summer), and the uncertainty in the measured test data for both Pf and If or in short Pf(If) and where the standard test conditions are constrained by steady-state or quasi-steady-state operating conditions for each test.
Existing LAMEE devices and passive RAMEE systems have not been
designed to meet specified performance factors other than designing the LAMEE device
with an internal geometry similar to flat plate heat exchangers constructed using stiff
elastic solids. That is, the systems have not met the desired set Pf because not all the
factors in the set If were understood, considered, measured or specified.

A need remains to specify or predetermine a complete set of design
parameters to construct a LAMEE and, for any inlet air conditions, select a narrow range
of system operating conditions (i.e. the complete set If) if the RAMEE systems using two
identical LAMEEs are to exceed all the required performance factors in the set Pf. When
the design specifications are complete, the set Pf for a passive RAMEE and its two
LAMEEs will be predictable in design, reproducible in manufacturing, and with
reproducible and certifiable steady-state standard test results. Another need remains for
LAMEEs used in a passive RAMEE system having an increased effectiveness. The
LAMEEs need to be designed and operated to satisfy conditions that are typical for
conventional energy exchange systems and that are required through international
standards or local or state building codes.

SUMMARY OF THE INVENTION

In one embodiment, an energy exchanger is provided having a housing
constructed to meet a predetermine exchanger aspect ratio. A plurality of panels extend
through the housing. The panels have a semi-permeable membrane forming an energy
exchange area of the panel. The panels form desiccant channels and air channels that are
separated by the semi-permeable membranes to facilitate contact between an air stream
flowing through the air channels and desiccant flowing through the desiccant channels
within the energy exchange areas of the panels. The energy exchange area of each panel
has a top and a bottom. A height of the energy exchange area is defined between the top
and the bottom. The energy exchange area of each panel has a front and a back. A
length of the energy exchange area is defined between the front and the back. The
exchanger aspect ratio is defined by the height of the energy exchange area of each panel
divided by the length of the energy exchange area of each panel. A desiccant inlet is
provided in flow communication with the desiccant channels. A desiccant outlet is provided in flow communication with the desiccant channels. The desiccant channels are configured to channel the desiccant from the desiccant inlet to the desiccant outlet in at least one of a counter-flow or cross-flow direction with respect to the direction of the air stream to facilitate heat and water vapor transfer through the semi-permeable membranes. The exchanger aspect ratio is selected to provide at least one of a predetermined membrane area, a predetermined length, or a predetermined duration of exposure of the air stream to the desiccant.

[0018] In another embodiment, an energy exchanger is provided having a housing. A plurality of panels form desiccant channels and air channels that extend through the housing. The air channels are configured to direct an air stream through the housing. The plurality of panels are spaced apart based on a predetermined air to desiccant channel rates that define an air channel width and a desiccant channel width. A desiccant inlet is provided in flow communication with the desiccant channels. A desiccant outlet is provided in flow communication with the desiccant channels. The desiccant channels are configured to channel desiccant from the desiccant inlet to the desiccant outlet in at least one of a counter-flow or cross-flow direction with respect to the direction of the air stream to facilitate heat and water vapor transfer between the desiccant in the desiccant channels and the air stream in the air channels. The air to desiccant channel rates are selected to provide a predetermined mass or volume rate of air stream flowing through the air channels and a predetermined mass or volume rate of desiccant flowing through the desiccant channels.

[0019] In another embodiment, an energy exchanger is provided having a housing. A plurality of panels form desiccant channels and air channels that extend through the housing. The air channels are configured to direct an air stream through the housing. A desiccant inlet is provided in flow communication with the liquid desiccant channels. A desiccant outlet is provided in flow communication with the liquid desiccant channels. The desiccant channels are configured to channel liquid desiccant from the desiccant inlet to the desiccant outlet in at least one of a counter-flow or cross-flow direction with respect to the direction of the air stream. A semi-permeable membrane
extends through each panel to facilitate heat and water vapor transfer between the desiccant in the desiccant channels and the air stream in the air channels. The air stream and the liquid desiccant pressure cause the semi-permeable membrane to deflect during operation. The desiccant membrane is selected based on predetermined channel deflection ranges that are defined to limit the amount of membrane deflection.

[0020] In another embodiment, an energy exchanger is provided having a housing. A plurality of panels form liquid desiccant channels and air channels that extend through the housing. The air channels are configured to direct an air stream through the housing. A desiccant inlet is in flow communication with the liquid desiccant channels. A desiccant outlet is in flow communication with the desiccant channels. The desiccant channels are configured to channel desiccant from the desiccant inlet to the desiccant outlet in at least one of a counter-flow or cross-flow direction with respect to the direction of the air stream to facilitate heat and water vapor transfer between the desiccant in the desiccant channels and the air stream in the air channels. The desiccant is selected based on predetermined salt solution concentration ranges for a selected life span and cost of the desiccant.

[0021] In another embodiment, an energy exchanger includes a housing. A plurality of panels form desiccant channels that extend through the housing. Each of the plurality of panels has a semi-permeable membrane that is selected to meet predetermined membrane resistance ranges defining physical properties of the membrane. Air channels are formed between the desiccant channels. The air channels are configured to direct an air stream through the housing. A desiccant inlet is in flow communication with the desiccant channels. A desiccant outlet is in flow communication with the desiccant channels. The desiccant channels are configured to channel desiccant from the desiccant inlet to the desiccant outlet so that the desiccant membranes facilitate heat exchange between the desiccant and the air stream. The membrane resistance ranges are selected to limit a flow of the desiccant through the desiccant membrane.

[0022] In another embodiment, an energy exchanger is provided having a housing. A plurality of panels form desiccant channels that extend through the housing.
The plurality of panels each have a desiccant membrane. Air channels are formed
between the desiccant channels. The air channels are configured to direct an air stream
through the housing. The air stream flows through the air channels at a predetermined air
flow ratio. A desiccant inlet is in flow communication with the desiccant channels. A
desiccant outlet is in flow communication with the desiccant channels. The desiccant
channels are configured to channel liquid desiccant from the desiccant inlet to the
desiccant outlet so that the semi-permeable membranes facilitate heat and water vapor
exchange between the liquid desiccant and air streams. The air mass flow rate ratio of
the air stream selected to meet a predetermined exposure of the air stream to the semi-
permeable membranes.

[0023] In another embodiment, an energy exchanger is provided having a
housing. A plurality of panels form desiccant channels extending through the housing.
Air channels are formed between adjacent desiccant channels. The air channels are
configured to direct an air stream through the housing. A desiccant inlet is in flow
communication with the desiccant channels. A desiccant outlet is in flow communication
with the desiccant channels. The desiccant channels are configured to channel desiccant
from the desiccant inlet to the desiccant outlet so that the desiccant membranes facilitate
heat exchange between the desiccant and the air stream. The energy exchanger operates
within predetermined exchanger performance ratios that define a sensible and latent
energy exchange between the desiccant and the air stream.

[0024] In another embodiment, a method of exchanging energy between a
desiccant and an air stream is provided. The method includes extending a plurality of
panels through a housing of the energy exchanger to form desiccant channels and air
channels. A desiccant membrane is selected for each of the panels. An air stream is
directed at a predetermined air flow ratio through the air channels. Desiccant is directed
through the desiccant channels. The desiccant membrane is selected based on membrane
resistance ranges defined to limit a flow of the desiccant through the desiccant
membrane. The air flow ratio of the air stream is selected to meet a predetermined
exposure of the air stream to the desiccant membrane. A flow rate of the desiccant with
respect to a flow rate of the air stream is controlled to achieve predetermined exchanger
performance ratios that define a thermal energy exchange between the desiccant and the air stream.

[0025] In another embodiment, a method of exchanging energy between a desiccant and an air stream is provided. The method includes extending a plurality of panels through a housing of the energy exchanger. The plurality of panels are spaced based on predetermined air to desiccant channel rates to form desiccant channels and air channels between adjacent panels. The predetermined air to desiccant channel mass or volume flow rates help to design an air channel width and a desiccant channel width. A membrane is selected to extend through the panels based on predetermined channel deflection ranges that are defined to limit an amount of membrane deflection with respect to the channel width. An air stream is directed through the air channels. A desiccant is directed through the liquid desiccant channels in at least one of a counter-flow or cross-flow direction with respect to the direction of the air stream so that the membrane facilitates heat and water vapor exchange between the liquid desiccant in the desiccant channels and the air stream in the air channels. The predetermined air to desiccant channel rates provide a predetermined volume rate of air stream flowing through the air channels and a predetermined volume rate of liquid desiccant flowing through the desiccant channels.

DETAILED DESCRIPTION OF THE DRAWINGS

[0045] The foregoing summary, as well as the following detailed description of certain embodiments will be better understood when read in conjunction with the appended drawings. As used herein, an element or step recited in the singular and proceeded with the word "a" or "an" should be understood as not excluding plural of said elements or steps, unless such exclusion is explicitly stated. Furthermore, references to "one embodiment" are not intended to be interpreted as excluding the existence of additional embodiments that also incorporate the recited features. Moreover, unless explicitly stated to the contrary, embodiments "comprising" or "having" an element or a plurality of elements having a particular property may include additional such elements not having that property.

[0046] In one embodiment, a LAMEE energy exchanger is provided. Each embodiment will represent at least one factor in the set If (presented below in Table 1 as independent factors G1-G10 and P1-P12). Many factors of the set If pertain to the LAMEE design and operation. Other factors pertain to the passive RAMEE system, comprising two identical LAMEEs, under a standard steady-state summer or winter test condition. The energy exchanger includes a housing having a front and a back and two sides. The housing has a top and a bottom extending between the front and the back. The housing is constructed to contain a set of air and liquid desiccant flow channels which are each separated by a semi-permeable membrane that permits heat and water vapor to be transferred between the air and liquid desiccant flows. Each of the flow channel energy exchange membrane areas is rectangular in shape, with liquid desiccant
flow either nearly counter-flow or cross-flow relative to the direction of the air flow in each adjacent fluid channel pair. Other predetermined geometric length ratios that may be specified for each LAMEE are the exchanger panel aspect ratio and liquid flow entrance/exit length ratio. The exchanger panel aspect ratio is defined by the height of each panel energy exchange membrane area divided by the length of the energy exchange membrane area in the panel. A plurality of panels forming desiccant liquid channels and air channels extend through the housing. The air channels are configured to direct an air stream uniformly, with equal mass flow rate among the total number of air channels in the housing. Likewise, the fluid flow through each liquid flow channel is uniformly distributed in each liquid flow channel and the mass flow rate for each channel is the same for all liquid flow channels. In alternative embodiments, the air stream and the fluid flow through the heat exchanger may be non-uniform. A desiccant inlet is provided in flow communication with the liquid desiccant channels in the housing. A desiccant outlet is provided in flow communication with the liquid desiccant channels.

[0047] The design and operational parameters of the LAMEEs and passive RAMEE system will include all of the geometric (G) and physical (P) ratios set forth in Table 1.

[0048] With respect to factor Gl, the desiccant channels are configured to channel equally the liquid desiccant mass flow rate through each of the liquid flow channels from the desiccant inlet to the desiccant outlet in at least one of a counter-flow or cross-flow direction with respect to the direction of the adjacent air streams to facilitate heat and water vapor transfer through the semi-permeable membrane between the liquid desiccant flow in the desiccant channels and the air stream in the air channels.

[0049] With respect to factor G2, the exchanger panel aspect ratio is selected to provide a predetermined exposure through the semi-permeable membrane between the air and liquid flow for adjacent channels in each LAMEE.

[0050] The liquid flow entrance/exit length ratio with respect to the length of the membrane energy transfer area (factor G3) may be utilized for flow channels that are
primarily counter-flow within a LAMEE. The effectiveness of the LAMEE may be partly determined using each of the factors G1-G3. Accordingly, fluid flow direction (factor G1), aspect ratio (factor G2) and entrance/exit flow length ratio (factor G3) in the set If may be used to partly determine the LAMEE performance.

[0051] With respect to the factor G3, for primarily counter-flow LAMEE exchangers, the ratio of the flow channel liquid inlet/outlet length, \( L_e \), divided by the flow channel length, \( L \) is approximately \( 0.02 < L_e/L < 0.2 \). For primarily cross-flow LAMEE exchangers, the ratio of the liquid flow inlet/outlet the ratio of the liquid flow channel inlet, \( L_e \), divided by the flow channel length, \( L \) is approximately \( 0.5 < L_e/L < o r = 1.0 \).

[0052] The determination of the statistical channel averaged hydraulic diameter variation for the liquid flow channels will be more difficult to determine for the liquid flow channels than the air flow channels because the volume flow rates and channel dimensions are small (e.g. 2 to 10 times smaller than the air channels). The decrease in the effectiveness due to mal-distribution of mass flows among the fluid flow channels of each LAMEE in the passive RAMEE system, comprising two identical LAMEEs, will be partly determined using the ratio of standard deviation of average channel hydraulic diameters to mean average channel hydraulic diameter (factor G4). For example, assuming a uniform flow through each channel but different flow rates among the set of channels in a LAMEE for air flow through a large set of channels, with a standard deviation of hydraulic diameter for the channels divided by the mean hydraulic diameter equal to 0.1 compared with one that has no variations in the liquid flow channels, the decrease in air pressure drop across the flow channels in a LAMEE relative to the same channels with no width variations will be about 3% for laminar flow and 6% for turbulent flow and the corresponding drop in RAMEE system effectiveness will be about 6% for laminar flow and 8% for turbulent flow (it will be made clear that laminar flows in the liquid channels may have strong destabilizing effects unless the buoyancy forces re-stabilize the flows). If the variations in flow channel widths are relatively identical for the liquid flow channels then the total decrease in the effectiveness for the RAMEE system would be approximately 8.5% and 11% for laminar and turbulent flows,
respectively. Variations in the channel widths for the typical flow channels, characterized by factor G5, will further decrease the system performance. Furthermore, since there may be a strong correlation between the liquid flow and air flow channel hydraulic diameters (widths) (i.e. the variation in channel widths are not statistically independent for each fluid), the drops in system effectiveness can be significantly larger. Furthermore, and as discussed below, mal-distribution of flow due to buoyancy effects in each liquid flow channel can result in an additional drop in effectiveness. Since the flow channel ratio of flow channel hydraulic diameters only deals with the variations in the average flow channel hydraulic diameters, other independent parameters will be needed to complete the set if in Table 1.

[0053] Another embodiment is provided wherein the distance between the membranes of air and liquid flow channels (also called channel widths or hydraulic diameters) are designed to be nearly uniform over each channel in a LAMEE during typical operating conditions. Due to manufacturing and operational tolerances, when averaged over each flow channel, the locally averaged hydraulic diameter may be different for each fluid (i.e. air or liquid desiccant), for local flow regions within each channel and among all the channels in a LAMEE. Manufactured LAMEEs under typical operating conditions will have a distribution of average channel hydraulic diameters that is statistically normal (i.e. Gaussian) or nearly normal in distribution considering the uncertainty bounds. The variation in channel average flow channel hydraulic diameters in a LAMEE will cause air and liquid flow mal-distributions for each fluid among the many flow channels in each LAMEE. Consequently the energy transfer effectiveness and the fluid pressure drop of the LAMEE will be lower than that for an ideal theoretical design with equal mass flow rates for each fluid channel. The variations among all the flow channel average hydraulic diameters that cause variations in each fluid mass flow rate should be designed to be small (i.e. the standard deviation of the flow channel hydraulic diameters for both the air and liquid flow channels should be small with respect to the mean average flow channel hydraulic diameter for each fluid within the LAMEE, G4). The flow channel average hydraulic diameter variation in a LAMEE is also a factor for counter-flow liquid channels because the pressure drop for the liquid flow entrance and exit regions in the channel may be a larger fraction of the total channel pressure drop.
and the flow path lengths may be longer (e.g. longer than the air flow path length through each channel). Channel width variations will be present for the typical air and liquid flow channels. Due to their normal distribution, these width variations within each panel are best characterized by their statistical properties as defined by geometric factor G5. In an exemplary embodiment a width of the air channels is selected based on a width of the desiccant channels.

[0054] As a summary of the geometric factors G6 to G10, the liquid channel screen insures a minimum spacing for the channel width and enhances the transition to turbulent flow for large liquid flow rates. The air and liquid flow channel screen area ratios (factor G6) is yet another predetermined embodiment because the ratios are directly related to turbulence enhancement and blockage fraction of the membrane for water vapor transfer on the air side of the membrane. The air channel spacer support structure ratio (factor G7) is another geometric embodiment that assists the transition to turbulent flow and partly determines the geometry of the flow channel through its structural supports. Factor G8 defines the best liquid flow direction with respect to gravity through each LAMEE exchanger which may be controlled to avoid liquid flow mal-distribution and factors G9 and G10 define LAMEE angles with respect to gravitational acceleration to get high performance factors for the RAMEE system and all its LAMEEs.

[0055] The new ratio of standard deviation for each liquid flow stream-tube hydraulic diameter in each liquid flow channel divided by the mean value can be used to analyze the decrease in expected effectiveness of each LAMEE and the passive RAMEE system in which it is used or tested. For example, if the flow tube standard deviation ratio is 0.05 (i.e. 5%) for the typical liquid flow channel in each identical LAMEE in the RAMEE system, then the decrease in total system effectiveness will be about 4% for turbulent flows but the loss of effectiveness may be much higher for laminar liquid flows where the flow field is unstable due to buoyancy effects.

[0056] Average or bulk mean flow streamlines in each of the air flow channels will, depending on the air channel support structure, be on average nearly parallel straight lines through the energy exchange area. The air flow channels are
mostly a void region with parallel flow spacer guide structures that cause the streamlines to be nearly straight while the inertial to viscous forces in the flow, characterized by the Reynolds numbers (i.e. \( \text{Re}_d = \frac{Vd_h}{k_v} \) where \( V \) is the bulk mean channel fluid speed, \( d_h \) is the hydraulic diameter of the flow channel, and \( k_v \) is the kinematic viscosity of the fluid) are moderately high (i.e. \( 300 < \text{Re}_{\text{air}} < 1500 \) which, as will be discussed in more detail later, may be laminar or turbulent). This is not the case for the liquid desiccant channels in counter/cross flow LAMEEs where the Reynolds numbers will be much lower and the flow is likely to be laminar at low values of \( \text{Cr}^* \). The average liquid flow streamlines can be much more complex than for the channel flow of air because the liquid flow passages cannot lead to parallel straight lines and when unstable buoyancy forces are much greater than the viscous forces, characterized by the Rayleigh number, \( \text{Ra} \), they induce flow instabilities that cause very complex streamlines (i.e. \( \text{Ra} > \text{Ra}_c \)) for counter-flow exchangers with parallel membranes (where \( \text{Ra} = -a^*B^*g d_h^2 H^2/(k_v t_d) \) where \( a^* \) is the temperature gradient in the vertical direction (i.e. with respect to gravitational acceleration when the tilt angle is small), \( B^* \) is the coefficient of thermal expansion, \( g \) is the acceleration due to gravity, \( H \) is the vertical height of the flow channel and \( t_d \) is the thermal diffusivity of the fluid). Since the viscous forces for turbulent flows are much higher than they are for laminar flows, the critical Rayleigh number, \( \text{Ra}_c \), at which buoyancy induced instabilities cause significant flow mal-distributions changes significantly with the type of flow. That is, the screens used in each fluid flow channel and the spacers used in the air flow channels can be used to enhance turbulence in each flow but, at the same time it is not desirable to unnecessarily increase the pressure drop due to each fluid flow. The preferred screen solid area to total screen area is given by factor G6. Even cross flow exchangers will have complex streamline patterns when \( \text{Ra} > \text{Ra}_c \) and so their performance factors will be lower than expected from theoretical values derived from typical simplifying assumptions. Operating LAMEE exchangers so that the Rayleigh number is always in the stable flow region (i.e. \( \text{Re}_{\text{air}} < \text{Ra}_c \)) allows the performance factors to be high compared to exchangers that are not designed and operated to account for the instability. The value for the critical Rayleigh number for a particular exchanger is an empirical quantity that depends on the exchanger design and its fluid properties and Reynolds number.
With respect to the factor G7, the distance between the air channel spacer support structures in the average bulk flow streamline direction, Dssa, divided by the distance between spacer support structures normal to the average bulk flow spacer support structures, Dsa, is a fraction or whole number, such that Dssa/Dsa = m/n and 0.01 < m/n < 5.0, where m and n are whole or integer numbers.

With respect to factor G8, the liquid flow direction through the liquid flow channels is controlled with respect to the direction of gravity (i.e. from the bottom inlet to the top outlet for liquid flows that are heated within the channel and vice versa for liquid flows that are cooled in the channel) to minimize mal-distribution effects and maintain high performance factors for the RAMEE system.

With respect to factor G9, an angle $Z_g$ between a vector normal to the plane of each flow channel and the vector for the acceleration of gravity is such that $45 < Z_g < 135°$. The angle $Z_g = 90°$ for most applications so that buoyancy effects will enhance the LAMEE performance when the correct flow direction is chosen for each exchanger.

With respect to factor G10, an angle $O^*$ between the vector parallel to the edge of each flow channel along its length and the acceleration of gravity is such that $60 < O^* < 120°$. This angle, or the LAMEE tilt angle $(90° - O^*)$, is normally selected to result in a positive enhancement of performance due to buoyancy effects.

Further embodiments are provided for with the flow channel flow conditions and their orientation, or combinations of several geometric and operational factors, for each LAMEE which involves flow field characterization through the Reynolds number and the flow stability factor, Rayleigh number. The Rayleigh number can be selected to be most favorable by arranging the temperature gradients in each LAMEE to be such that the fluid density always increases in the downward direction of gravitational acceleration. This implies that the flow channels in a LAMEE should be aligned so that their normal area vector is horizontal and the length vector of the flow channel is tilted with a large enough angle to cause a favorable and significant density gradient for uniform flows in each channel and among all the channels. Channel flows in long thin channels with small or negligible entrance lengths for the flows are well known
to be one of: (a) fully developed laminar flow at low Reynolds number, (b) fully
developed turbulent flow at high Reynolds number, or (c) transition turbulent flows at
intermediate Reynolds numbers between the two low and high transition Reynolds
numbers. The flow transition Reynolds number that causes the flow to transfer from
laminar to transition turbulence tends to be fixed for any given channel (see factor PI)
where the Rayleigh number indicates no buoyancy induced mal-distributions (see factors
G8, G9, & G10), but very small changes to the surfaces inside each channel can cause
large changes to the transition Reynolds number. That is, the flow in a channel can
become turbulent when small increased surface roughness or flow separations within the
channel flow changes are introduced at some low Reynolds numbers compared to laminar
flow in the same channels with no roughness additions. In one embodiment, a
characteristic Reynolds number for the air stream through the air channels is greater than
a critical Reynolds number for turbulent flow in the air channels. In another
embodiment, a characteristic Rayleigh number for desiccant flow in the desiccant
channels is less than a critical Rayleigh number for thermally induced liquid density
instability causing non-uniform mal-distributed flow at a Reynolds number for desiccant
flow.

[0062] The fluid inertial, viscous and buoyancy forces all play important roles
for a well designed and operated LAMEE and their ratios are characterized by the
Reynolds number and Rayleigh number in factor PI where it is stated that we prefer to
have turbulent flow when practical and we should always avoid adverse buoyancy effects
in the liquid flows. The Reynolds number for the liquid flow through the liquid flow
channels will typically be very low (i.e. $0.1 < \text{Re}_{\text{liq}} < 100$). Under these circumstances,
the liquid flow may be laminar for the lowest Reynolds numbers in the range but, for
some specially designed internal geometries the flow will become complex-laminar-
turbulent or turbulent as the Reynolds number is increased from the low to the high end
of this Reynolds number range. Therefore the liquid channel flow, which may exhibit
laminar flow mass flux channeling or fingering of the liquid for unfavorable Rayleigh
numbers at the low Reynolds numbers in the above range, will, due to turbulent mixing,
locally self adjust at higher Reynolds number so that mal-distribution effects are much
smaller. On the other hand, the air flow channels will most likely have turbulent flow,
especially if some surface roughness is introduced to cause the flow to be turbulent. In an exemplary embodiment, the air channels include turbulence enhancing surface roughness features to facilitate increasing energy transfer that exceeds an additional air pressure drop energy loss when convective heat and latent energy transfer increase. In another embodiment, the desiccant include turbulence enhancing surface roughness features when a Rayleigh number is less than a critical Rayleigh number at a Reynolds number for the flow.

[0063] Since the liquid is under a pressure greater than the adjacent channel air pressure, it causes the flexible semi-permeable membrane and its support structure in the air channel on either side of each liquid flow channel to deflect or deform elastically. As previously noted, the liquid flow should be directed through each channel so that it minimizes flow mal-distributions (i.e. Ra < Ra_c for laminar flow and, when flow rates are higher, Re > Re_c for turbulent flow). The design and operational conditions imply that the liquid flow direction will be such that the liquid flow will be from a bottom inlet to the top outlet for the supply LAMEE exchanger and from the top inlet to the bottom outlet for the exhaust LAMEE exchanger for the standard summer test conditions. The flow directions through each LAMEE will be reversed for the winter standard test conditions. That is, a liquid flow direction controller will be used so that the inlet direction will be bottom or top of each LAMEE exchanger depending on the value of the Rayleigh number for each exchanger and the angles of the flow channels with respect to the acceleration direction of gravity as defined in Table 1 for factors G9 and G10. With these controlled liquid flow directions and a small performance enhancing tilt angle for the LAMEE, the problems of flow mal-distribution will have been reduced to a minimum for the geometric configurations of the flow channels and the channel Reynolds number. In fact, the restoring forces of favorable buoyancy forces that induce flow uniformity into the liquid flow channels that, due to flow channel width variations, can reduce the declination of performance factors for a LAMEE using factors G9 and G10 compared to the case of no restorative buoyancy forces.

[0064] On the liquid flow side of the membrane, turbulent mixing within the flow channel may be a factor if there is a tendency toward laminar flow buoyancy
induced mass flux fingering at high Rayleigh numbers and very low Reynolds numbers result in non-uniform exposure of the bulk flow to the molecular diffusion transfer process in the liquid. In one embodiment, for the factor PI, turbulence enhancement of the air and liquid flows through the LAMEE energy exchange channels is used to enhance turbulent transition and liquid flow directions are chosen for each LAMEE operating condition to decrease buoyancy induced instabilities in the liquid flow channels. For a given flow channel geometry, which is characterized by the hydraulic diameter and surface roughness, the Reynolds number is the only operating factor that determines whether the flow is laminar or turbulent. The performance effectiveness and RER of the passive RAMEE and its LAMEEs will be enhanced with some turbulent mixing.

[0065] In other embodiments, an energy exchanger is provided. The exchanger includes a housing for the air and liquid desiccant channels each separated by a semi-permeable membrane. A plurality of panels forming desiccant channels and air channels extend through the housing. The air channels are configured to direct an air stream through the housing. The plurality of panels are spaced apart partly based on predetermined air to desiccant mass rates (P3) and the air channel width or spacing and a desiccant channel width or spacing. The air to desiccant mass flow rate may be selected to achieve predetermined exchanger performance ratios that define a sensible and latent energy exchange rate between the desiccant and the air stream. The panel spacing may also be dependent on factors G4, G5, and P5. The air to desiccant mass flow rates may define an air channel width and/or a desiccant channel width. The air-to-desiccant channel mass flow rates may be selected to provide a predetermined mass or volume of air stream flowing through the air channels and/or a predetermined mass or volume of desiccant flowing through the desiccant channels. The desiccant channels may have an approximately constant desiccant channel width. Additionally, the air channels may have an approximately constant air channel width. In one embodiment, a ratio of the average air channel width divided by the average desiccant channel width is within a range of 1 to 5.
[0066] A desiccant inlet header is provided in flow communication with all the desiccant channels. A desiccant outlet is provided in flow communication with the desiccant channels. The desiccant channels are configured to channel desiccant from the desiccant inlet to the desiccant outlet in at least one of a counter-flow or cross-flow direction with respect to the direction of the air stream to facilitate heat and water vapor transfer between the desiccant in the desiccant channels and the air stream in the air channels.

[0067] For a predetermined test condition of the passive RAMEE system, a predetermined equal mass flow rate of supply and exhaust air pass through each identical LAMEE. By so doing, the number of transfer units for heat transfer (NTU) in each LAMEE is predetermined (factor P2). When the pumping rate of liquid desiccant is chosen, the heat capacity rate ratio (i.e. the mass flow rate times the specific heat of desiccant liquid flow divided by the mass flow rate of air) through each LAMEE, \( Cr^* \), is predetermined (factor P3). There may be a trade-off for the selection of \( Cr^* \) because increasing the liquid flow rate may enhance turbulence in the liquid flow channels and will increase \( Cr^* \), which can have positive and negative effects on the effectiveness. Accordingly, the value of \( Cr^* \) should be selected so that the effectiveness of the LAMEE is a maximum when the highest performance is required.

[0068] Other embodiments for energy exchangers are provided. The exchanger includes a housing containing the air and liquid flow channels each separated by a semi-permeable membrane. A plurality of panels forming desiccant channels and air channels extend through the housing. The air channels are configured to direct an air stream through the housing. A desiccant inlet header is provided in flow communication with all the desiccant channels. A desiccant outlet is provided in flow communication with the desiccant channels. The desiccant channels are configured to channel liquid desiccant from the desiccant inlet to the desiccant outlet in at least one of a counter-flow or cross-flow direction with respect to the direction of the air stream. A semi-permeable membrane extends through each panel to facilitate heat and water vapor transfer between the desiccant liquid in the desiccant channels and the air stream in the air channels. The membrane may be selected based on membrane resistance ranges defined to reduce a
flow of desiccant through the membrane. The semi-permeable membrane possesses a resistance to water vapor diffusion which, relative to the typical convection water vapor transport resistance in the air channels, lies within a specified range given by factor P4. A water vapor transfer resistance ratio is defined by a ratio of the membrane water vapor resistance \((R_{m,wv})\) to convective water vapor mass transfer resistance \((R_{a,wv})\). The ratio of the membrane water vapor resistance \((R_{m,wv})\) to convective water vapor mass transfer resistance \((R_{a,wv})\) may be within a range of 0.2 to 3.

[0069] The static air pressure drop as it passes from air inlet to outlet in each LAMEE in a RAMEE system is the same for each air channel. The range of acceptable air pressure drops for a LAMEE so that the passive RAMEE system will have a high RER value in the set Pf is presented using factor P5. In one embodiment, the air flow pressure drop ratio is defined as \((p_{h}A_{c}/V_{c})\), wherein \(p_{h}\) is a pressure drop of the air stream across the energy exchanger, \(A_{c}\) is an area of an air channel, and \(V_{c}\) is a volume of the air channel. In one embodiment, the air flow pressure drop ratio is between \(1\times10^{3}\) and \(1\times10^{4}\).

[0070] With respect to factor P6, a flow channel ratio of convective heat transfer coefficient, \(h\), (i.e. for turbulent flow) with respect to the theoretical laminar flow convective heat transfer coefficient, \(h_{i,am}\), at the same channel Reynolds number is \([1.1 < h/h_{i,am} < 2.0]\). The channel average friction flow coefficients for turbulent and laminar flow, \(f\) and \(f_{i,am}\), satisfy \([f/f_{i,am} < h/h_{i,am}]\).

[0071] Turbulent flows in channels with flow at a particular Reynolds number will have enhanced heat and mass transfer rates compared with those with laminar flows. Taking advantage of this fact is the purpose of factor P6. Accordingly, the internal surface roughness may be enhanced for channel flows that would have been laminar for smooth internal surfaces but turbulent for the same channel with rough surfaces or flow separation causing surfaces at the same Reynolds number (i.e. operating close to the flow transition Reynolds number between laminar and transition turbulence so as to cause the laminar flow to become turbulent). The heat or mass transfer enhancement is a factor for the air flow channels where the relatively high laminar flow characteristic convection
resistance dominates the total resistance and the design need for the LAMEE energy exchange total area and LAMEE total volume and geometry. Air channel support structures must be chosen and positioned to provide the desired membrane channel width and concurrently induce a turbulent flow transition from laminar to turbulent flow, but not cause an excessive increase air pressure drop for the flow channel. The ratios for the same channel flow Reynolds number are empirically selected for enhanced heat and mass transfer coefficients compared to laminar flow heat and mass transfer coefficients, which may be large, while the ratios for increased friction coefficients compared to laminar flow friction coefficients may be smaller (i.e. there is a net heat and mass transfer benefit for the turbulence enhancement relative to the air flow pressure drop increase).

[0072] The semi-permeable membrane is designed (or selected) and operated to avoid the transfer of any liquid from the liquid channels to the air channels. Factors P7 and P8 define the acceptable liquid pressure ratios that should be used for selecting the semi-permeable membrane and its edge seals in each LAMEE.

[0073] The difference between the static desiccant liquid pressure and the adjacent static air pressure cause the semi-permeable membrane to deflect during normal operation and the deflections will, as discussed above, result in a distribution of typical inter-channel hydraulic diameters that decrease the LAMEE and RAMEE system effectiveness. The deflections of the semi-permeable membrane through its air side support screen will be determined using its elastic properties, the geometry of the screen pores, and the liquid pressure. The operating properties are combined into a ratio (factor P9) that should be selected within a specified range for the design and operation of each LAMEE. In one embodiment, the membrane is selected based on a predetermined channel deflection range that is defined to limit the amount of membrane deflection. A standard deviation of the hydraulic diameter of all of the air channels and desiccant channels divided by a mean value of a hydraulic diameter for one of the air channels or desiccant channels may be within a range of 0.0 to 0.2. A standard deviation of a hydraulic diameter for one air channel or desiccant channel divided by a mean hydraulic diameter for the air channel or desiccant channel may be within a range of 0.0 to 0.2.
In another embodiment, an energy exchanger is provided. The exchanger includes a housing containing the air and liquid flow channels separated by a semi-permeable membrane. A plurality of panels forming desiccant channels and air channels extend through the housing. The air channels are configured to direct an air stream through the housing air channels. A desiccant inlet is provided in flow communication with the desiccant liquid channels. A desiccant outlet is provided in flow communication with the desiccant liquid channels. The desiccant channels are configured to channel desiccant from the desiccant inlet to the desiccant outlet in at least one of a counter-flow or cross-flow direction with respect to the direction of the air stream to facilitate heat and water vapor transfer between the desiccant in the desiccant liquid channels and the air stream in the air channels. The liquid desiccant salt concentration mixture is selected based on predetermined salt solution saturation concentration limit and membrane surface air side relative humidity for each climatic region in which the RAMEE system is to operate in applications. In one embodiment, the desiccant is selected based on at least one of an operating temperature or humidity ratio of the air stream, wherein the humidity ratio is defined by a moisture to air content of the air stream. The annual time fraction duration of RAMEE system operation without the risk of salt crystallization problems for a particular climatic region (factor P10) and the expected life-cycle costs relative to that for a system using pure LiCl or LiBr for the system (factor P11) are partly based on the desiccant selection. Each of the above embodiments (factors P10 and P11) are uniquely defined for the LAMEEs operating within a passive RAMEE system under steady-state test conditions.

With respect to factor P12, the LAMEE heat exchange rate with the surroundings (Q_{sur}) divided by the heat rate transferred to or from the air flowing through the exchanger (Q_{exh}) during a standard test of a RAMEE system using two identical LAMEEs is $0.0 < Q_{sur}/Q_{exh} < 0.05$.

Since the liquid is under a pressure greater than the adjacent channel air pressure, it causes the flexible semi-permeable membrane and its support structure in the air channel on either side of each liquid flow channel to deflect or deform elastically. As previously noted, the liquid flow should be directed through each channel so that it
minimizes flow mal-distributions (i.e. $\text{Ra} < \text{Ra}_c$ for laminar flow and, when flow rates are higher, $\text{Re} > \text{Re}_c$ for turbulent flow). The design and operational conditions imply that the liquid flow direction will be such that the liquid flow will be from a bottom inlet to the top outlet for the supply LAMEE exchanger and from the top inlet to the bottom outlet for the exhaust LAMEE exchanger for the standard summer test conditions. The flow directions through each LAMEE will be reversed for the winter standard test conditions. That is, a liquid flow direction controller will be used so that the inlet direction will be bottom or top of each LAMEE exchanger depending on the value of the Rayleigh number for each exchanger and the angles of the flow channels with respect to the acceleration direction of gravity as defined in Table 1 for factors G9 and G10. With these controlled liquid flow directions and a small performance enhancing tilt angle for the LAMEE, the problems of flow mal-distribution will have been reduced to a minimum for the geometric configurations of the flow channels and the channel Reynolds number.

[0077] The Reynolds number for the liquid flow through the liquid flow channels will typically be very low (i.e. $0.1 < \text{Re}_{\text{LAM},\text{L}} < 100$). Under these circumstances, the liquid flow may be laminar for the lowest Reynolds numbers in the range but, for some specially designed internal geometries the flow will become complex-laminar-turbulent or turbulent as the Reynolds number is increased from the low to the high end of this Reynolds number range. Therefore the liquid channel flow, which may exhibit laminar flow mass flux channeling or fingering of the liquid for unfavorable Rayleigh numbers at the low Reynolds numbers in the above range, will, due to turbulent mixing, locally self adjust at higher Reynolds number so that mal-distribution effects are much smaller.

[0078] This is also a problem for laminar flows and heat and mass transfer coefficients. The liquid channel screen insures a minimum spacing for the channel width and enhances the transition to turbulent flow for large liquid flow rates. The air and liquid flow channel screen area ratios (factor G6) is yet another predetermined embodiment because the ratios are directly related to turbulence enhancement and blockage fraction of the membrane for water vapor transfer on the air side of the membrane. The air channel spacer support structure ratio (factor G7) is another
geometric embodiment that assists the transition to turbulent flow and partly determines the geometry of the flow channel through its structural supports. Factor G8 defines the best liquid flow direction with respect to gravity through each LAMEE exchanger which may be controlled to avoid liquid flow mal-distribution and factors G9 and G10 define LAMME angles with respect to gravitational acceleration to get high performance factors for the RAMEE system and all its LAMEEs.

[0079] The new ratio of standard deviation for each liquid flow stream-tube hydraulic diameter in each liquid flow channel divided by the mean value can be used to analyze the decrease in expected effectiveness of each LAMEE and the passive RAMEE system in which it is used or tested. For example, if the flow tube standard deviation ratio is 0.05 (i.e. 5%) for the typical liquid flow channel in each identical LAMEE in the RAMEE system, then the decrease in total system effectiveness will be about 4% for turbulent flows but the loss of effectiveness may be much higher for laminar liquid flows where the flow field is unstable due to buoyancy effects.

[0080] Another embodiment is provided for the flow channels in each LAMEE which involves flow field characterization through the Reynolds number and the flow stability factor, Rayleigh number. The Rayleigh number can be selected to be most favorable by arranging the temperature gradients in each LAMEE to be such that the fluid density always increases in the downward direction of gravitational acceleration. This implies that the flow channels in a LAMEE should be aligned so that their normal area vector is horizontal and the length vector of the flow channel is tilted with a large enough angle to cause a favorable and significant density gradient for uniform flows in each channel and among all the channels. Channel flows in long thin channels with small or negligible entrance lengths for the flows are well known to be one of: (a) fully developed laminar flow at low Reynolds number, (b) fully developed turbulent flow at high Reynolds number, or (c) transition turbulent flows at intermediate Reynolds numbers between the two low and high transition Reynolds numbers. The flow transition Reynolds number that causes the flow to transfer from laminar to transition turbulence tends to be fixed for any given channel where the Rayleigh number indicates no buoyancy induced mal-distributions, but very small changes to the surfaces inside each
channel can cause large changes to the transition Reynolds number. That is, the flow in a channel can become turbulent when small increased surface roughness or flow separations within the channel flow changes are introduced at some low Reynolds numbers compared to laminar flow in the same channels with no roughness additions.

[0081] Turbulent flows in channels with flow at a particular Reynolds number will have enhanced heat and mass transfer rates compared with those with laminar flows. Accordingly, the internal surface roughness may be enhanced for channel flows that would have been laminar for smooth internal surfaces but turbulent for the same channel with rough surfaces or flow separation causing surfaces at the same Reynolds number (i.e. operating close to the flow transition Reynolds number between laminar and transition turbulence so as to cause the laminar flow to become turbulent). The heat or mass transfer enhancement is a factor for the air flow channels where the relatively high laminar flow characteristic convection resistance dominates the total resistance and the design need for the LAMEE energy exchange total area and LAMEE total volume and geometry. Air channel support structures must be chosen and positioned to provide the desired membrane channel width and concurrently induce a turbulent flow transition from laminar to turbulent flow, but not cause an excessive increase air pressure drop for the flow channel. The ratios for the same channel flow Reynolds number are empirically selected for enhanced heat and mass transfer coefficients compared to laminar flow heat and mass transfer coefficients, which may be large, while the ratios for increased friction coefficients compared to laminar flow friction coefficients may be smaller (i.e. there is a net heat and mass transfer benefit for the turbulence enhancement relative to the air flow pressure drop increase).

[0082] On the liquid flow side of the membrane, turbulent mixing within the flow channel may be a factor if there is a tendency toward laminar flow buoyancy induced mass flux fingering at high Rayleigh numbers and very low Reynolds numbers result in non-uniform exposure of the bulk flow to the molecular diffusion transfer process in the liquid. In one embodiment, for the factor PI, turbulence enhancement of the air and liquid flows through the LAMEE energy exchange channels is used to enhance turbulent transition and liquid flow directions are chosen for each LAMEE
operating condition to decrease buoyancy induced instabilities in the liquid flow channels. For a given flow channel geometry, which is characterized by the hydraulic diameter and surface roughness, the Reynolds number is the only operating factor that determines whether the flow is laminar or turbulent. The performance effectiveness and RER of the passive RAMEE and its LAMEE's will be enhanced with some turbulent mixing.

[0083] In other embodiments, an energy exchanger is provided. The exchanger includes a housing for the air and liquid desiccant channels each separated by a semi-permeable membrane. A plurality of panels forming desiccant channels and air channels extend through the housing. The air channels are configured to direct an air stream through the housing. The plurality of panels are spaced apart based on predetermined air to desiccant channel rates that define an air channel width or spacing and a desiccant channel width or spacing. A desiccant inlet header is provided in flow communication with all the desiccant channels. A desiccant outlet is provided in flow communication with the desiccant channels. The desiccant channels are configured to channel desiccant from the desiccant inlet to the desiccant outlet in at least one of a counter-flow or cross-flow direction with respect to the direction of the air stream to facilitate heat and water vapor transfer between the desiccant in the desiccant channels and the air stream in the air channels. For a predetermined test condition of the passive RAMEE system, a predetermined equal mass flow rate of supply and exhaust air pass through each identical LAMEE. By so doing, the number of transfer units for heat transfer (NTU) in each LAMEE is predetermined (factor P2). When the pumping rate of liquid desiccant is chosen, the heat capacity rate ratio (i.e. the mass flow rate times the specific heat of desiccant liquid flow divided by the mass flow rate of air) through each LAMEE, Cr*, is predetermined (factor P3). There may be a trade-off for the selection of Cr* because increasing the liquid flow rate may enhance turbulence in the liquid flow channels and will increase Cr*, which can have positive and negative effects on the effectiveness. Accordingly, the value of Cr* should be selected so that the effectiveness of the LAMEE is a maximum when the highest performance is required.
[0084] Other embodiments for energy exchangers are provided. The exchanger includes a housing containing the air and liquid flow channels each separated by a semi-permeable membrane. A plurality of panels forming desiccant channels and air channels extend through the housing. The air channels are configured to direct an air stream through the housing. A desiccant inlet header is provided in flow communication with all the desiccant channels. A desiccant outlet is provided in flow communication with the desiccant channels. The desiccant channels are configured to channel desiccant from the desiccant inlet to the desiccant outlet in at least one of a counter-flow or cross-flow direction with respect to the direction of the air stream. A desiccant membrane extends through each panel to facilitate heat and water vapor transfer between the desiccant liquid in the desiccant channels and the air stream in the air channels. The semi-permeable membrane possesses a resistance to water vapor diffusion which, relative to the typical convection water vapor transport resistance in the air channels, lies within a specified range given by factor P4.

[0085] The static air pressure drop as it passes from air inlet to outlet in each LAMEE in a RAMEE system is the same for each air channel. The range of acceptable air pressure drops for a LAMEE so that the passive RAMEE system will have a high RER value in the set Pf is presented using factor P5.

[0086] As discussed previously, inducing turbulence for otherwise laminar flows, for both the air-flow and liquid-flow channels, can enhance the heat and mass transfer coefficients more than the flow friction coefficients. Factor P6 defines the circumstance when there will be a net benefit for inducing turbulence in either the air or liquid channels.

[0087] In another embodiment for a passive RAMEE system, the exchanger includes a housing. A plurality of panels forming desiccant channels extend through the housing. Each of the plurality of panels has a semi-permeable membrane separating the air flow channels from the liquid flow channels. Air channels are formed between the desiccant liquid channels. The air channels are configured to direct an air stream through the housing. A desiccant inlet is provided in flow communication with the desiccant
channels. A desiccant outlet is provided in flow communication with the desiccant channels. The desiccant channels are configured to channel desiccant from the desiccant inlet to the desiccant outlet so that the semi-permeable membranes facilitate heat and water vapor exchange between the liquid desiccant and the adjacent air streams in a LAMEE. During a standard test with two identical LAMEEs in a passive RAMEE test loop, heat will be transferred between the LAMEEs and their surroundings. The relative magnitude of the heat transfer between the surroundings and each LAMEE is designed to be a small fraction of the heat rate between the air flows passing through the LAMEEs (factor P12).

[0088] Figure 1 illustrates a passive run-around membrane energy exchange (RAMEE) system 100 formed in accordance with an embodiment. The RAMEE system 100 is configured to partly or fully condition air supplied to a structure 101. The RAMEE system 100 includes an inlet 102 for a pre-conditioned air flow path 104. The pre-conditioned air flow path 104 may include outside air, air from a building adjacent to the enclosed structure 101, or air from a room within the enclosed structure 101. Airflow in the pre-conditioned air flow path 104 is moved through the pre-conditioned air flow path 104 by a fan 106. The illustrated embodiment includes one fan 106 located upstream of the LAMEE 108. Optionally, the pre-conditioned air flow path 104 may be moved by a down-stream fan and by multiple fans or a fan array or before and after each LAMEE in the system. The fan 106 directs the pre-conditioned air flow through path 104 to a supply liquid-to-air membrane energy exchanger (LAMEE) 108. The supply LAMEE 108 conditions the pre-conditioned air flow in path 104 to generate a change in air temperature and humidity (i.e. to pre-conditioned the air partly or fully) toward that which is required for a supply air flow condition to be discharged into the enclosed space 101. During a winter mode operation, the supply LAMEE 108 may condition the pre-conditioned air flow path 104 by adding heat and moisture to the pre-conditioned air in flow path 104. In a summer mode operation, the supply LAMEE 108 may condition the pre-conditioned air flow path 104 by removing heat and moisture from the pre-conditioned air in flow path 104. The pre-conditioned air 110 is channeled to a HVAC system 112 of the enclosed structure 101. The HVAC system 112 may further condition
the pre-conditioned air 110 to generate the desired temperature and humidity for the
supply air at 114 that is supplied to the enclosed structure 101.

[0089] Return air 116 is channeled out of the enclosed structure 101. A mass
flow rate portion 118 of the return air 116 is returned to the HVAC system 112. Another
mass flow rate portion 119 of the return air 116 is channeled to a return LAMEE 120.
The portions 118 and 119 may be separated with a damper 121 or the like. For example,
80% of the return air 116 may be channeled to the HVAC system 112 and 20% of the
return air 116 may be channeled to the return air regeneration LAMEE 120 in the
RAMEE loop. The return air LAMEE 120 exchanges energy between the portion 118 of
the return air 116 and the pre-conditioned air 110 in the supply air LAMEE 108. During a
winter mode, the return air LAMEE 120 collects heat and moisture from the portion 118
of the return air 116. During a summer mode, the return air LAMEE 120 discharges heat
and moisture into the regeneration air flow 119. The return air LAMEE 120 generates
exhaust air 122. The exhaust air 122 is discharged from the structure through an outlet
124. A fan 126 is provided to move the exhaust air 122 from the return air LAMEE 120.
The RAMEE system 100 may includes multiple fans 126 or one or more fan arrays
located either up-stream or down-stream (as in Fig. 1) of the exhaust air LAMEE 120.

[0090] A desiccant fluid 127 flows between the supply air LAMEE 108 and
the return air LAMEE 120. The desiccant fluid 127 transfers the heat and moisture
between the supply air LAMEE 108 and the return air LAMEE 120. The RAMEE
system 100 includes desiccant storage tanks 128 in fluid communication between the
supply air LAMEE 108 and the return air LAMEE 120. The storage tanks 128 store the
desiccant fluid 127 as it is channeled between the supply air LAMEE 108 and the return
air LAMEE 120. Optionally, the RAMEE system 100 may not include both storage tanks
128 or may have more than two storage tanks. Pumps 130 are provided to move the
desiccant fluid 127 from the storage tanks 128 to one of the supply LAMEE 108 or the
return LAMEE 120. The illustrated embodiment includes two pumps 130. Optionally,
the RAMEE system 100 may be configured with as few as one pump 130 or more than
two pumps 130. The desiccant fluid 127 flows between the supply air LAMEE 108 and
the return air LAMEE 120 to transfer heat and moisture between the conditioned air 110 and the portion 118 of the return air 116.

[0091] The embodiments described herein utilize a set of predetermined geometric design factors (G1-G10) and physical property and operating parameters (P1-P12) for the supply and exhaust air LAMEEs 108 and 120 and the RAMEE system 100 and maintain predetermined ranges for each parameter for LAMEEs 108 and 120 and for the RAMEE system 100, as illustrated in Table 1. As a set, the design and operating parameters enable the systems to meet selected performance factors. The set of predetermined geometric design and physical property and operating parameters is comprised of a subset of geometric design length ratios and a subset of physical property and operating parameters each comprised of physical property or operating condition ratios that may include some geometric lengths as well as other physical properties in some cases. The defined geometric design and physical ratios represent dimensionless ratios or factors that do not require specific length scales or property units except with respect to another defined length or parameter with the same units in the same ratio (i.e. each of them is dimensionless). The geometric design and physical parameters are discussed herein in connection with various embodiments.

[0092] The performance factors for a RAMEE system 100 employing supply and exhaust air counter-flow or cross-flow LAMEEs 108 and 120, in accordance with the embodiments, may be determined using ASHRAE Std. 84-2008 using a defined set of steady-state test conditions defined in AHRI Std.1060-2005. In one embodiment, a thermal insulation surrounding the panels is such that a heat exchange rate between the panels is less than 5% of a heat rate between supply and exhaust air flow streams during standard summer or winter testing with AHRI 1060 air inlet operating conditions. The operating conditions for the RAMEE system 100 during a test with balanced air flows and with the system at or very near steady-state will be determined by specifying: Cr*, NTU, NTU_m and the relative flow direction and geometry of each LAMEE (where each of the dimensionless terms have been defined previously or will be defined herein). The deduction of the effectiveness of performance of a single LAMEE 108 from the steady-state or quasi-steady-state RAMEE system 100 test data, which includes two similar
LAMEEs, 108 and 120, may be deduced from steady-state energy and mass balance equations. That is, both the overall run-around system effectiveness, $E_0$, and the individual exchanger effectiveness, $E$, in the run-around loop depends on $Cr^e$, NTU and NTU $m$ at or near steady state so the relationship for $E$ can be readily determined once $E_0$ is measured. For the simple example of a run-around heat exchanger system with equal supply and exhaust air flow rates using two identical counter flow heat exchangers, it can be shown that $Cr = 1.0$ at the maximum heat rate and system overall effectiveness, $E_0$, and the individual supply or exhaust exchanger effectiveness is given by:

$$E = \frac{2E_0/(1+E_0)}{2U(E_0)/[E_0(1+E_0)^2]}$$

which will have a relative uncertainty of $U(E)/E = 2U(E_0)/[E_0(1+E_0)^2]$ where both $E$ and $E_0$ are less than 1.0 for heat exchangers

\{e.g. when $E_0 = 2/3$ (or 67%) (calculated from the measured data) and $U(E_0)/E_0 = 0.05$ (also determined from data) then $E = 0.80 +/- 0.04$ (or 80 +/- 4 %)}

[0093] In one embodiment, the flow panel aspect ratio is defined by the height of the energy exchange area of each flow panel divided by the length of the same exchange area in the LAMEE. In another embodiment, the entrance length to total panel length ratio is defined for LAMEEs that are either primarily counter-flow or cross-flow exchangers. In another embodiment, the ratio of the flow channel standard deviation of average panel channel hydraulic diameters (widths) for each fluid with respect to average flow hydraulic diameter (width) for each fluid for the LAMEE is limited to reduce mal-distribution of fluid flows among the channels. In another embodiment, the ratio of the stream-tube standard deviation in hydraulic diameter to mean stream-tube hydraulic diameter is limited to reduce flow mal-distributions within a typical flow channel. The liquid desiccant to air capacity rate ratio also implies a particular mass flow rate ratio. Therefore, for a predetermined volume or mass flow rate of air flowing through the air channels of a LAMEE and a particular volume or mass flow rate of liquid desiccant may be required to flow through the adjacent liquid desiccant channels.
[0094] In another embodiment, turbulent flow conditions are induced in the air and liquid flow channels of the LAMEE by selecting a distribution and geometric shape for the air and liquid flow channel spacers in the LAMEE. The turbulence can be used to enhance the heat and mass transfer convection coefficients in the air flow channels which can be used to increase the effectiveness and/or decrease the LAMEE size. In other embodiments for the liquid flow channels, turbulence in the liquid flow channels is facilitated to enhance the bulk mean flow distribution (and eliminate laminar flow fingering and mal-distributions) and increase the convective heat and moisture transfer coefficients (i.e. decrease mal-distributions in the liquid flows) because the physical effect increases the effectiveness of a given LAMEE and its RAMEE system and can be used to decrease the physical size of each LAMEE.

[0095] In another embodiment, the elastic tensile limit for the semi-permeable membrane is selected to partly limit the deflection of the semi-permeable membrane with respect to its structural support screen in the LAMEE.

[0096] In another embodiment, the membrane and membrane frame liquid flow penetration resistance ranges are selected to eliminate any flow of the liquid desiccant through the semi-permeable membrane and its edge seal frame for each panel pair of channels in the LAMEE.

[0097] In another embodiment, the air mass flow ratio of the two air streams inlet to the two identical LAMEEs in the RAMEE system is selected to meet a predetermined exposure of the air stream to the semi-permeable membranes.

[0098] In another embodiment, the air pressure drop ratio for a selected mass flow rate of air is selected to ensure a high RER performance factor for a RAMEE system.

[0099] In another embodiment, the salt solution concentration ranges are used to limit the time fraction when there may be a risk of crystallization for a climatic region for particular application and reduce the life-cycle costs for an application.
In another embodiment, the heat exchange with the surroundings is by using appropriate energy exchange cavity insulation reduced to a small fraction of the heat rate for the RAMEE system under a standard test.

Figure 2 illustrates a LAMEE 300 formed in accordance with an embodiment. The LAMEE 300 may be used as the supply air LAMEE 108 and/or the return or exhaust air LAMEE 120 (shown in Figure 1). The LAMEE 300 includes a housing 302 having a body 304. The body 304 includes an air inlet end 306 and an air outlet end 308. A top 310 extends between the air inlet end 306 and the air outlet end 308. A stepped-down top 312 is positioned at the air inlet end 306. The stepped-down top 312 is stepped a distance 314 from the top 310. A bottom 316 extends between the air inlet end 306 and the air outlet end 308. A stepped-up bottom 318 is positioned at the air outlet end 308. The stepped-up bottom 318 is stepped a distance 320 from the bottom 316. In alternative designs the stepped-up 318 or stepped-down 312 sections may have different sizes of steps or no step at all.

An air inlet 322 is positioned at the air inlet end 306. An air outlet 324 is positioned at the air outlet end 308. Sides 326 extend between the air inlet 322 and the air outlet 324. Each panel in the LAMEE 300 has a semi-permeable membrane length 364, as shown in Figure 3a. Also shown in Figure 3a, each panel in the LAMEE 300 has a semi-permeable membrane height 362 defining an energy exchange area extends a height (H) between a top and a bottom defined by the top and bottom of the semi-permeable membrane. The energy exchange area extends a length (L) between a front and a back that is defined by the front and the back of the semi-permeable membrane. An exchanger aspect ratio (AR) is defined by a height (H) 362 of each semi-permeable membrane energy exchange area divided by a length (L) 364 of the energy exchange area. The exchanger aspect ratio (AR) represents the physical design factor G2 (shown in Table 1) and is at least one factor for partly achieving a predetermined performance of the LAMEE 300. The aspect ratio (AR) is a dimensionless ratio. The aspect ratio (AR) is determined using the equation AR = H/L. In an exemplary embodiment for a counter/cross flow LAMEE, factor G2, the aspect ratio (AR), is within a range of 0.1 < AR < 3.0. In one embodiment, the exchanger aspect ration is within a range of 0.5 to 2.
The exchanger aspect ratio is selected to provide at least one of a predetermined membrane area, a predetermined length, or a predetermined duration of exposure of the air stream to the desiccant.

[00103] An energy exchange cavity 330 extends through the housing of the LAMEE. The energy exchange cavity 330 extends from the air inlet end 306 to the air outlet end 308. An air stream 332 is received in the air inlet 322 and flows through the energy exchange cavity 330. The air stream 332 is discharged from the energy exchange cavity 330 at the air outlet 324. The energy exchange cavity 330 includes a plurality of panels 334. Each liquid flow panel forms a liquid desiccant channel 376 that is confined by the semi-permeable membranes 378 on either side and is configured to carry desiccant 341 therethrough. The semi-permeable membranes 378 are arranged in parallel to form air channels 336 with an average flow channel width \((d_{w,i})\) of 337 and liquid desiccant channels 376 with an average flow channel width \((d_{w,j,q})\) of 377. In one embodiment, the semi-permeable membranes 378 are spaced to form uniform air channels 336 and liquid desiccant channels 376 with \(d_{w,air}\) and \(d_{w,j,q}\) implied by what is practical to reduce statistical variations for each as illustrated in factor G4 of Table 1. The air stream 332 travels through the air channels 336 between the semi-permeable membranes 378. The desiccant 341 in each desiccant channel 376 exchanges heat and moisture with the air stream 332 in the air channels 336 through the semi-permeable membranes 378.

[00104] A desiccant inlet reservoir 338 is positioned on the stepped-up bottom 318. The desiccant inlet reservoir 338 may have a height 340 equal to the distance 320 between the bottom 316 and the stepped-up bottom 318. Alternatively, the liquid desiccant inlet reservoir 338 may have any height 340 that meets a predetermined performance of the LAMEE 300. The desiccant inlet reservoir 338 extends a length 339 of the LAMEE body 304. The desiccant inlet reservoir 338 extends a length 339 that is configured to meet a predetermined performance of the LAMEE 300. In one embodiment the desiccant inlet reservoir 338 extends no more than one fourth of the length 327 of the LAMEE body 304. Alternatively, the desiccant inlet reservoir 338 may extend along one fifth of the length 327 of the LAMEE body 304.
The liquid desiccant inlet reservoir 338 is configured to receive desiccant 341 from a storage tank 128 (shown in Figure 1). The desiccant inlet reservoir 338 includes an inlet 342 in flow communication with the storage tank 128. The desiccant 341 is received through the inlet 342. The desiccant inlet reservoir 338 includes an outlet 344 that is in fluid communication with the desiccant channels 376 in the energy exchange cavity 330. The liquid desiccant 341 flows through the outlet 344 into the desiccant channels 376. The desiccant 341 flows along the panels 334 through desiccant channel 376 to a desiccant outlet reservoir 346.

The desiccant outlet reservoir 346 is positioned on the stepped-down top 312 of the LAMEE housing 302. Alternatively, the desiccant outlet reservoir 346 may be positioned at any location along the top 312 of the LAMEE housing 302 or alternatively on the side of the reservoir with a flow path connected to all the panels. The desiccant outlet reservoir 346 has a height 348 that may be equal to the distance 314 between the top 310 and the stepped-down top 312. The desiccant outlet reservoir 346 extends along the top 312 of the LAMEE housing 302 for a length 350. In one embodiment of a counter/cross flow exchanger, the desiccant outlet reservoir 346 extends a length 350 that is no more than one fourth the length 327 of the flow panel exchange area length 302. In another embodiment of a counter/cross flow LAMEE the desiccant outlet reservoir 346 extends a length 350 that is one fifth the length 327 of the panel exchange area length 302 (i.e. factor G3).

The desiccant outlet reservoir 346 is configured to receive desiccant 341 from the desiccant channels 376 in the energy exchange cavity 330. The desiccant outlet reservoir 346 includes an inlet 352 in flow communication with the desiccant channels 376. The desiccant 341 is received from the desiccant channels 376 through the inlet 352. The desiccant outlet reservoir 346 includes an outlet 354 that is in fluid communication with a storage tank 128. The desiccant 341 flows through the outlet 354 to the storage tank 128 where the desiccant 341 is stored for use in another LAMEE 300. In an alternative embodiment, the desiccant outlet reservoir 346 may be positioned along the bottom 318 of the LAMEE housing 302 and the desiccant inlet reservoir 338 may be positioned along the top 310 of the LAMEE housing 302.
In the illustrated embodiment, the LAMEE 300 includes one liquid desiccant outlet reservoir 346 and one liquid desiccant inlet reservoir 338. Alternatively, the LAMEE 300 may include liquid desiccant outlet reservoirs 346 and liquid desiccant inlet reservoirs 338 on the top and bottom of each of each end of a LAMEE 300. A liquid flow controller may direct the liquid flow to either the top or bottom depending on the value of Ra for factor PI in the independent factor set If in Table 1.

During testing of the RAMEE system 100 using ASHRAE Std. 84-2008 and the steady-state test conditions defined in AHRI Std. 1060-2005, wherein the RAMEE system 100 has balanced air flows and is at or very near steady-state, an exchanger thermal capacity ratio $Cr^*$ (operational independent factor P3 as illustrated in Table 1) is defined. $Cr^*$ is a dimensionless ratio representing the mass flow rate of the liquid desiccant times the heat capacity of the liquid desiccant divided by the mass flow rate of the air times the heat capacity of the air. $Cr^*$ is measured by measuring the flow rates of the air and liquid desiccant and using known heat capacities of the liquid desiccant and the air. In one embodiment, $Cr^*$ falls within a range during RAMEE testing that is between $1.0 < Cr^* < 10.0$. In one example for a run-around heat exchanger system having equal supply and exhaust air flow rates and using two identical counter flow heat exchangers, $Cr^*$ may equal 1.0 at a maximum heat rate and overall effectiveness, $E_0$.

During RAMEE testing, the exchanger number of transfer units (NTU) for heat transfer (operational independent factor P2 as illustrated in Table 1) may also be defined. In general, the effectiveness of a heat exchanger increases directly with the value of NTU. A heat capacity rate for the air stream 332 and the desiccant 341 is used to determine the maximum feasible heat transfer between the air stream 332 and the desiccant 341. The effectiveness of the RAMEE system for heat transfer between the supply air flow and the exhaust air flow is determined by measuring the two mass flow rates of air and the temperature increase of the air flowing through the supply air exchanger and the temperature difference between the inlet air to the supply and exhaust air exchangers. In one embodiment, NTU is within a range $1 < NTU < 15$. Having an NTU within this range may provide a predetermined performance of the RAMEE system.
In one embodiment, the range of NTU may function concurrently with other performance factors defined herein to achieve the predetermined performance of the LAMEE 300 and the RAMEE system 100.

[0011] During RAMEE 100 testing, an air flow pressure drop ratio (operational design factor P4 as illustrated in Table 1) may also be defined for the LAMEEs 300. The air flow pressure drop ratio is calculated using the ratio $p_{hA}$/$V_c$, wherein $p_{h}$ is the air flow pressure head drop across the LAMEE 300, $A_c$ is the energy exchange area of one air flow channel in LAMEE 300, and $V_c$ is the volume of each air channel. The air flow pressure drop ratio is used to define a pressure drop in the air stream 332 between the air inlet 322 and the air outlet 324 of the LAMEE 300. In one embodiment, the air flow pressure drop ratio is with a range of $10^3$ to $10^4$ to achieve a predetermined RER performance factor for the RAMEE system 100.

[0012] Figure 3a illustrates the LAMEE 300 having a cutout along the line 3-3 shown in Figure 2. The top 310 and the bottom 318 of the LAMEE housing 302 include insulation 360 joined thereto. The sides 326 of the LAMEE housing 302 also include insulation 360. Except for the air inlet and outlet areas, the insulation 360 extends around the energy exchange cavity 330. The insulation 360 limits an amount of heat that may be exchanged between the air and liquid desiccant flowing through the energy exchange cavity and the surroundings as the air and liquid desiccant flow through the channels in the energy exchange cavity compared to the heat rate for the air for the supply and exhaust air flows (i.e. factor P12). The insulation 360 may include foam insulation, fiber insulation, gel insulation, or the like. The insulation 360 is selected to at least partially meet a predetermined performance of the LAMEE 300.

[0013] The energy exchange cavity 330 has a height 362, a length 364, and a width 366. The height 362 is defined between the top and bottom of the energy exchange cavity 330. The width 366 is defined between the insulation side walls of the energy exchange cavity 330. The length 364 is defined between the air inlet 322 and the air outlet 324 of the energy exchange cavity 330. Each energy exchange panel 334 extends
the height 362 and length 364 of the energy exchange cavity 330. The panels 334 are spaced along the width 366 of the energy exchange cavity 330.

[0014] For the counter/cross flow LAMEE, the liquid desiccant flow inlet 334 of the desiccant inlet reservoir 338 is in flow communication with the energy exchange cavity 330 at the air outlet end 308 of the LAMEE 300. The liquid desiccant outlet 352 of the desiccant outlet reservoir 346 is in flow communication with the energy exchange cavity 330 at the air inlet end 306 of the LAMEE 300. The desiccant inlet reservoir 338 and the desiccant outlet reservoir 346 are in fluid communication with the liquid channel 376. The panels 334 define a non-linear liquid desiccant flow path 368 between the desiccant inlet reservoir 338 and the desiccant outlet reservoir 346. The flow path 368 illustrates one embodiment of a counter/cross flow path with respect to the direction of the air stream 332. In one embodiment, a desiccant flow direction through the desiccant channels 376 is controlled so that lower density desiccant flows separately from higher density desiccant.

[0015] Figure 3b illustrates a front view of the panels 334. The panels 334 are spaced to form air channels 336 and the liquid desiccant channels 376 there-between separated by semi-permeable membranes 378. The air channels 336 alternate with the liquid desiccant channels 376. Except for the two side panels of the energy exchange cavity, each air channel 336 is positioned between adjacent liquid desiccant channels 376. The liquid desiccant channels 376 are positioned between adjacent air channels 336. The air channels 336 have an average channel width 337 defined between adjacent panels 334. The liquid desiccant channels 376 have an average channel width 377 defined between adjacent panels 334. The width 337 of the air channels 336 and the width 377 of the liquid desiccant channels 376 are nearly constant over the area of each panel and for the set of panels in the LAMEE energy exchange cavity with the exception of independent geometric design factors G4 and G5 as illustrated in Table 1. In one embodiment, the standard deviation of the average channel hydraulic diameter (directly related to the width 337 of the air channels 336 or average channel width 377 of the liquid desiccant channels 376) divided by the corresponding mean average channel hydraulic diameter for each fluid is an independent geometric design factor (physical
design factor G4 as illustrated in Table 1) restricted for each type of fluid channel to at least partly achieve the predetermined set of performance factors Pf of the RAMEE system with its LAMEEs 300. In another embodiment, the statistical variations in the stream-tube hydraulic diameters will be such that the standard deviation of the flow tubes hydraulic diameters for a typical type of fluid channel in a LAMEE divided by the mean stream-tube hydraulic diameter for the typical flow channel of a fluid will be restricted as specified by factor G5 in Table 1.

[0016] Figure 4 illustrates a panel 334 to contain the desiccant liquid flow for one channel formed in accordance with an embodiment. The panel 334 includes support structures including a top support 370, a bottom support 372 that is opposite the top support 370, and a pair of opposite side supports 374 extending between the top support 370 and the bottom support 372. The supports 370, 372, and 374 retain the membranes 392 and a liquid desiccant inlet diffuser 396 and outlet diffuser 400. The panel 334 includes a top 381 and a bottom 383. The panel 334 has an overall height 382 defined between the top 381 and the bottom 383. The energy exchange membrane 392 includes a top 385 and a bottom 387. The membrane 392 has an overall height 384 defined between the top 385 and the bottom 387. The height 384 of the membrane 392 is less than the height 382 of the panel 334. The panel 334 has a front end 389 and a back end 391. The panel 334 has an overall length 386 defined between the front end 389 and the back end 391. The membrane 392 includes a front end 393 and a back end 395 corresponding to the air inlet and outlet for the adjacent air flow channels respectively. The membrane 392 has an overall length 388 defined between the front end 393 and the back end 395. The length 388 of the membrane 392 is less than the length 386 of the panel 334. Ratios of the heights 382 and 384 to the lengths 386 and 388, respectively, may be configured based at least partly on a predetermined performance of the LAMEE 300. In one embodiment for a counter/cross-flow panel, the height 384 of the membrane 392 is within a range of 0.1 to 3.0 times the length 388 of the membrane 392 (i.e. factor G2).

[0017] The panel 334 has a desiccant inlet end 378 and a desiccant outlet end 380. A desiccant flow path 368 shows a typical bulk mean streamline for flow from the liquid desiccant inlet 396 to the desiccant outlet 400 in a non-linear flow path that is
primarily opposite to the direction of the air stream 332. The desiccant inlet end 378 includes an inlet 390 that extends through the bottom support 372 and between adjacent panels 334. The inlet 390 has a length 396. A ratio of the length 396 of the inlet 390 to the length 388 of the panel 334 is selected based on a predetermined performance of the LAMEE. The desiccant outlet end 380 includes an outlet 398 that extends through the top support 370 and between adjacent panels 334. The outlet 398 has a length 400 which is equal to the inlet length 396. A ratio of the length 400 of the outlet 398 to the length 388 of the panel 334 is selected based at least partly on a predetermined performance of the LAMEE 300. The desiccant flow path 368 flows from the inlet 390 to the outlet 398.

[0018] The liquid desiccant flow path-line 368 is the same as one possible bulk-mean streamline which is necessarily curved, especially near the liquid ingest and egress regions of the channel, through a counter/cross-flow panel of a LAMEE. The curved streamline is contrasted with the essentially straight bulk-mean air streamline 332 in the air channels 336. The bulk-mean liquid desiccant flow path direction or velocity is mostly upstream of that for the adjacent channel bulk-mean air stream 332. An inlet flow ingest region cross segment 402 of the liquid desiccant bulk-mean streamline 368 is formed as the desiccant enters the desiccant channel 376 from the inlet 390. Liquid desiccant 341 flowing from the inlet 390 into the desiccant channel 376 flows upward through the inlet cross segment 402. Liquid desiccant 341 in the inlet cross segment 402 flows partly in a cross flow direction to that for the adjacent air flow channel streamline 332.

[0019] Since the liquid desiccant 341 is channeled from the inlet 390, the desiccant 341 fills the channel 376 and flows through a primarily an air/liquid counter flow segment 404 of the liquid desiccant bulk-mean streamline 368. The liquid/air counter flow segment 404 extends approximately a length 406 through the liquid desiccant flow channel 376. The length 406 is based partly on a predetermined performance of the LAMEE 300. The liquid/air counter flow segment 404 is essentially parallel to direction of the air stream 332 in the air channels 336. The liquid/air counter flow segment 404 has the liquid flow opposite to the direction of the adjacent air flow 332. The counter flow arrangement at least partly provides a predetermined heat and
moisture exchange effectiveness between the liquid desiccant 341 in the desiccant channel 376 and the air stream 332 in the air channels 336.

[00120] The liquid desiccant 341 in the counter segment 404 flows into a counter/cross-flow liquid flow egress region 408 of the liquid desiccant flow path 368. The liquid desiccant 341 in the outlet counter/cross flow region segment 408 flows with curved bulk mean streamlines from the counter segment 404 to the outlet 398. The liquid desiccant 341 in the outlet counter/cross flow region 408 flows at least partly in a cross flow direction that is perpendicular to the direction of the air stream 332 in the air channels 336.

[00121] The counter/cross-flow arrangement of the liquid desiccant bulk-mean streamline flow path 368 provides a liquid desiccant nearly counter flow with respect to the air stream 332. The counter flow arrangement improves the effectiveness of the LAMEE 300 compared to a unit with equal mass flow rates, inlet properties and exchanger energy exchange area. The counter/cross flow arrangement does not require large headers that increase the space required for the LAMEE 300. The illustrated embodiment shows the desiccant flow path 368 flowing upward from the inlet 390 to the outlet 398. Optionally, the inlet 390 may be positioned at the top support 370, but at the same end of the panel 334 and the outlet 398 may be positioned at the bottom support 372 but at the same end of the panel 334. In such an embodiment, the desiccant flow path 368 may flow downward from the inlet 390 to the outlet 398. The flow direction option facilitates avoiding liquid channel flow mal-distributions caused by buoyancy induced instability in one of the two LAMEEs under typical summer and winter operating for a RAMEE system.

[00122] Figure 5a is an exploded view of the liquid desiccant flow panel 334. The panel 334 includes a liquid-desiccant flow guide and turbulence-enhancement screen diffuser 410 and a pair of semi-permeable membranes 412. The liquid-desiccant screen diffuser 410 is retained between the semi-permeable membranes 412. The semi-permeable membranes 412 are bonded (by heat sealing or glue) to the membrane support structural elements 418 and 424. The membrane support screens 414 in the adjacent air
flow channels 336 may also include air flow channel spacers. An air channel support
screen may include a solid area that is a fraction of a total area of the air channel support
screen. Additionally, a desiccant channel support screen may have a solid area that is a
fraction of a total area of the desiccant channel support screen. In one embodiment, a
distance between air channel support screens in the flow direction of the air stream
divided by a distance between air channel support screens normal to the flow direction of
the air steam is within a range of 0.01 to 5.0. The air flow channels 336 are formed
between adjacent liquid-desiccant flow panels 334. The desiccant 341 is configured to
have a bulk-mean flow parallel to the semi-permeable membranes 412. The semi-
permeable membranes 412 allow heat and moisture exchange between the flowing liquid-
desiccant 341 in the desiccant channels 376 and the flowing air stream 332 in the air
channels 336. The membrane 412 is semi-permeable and formed with a high density of
micron-sized pores that allow water vapor to diffuse through the membrane 412 between
the liquid desiccant 341 and the air stream 332. The pores have a size that, due to air-
liquid suffice tension forces, prevents the liquid desiccant 341 from flowing through the
pores of the membrane 412. The semi-permeable membrane material may be selected in
part based on a required performance of the LAMEE 300.

[00123] Figure 5b is a more detailed view of the air flow channels comprising
two membranes, two structural support screens and many air flow channel structural
spacers. In an alternative design the spacers may be porous rigid tubes. The parameters
for structurally supporting the flexible membranes for the air channel are specified by
factor G7.

[00124] The membrane material may be selected, in part, based on a water
vapor resistance diffusion \( R_{m,wv} \) divided by a convective water vapor transfer resistance
into the adjacent air flow channels \( R_{a,l,wv} \) (independent operational design factor P4 as
illustrated in Table 1). The water vapor resistance \( R_{m,wv} \) is defined as the membrane’s
resistance to water vapor diffusing through the membrane 412 between the air channel
336 and the liquid channel 376. The convective water vapor transfer resistance \( R_{a,l,wv} \) is
defined as the membrane’s ability to resist water vapor transfer between the bulk-mean
flow of air in channels 336 and the liquid channels 376 through the semi-permeable
membrane 412. The ratio of the water vapor diffusion resistance \((R_{m,wv})\) of the semi-permeable membrane 412 to the convective water vapor transfer resistance \((R_{a,wv})\) of the membrane 412 may have a range of \(0.1 < (R_{m,wv})/(R_{a,wv}) < 3.0\) in factor P4. In one embodiment, the ratio is selected to be as small as practical.

[00125] The semi-permeable membrane 412 may also be partly selected based on a liquid break through pressure of the membrane 412 (operational design factor P7 as illustrated in Table 1). The liquid break through pressure is defined by a standard test as a liquid pressure within the LAMEE 300 that is required for liquid desiccant 341 to flow through the semi-permeable membrane 412. In one embodiment, factor P8, the membrane liquid break through pressure \((p_{m,bt})\) is selected to satisfy the inequality \((p_{m,bt})/(\rho g h) > 20\), where \(\rho\) is the density of the liquid desiccant solution, \(g\) is the acceleration of gravity and \(h\) is the height of the semi-permeable membrane in the energy exchange area of the surface for each channel. A liquid break through pressure ratio is defined by \(p_{m,bt}/(\rho g h)\), wherein \(p_{m,bt}\) is the membrane liquid break-through pressure, \(g\) is gravity, and \(h\) is the height of the membrane panel energy exchange area. In one embodiment, the membrane liquid break through pressure may be greater than 20.

[00126] A channel edge seal liquid break-through pressure \((p_{es,bt})\) (operational design factor P8 as illustrated in Table 1) defines a pressure within the LAMEE 300 that is required for the desiccant 341 to flow through the edge seal of the membrane 412. The channel edge seal liquid break-through pressure \((p_{es,bt})\) is selected to satisfy the inequality \(p_{es,bt}/(\rho g h) > 20\). When the operating pressure of the liquid flow channels is less than \(p_{es,bt}\) or \(p_{es,bt}\) no liquid leaks will occur through the membrane 412 or the edge seals. In one embodiment, the edge seal liquid break through pressure may be greater than 20.

[00127] The membrane material may also be at least partly selected based on an elastic tensile yield limit \((T_{m,y})\) (operational design factor P9 as illustrated in Table 1). The elastic tensile yield limit \((T_{m,y})\) defines the membrane's elastic deformation limits when subjected to liquid pressure from the desiccant 341 flowing through the desiccant channel 376. In one embodiment, factor P9, the elastic tensile yield limit \((T_{m,y})\) for the membrane 412, will lie in the range of \(0.02 < (T_{m,y})/(p_{i,op} s_{wb}) < 1.5\), where \(p_{i,op}\) is a
typical operating pressure for the liquid in each LAMEE and \( s_{w_i} \) is a wire spacing distance for the air-side screen 416 used to resist the liquid pressure for each desiccant channel 376. The operating pressure of the LAMEE is confined to a value that will not exceed the elastic deformation limits for the membrane 412 for each desiccant channel 376. An elastic tensile yield limit ratio for the membrane is defined by \( \frac{T_{m, yi}}{p_{top}} \), wherein \( T_{m, yi} \) is the tensile yield limit for the membrane, \( p_{top} \) is a typical operating pressure for the liquid in each LAMEE, and \( s_{w_i} \) is a wire spacing distance for a screen used to resist the liquid pressure for each liquid flow channel

[00128] Membrane air-side screen support structures 414 are positioned adjacent to the membranes 412. Each membrane 412 is positioned between an air-side membrane support structure 414 and the desiccant flow channel liquid-flow-guide screen diffuser 410. The membrane support structures 414 retain the membranes 412 to limit the elastic deflections of the membranes 412. Deflection of the membranes 412 will occur due to liquid static pressure that is higher than that for the adjacent air channels 332. The liquid desiccant will create pressure on the membranes 412 that causes the membranes 412 to bow and/or elastically deform. The mass flow mal-distribution on the adjacent liquid and air sides is tightly controlled for the design and quality control of the manufacturing process and operation of the RAMEE system and its LAMEEs.

[00129] In an example embodiment, the membrane air-side support structures 414 are formed from a screen material. Optionally, the membrane support structures 414 may be formed from a permeable backing, plastic support structures, rods, metal screens, spacers and/or the like. The membrane support structures 414 include openings 416 therethrough that allow the transfer of heat and moisture between the liquid desiccant and the air stream 332.

[00130] The liquid-side structural spacers 418 and 424 are positioned around the liquid-desiccant flow guide screen 410. The spacers separate the two membranes 412 that are bonded onto each side of the spacers 418 and 424. The membranes 412 are coupled to the diffuser spacers 418 to form a gap or liquid-flow channel between each membrane 412. Ends 424 and 420 form the air-flow entrance and exit supports of the
liquid flow panel 334. A top 422 of one liquid-flow channel spacer 418 forms a portion of the top support 370 of the liquid-flow panel 334. A bottom 424 of the other liquid-flow channel spacer 418 forms a portion of the bottom support 372 of the liquid-flow panel 334. The top support 370 and the bottom support 372 are also formed by air channel spacers 426. The air channel spacers 426 are configured to abut the air channel spacers 426 of an adjacent panel 334. The air channel spacers 426 form an air-flow gap between adjacent liquid-flow panels 334. The air-flow gaps between adjacent liquid-flow panels 334 form the air channels 336 within the energy exchange cavity.

[00131] Figure 6a illustrates an air channel 336 formed between adjacent membranes for liquid-flow panels 334. The air channel 336 is configured to carry the air stream 332 therethrough. The air channel 336 is designed to have a uniform width 430 along a length 432 of the air channel 336. However, due to elastic deformations of the membrane support structures 414 of the panel 334, there may be significant variations in the air channel width. The air-side membrane support structures 414 limits the amount of membrane deflection restricting the air flow channel width that is caused by the difference in static pressure in the liquid channel 334 and air channel 332. For example, the membrane support structures 414 limit the amount of deflection over small fraction, but a finite region, of each membrane. With respect to factor G4, the air and liquid flow channel statistical variations for typical individual flow tube hydraulic diameter variations may limited. With respect to factor G3, the average channel widths statistical variations for each fluid, among all the channels in the LAMEE, may be limited.

[00132] Figure 6b illustrates an air-flow channel 336 that has been deformed by liquid air static pressure difference between adjacent liquid-flow and air-flow channels for a small finite region of the air-flow panel 334. Statistical variations in the deflections in the membrane air-flow and liquid flow channels can be deduced using mass or volume of liquid in the LAMEE under typical liquid pressures measurements, carefully developed pressure drop measurements across flow channels for each fluid and optical laser beam measurements for the minimum air-flow channel widths. The measurements can then be used along with other data for the determinations of the air and liquid channel average and standard deviations of flow hydraulic diameters for each fluid, which may be
specified separately for the typical channel (factor G4) and the set of channels in each LAMEE (factor G3). The design and manufacturing quality control and operation of a LAMEE may depend in part on knowing the data.

[00133] Figure 7 is a graph 450 showing simulation results for optimum thermal capacity rate ratio as a parameter on a chart of air humidity ratio versus air temperature for a passive RAMEE system, at steady-state operating conditions with the assumed indoor air at a wide range of outdoor air conditions. The graph 450 presents the optimum value of the thermal capacity rate ratio lines 452 that should be selected for maximum energy transfer effectiveness of the passive RAMEE system with two identical LAMEE units subject to the assumed constraints with each and every air channel with a uniform width of 4.4 mm (with no internal support structure) and liquid-desiccant channel with a uniform width of 2.7 mm (also with no internal structure), a membrane water vapor permeability of 1.66E-6 kg/(m²s), and with fully developed laminar air and liquid flow in each channel. For different operating conditions and geometric ratios graph 450 would have different values for the optimum value of Cr*, as described below.

[00134] The results for the optimum thermal capacity rate ratio with the assumed constant widths of the air and liquid-desiccant channels and fully developed laminar flow for each fluid is exemplary of one theoretical case only that differs significantly from what is physically possible. Although variable channel widths and turbulent channel flows are likely to occur, presenting similar results for these cases would be much more complex; but, it can be done using the same computational procedures. In such cases, the optimum thermal capacity rate ratios will be very different than those presented in graph 450 for the same outdoor air conditions.

[00135] Using graph 450 as an exemplary illustration of the design and operational procedure to obtain the optimum steady-state effectiveness (and energy transfer rate) of a passive RAMEE system with two identical LAMEEs each subject to the same mass flow rate of air, the system operator or automatic controller selects or controls the pumping rate of the liquid desiccant based on the outdoor air conditions of temperature and humidity. That is, the optimum thermal capacity rate ratio 452 for the
particular outdoor air condition is selected to compute the mass flow rate of liquid desiccant knowing the mass flow rate of air. The result is used to set the optimum pumping rate. When the outdoor air conditions change significantly or the air flow rate is changed significantly, a new optimum pumping rate is determined. In one embodiment, the flow rate of the desiccant with respect to the flow rate of the air stream is controlled to achieve predetermined exchanger performance ratios that at least partially define a sensible and latent energy exchange between the desiccant and the air stream.

[00136] Figure 8 is a graph 500 showing equilibrium, saturation, salt-solution concentration lines 502 superimposed on a psychrometric chart of humidity ratio versus temperature for several salts that may be used as liquid desiccants with the system 100. The graph 500 illustrates a temperature 504 of the air flowing through the LAMEE and a humidity ratio 506 of the air at standard atmospheric pressure flowing through the LAMEE. The equilibrium, saturation, salt-solution concentration lines 502 depend only on the type of salt, air temperatures 504 and the humidity ratios 506 at which the desiccant will start to crystallize within the panels of the LAMEE. At the saturation concentration, a particular salt solution will crystallize salt on the nearby membrane surfaces within the liquid-desiccant flow channel for any decrease in the adjacent air flow channel temperature or humidity ratio (i.e. below the line 502 for the particular salt). Based on the expected conditions for a particular climatic region of the air flow through the LAMEE, the graph 500 may be used along with other data to select an appropriate desiccant for the air flow conditions for an HVAC application.

[00137] Line 508 represents the adjacent air temperatures 504 and humidity ratios 506 at which a saturation magnesium chloride solution crystallizes if the air temperature and humidity were to drop below this line. Line 510 represents the similar saturation calcium chloride solution crystallization line. Line 512 represents the similar saturation lithium iodide solution crystallization line. Line 514 represents the similar saturation lithium chloride crystallization line. Line 516 represents the similar saturation lithium bromide crystallization line.
Lithium bromide is capable of functioning as a liquid desiccant in the harshest conditions because only very low adjacent air humidity ratios would cause crystallization. However, lithium bromide is relatively expensive in comparison to other salts with no lithium content. In an exemplary embodiment, the system 100 utilizes a desiccant mixture of magnesium chloride with other salts. The mixture may include magnesium chloride and at least one of lithium chloride or lithium bromide. Alternatively, the mixture includes calcium chloride in place of magnesium chloride and at least one of lithium chloride or lithium bromide. In another embodiment, the mixture includes at least three of magnesium chloride, calcium chloride, lithium chloride and/or lithium bromide. The concentration of magnesium chloride can range from 0% to 35.5% (i.e. saturation salt concentration). Above the saturation salt solution line for a particular salt in graph 500, the equilibrium salt concentration is based on a temperature and humidity of the air flowing through the LAMEE. A salt solution is comprised of water and ions of salts. The concentration of lithium chloride can range from 0% to 45.9% (i.e. saturation salt concentration). In one embodiment, the mixture is 50% magnesium chloride and 50% lithium chloride. The mixture can operate without crystallization at temperatures 504 and humidity ratios 506 below the line 508 for magnesium chloride. The mixture provides a liquid desiccant that can operate at dryer air conditions for the outdoor air conditions for the RAMEE system than pure magnesium chloride or calcium chloride solutions.

In one embodiment, the desiccant is selected based on operational design parameters P10 and P11 as illustrated in Table 1. The desiccant may be selected based on a time duration (t_{it,risk}) for a risk of crystallization in the desiccant over a typical year of weather data for a building located in a particular climate. In particular, the time duration (t_{it,risk}) for a risk of crystallization in the desiccant is divided by the total yearly time duration of system operation (t_{op}). In one embodiment, the parameter P10 is within a range of t_{it,risk}/t_{op} < 0.15. In another embodiment, the desiccant is selected based on a cost of salt or mixture of salts used in the RAMEE system 100 divided by the corresponding cost of LiCl for the system (C_{it,mix}/CLiCl). In one embodiment, the parameter P11 is within a range of C_{it,mix}/CLiCl < 1. The parameters P10 and P11 may be individually selected in part to achieve a predetermined performance
of the LAMEE 300 and the RAMEE system 100. In another embodiment, both of the
design parameters P10 and P11 may be utilized to achieve the predetermined
performance.

[00140] The geometric design and operating factors G1 to G8 and the physical
operational and design factors P1 to P12 shown in Table 1 are selected to achieve a
predetermined performance of the LAMEE 300 and/or the RAMEE system 100. The
geometric factors G1-G10 and the physical factors P1-P12 may each be selected to
achieve the predetermined performance of the LAMEE 300 and/or the RAMEE system
100. In another embodiment, at least some of the factors G1-G10 and P1-P12 may be
selected to achieve the predetermined performance of the LAMEE 300 and the RAMEE
system 100.

[00141] When LAMEE devices are used in passive RAMEE systems for
energy recovery, the aforementioned performance factors are sufficient for applications
where the system operates at or near steady-state. When the LAMEE devices are installed
in actively controlled RAMEE and HVAC systems for air conditioning supply air, most
of the above described LAMEE performance factors still apply; however, the HVAC
system performance may be characterized using different dimensionless ratios. For the
purpose a coefficient of performance (COP) or energy efficiency ratio (EER) can be used
for any typical steady-state or quasi-steady-state operating condition of the controlled
ramee system and the ratios can be modified for the annual integrated time average
values called seasonal energy efficiency ratio (SEER) for both the heating and cooling of
a building located in a particular city. The COP or EER for the HVAC system is defined
as the useful energy rate change of the supply air from inlet to discharge conditions
divided by all the auxiliary energy rate inputs to the HVAC system. Data for the
calculation of COP or EER could be measured occasionally or continuously.

[00142] Because the cost of auxiliary energy is usually very different for
cooling and heating, the ratios should be treated separately. The SEER value for cooling
the supply air in summer may be listed separate from the SEER value for heating supply
air in winter. Since both heating and cooling are used with mechanical cooling and
desiccant dehumidification systems, both forms of input energy may be used for the summer operations. To obtain a high SEER for the HVAC system in a building, waste energy from exhaust air or other process sources can be used directly to condition or partly condition the supply air using RAMEE systems or indirectly using heat pumps (and/or refrigerators) with ambient air or ground water as the energy sources. The use of an economizer by-pass may also raise the SEER.

[00143] When modified RAMEE systems are used over the year in both active and passive modes, the calculation of the SEER values for the HVAC system should account for the changes of mode as well as any extra energy use for all the energy recovery or pumped energy.

[00144] From the above discussion of active HVAC system options, it is evident that claims for high SEER values are likely to change significantly for the same or different buildings in different climates. Comparisons of the dimensionless performance ratios for actively controlled modified RAMEE systems within an HVAC system may be done with software to show the life-cycle cost savings and the payback period for a particular design in a particular climate. Passive performance of a RAMEE system is still very useful because it will vary directly with cost savings for energy recovery and it can provide the best quantifiable proof of performance for both the RAMEE system and its two LAMEEs. As well, the passive performance should be used directly for the estimation of the HVAC system performance, with a heat pump assisted RAMEE system and its cost savings.

[00145] Figure 9 illustrates a LAMEE 200 formed in accordance with an alternative embodiment. The LAMEE 200 may be used as the supply air LAMEE 108 and/or the return air LAMEE 120 (shown in Figure 1). The LAMEE 200 includes a housing 202 having a body 204. The body 204 includes a front 206 and a back 208 opposite the front 206. The body 204 is elongated to extend along a length 210 between the front 206 and the back 208. The body 204 includes a top 212 and a bottom 214 that are parallel to one another. The body 204 includes a height 216 that extends between the top 212 and the bottom 214. The body 204 includes a first side 218 and a second side
The first side 218 and the second side 220 span the length 210 between the front 206 and the back 208. The first side 218 and the second side 220 span the height 216 between the top 212 and the bottom 214. The first side 218 and the second side 220 are arranged parallel to one another and are separate by a width 222.

The LAMEE body 204 includes an air inlet 205 at the front 206 of the body 204 and an air outlet 207 at the back 208 of the body 204. The LAMEE body 204 forms an energy exchange cavity 224. The energy exchange cavity 224 extends the length 210, height 216, and width 222 between the front 206, the back 208, the top 212, the bottom 214, the first side 218, and the second side 220. The length 210, height 216, and/or width 222 represent physical design factors that are selected to satisfy predetermined ratios with one another and/or with predetermined ratios with other design parameters, as explained hereafter. The ratios of the height 216 to the length 210, the width 222 to the length 210, and/or the width 222 to the height 216 represent dimensionless physical ratios, and more generally, dimensionless design factors.

The energy exchange cavity 224 includes a plurality of energy exchange panels 226 extending therethrough. The panels 226 extend the length 210 and height 216 of the energy exchange cavity 224. Each panel 226 forms a desiccant channel that carries desiccant 241 through the energy exchange cavity 224. The panels 226 are arranged parallel to one another and spaced apart to form air channels 230 and desiccant channels 231 therebetween. The air channels 230 extend between the air inlet 205 and the air outlet 207. Each air channel 230 is formed between adjacent desiccant channels 231. The air channels 230 direct an air stream 234 from the front 206 of the LAMEE 200 to the back 208 of the LAMEE 200.

A desiccant inlet housing 236 is joined to the LAMEE housing 202. In the illustrated embodiment, the desiccant inlet housing 236 is joined to the bottom 214 of the LAMEE housing 202. The desiccant inlet housing 236 is positioned adjacent the back 208 of the LAMEE housing 202. The desiccant inlet housing 236 extends from the back 208 of the LAMEE housing 202 along the bottom 214 of the LAMEE housing 202. The desiccant inlet housing 236 extends partially between the back 208 and front 206 of
the LAMEE housing 202. Alternatively, the desiccant inlet housing 236 may positioned at any location along the LAMME body 204. In one embodiment, the LAMEE 200 may include more than one desiccant inlet body 204. The desiccant inlet housing 236 extends a length 238 along the bottom 214 of the LAMEE housing 202. The length 238 that the desiccant inlet housing 236 extends is based on a predetermined performance of the LAMEE 200. In one embodiment, the desiccant inlet housing 202 extends no more than one fourth of the length 210 of the LAMEE body 204. In another embodiment, the desiccant inlet housing 236 extends one fifth of the length 210 of the LAMEE body 204.

[00149] The desiccant inlet housing 236 includes an inlet 240 and an outlet 242. The inlet 240 is configured to receive desiccant 241 from a storage tank 128 (shown in Figure 1). The inlet 240 and the outlet 242 are in fluid communication with the desiccant channels 231 extending through the energy exchange cavity 224. The desiccant 241 flows from the desiccant inlet housing 236 into the desiccant channels 231. The desiccant 241 flows through the desiccant channels 231 from the back 208 of the LAMEE housing 202 toward the front 206 of the LAMEE housing 202. The desiccant 241 flows in a direction opposite the direction of the air stream 234. The desiccant 241 flows through the desiccant channels 231 toward a desiccant outlet housing 244.

[00150] The desiccant outlet housing 244 is joined to the top 212 of the LAMEE housing 202. The desiccant outlet housing 244 is positioned proximate to the front 206 of the LAMEE housing 202. Alternatively, the desiccant outlet housing 244 may be positioned at any location along the top 212 of the LAMEE housing 202. The desiccant outlet housing 244 is offset from the desiccant inlet housing 236 along the direction of the air stream 234. The desiccant outlet housing 244 extends from the front 206 of the LAMEE housing 202 along the top 212 of the LAMEE housing 202. The desiccant outlet housing 244 extends partially between the front 206 and the back 208 of the LAMEE housing 202. The desiccant outlet housing 244 extends a length 246 along the top 212 of the LAMEE housing 202. The length 246 that the desiccant outlet housing 244 extends is based on a predetermined performance of the LAMEE 200. In one embodiment, the desiccant outlet housing 244 extends a length 246 that is no more than one fifth the channel energy exchange length 210 of the LAMEE body 204. In one
embodiment, the desiccant outlet housing 244 extends a length 246 that is one fifth of the length 210 of the LAMEE body 204.

[00151] The desiccant outlet housing 244 includes an inlet 248 and an outlet 250. The inlet 248 is in fluid communication with the desiccant channels 231. The desiccant outlet housing 244 receives desiccant 241 from the desiccant channels 231. The desiccant outlet housing 244 channels the desiccant 241 through the outlet 250. The outlet 250 is in fluid communication with a storage tank 128 (shown in Figure 1).

[00152] The desiccant inlet housing 236 and the desiccant outlet housing 244 form a non-linear desiccant flow path 252 through the panels 226. The desiccant flow path 252 flows in a direction opposite to the air stream 234. The desiccant flow path 252 travels upstream with respect to the direction of the air stream 234. The desiccant flow path 252 is a cross/counter flow path with respect to the air stream 234 flowing through the air channels 230. An inlet cross segment 254 of the desiccant flow path 252 is formed as the desiccant 241 enters the panels 226 from the desiccant inlet housing 236. Desiccant 241 flowing from the desiccant inlet housing 236 into the panels 226 flows upward through the inlet cross segment 254. Desiccant in the inlet cross segment 254 flows in a cross flow arrangement that is substantially perpendicular to the direction of the air stream 234.

[00153] As the desiccant 241 is channeled from the desiccant inlet housing 236 fills the panels 226, the desiccant 241 begins flowing through a counter segment 256 of the desiccant flow path 252. The counter segment 256 extends a length 258 through the panels 226. The length 258 is based on a predetermined performance of the LAMEE 200. The counter segment 256 flows in a counter flow arrangement with respect to the direction of the air stream 234 flowing through the air channels 230. The counter segment 256 flows substantially parallel to the direction of the air stream 234. The counter segment 256 flows upstream with respect to the direction of the air stream 234. The counter flow arrangement provides a predetermined heat and moisture exchange between the desiccant in the panels 226 and the air stream 234 in the air channels 230.
[00154] The desiccant 241 in the counter segment 256 flows into an outlet cross segment 260 of the desiccant flow path 252. The outer cross segment 260 flows substantially perpendicular to the direction of the air stream 234. The desiccant in the outlet cross segment 260 flows in a cross flow arrangement with respect to the air 234 in the air channels 230. The desiccant in the outlet cross segment 260 flows upward from the counter segment 256 to the desiccant outlet housing 244.

[00155] The cross/counter flow arrangement of the desiccant flow path 252 provides desiccant counter flow with respect to the direction of the air stream 234. The counter flow arrangement improves an efficiency of the LAMEE 200. The cross/counter flow arrangement does not require large headers that would otherwise increase the space required for the LAMEE 200. The illustrated embodiment shows the desiccant flow path 252 flowing upward from the bottom 214 of the LAMEE 200 to the top 212 of the LAMEE 200. Optionally, the desiccant inlet housing 236 may be positioned on the top 212 of the LAMEE 200 and the desiccant outlet housing 244 may be positioned on the bottom 214 of the LAMEE 200. In such an embodiment, the desiccant flow path 252 may flow downward from the top 212 of the LAMEE 200 to the bottom 214 of the LAMEE 200.

[00156] The geometric design factors G1-G8 and the physical operational and design factors P1-P12 shown in Table 1 should be used to achieve a predetermined performance of the LAMEE 200. Although each of the dimensionless independent factors in the set, G1-G10 and P1-P12, should be selected within the specified ranges in Table 1 to achieve the predetermined performance of the passive RAMEE system with its two LAMEE 200 units operating at steady-state, it may be possible to relax the design and operational range of a few independent factors in Table 1 for some narrow range of system operating conditions and still achieve an acceptable system performance. Therefore, in another embodiment, only some of the factors, G1-G10 and P1-P12, need to be selected in the ranges specified in Table 1 to achieve an acceptable predetermined performance of the LAMEE 200 when tested as part of a passive RAMEE system.
[00157] Figure 10 illustrates a LAMEE 600 formed in accordance with an alternative embodiment. The LAMEE 600 includes a housing 602 having a body 604 with a top 606 and a bottom 608. The LAMEE 600 includes an air inlet 610 and an air outlet 612. An energy exchange cavity 614 extends through the body 604 between the air inlet 610 and the air outlet 612. An air stream 616 flows through the energy exchange cavity 614 from the air inlet 610 to the air outlet 612. The energy exchange cavity 614 includes panels 618 that form desiccant channels 615 to carry desiccant therethrough.

[00158] A desiccant inlet 620 is provided at the bottom 608 of the LAMEE body 604. The desiccant inlet 620 may be positioned at any location along the bottom 608 of the LAMEE body 604. Alternatively, the LAMEE 600 may include any number of desiccant inlets 620. The desiccant inlet 620 is in flow communication with the desiccant channels 615. A first desiccant outlet 622 and a second desiccant outlet 624 are positioned at the top 606 of the LAMEE body 604. The first and second desiccant outlets 622 and 624 may be positioned at any location along the top 606 of the LAMEE body 604. The first and second desiccant outlets 622 and 624 are offset from the desiccant inlet 620 along the direction of the air stream 616. The desiccant inlet 620 and the desiccant outlets 622 and 624 from desiccant flow paths from the bottom 608 of the LAMME body 604 to the top 606 of the LAMEE body 604. Alternatively, the desiccant inlet 620 may be positioned along the top 606 of the LAMEE body 604 and the desiccant outlets 622 and 624 may be positioned along the bottom 608 of the LAMEE body 604. In such an embodiment, the desiccant flows from the top 606 of the LAMEE body 604 to the bottom 608 of the LAMEE body 604.

[00159] The desiccant inlet 620 and the first desiccant outlet 622 form a first desiccant flow path 626 that flows non-linearly through the panels 618. The first desiccant flow path 626 includes an inlet segment 628 that flow from the desiccant inlet 620. The inlet segment 628 flows in a cross flow direction substantially perpendicular to the direction of the air stream 616. The inlet segment 628 flow into an intermediate segment 630 that flows substantially parallel to the direction of the air stream 616. The intermediate segment 630 flows in the same direction as the direction of the air stream 616. The intermediate segment 630 flows into an outlet segment 632 that flows to the
The outlet segment 632 flows in a direction that is substantially perpendicular to the direction of the air stream 616.

[00160] The desiccant inlet 620 and the second desiccant outlet 624 form a second desiccant flow path 634 that flows non-linearly through the panels 618. The second desiccant flow path 634 includes an inlet segment 636 that flows from the desiccant inlet 620. The inlet segment 636 flows in a cross flow direction substantially perpendicular to the direction of the air stream 616. The inlet segment 636 flows into an intermediate segment 638 that flows substantially parallel to the direction of the air stream 616. The intermediate segment 638 flows in an opposite direction to the direction of the air stream 616. The intermediate segment 638 flows into an outlet segment 640 that flows to the second desiccant outlet 624. The outlet segment 640 flows in a direction that is substantially perpendicular to the direction of the air stream 616.

[00161] The physical design geometric factors G1-G10 and the operational design factors P1-P12 shown in Table 1 may be used to achieve a predetermined performance of the LAMEE 600. The physical design geometric factors G1-G10 and the operational design factors P1-P12 may each be selected to achieve the predetermined performance of the LAMEE 600. In another embodiment, only some of the physical design geometric factors G1-G10 and the operational design factors P1-P12 may be selected to achieve the predetermined performance of the LAMEE 600.

[00162] Figure 11 illustrates a LAMEE 650 formed in accordance with an alternative embodiment. The LAMEE 650 includes a housing 652 having a body 654 with a top 656 and a bottom 658. The LAMEE 650 includes an air inlet 660 and an air outlet 662. An energy exchange cavity 664 extends through the body 654 between the air inlet 660 and the air outlet 662. An air stream 666 flows through the energy exchange cavity 664 from the air inlet 660 to the air outlet 662. The energy exchange cavity 664 includes panels 668 that form desiccant channels 669 to carry a desiccant therethrough.

[00163] A desiccant outlet 670 is provided at the top 656 of the LAMEE body 654. The desiccant outlet 670 may be positioned at any location along the top 656 of the LAMEE body 654. Alternatively, the LAMEE 650 may include any number of desiccant
outlets 670. The desiccant outlet 670 is in flow communication with the desiccant channels 669. A first desiccant inlet 672 and a second desiccant inlet 674 are positioned at the bottom 658 of the LAMEE body 654. The first and second desiccant inlets 672 and 674 may be positioned at any location along the bottom 658 of the LAMEE body 654. The first and second desiccant inlets 672 and 674 are offset from the desiccant outlet 670 along the direction of the air stream 666. The desiccant outlet 670 and the desiccant inlets 672 and 674 form desiccant flow paths from the bottom 658 of the LAMME body 654 to the top 656 of the LAMEE body 654. Alternatively, the desiccant outlet 670 may be positioned along the bottom 658 of the LAMEE body 654 and the desiccant inlets 672 and 674 may be positioned along the top 656 of the LAMEE body 654. In such an embodiment, the desiccant flows from the top 656 of the LAMEE body 654 to the bottom 658 of the LAMEE body 654.

[00164] The desiccant outlet 670 and the first desiccant inlet 672 form a first desiccant flow path 676 that flows non-linearly through the panels 668. The first desiccant flow path 676 includes an inlet segment 678 that flow from the first desiccant inlet 672. The inlet segment 678 flows in a cross flow direction substantially perpendicular to the direction of the air stream 666. The inlet segment 678 flows into an intermediate segment 680 that flows substantially parallel to the direction of the air stream 666. The intermediate segment 680 flows in a direction opposite to the direction of the air stream 666. The intermediate segment 680 flows into an outlet segment 682 that flows to the desiccant outlet 670. The outlet segment 682 flows in a direction that is substantially perpendicular to the direction of the air stream 666.

[00165] The desiccant outlet 670 and the second desiccant inlet 674 form a second desiccant flow path 684 that flows non-linearly through the panels 668. The second desiccant flow path 684 includes an inlet segment 686 that flows from the first desiccant inlet 674. The inlet segment 686 flows in a cross flow direction substantially perpendicular to the direction of the air stream 666. The inlet segment 686 flows into an intermediate segment 688 that flows substantially parallel to the direction of the air stream 666. The intermediate segment 688 flows in the same direction as the direction of the air stream 666. The intermediate segment 688 flows into an outlet segment 690 that
flows to the desiccant outlet 670. The outlet segment 690 flows in a direction that is substantially perpendicular to the direction of the air stream 666.

[00166] The physical design geometric factors G1-G10 and the operational design factors P1-PI2 shown in Table 1 may be used to achieve a predetermined performance of the LAMEE 650. The physical design geometric factors G1-G10 and the operational design factors P1-PI2 may each be selected to achieve the predetermined performance of the LAMEE 650. In another embodiment, only some of the physical design geometric factors G1-G10 and the operational design factors P1-PI2 may be selected to achieve the predetermined performance of the LAMEE 650.

[00167] Figure 12 illustrates a LAMEE 700 formed in accordance with an alternative embodiment. The LAMEE 700 includes a housing 702 having a body 704 with a top 706 and a bottom 708. The LAMEE 700 includes a first end 710 and a second end 712. An energy exchange cavity 714 extends through the body 704 between the first end 710 and the second end 712. An air stream 716 flows through the energy exchange cavity 714 from the first end 710 to the second end 712. The energy exchange cavity 714 includes panels 718 that form desiccant channels 719 to carry a desiccant therethrough.

[00168] A desiccant flow path 726 flows through the desiccant channels 719 from the second end 712 to the first end 710. The desiccant flow path 726 is arranged in a counter-flow arrangement with respect to the air stream 716. Heat is transferred through the panels 719 between the desiccant flow path 726 and the air stream 716.

[00169] The physical design geometric factors G1-G10 and the operational design factors P1-PI2 shown in Table 1 may be used to achieve a predetermined performance of the LAMEE 700. The physical design geometric factors G1-G10 and the operational design factors P1-PI2 may each be selected to achieve the predetermined performance of the LAMEE 700. In another embodiment, only some of the physical design geometric factors G1-G10 and the operational design factors P1-PI2 may be selected to achieve the predetermined performance of the LAMEE 700.
Figure 13 illustrates a LAMEE 750 formed in accordance with an alternative embodiment. The LAMEE 750 includes a housing 752 having a body 754 with a top 756 and a bottom 758. The LAMEE 750 includes a first end 760 and a second end 762. An energy exchange cavity 764 extends through the body 754 between the first end 760 and the second end 762. An air stream 766 flows through the energy exchange cavity 764 from the first end 760 to the second end 762. The energy exchange cavity 764 includes panels 768 that form desiccant channels to carry a desiccant therethrough.

A desiccant flow path 776 flows through the desiccant channels from the top 756 to the bottom 758. The desiccant flow path 776 is arranged in a cross-flow arrangement with respect to the air stream 766. Heat is transferred through the panels 768 between the desiccant flow path 776 and the air stream 766.

The physical design geometric factors G1-G10 and the operational design factors P1-P12 shown in Table 1 may be used to achieve a predetermined performance of the LAMEE 750. The physical design geometric factors G1-G10 and the operational design factors P1-P12 may each be selected to achieve the predetermined performance of the LAMEE 750. In another embodiment, only some of the physical design geometric factors G1-G10 and the operational design factors P1-P12 may be selected to achieve the predetermined performance of the LAMEE 750.

Figure 14 illustrates an exemplary energy exchange system 850 formed in accordance with the set of embodiments specified in Table 1. The energy exchange system 850 is configured to condition air supplied to an enclosed structure 852 having a plurality of rooms 854. The energy exchange system 850 receives pre-conditioned air 856 that is direct through the system 850 with a fan 858. The pre-conditioned air 856 is directed to a supply LAMEE 860 that conditions the pre-conditioned air 856 to generate supply air 862. The supply LAMEE 860 conditions the pre-conditioned air 856 by adding or removing heat and moisture to or from the pre-conditioned air 856. The supply air 862 is discharged into the rooms 854.

Each room 854 includes a return air LAMEE 864 configured to receive return air 866 from the room 854. The return air LAMEE 864 conditions the
return air 866 by adding or removing heat and moisture to or from the return air 866. The
return air LAMEEs 864 exchange the heat and moisture with the supply air LAMEE 860
to transfer the heat and moisture between the return air 866 and the pre-conditioned air
856. The return LAMEEs 864 generate exhaust air 868 that is discharged from the
energy exchange system 850 by a fan 870.

[00175] Liquid desiccant 872 flows between the supply LAMEE 860 and the
return air LAMEEs 864. The desiccant 872 transfers the heat and moisture between the
supply LAMEE 860 and the return air LAMEEs 864. Storage tanks 874 are provided to
retain the desiccant 872 as it flows between the supply LAMEE 860 and the return air
LAMEEs 864. Pumps 876 may be provided to move the liquid desiccant 872 between the
supply LAMEE 860 and the return air LAMEEs 864.

[00176] Figure 15 illustrates an alternative exemplary energy exchange system
900 formed in accordance with the set of embodiments. The energy exchange system
900 is configured to condition air supplied to a structure 901. The structure 901 includes
a plurality of rooms 903. The energy exchange system 900 includes an inlet 902 that
receives pre-conditioned air 904 that may be moved by a fan 905. The pre-conditioned
air 904 is divided into each of the rooms 903 of the structure 901. The pre-conditioned
air 904 is moved through the energy exchange system 900 with a fan 905. The pre-
conditioned air 904 may be divided equally between each of the rooms 903. Optionally,
the pre-conditioned air 904 may be divided between the rooms 903 based on a capacity of
each room 903 and/or a supply air need in each room 903. Each room 903 includes a
supply LAMEE 906 that is configured to condition the pre-conditioned air 904. The
supply LAMEE 906 conditions the per-conditioned air by adding or removing heat and
moisture to the pre-conditioned air 904. The supply LAMEE 906 generates supply air
908 that is discharged into the room 903.

[00177] Return air 910 from each room 903 is channeled to a return LAMEE
912. The return LAMEE 912 conditions the return air 910 to generate exhaust air 915.
The exhaust air 915 is moved through the energy exchange system 900 with a fan 907
that directs the exhaust air 915 to an outlet 909. The return LAMEE 912 conditions the
return air 910 by adding or removing heat and moisture from the return air 910. Heat and moisture is transferred between the supply LAMEE 906 and the return LAMEE 912 to exchange the heat and moisture between the return air 910 and the pre-conditioned air 904.

[00178] Desiccant 914 flows between the supply LAMEE 906 and the return LAMEE 912. The desiccant 914 transfers the heat and moisture between the supply LAMEE 906 and the return LAMEE 912. Storage tanks 916 are provided between the supply LAMEE 906 and the return LAMEE 912. The storage tanks 916 retain desiccant traveling between the supply LAMEE 906 and the return LAMEE 912. Pumps 918 are provided to move the desiccant 914 between the supply LAMEE 906 and the return LAMEE 912.

[00179] In another embodiment, an energy exchange system may be provided that includes individual supply LAMEEs and return LAMEEs for each room of a structure. Alternatively, an energy exchange system may be provided that utilizes heat and moisture from a first room of a structure to condition air in a second room of the structure. Such an embodiment would include a first LAMEE positioned within the first room and a second LAMEE positioned within the second room. The heat and moisture from the first room would be transferred from the first LAMEE to the second LAMEE to add the heat and moisture to the air in the second room.

[00180] The embodiments described herein provide a LAMEE that utilizes either a counter/cross-flow or cross-flow to improve the effectiveness of the LAMEE. The dimensions of the LAMEE are selected to provide a predetermined performance of the LAMEE. The predetermined performance of the LAMEE is based on the surrounding environment. The LAMEE is configured to reach the predetermined performance based on the conditions of the air flow through the LAMEE. The embodiments herein also provide a desiccant solution that is configured to operate at dry ambient air conditions.

[00181] It should be noted that the LAMEEs illustrated in Figures 2 and 9-13 are exemplary only and the physical design geometric factors G1-G10 and the operational
design factors P1-P12 may be utilized with any LAMEE having any suitable geometry. Further, the energy exchange systems illustrated in Figures 14 and 15 are exemplary only and the physical design geometric factors G1-G10 and the operational design factors P1-P12 may be utilized with any suitable energy exchange system.

[00182] It is to be understood that the above description is intended to be illustrative, and not restrictive. For example, the above-described embodiments (and/or aspects thereof) may be used in combination with each other. In addition, many modifications may be made to adapt a particular situation or material to the teachings of the various embodiments of the invention without departing from their scope. While the dimensions and types of materials described herein are intended to define the parameters of the various embodiments of the invention, the embodiments are by no means limiting and are exemplary embodiments. Many other embodiments will be apparent to those of skill in the art upon reviewing the above description. The scope of the various embodiments of the invention should, therefore, be determined with reference to the appended claims, along with the full scope of equivalents to which such claims are entitled. In the appended claims, the terms "including" and "in which" are used as the plain-English equivalents of the respective terms "comprising" and "wherein." Moreover, in the following claims, the terms "first," "second," and "third," etc. are used merely as labels, and are not intended to impose numerical requirements on their objects. Further, the limitations of the following claims are not written in means-plus-function format and are not intended to be interpreted based on 35 U.S.C. § 112, sixth paragraph, unless and until such claim limitations express use the phrase "means for" followed by a statement of function void of further structure.

[00183] This written description uses examples to disclose the various embodiments of the invention, including the best mode, and also to enable any person skilled in the art to practice the various embodiments of the invention, including making and using any devices or systems and performing any incorporated methods. The patentable scope of the various embodiments of the invention is defined by the claims, and may include other examples that occur to those skilled in the art. Such other examples are intended to be within the scope of the claims if the examples have structural
elements that do not differ from the literal language of the claims, or if the examples include equivalent structural elements with insubstantial differences from the literal languages of the claims.
WHAT IS CLAIMED IS:

1. An energy exchanger comprising:
   
a housing constructed to meet a predetermined exchanger aspect ratio;
   
a plurality of panels extending through the housing, the panels having a semi-
permeable membrane forming an energy exchange area of the panel, the panels forming
desiccant channels and air channels that are separated by the semi-permeable membranes
to facilitate contact between an air stream flowing through the air channels and desiccant
flowing through the desiccant channels within the energy exchange areas of the panels,
the energy exchange area of each panel having a top and a bottom, a height of the energy
exchange area defined between the top and the bottom, the energy exchange area of each
panel having a front and a back, a length of the energy exchange area defined between
the front and the back, the exchanger aspect ratio being defined by the height of the
energy exchange area of each panel divided by the length of the energy exchange area of
each panel;
   
a desiccant inlet in flow communication with the desiccant channels; and
   
a desiccant outlet in flow communication with the desiccant channels, the
desiccant channels configured to channel the desiccant from the desiccant inlet to the
desiccant outlet in at least one of a counter-flow or cross-flow direction with respect to
the direction of the air stream to facilitate heat and water vapor transfer through the semi-
permeable membranes, the exchanger aspect ratio selected to provide at least one of a
predetermined membrane area, a predetermined length, or a predetermined duration of
exposure of the air stream to the desiccant.

2. The energy exchanger of claim 1, wherein the exchanger aspect ratio is
within a range of 0.5 to 2.

3. The energy exchanger of claim 1, wherein the desiccant inlet is offset
from the desiccant outlet along the direction of the air stream.
4. The energy exchanger of claim 1, wherein the desiccant flows through the desiccant channels along a non-linear flow path between the inlet and outlet.

5. The energy exchanger of claim 1, wherein the desiccant flows through the desiccant channels along a flow path, the flow path having a cross-flow segment and a counter-flow segment, the cross-flow segment extending in a flow direction substantially perpendicular to the flow direction of the air stream, the counter-flow segment extending in a direction approximately 180° from the flow direction of the air stream.

6. The energy exchanger of claim 1, wherein the desiccant flows along a flow path in a flow direction that is at least partially counter-flow with respect to the flow direction of the air stream.

7. The energy exchanger of claim 1, wherein the desiccant outlet extends no more than one fourth of a length of the housing.

8. The energy exchanger of claim 1, wherein the desiccant inlet extends no more than one fourth of a length of the housing.

9. The energy exchanger of claim 1, wherein a flow rate of the desiccant with respect to a flow rate of the air stream is controlled to achieve predetermined exchanger performance ratios that at least partially define a sensible and latent energy exchange between the desiccant and the air stream.

10. The energy exchanger of claim 1, wherein the desiccant is selected based on operating temperatures and humidity ratios of the air stream.

11. The energy exchanger of claim 1, wherein the desiccant includes at least one of magnesium chloride or calcium chloride.

12. The energy exchanger of claim 1, wherein the desiccant is formed from a mixture of magnesium chloride and at least one of lithium chloride or lithium bromide.

13. The energy exchanger of claim 1, wherein a width of the air channels is selected based on a width of the desiccant channels.
14. The energy exchanger of claim 1, wherein the semi-permeable membrane is selected based on at least one of a water vapor transfer resistance ratio, a liquid break through pressure ratio, or an elastic tensile yield limit ratio of the membrane.

15. The energy exchanger of claim 1, wherein the plurality of panels include support structures to limit deformation of the panel membrane.

16. The energy exchanger of claim 1, wherein a characteristic Reynolds number for the air stream through the air channels is greater than a critical Reynolds number for turbulent flow in the air channels.

17. The energy exchanger of claim 1, wherein the air channels include turbulence enhancing surface roughness features to facilitate increasing energy transfer that exceeds an additional air pressure drop energy loss when convective heat and latent energy transfer increase.

18. The energy exchanger of claim 1, wherein a characteristic Rayleigh number for desiccant flow in the desiccant channels is less than a critical Rayleigh number for thermally induced liquid density instability causing non-uniform mal-distributed flow at a Reynolds number for desiccant flow.

19. The energy exchanger of claim 1, wherein desiccant channels include turbulence enhancing surface roughness features when a Rayleigh number is less than a critical Rayleigh number at a Reynolds number for the flow.

20. The energy exchanger of claim 1, wherein a thermal insulation surrounding the panels is such that a heat exchange rate between the panels is less than 5% of a heat rate between supply and exhaust air flow streams during a standard summer or winter test with AHRI 1060 air inlet operating conditions.

21. An energy exchanger comprising:

   a housing;
a plurality of panels forming desiccant channels and air channels extending through the housing, the air channels configured to direct an air stream through the housing, the plurality of panels spaced apart based on predetermined air to desiccant mass flow rates that define an air channel width and a desiccant channel width;

a desiccant inlet in flow communication with the desiccant channels; and

a desiccant outlet in flow communication with the desiccant channels, the desiccant channels configured to channel desiccant from the desiccant inlet to the desiccant outlet in at least one of a counter-flow or cross-flow direction with respect to the direction of the air stream to facilitate heat and water vapor transfer between the desiccant in the desiccant channels and the air stream in the air channels, the air to desiccant mass flow rates selected to provide a predetermined mass or volume of air stream flowing through the air channels or a predetermined mass or volume of desiccant flowing through the desiccant channels.

22. The energy exchanger of claim 21, wherein the desiccant channels have an approximately constant desiccant channel width through the housing and the air channels have an approximately constant air channel width through the housing.

23. The energy exchanger of claim 21, wherein a ratio of the average air channel width divided by the average desiccant channel width is within a range of 1 to 5.

24. The energy exchanger of claim 21, wherein the air to desiccant mass flow rate is selected to achieve predetermined exchanger performance ratios that define a sensible and latent energy exchange rate between the desiccant and the air stream.

25. An energy exchanger comprising:

a housing;

a plurality of panels forming desiccant channels and air channels extending through the housing, the air channels configured to direct an air stream through the housing;
a desiccant inlet in flow communication with the desiccant channels;

a desiccant outlet in flow communication with the desiccant channels, the desiccant channels configured to channel desiccant from the desiccant inlet to the desiccant outlet in at least one of a counter-flow or cross-flow direction with respect to the direction of the air stream; and

a semi-permeable membrane extending through each panel to facilitate heat and water vapor transfer between the desiccant in the desiccant channels and the air stream in the air channels, the air stream and the desiccant causing the semi-permeable membrane to deflect during operation, the desiccant membrane selected based on predetermined channel deflection ranges that are defined to limit the amount of membrane deflection.

26. The energy exchanger of claim 25, wherein a standard deviation of a hydraulic diameter of all of the air channels and desiccant channels divided by a mean value of a hydraulic diameter for one of the air channels or desiccant channels is within a range 0.0 to 0.2.

27. The energy exchanger of claim 25, wherein a standard deviation of a hydraulic diameter for one air channel or desiccant channel divided by a mean hydraulic diameter for the air channel or desiccant channel is within the range 0.0 to 0.2.

28. The energy exchanger of claim 25 further comprising:

an air channel support screen having a solid area that is a fraction of a total area of the air channel support screen; and

a desiccant channel support screen having a solid area that is a fraction of a total area of the desiccant channel support screen.

29. The energy exchanger of claim 25 further comprising an air channel support screen, a distance between the air channel support screens in the flow direction of the air stream divided by a distance between the air channel support screens normal to flow direction of the air stream is within a range of 0.01 to 5.0.
30. The energy exchanger of claim 25, wherein a desiccant flow direction through the desiccant channels is controlled so that lower density desiccant flows separately from higher density desiccant.

31. The energy exchanger of claim 25, wherein an angle between a normal vector to a plane of each air channel and desiccant channel and an acceleration of gravity vector is within a range of 45° to 135°.

32. The energy exchanger of claim 25, wherein an angle between a vector parallel to a length of each panel and a vector direction of gravitational acceleration is within a range of 60° to 120°.

33. An energy exchanger comprising:

   a housing;

   a plurality of panels forming desiccant channels and air channels extending through the housing, the air channels configured to direct an air stream through the housing;

   a desiccant inlet in flow communication with the desiccant channels;

   a desiccant outlet in flow communication with the desiccant channels, the desiccant channels configured to channel desiccant from the desiccant inlet to the desiccant outlet in at least one of a counter-flow or cross-flow direction with respect to the direction of the air stream to facilitate heat and water vapor transfer between the desiccant in the desiccant channels and the air stream in the air channels, wherein the desiccant is selected based on predetermined salt solution concentration ranges for a selected life span and cost of the desiccant.

34. The energy exchanger of claim 33, wherein the time duration for a risk of crystallization in the desiccant flow channels over a year divided by a total yearly time of energy exchanger operation is less than 0.15.
35. The energy exchanger of claim 33, wherein the cost of the desiccant divided by the cost of a lithium chloride solution is less than 1.

36. An energy exchanger comprising:

a housing;

a plurality of panels forming desiccant channels extending through the housing, each of the plurality of panels having a semi-permeable membrane that is selected to meet predetermined membrane resistance ranges defining physical properties of the membrane;

air channels formed between the desiccant channels, the air channels configured to direct an air stream through the housing;

a desiccant inlet in flow communication with the desiccant channels; and

a desiccant outlet in flow communication with the desiccant channels, the desiccant channels configured to channel desiccant from the desiccant inlet to the desiccant outlet so that the semi-permeable membranes facilitate heat and water vapor exchange between the desiccant and the air stream, the membrane resistance ranges selected to reduce flow of the desiccant through the semi-permeable membrane.

37. The energy exchanger of claim 36, wherein the semi-permeable membrane has a water vapor diffusion resistance and the air stream in the air channel has a convective water vapor mass transfer resistance, a ratio of the membrane water vapor transfer resistance divided by the convective water vapor mass transfer resistance of the membrane is within a range of 0.2 to 3.

38. The energy exchanger of claim 36, wherein the semi-permeable membrane has a membrane liquid break-through pressure defined as the pressure required for desiccant to flow through the membrane, a ratio of the membrane liquid break-through pressure divided by \((\rho g H)\), wherein \(\rho\) is the density of the desiccant, \(g\) is gravity and \(H\) is a height of the membrane, is greater than 20.
39. The energy exchanger of claim 36, wherein the membrane has an edge seal liquid break-through pressure defined as the pressure required for desiccant to flow through an edge seal of the membrane, a ratio of the edge seal liquid break-through pressure divided by \((\rho g H)\), wherein \(\rho\) is the density of the desiccant, \(g\) is gravity, and \(H\) is a height of the membrane, is greater than 20.

40. The energy exchanger of claim 36, wherein the membrane includes a screen having wires, the wires having a spacing \((s_w)\), the desiccant having an operating pressure \((p_{op,1})\), and the membrane having a tensile yield limit \((T_{m,1})\), a ratio of \(T_{m,1}/(p_{op,1} s_w)\) is less than 1.5.

41. The energy exchanger of claim 36, wherein the membrane resistance ranges are selected to achieve predetermined exchanger performance ratios that define a thermal and latent energy exchange between the desiccant and air streams.

42. An energy exchanger comprising:

a housing;

a plurality of panels forming desiccant channels extending through the housing, the plurality of panels each having a semi-permeable membrane;

air channels formed between the desiccant channels, the air channels configured to direct an air stream through the housing, the air stream flowing through the air channels at a predetermined air flow;

a desiccant inlet in flow communication with the desiccant channels; and

a desiccant outlet in flow communication with the desiccant channels, the desiccant channels configured to channel desiccant from the desiccant inlet to the desiccant outlet so that the semi-permeable membranes facilitate heat and water vapor exchange between the desiccant and air streams, the air flow of the air stream selected to meet a predetermined exposure of the air stream to the semi-permeable membranes.
43. The energy exchanger of claim 42, wherein an air flow pressure drop ratio is defined as \( \frac{p_h A_c}{V_c} \), wherein \( p_h \) is a pressure drop of the air stream across the energy exchanger, \( A_c \) is an area of an air channel, and \( V_c \) is a volume of the air channel, wherein the air flow pressure drop ratio is between \( 1 \times 0^3 \) and \( 1 \times 10^3 \).

44. The energy exchanger of claim 42, wherein the air mass flow rate ratio is selected to achieve predetermined exchanger performance ratios that define a thermal and latent energy exchange performance factors between the desiccant and air stream.

45. An energy exchanger comprising:

a housing;

a plurality of panels forming desiccant channels extending through the housing;

air channels formed between adjacent desiccant channels, the air channels configured to direct an air stream through the housing;

a desiccant inlet in flow communication with the desiccant channels; and

a desiccant outlet in flow communication with the desiccant channels, the desiccant channels configured to channel desiccant from the desiccant inlet to the desiccant outlet so that the semi-permeable membranes facilitate heat exchange between the desiccant and the air stream,

wherein the energy exchanger operates within predetermined exchanger performance ratios that define a thermal and latent energy exchange between the desiccant and the air stream.

46. The energy exchanger of claim 45, wherein an exchanger number of transfer units with the energy exchanger is within a range of 1 to 15.

47. The energy exchanger of claim 45, wherein an exchanger thermal capacity rate ratio within the exchanger is within a range of 1 to 10.
48. A method of exchanging energy between a desiccant and an air stream, the method comprising:

- extending a plurality of panels through a housing of the energy exchanger to form desiccant channels and air channels;
- selecting a semi-permeable membrane for each of the panels;
- directing an air stream at a predetermined air mass flow ratio through the air channels; and

- directing desiccant through the desiccant channels,

wherein the semi-permeable membrane is selected based on membrane resistance ranges defined to limit a flow of the desiccant through the desiccant membrane, the air flow ratio of the air stream is selected to meet a predetermined exposure of the air stream to the desiccant membrane, and a flow rate of the desiccant with respect to a flow rate of the air stream is controlled to achieve predetermined exchanger performance ratios that define a thermal energy exchange between the desiccant and the air stream.

49. The method of claim 48, wherein an exchanger thermal capacity rate ratio of the energy exchanger is within a range of 1 to 10.

50. The energy exchanger of claim 48, wherein an exchanger number of transfer units with the energy exchanger is within a range of 1 to 15.

51. The energy exchanger of claim 48, wherein the membrane has a water vapor diffusion resistance and a convective water vapor mass transfer resistance in the air channel, a ratio of the membrane water vapor diffusion resistance divided by the convective water vapor mass transfer resistance of the membrane is within a range of 0.2 to 3.

52. The energy exchanger of claim 48, wherein the membrane has a membrane liquid break-through pressure defined as the pressure required for desiccant to flow through the membrane, a ratio of the membrane liquid break-through pressure
divided by \((\rho \ast g \ast H)\), wherein \(\rho\) is the density of the desiccant, \(g\) is gravity and \(H\) is a height of the membrane, is greater than 20.

53. The energy exchanger of claim 48, wherein the membrane has an edge seal liquid break-through pressure defined as the pressure required for desiccant to flow through an edge seal of the membrane, a ratio of the edge seal liquid break-through pressure divided by \((\rho \ast g \ast H)\), wherein \(\rho\) is the density of the desiccant, \(g\) is gravity and \(H\) is a height of the membrane, is greater than 20.

54. The energy exchanger of claim 48, wherein the membrane includes a screen having wires, the wires having a spacing \((s_{\text{w}})\), the desiccant having an operating pressure \((p_{\text{in}})\), and the membrane having a tensile yield limit \((T_{m,yi})\), a ratio of \(T_{m,yi} / (p_{\text{in}} \ast s_{\text{w}})\) is less than 1.5.

55. The energy exchanger of claim 48, wherein the air flow resistance ratio is defined as \((p_{\text{h}} \ast A_{c} / V_{c})\), wherein \(p_{\text{h}}\) is a pressure drop of the air stream across the energy exchanger, \(A_{c}\) is an area of an air channel, and \(V_{c}\) is a volume of the air channel, wherein the air flow resistance ratio is between \(10^{3}\) and \(10^{4}\).

56. The method of claim 48 further comprising controlling the mass flow rate of the desiccant with respect to the mass flow rate of the air stream based on a temperature and humidity ratio of the air stream.

57. The method of claim 48 further comprising controlling the mass flow rate of the desiccant so that the thermal capacity rate ratio of the desiccant is no more than 5 times the thermal capacity rate ratio of the air stream.

58. A method of exchanging energy between a desiccant and an air stream, the method comprising:

extending a plurality of panels through a housing of the energy exchanger;

spacing the plurality of panels based on predetermined air to desiccant channel rates to form desiccant channels and air channels between adjacent panels, the
predetermined air to desiccant channel rates defining an air channel width and a desiccant channel width;

selecting a semi-permeable membrane to extend through the panels based on predetermined channel deflection ranges that are defined to limit an amount of membrane deflection;

directing an air stream through the air channels; and

directing desiccant flow through the desiccant channels in at least one of a counter-flow or cross-flow direction with respect to the direction of the air stream so that the membrane facilitates heat and water vapor exchange between the desiccant in the desiccant channels and the air stream in the air channels, the predetermined air to desiccant channel rates to providing a predetermined volume rate of air stream flowing through the air channels and a predetermined volume rate of desiccant flowing through the desiccant channels.

59. The method of claim 58 further comprising constructing the housing and energy exchange panels so that a height of the heat and water vapor exchange area in each channel divided by a length of the exchange area is within a range of 0.5 to 2.

60. The method of claim 58, wherein the desiccant channel width is nearly constant through the housing and the air channel width is substantially constant through the housing.

61. The method of claim 58, wherein a ratio of the average air channel width divided by the average desiccant channel width is within a range of 1 to 5.

62. The method of claim 58 further comprising:

providing a desiccant inlet in fluid communication with the desiccant channels;

providing a desiccant outlet in fluid communication with the desiccant channels; and
offsetting the desiccant inlet from the desiccant outlet along a direction of the air stream.

63. The method of claim 58 further comprising directing the desiccant along a flow path having a cross segment and a counter segment, the cross segment extending in a direction substantially perpendicular to a direction of the air stream, the counter segment extending in a direction substantially parallel to a direction of the air stream.

64. The method of claim 58 further comprising directing the desiccant along a flow path in a direction upstream with respect to a direction of the air stream.

65. The method of claim 58 further comprising controlling a flow rate of the desiccant with respect to a flow rate of the air stream to achieve predetermined exchanger performance ratios that define a thermal energy exchange between the desiccant and the air stream.
