THE DESCRIPTION

NOVEL FUSED PYRIDINE DERIVATIVES USEFUL AS c-MET TYROSINE KINASE INHIBITORS

Technical Field

This invention relates to certain novel fused pyridine derivatives as c-Met inhibitors, their synthesis and their use for treating a c-Met mediated disorder.

Background Art

The study of signal transduction pathways in normal and pathological states is of considerable interest because of the potential therapeutic benefit arising from new molecular agents targeting certain of these pathways associated with disease.

Receptor tyrosine kinases (RTKs) are key enzymes in signal transduction pathways that catalyse the autophosphorylation of tyrosine residues within the cytosolic, C-terminal domain of the protein. This generates docking sites for the recruitment of downstream proteins and the subsequent propagation of signals involved in an array of cellular events including growth, proliferation and survival. More generally deregulated kinase signalling is implicated in a diverse range of pathological states including immunological and inflammatory disorders, cardiovascular and neurodegenerative disease. The known receptor tyrosine kinases encompass 20 families and many are oncogenes (Blume- Jensen P et al. 2001. Nature 411 355-365). c-Met is the prototypic member of a subfamily of RTKs which includes the related proteins Ron (macrophage-stimulating protein receptor) and its chicken orthologue, Sea. The endogenous ligand is the growth and motility factor hepatocyte growth factor (HGF, also known as Scatter Factor). c-Met and HGF are expressed in a range of tissue types although their expression is normally restricted to cells of epithelial and mesenchymal origin. In contrast, tumour cells often express constitutively activated c-Met.

There is now a growing body of compelling evidence from both animal studies and cancer patients that HGF-Met signalling plays an important role in the development and progression of malignancy and is associated in particular with invasive phenotypes. c-Met and HGF are highly
expressed relative to surrounding tissue in numerous cancers and their expression correlates with poor patient prognosis (Jiang, W et al. 1999 Crit. Rev. Oncol. -hematol., 29, 209-248.) Activating point mutations in the kinase domain of c-Met are implicated in the cause of sporadic and hereditary forms of papillary renal carcinoma (Danilkovich-Miagkova, A et al 2002. J. Clin. Invest. 109, 863-867). c-Met is a marker for both cancer and malignancy and agents that inhibit c-Met-HGF signalling can be expected to ameliorate disease progression in relevant cancers.

It is intended that the definition of any substituent or variable at a particular location in a molecule be independent of its definitions elsewhere in that molecule. It is understood that substituents and substitution patterns on the compounds of this invention can be selected by one of ordinary skill in the art to provide compounds that are chemically stable and that can be readily synthesized by techniques know in the art as well as those methods set forth herein.

Since the compounds of Formula (I) are intended for pharmaceutical use they are preferably provided in substantially pure form, for example at least 60% pure, more suitably at least 75% pure, especially at least 98% pure (% are on a weight for weight basis).

The pharmaceutical compositions of the present invention comprise a compound represented by Formula I (or a pharmaceutically acceptable salt thereof) as an active ingredient, a pharmaceutically acceptable carrier and optionally other therapeutic ingredients or adjuvants. The compositions include compositions suitable for oral, rectal, topical, and parenteral (including subcutaneous, intramuscular, and intravenous) administration, although the most suitable route in any given case will depend on the particular host, and nature and severity of the conditions for which the active ingredient is being administered. The pharmaceutical compositions may be conveniently presented in unit dosage form and prepared by any of the methods well known in the art of pharmacy.

In practice, the compounds represented by Formula I, or a prodrug, or a metabolite, or pharmaceutically acceptable salts thereof, of this invention can be combined as the active ingredient in intimate admixture with a pharmaceutical carrier according to conventional pharmaceutical compounding techniques. The carrier may take a wide variety of forms depending on the form of preparation desired for administration, e.g., oral or parenteral (including intravenous). Thus, the pharmaceutical compositions of the present invention can be presented as discrete units suitable for oral administration such as capsules, cachets or tablets each containing a predetermined amount of the active ingredient. Further, the compositions can be presented as a powder, as granules, as a solution, as a suspension in an aqueous liquid, as a non-aqueous liquid, as an oil-in-water emulsion, or as a water-in-oil liquid emulsion. In addition to the common dosage forms set out above, the compound represented by Formula I, or a pharmaceutically acceptable salt thereof, may also be administered by controlled release means and/or delivery devices. The compositions may be prepared by any of the methods of pharmacy. In general, such methods include a step of bringing into association the active ingredient with the
carrier that constitutes one or more necessary ingredients. In general, the compositions are prepared by uniformly and intimately admixing the active ingredient with liquid carriers or finely divided solid carriers or both. The product can then be conveniently shaped into the desired presentation.

Thus, the pharmaceutical compositions of this invention may include a pharmaceutically acceptable carrier and a compound, or a pharmaceutically acceptable salt, of Formula I. The compounds of Formula I, or pharmaceutically acceptable salts thereof, can also be included in pharmaceutical compositions in combination with one or more other therapeutically active compounds.

The pharmaceutical carrier employed can be, for example, a solid, liquid, or gas. Examples of solid carriers include lactose, terra alba, sucrose, talc, gelatin, agar, pectin, acacia, magnesium stearate, and stearic acid. Examples of liquid carriers are sugar syrup, peanut oil, olive oil, and water. Examples of gaseous carriers include carbon dioxide and nitrogen. In preparing the compositions for oral dosage form, any convenient pharmaceutical media may be employed. For example, water, glycols, oils, alcohols, flavoring agents, preservatives, coloring agents, and the like may be used to form oral liquid preparations such as suspensions, elixirs and solutions; while carriers such as starches, sugars, microcrystalline cellulose, diluents, granulating agents, lubricants, binders, disintegrating agents, and the like may be used to form oral solid preparations such as powders, capsules and tablets. Because of their ease of administration, tablets and capsules are the preferred oral dosage units whereby solid pharmaceutical carriers are employed. Optionally, tablets may be coated by standard aqueous or nonaqueous techniques.

A tablet containing the composition of this invention may be prepared by compression or molding, optionally with one or more accessory ingredients or adjuvants. Compressed tablets may be prepared by compressing, in a suitable machine, the active ingredient in a free-flowing form such as powder or granules, optionally mixed with a binder, lubricant, inert diluent, surface active or dispersing agent. Molded tablets may be made by molding in a suitable machine, a mixture of the powdered compound moistened with an inert liquid diluent. Each tablet preferably contains from about 0.05mg to about 5g of the active ingredient and each cachet or capsule preferably containing from about 0.05mg to about 5g of the active ingredient. For example, a formulation intended for the oral administration to humans may contain from about 0.5mg to
about 5g of active agent, compounded with an appropriate and convenient amount of carrier material which may vary from about 5 to about 95 percent of the total composition. Unit dosage forms will generally contain between from about 1mg to about 2g of the active ingredient, typically 25mg, 50mg, 100mg, 200mg, 300mg, 400mg, 500mg, 600mg, 800mg, or 1000mg.

Pharmaceutical compositions of the present invention suitable for parenteral administration may be prepared as solutions or suspensions of the active compounds in water. A suitable surfactant can be included such as, for example, hydroxypropylcellulose. Dispersions can also be prepared in glycerol, liquid polyethylene glycols, and mixtures thereof in oils. Further, a preservative can be included to prevent the detrimental growth of microorganisms.

Pharmaceutical compositions of the present invention suitable for injectable use include sterile aqueous solutions or dispersions. Furthermore, the compositions can be in the form of sterile powders for the extemporaneous preparation of such sterile injectable solutions or dispersions. In all cases, the final injectable form must be sterile and must be effectively fluid for easy syringability. The pharmaceutical compositions must be stable under the conditions of manufacture and storage; thus, preferably should be preserved against the contaminating action of microorganisms such as bacteria and fungi. The carrier can be a solvent or dispersion medium containing, for example, water, ethanol, polyol (e.g., glycerol, propylene glycol and liquid polyethylene glycol), vegetable oils, and suitable mixtures thereof.

Pharmaceutical compositions of the present invention can be in a form suitable for topical use such as, for example, an aerosol, cream, ointment, lotion, dusting powder, or the like. Further, the compositions can be in a form suitable for use in transdermal devices. These formulations may be prepared, utilizing a compound represented by Formula I of this invention, or a pharmaceutically acceptable salt thereof, via conventional processing methods. As an example, a cream or ointment is prepared by admixing hydrophilic material and water, together with about 5wt% to about 10wt% of the compound, to produce a cream or ointment having a desired consistency.

Pharmaceutical compositions of this invention can be in a form suitable for rectal administration wherein the carrier is a solid. It is preferable that the mixture forms unit dose suppositories. Suitable carriers include cocoa butter and other materials commonly used in the art.
The suppositories may be conveniently formed by first admixing the composition with the softened or melted carrier(s) followed by chilling and shaping in molds.

In addition to the aforementioned carrier ingredients, the pharmaceutical formulations described above may include, as appropriate, one or more additional carrier ingredients such as diluents, buffers, flavoring agents, binders, surface-active agents, thickeners, lubricants, preservatives (including antioxidants) and the like. Furthermore, other adjuvants can be included to render the formulation isotonic with the blood of the intended recipient. Compositions containing a compound described by Formula I, or pharmaceutically acceptable salts thereof, may also be prepared in powder or liquid concentrate form.

Generally, dosage levels on the order of from about 0.01mg/kg to about 150mg/kg of body weight per day are useful in the treatment of the above-indicated conditions, or alternatively about 0.5mg to about 7g per patient per day. For example, inflammation, cancer, psoriasis, allergy/asthma, disease and conditions of the immune system, disease and conditions of the central nervous system (CNS), may be effectively treated by the administration of from about 0.01 to 50mg of the compound per kilogram of body weight per day, or alternatively about 0.5mg to about 3.5g per patient per day.

It is understood, however, that the specific dose level for any particular patient will depend upon a variety of factors including the age, body weight, general health, sex, diet, time of administration, route of administration, rate of excretion, drug combination and the severity of the particular disease undergoing therapy.

These and other aspects will become apparent from the following written description of the invention.

As defined herein, the term "subject" or “patient” refers to an animal, preferably a mammal, most preferably a human, who has been the object of treatment, observation or experiment. The
term"therapeutically effective amounts used herein, means that amount of active compound or pharmaceutical agent that elicits the biological or medicinal response in a tissue system, animal or human that is being sought by a researcher, veterinarian, medical doctor or other clinician, which includes alleviation of the symptoms of the disease or disorder being treated.

The term"substituted", as defined herein, includes multiple substituents (e.g., Phe, aryl, heteroaryl), preferably from one to five substituents, more preferably from one to three substituents, most preferably from one to two substituents, independently selected from the list of substituents. Typical substituents include, but are not limited to, -X, -CH₃, -C₂H₅, -OH, =O, -SH, =S, -NH₂, -CX₃, -CF₃, -CN, -NO₂, -OS(O₂)OH, -C(O)OH, where each X is independently a halogen. The term "substituted" specifically envisions and allows for substitutions that are common in the art. However, it is generally understood by those skilled in the art that the substituents should be selected so as to not adversely affect the pharmacological characteristics of the compound or adversely interfere with the use of the medicament.

The compounds of the present invention may have asymmetric carbon atoms. Such diastereomeric mixtures can be separated into their individual diastereomers on the basis of their physical chemical differences by methods known to those skilled in the art, for example, by chromatography or fractional crystallization. Enantiomers can be separated by converting the enantiomeric mixtures into a diastereomeric mixture by reaction with an appropriate optically active compound (e.g., alcohol), separating the diastereomers and converting (e.g., hydrolyzing) the individual diastereomers to the corresponding pure enantiomers. All such isomers, including diastereomer mixtures and pure enantiomers are considered as part of the invention.

In general, the compounds of the present invention can be prepared according to Scheme 1 depicts general synthetic routes for compounds of the invention and are not intended to be limiting. More specifically, Scheme 1 depicts synthesis of fused pyridine compounds. Specific examples are described subsequently to these general synthetic descriptions so as to allow one skilled in the art to make and use either quinazolines or quinolines of the invention.

Scheme 1 outlines the general procedures one could use to provide compounds of the present invention, for example Z is NHR₆ in formula I.
The compounds of formula I of present invention, \( Z \) is \( \text{NHR}_6 \) in formula I can be prepared from intermediates 5 and suitable acid compounds, \( R_6\text{-OH} \), where \( R_6 \) is defined above, using standard coupling reaction condition for amide formation. Suitable acid compounds, \( R_6\text{-OH} \), where \( R_6 \) is defined above, are commercial available, known in the literature or may be conveniently prepared by a variety methods familiar to those skilled in the art.

One common route for intermediates 5 is illustrated in Scheme 1. Compounds 1 can react with intermediate 2 at elevated temperature, in the present of a suitable base such as sodium bicarbonate in a proper solvent such as DMF, followed by standard nitro group reduction, to provides the intermediates 5. Alternate route for the preparation of intermediates 5 may be the substitution reaction of compounds 1 with aniline intermediate 3 in elevated temperature in the present of a suitable base such as sodium bicarbonate in a proper solvent such as DMF, as shown in Scheme 1.

Scheme 2 outlines the general procedures one could use to provide compounds of the present invention, for example \( Z \) is groups in formula II.
Scheme 2

Suitable intermediates 6, where $R_{18}$ and $R_{19}$ are defined above, are commercial available, known in the literature or may be conveniently prepared by a variety methods familiar to those skilled in the art. Intermediates 6 can react with Compounds 1 at elevated temperature, in the present of a suitable base such as sodium bicarbonate in a proper solvent such as DMF, to provides compounds of the present invention, for example Z is groups in formula II.

To prepare the pharmaceutical compositions of this invention, one or more compounds of Formula (I) or salt thereof as the active ingredient, is intimately admixed with a pharmaceutical carrier according to conventional pharmaceutical compounding techniques, which carrier may take a wide variety of forms depending of the form of preparation desired for administration (e.g. oral or parenteral). Suitable pharmaceutically acceptable carriers are well known in the art. Descriptions of some of these pharmaceutically acceptable carriers may be found in The Handbook of Pharmaceutical Excipients, published by the American Pharmaceutical Association and the Pharmaceutical Society of Great Britain During any of the processes for preparation of the compounds of the present invention, it may be necessary and/or desirable to protect sensitive or reactive groups on any of the molecules concerned. This may be achieved by means of conventional protecting groups, such as those described in Protective Groups in Organic Chemistry, ed. J. F. W. McOmie, Plenum Press, 1973; and T. W. Greene & P. G. M. Wuts, Protective Groups in Organic Synthesis, John Wiley & Sons, 1991. The protecting groups may be removed at a convenient subsequent stage using methods known in the art.

Administration of the active compounds can be effected by any method which enables delivery of the compounds to the site of action (e.g., cancer cells). These methods include oral routes, rectal routes, intraduodenal routes, parenteral injection (including intravenous, subcutaneous, intramuscular, intravascular or infusion), topical administration, etc. The amount of active compound administered will, of course, be dependent on the subject being treated, on
the severity of the affliction, on the manner of administration and on the judgement of the
prescribing physician. However an effective dosage is in the range of approximately 0.001 mg to
about 300 mg (preferably, from about 0.01 mg to about 100 mg; and, more preferably, from about
0.1 mg to about 30 mg) and may be given at a dosage of from about 0.001 mg/kg/day to about 300
mg/kg/day (preferably, from about 0.01 mg/kg/day to about 100 mg/kg/day; and, more preferably,
from about 0.1 mg/kg/day to about 30 mg/kg/day).

The composition may, for example, be in a form suitable for oral administration such as a
tablet, capsule, pill, powder, sustained release formulation, solution, or suspension; for parenteral
injection such as a sterile solution, suspension or emulsion; or for topical administration such as
an ointment or cream or for rectal administration as a suppository. The pharmaceutical
composition may be in unit dosage forms suitable for single administration of precise dosages.
The pharmaceutical composition will include a conventional pharmaceutical carrier or excipient
and a compound according to the present invention as an active ingredient. In addition, it may
include other medicinal or pharmaceutical agents, carriers, adjuvants, etc.

Exemplary parenteral administration forms include solutions or suspensions of active
compounds in sterile aqueous solutions, for example aqueous propylene glycol or dextrose
solutions. Such dosage forms can be suitably buffered, if desired.

Suitable pharmaceutical carriers include inert diluents or fillers, water and various organic
solvents. The pharmaceutical compositions may, if desired, contain additional ingredients such as
flavorings, binders, excipients and the like. Thus for oral administration, tablets containing
various excipients, such as citric acid may be employed together with various disintegrants such
as starch, alginic acid and certain complex silicates and with binding agents such as sucrose,
gelatin and acacia. Additionally, lubricating agents such as magnesium stearate, sodium lauryl
sulfate and talc are often useful for tableting purposes.

Solid compositions of a similar type may also be employed in soft and hard filled gelatin
capsules. Preferred materials, therefor, include lactose or milk sugar and high molecular weight
polyethylene glycols. When aqueous suspensions or elixirs are desired for oral administration the
active compound therein may be combined with various sweetening or flavoring agents, coloring
matters or dyes and, if desired, emulsifying agents or suspending agents, together with diluents
such as water, ethanol, propylene glycol, glycerin, or combinations thereof.

The following assays demonstrate that certain compounds of the present invention potently inhibit c-Met phosphorylation in vitro, potently inhibit c-Met in vivo, and have dose dependent anti-tumor activity in certain xenograft models.

**Biological Assays**

Met (h) is incubated with 8mM MOPS pH7.0, 0.2mM EDTA, 250μM KKKSPGEYVNFEG, 10 mM Mgacetate, [γ-33P-ATP] (specific activity approx. 500 cpm/pmol, concentration as required) and 0.2μM test compound. The reaction is initiated by the addition of the MgATP mix. After incubation for 40 minutes at room temperature, the reaction is stopped by the addition of 3% phosphoric acid solution. 10 μL of the reaction is then spotted onto a P30 filtermat and washed three times for 5 minutes in 75 mM phosphoric acid and once in methanol prior to drying and scintillation counting. This assay is performed by Millipore. The experiment is carried out in duplicate. The value for the control sample (DMSO) was set to 100%, and the values for the compound-treated samples were expressed as activity relative to the control sample.

**Cellular proliferation analysis**

Cell proliferation analysis was conducted by the MTS assay protocol. Briefly, U87-MG cells will be cultured in EMEM medium, EBC-1 cells and SNU-5 cells will be cultured in MEM medium, MKN45 cells, NCI-H1975 cells and NCI-H1993 cells will be cultured in RPMI1640 medium, A549 cells will be cultured in McCoy’s 5a medium. All the cells will be cultured in the media supplemented with 10% FBS, in the temperature of 37°C, 5% CO₂ and 95% humidity. All culture media will be purchased from Gibco (USA). The cells will be harvested respectively during the logarithmic growth period and counted with hemocytometer. The cell viability is over 98% by trypan blue exclusion. Adjust cell concentrations to 2.22×10⁵ or 1.11×10⁵ or 5.56×10⁴ cells/ml with respective medium. Add 90 µl cell suspensions to 96-well plates (triplicates for each cell concentration), the final cell densities are 2×10⁴ or 1×10⁴ or 5×10³ cells/well. The density of 5×10³ cells/well will be used for our first test. The appropriate cell density will be determined and adjusted according to the results of our first test. The next day, dissolve the test article or positive drugs with DMSO or PBS as stock solution. Dispense 2 µl drug solution in 1ml culture media. Add 200µl drug media into 96-well plates (triplicate for each drug concentration) after discard the old media. The final concentration of drug will be 0, 0.03, 0.1, 0.3, 1, 3, 10, 30 or 100 µM. The plates will be cultured for another 7 days, then measured by means of MTS assay. Prepare MTS/PMS solution immediately prior to use, pipet 20 µl of the mixture into each well of the 96 well assay plate containing 100 µl culture media. (The final reaction volume is 120 µl). Incubate the plate for 1-4 hours at 37 °C in a humidified, 5% CO₂ atmosphere. Record the absorbance at 490 nm using Victor X5 microplate spectrophotometer.

Xenograft tumor models

Human non small cell lung cancer cells A549, human gastric cancer cells MKN45, and human lung squamous cell carcinoma cells EBC-1 are expanded in culture, harvested, and injected subcutaneously onto the right flank of BALB/c nude mice. Testing compound is prepared in an appropriate vehicle and is administered by oral gavage when tumors are established (6-10 days after implant). Tumor response is determined by tumor volume measurement performed twice a week during the course of treatment. Tumor volume inhibition (% growth inhibition) is calculated by comparing treated groups to vehicle control group. Body weight is taken as a general measurement of toxicity. The Compound of Example 1 demonstrates excellent anti-tumor activity in these models. For example, when dosed at 60 and 120 mg/kg (qd x24), Example 1 is able to cause 76.6% and 96.7% growth inhibition of A549 tumors, respectively. When dosed at 60 and 120 mg/kg (qd x22), Example 1 is able to cause 38.9% and 71.9% growth inhibition of MKN45 tumors, respectively. When dosed at 40 and 80 mg/kg (qd x17), Example 1 is able to cause 56.5% and 100% growth inhibition of EBC-1 tumors, respectively.
