(54) Title: TELESCOPING SUSPENSION FORK HAVING A QUICK RELEASE WHEEL AXLE CLAMP

(57) Abstract: A telescoping fork for the front wheel of a two wheel vehicle comprises a pair of outer tubes that each have a bottom end and a top end. An upper structural member and a lower structural member connect the outer tubes. Further, each outer tube tapers outwardly, both externally and internally, in a direction from the bottom end toward the lower structural member and from the top end toward the lower structural member. The structural members may attach to a top and bottom of a steering column.
For two-letter codes and other abbreviations, refer to the "Guidance Notes on Codes and Abbreviations" appearing at the beginning of each regular issue of the PCT Gazette.
NOT TO BE TAKEN INTO CONSIDERATION FOR THE PURPOSES OF INTERNATIONAL PROCESSING
in a direction both from the top end and the bottom end toward the lower structural member. With such a configuration, the strength of the outer tubes is increased without significantly increasing the weight of the fork.

[0006] In one aspect, the lower structural member is welded to the outer tubes, and steering bearings are coupled between the upper structural member and the lower structural member. With this configuration, the steering bearings may be used to attach the fork to a vehicle frame. In another aspect, the lower structural member may have a hollow box sectional shape.

[0007] In one particular arrangement, the fork further includes a pair of inner tubes that are disposed to slide within the pair of outer tubes. The inner tubes each have a bottom end and a top end, and the bottom ends of the inner tubes extend out of the bottom ends of the outer tubes. In one option, a single bushing may be disposed between each outer tube and each inner tube. The bushings may be located at the bottom ends of the outer tubes and have a length that is longer than a diameter of the inner tube. The use of such a bushing helps maintain an oil layer between the bushing and the inner tube.

[0008] In another particular aspect, the fork may include a bracket disposed at the bottom end of each inner tube. The brackets are employed to clamp a front wheel axle to the inner tubes. Optionally, at least one of the brackets may have a mount for receiving a disk brake caliper.

[0009] Another feature of the fork is the use of a handle bar clamping device that is coupled to the upper structural member. In this way, a handle bar may be coupled to the fork.

[0010] One particular embodiment of the invention is an adjustable fluid damping system. The fluid damping system may comprise a damper tube extending upward from the top end of the inner tube (and in some cases the damper tube may simply be an extension of the inner tube), a hollow damper rod coupled to the top end of the outer tube and extending into the damper tube, and a damper piston valve coupled to the damper rod that seals against the damper tube. The fluid clamping system may further include a lock tube that is disposed within the damper rod. The damper rod may have at least one upper orifice and one lower orifice, and the lock tube may be rotatable from the top end of the outer tube to close the lower orifice to limit the amount of extension of the lower tube out of the upper tube. In this way, the amount of extension of the suspension system may easily be adjusted from outside of the fluid damping system. For instance, when ready to climb a steep hill, the rider may quickly adjust the lock tube by turning a knob to limit the amount of extension during climbing.
In one particular aspect, this is accomplished by configuring the damper piston valve as a one-way valve that permits fluid flow in an upward direction upon compression of the inner tube into the outer tube. Further, a sleeve may be disposed over a top portion of the damper rod and the lock tube. The sleeve is configured to close the upper orifice as the upper tube extends relative to the lower tube, such that further extension is prevented if the lower orifice is closed by the lock tube. Conveniently, a stop may be positioned between the top of the outer tube and the top of the inner tube to stop compression of the inner tube into the outer tube.

In one alternative aspect, the inner tube may have a closed end or section, and a sealed piston may be disposed inside the inner tube. The piston may be connected to a rod that extends and attaches to the top end of the outer tube. Further, a gas may be held within the inner tube and is compressed by the piston to provide a damping effect. Optionally, a spring may be disposed between the bottom end of the inner tube and the piston to form a biasing effect. The rod may also be hollow to permit the gas pressure in the inner tube to be adjusted by a valve at the top end of the outer tube.

In a further embodiment, the invention provides a releasable clamp system for clamping a wheel axle of wheel to a two-wheeled vehicle. The clamp system comprises a frame member that defines a shape that is configured to receive a portion of the wheel axle. A cover plate is pivotally attached to the frame member and is configured to receive another portion of the wheel axle. In this way, the cover plate may be moved to a closed position where the frame member and the cover plate generally encompass and clamp the wheel axle, and to an open position where the wheel axle may be removed. A lever is pivotally attached to the cover plate, and a hook member is pivotally attached to the lever. The hook member is configured to hook onto the frame member and be pulled by the lever to secure the cover plate to the frame member when the cover plate is moved to the closed position.

In one aspect, the cover plate may be pivotally attached to a top end of the frame member to permit the wheel axle to be vertically released from the frame member. In another aspect, the inner surfaces of the frame member and the cover plate that are adjacent the wheel axle are each semi-circular in geometry.

In a further aspect, the hook member may be T-shaped, and the frame member may include a shoulder with a slot into which the hook member is received. Optionally, the hook member may be constructed of two pieces that are threadably connected together. In this way, the clamping force on the wheel axle may be adjusted by rotating the pieces relative to each other prior to clamping.
[0016] In yet another aspect, torsion springs may be provided at pivot points located where
the cover plate attaches to the frame member and where the lever attaches to the cover plate.
The torsion springs hold the cover plate open when not clamping the wheel axle. Further, a
mount may be provided on the frame member to mount a disk brake caliper to the frame
member.

[0017] The invention also provides alternative techniques for externally adjusting the
amount of travel of a telescoping suspension system. Such telescoping suspension systems
may be constructed of a telescoping tube arrangement where two tubes slide relative to each
other. To adjust the amount of travel of the telescoping tube arrangement, a travel adjustment
mechanism may be used. The travel adjustment mechanism may be constructed of a tube
member having a closed end and an open top end. A seal head is disposed at the top end of
the tube member, and a hollow rod unit passes through the seal head. The rod unit has a top
end and a bottom end, and a piston is coupled to the bottom end of the hollow rod so as to be
disposed in the tube member. The travel adjustment mechanism is operably coupled rod unit
and is operable from outside of the telescoping tube arrangement to adjust the effective length
of the rod unit. In so doing, the amount of extension of the telescoping tube arrangement is
adjusted. More specifically, by adjusting the length of the rod unit, the point at which the
piston engages the seal head is varied. As such, the amount of extension of telescoping tube
arrangement is limited to thereby limit the total suspension travel.

[0018] Conveniently, the travel adjustment mechanism may include an adjustment knob
that is rotatable to adjust the effective length of the rod unit. The adjustment knob may be
located outside of the telescoping tube arrangement so that the adjustment may easily occur
from outside of the suspension system.

[0019] The telescoping tube arrangement may comprise an outer tube and an inner tube that
is slidable within the inner tube. The telescoping tube arrangement may be configured so that
the wheel axle is operably coupled to either the outer tube or the inner tube. As such. The
tube member containing the piston may be operably coupled to either the inner tube or the
outer tube. Also, the travel adjustment mechanism may be coupled to either the outer tube or
the inner tube by a top cap, with the adjustment knob extending out of the top cap.

[0020] In one aspect, a biasing material is disposed within the tube member between the
closed end and the piston. This biasing material may comprise a spring or some type of fluid,
such as a gas. In this way, telescoping tube arrangement functions as a spring type suspension.

[0021] In a specific aspect, the travel adjustment mechanism comprises a housing containing a pressurized gas, alone or in combination with a liquid, and a first shaft that extends through the housing and that has a pair of spaced apart orifices. A piston coupled to the first shaft between the orifices to define an upper chamber and a lower chamber within the housing. The travel adjustment mechanism further includes a second shaft and a valve that is disposed between the two orifices. In this way, the second shaft is movable to open the valve and to permit the pressurized fluid to flow between the upper chamber and the lower chamber through the two orifices. With such a configuration, the adjustment knob may be manipulated to move the second shaft within the first shaft to open the valve and permit the fluid to flow between the two chambers.

[0022] Advantageously, the first shaft may have a outer diameter above the piston that is larger than the outer diameter below the piston so that when the valve is opened, a biasing effect is produced that tends to lengthen the travel adjustment mechanism. Hence, when the knob is manipulated the telescoping tube arrangement will tend to extend. To make the proper adjustment, a downward force may be applied to the fork to compress the telescoping tube arrangement. In so doing, pressurized gas is transferred from the lower chamber of the housing to the upper chamber. When the proper configuration is reached, the adjustment knob may be turned in the opposite direction to close the valve and maintain the telescoping tube arrangement in the same position.

[0023] Another feature is that the first shaft may include a tapered seat that is positioned between the two orifices. The second shaft may also include a tapered bottom end that engages the tapered seat to form the valve. In a further aspect, the travel adjustment mechanism, the hollow rod unit and the piston may define a fluid flow passage into the tube member to permit the pressure within the tube member to be adjusted at the travel adjustment mechanism. For example, a valve may be provided in the adjustment knob to permit a pressurized fluid to be input into or exhausted from the tube member.

BRIEF DESCRIPTION OF THE DRAWINGS

[0024] Fig. 1 is a front isometric view of a telescoping fork releasably coupled to a front wheel of a two wheeled vehicle according to the invention.

DETAILED DESCRIPTION OF THE INVENTION

[0045] In one aspect, the invention provides various suspension systems having a variety of features. One such feature is the use of fork that is constructed of telescoping outer tubes.

SUBSTITUTE SHEET (RULE 26)
The tubes have an inner diameter and an outer diameter that both increases in a direction from the axle mount upward as well as from the top of the fork downward. The maximum amount of taper may occur near where the two tubes are joined together by a structural member. For example, the tubes may taper outward from an inner diameter in the range from about 32 mm to about 34 mm and an outer diameter in the range from about 34 mm to about 38 mm, to an inner diameter in the range from about 44 mm to about 48 mm and an outer diameter in the range from about 48 mm to about 52 mm, although other dimensions are possible. Such a configuration increases the strength of the fork without appreciably increasing its weight.

[0046] Another feature of the invention is the ability to limit the amount of extension of the suspension system. This may be done manually from outside of the suspension system. For example, such an adjustment may be done by simply turning a knob. Such a feature is useful when peddling uphill to keep the front end of the bicycle closer to the ground to prevent tipping backward. When on level or down sloping terrain, the suspension system may again be adjusted to permit full extension.

[0047] A further feature is a releasable clamp system that provides for a quick release of the wheel from the fork. By the simple operation of a lever, the wheel may be vertically released from the fork.

[0048] Referring now to Fig. 1, one embodiment of a fork 10 of a two-wheeled vehicle will be described. Fork 10 is constructed of a pair of outer tubes 12 and 14 that may both be fashioned in a substantially similar manner. Outer tubes 12 and 14 are coupled together by a lower structural member 16 and an upper structural member 18. Outer tubes 12 and 14 may be constructed of a strong and rigid material, such as steel, aluminum, or the like. Lower structural member 16 may be constructed of a similar material and may be welded to outer tubes 12 and 14. Upper structural member 18 may be coupled to tubes 12 and 14 using screws 20 (see also Fig. 2) that may be tightened or loosened using an Allen wrench. Alternatively, upper structural member 18 may be welded to tubes 12 and 14. Upper structural member 18 also includes a coupling arrangement 22 for coupling a handlebar 24 (see Fig. 3) to fork 10. Optionally, this may be incorporated directly into upper structural member 18.

[0049] Coupled between structural members 16 and 18 is a rotatable member 26 having steering bearings. Rotatable member 26 is a steering column that is configured to be coupled to a vehicle frame as is known in the art to complete the vehicle.

[0050] Extending out of outer tubes 12 and 14 are inner tubes 28 and 30. Inner tubes 28
and 30 are slidable within outer tubes 12 and 14 and are coupled to a clamping system 34, 36 as described hereinafter. As also described hereinafter, an adjustment knob 78 is at a top end of outer tube 12 and may be used to adjust the amount of extension of inner tubes 28 and 30 out of outer tubes 12 and 14.

[0051] Coupled to inner tubes 28 and 30 are clamp systems 34 and 36 that are each substantially identical. Clamp systems 34 and 36 are employed to couple an axle 38 of a wheel 40 to fork 10 and will be described in greater detail hereinafter.

[0052] Lower structural member 16 is shown in cross section in Fig. 4 and has a box sectional shape. Such a shape is useful in that it provides the greatest amount of rigidity for the least weight.

[0053] As best shown in Fig. 5, outer tube 12 (as well as outer tube 14) tapers outward, both externally and internally, from near its bottom end 42 to a location 44 where tube 12 is coupled to lower structural member 16 (see Fig. 1). Outer tube 12 also tapers outward, both externally and internally from its top end to location 44. This configuration permits outer tube 12 to have an inner diameter at bottom end 42 that is slightly larger than inner tube 28, and to have a greater inner diameter at location 44 where greater stresses occur. In this way, the overall strength of fork 10 is increased. Further, by also increasing the outer diameter of tube 12, a relatively small wall thickness may be maintained to reduce the weight of fork 10.

[0054] Referring to Figs. 5-7, construction and operation of a damping system 50 will be described. Damping system 50 is constructed out of outer tube 12 and inner tube 28 that slides within outer tube 12. Inner tube 28 is coupled to a damper tube 52 that has threads 54 that thread into corresponding threads of inner tube 28. Damper tube 52 has a closed bottom end 56 and a top end having a seal head 58. In some cases, damper tube 52 may simply be an integrally formed extension of inner tube 28. Extending down from seal head 58 and into damper tube 52 is an outer sleeve 60. An O-ring 62 is coupled to the bottom end of outer sleeve 60. Extending through outer sleeve 60 and seal head 58 is a hollow damper rod 64. An O-ring 65 provides a seal between seal head 58 and damper rod 64. Coupled to a bottom end of damper rod 64 by a nut 63 is a damper valve piston 66 that is configured as a one-way valve. Piston valve 66 also divides damper tube 52 into a lower oil chamber 68 and an upper oil chamber 70, although other fluids may be used as well. Piston valve 66 includes a flexible valve washer 71 that is shown in an open position in Fig. 6 during compression of damping system 50 to permit fluid flow through a valve 72. As shown in Fig. 7, washer 71 is an a closed position during extension of damping system 50 to prevent flow through orifice 72. Disposed above piston valve 66 is a bottom extension orifice 74 (although more than one
may be used). Also, positioned above bottom orifice 74 is one or more top extension orifices 75.

[0055] Coupled to a top end of damper tube 64 is a top cap 76 that in turn is coupled to outer tube 12 (see Fig. 5). A bottom out pad 79 is coupled to top cap 76 and may comprise an O-ring. Pad 79 is used to soften the impact and protect top cap 76 if damping system 50 bottoms out, i.e., when seal head 58 reaches top cap 76. Optionally, pad 79 may be provided anywhere along damper rod 64, and damper rod 64 may be provided with a shoulder to hold pad 79 in place. Disposed on top of top cap 76 is an adjuster knob 78 that in turn is coupled to a lock tube 80. In turn, lock tube 80 is adjacent to and coaxially disposed within damper rod 64. Knob 78 is rotatable to rotate lock tube within damper rod 64. Lock tube 80 also includes a set of upper orifices 82 that are aligned with top orifices 75 of damper rod 64. Orifices are preferably configured as slots so that when knob 78 is rotated, a fluid flow path remains through damper rod 64 and lock tube 80.

[0056] Lock tube 80 also includes a lower orifice 84 that is aligned with bottom extension orifice 74 of damper rod 64. Upon rotation of knob 78, orifice 84 may be rotated out of alignment with orifice 74 so that fluid flow between upper oil chamber 70 and the interior of damper rod 64 through orifice 74 is prevented when orifice 75 passes above O-ring 62. Damper rod 64 also includes an opening 86 at its bottom end that permits fluid to flow both into and out of damper rod 64.

[0057] By utilizing lock tube 80, damper system 50 may be operated in one of two modes simply by rotating knob 78. In Figs. 6 and 7, damper system 50 is shown in an unrestricted mode where orifice 84 is aligned with orifice 74. In Fig. 6, damper system 50 is being compressed, such as when a rider encounters a bump. In such cases, inner tube 28 slides into outer tube 12. Since damper tube 52 is coupled to inner tube 28 and top cap 76 is coupled to outer tube 12, damper rod 64 and lock tube 80 move further into damper tube 52. In so doing, the fluid within lower chamber 68 moves upwardly through valve orifice 72 and into upper chamber 70, as well as upwardly through damper rod 64 as shown by the flow lines in Fig. 6. The fluid flowing upward through damper rod 64 may exit into upper chamber 70 through orifices 74 or 75 as shown. The “stiffness” of damping system 50 during compression may be varied by varying the flexibility of valve washer 71, as well as the number and/or size of the exit orifices.

[0058] During extension (as shown in Fig. 7), valve washer 71 is forced downward to close orifice 72. As such, fluid in upper chamber 70 may only pass into lower chamber 68 through damper rod 64 as shown by the flow lines. If the amount of extension becomes so great that
orifices 75 move within outer sleeve 60, fluid in upper chamber 70 may still pass into lower chamber 68 through orifices 74 and 84.

[0059] Damper system 50 may be placed into an extension limiting mode by simply turning knob 78 until orifice 84 is out of alignment with orifice 74. In this configuration, lock tube 80 prevents fluid flow through orifice 74 and into damper rod 64. Hence, once damper system 50 extends sufficient to move orifice 75 beyond O-ring 62, outer sleeve 60 prevents fluid flow from upper chamber 70 and into damper rod 64 via orifice 75. Moreover, because orifice 74 also is closed, none of the fluid in upper chamber 70 may pass into lower chamber 68, thus stopping further extension.

[0060] Hence, a rider may quickly and easily control the amount of extension simply by rotating knob 78 which is easily accessible since it is outside of outer tube 12. For example, when climbing a hill a rider may want to keep the front end of the bicycle closer to the ground. To do so, knob 78 may simply be turned to limit the amount of extension. When at the top of the hill, knob 78 may be moved back to place damping system 50 in normal operation. As will be appreciated, the amount of extension may also be controlled by the number, size and/or location of orifices 75. For example, by moving orifices downward, more extension may be achieved.

[0061] Fig. 8 illustrates the slidable connection between inner tube 28 and outer tube 12. For convenience of illustration, damper system 50 has been removed. Coupled to outer tube 12 is a bushing 90 that is held in place by a sheath member 92. Also coupled to sheath member 92 is a seal or dust wiper 94 that helps prevent dirt and other particulate from passing between inner tube 28 and outer tube 12. Bushing 90 is configured to maintain a layer of oil between itself and inner tube 28 during compression and expansion. This is accomplished by using only a single bushing so that edges do not exist between multiple bushings. Further, bushing 90 has a length that is longer than the diameter of inner tube 28. This length also helps to maintain the oil layer.

[0062] Referring now to Figs. 9-12, clamp systems 34 and 36 will be described in greater detail. Clamp systems 34 and 36 are constructed of identical components and will each be described using the same reference numerals. Clamp system 34 is constructed of a frame member 100 that is coupled to inner tube 28. Frame member 100 has an inner surface 102 for receiving wheel axle 38 and may be approximately semi-circular in shape, although other shapes are possible. Pivotal attached to frame member 100 by a pivot pin 104 is a cover plate 106 that also has an inner surface 108 for receiving the other half of wheel axle 38. As such, inner surface 108 may also be approximately semi-circular. Pivotal coupled to cover
plate 106 by a pivot pin 110 is a lever 112, and pivotally coupled to lever 112 by a pivot pin 114 is a hook member 116. Hook member 116 is constructed of a housing 118 and a hook 120 that is T-shaped. Hook 120 is threadably connected to housing 118 to permit the distance between hook 120 and lever 112 to be adjusted.

Frame member 100 includes a shoulder 122 having a slot 124 for receiving hook 120 when clamping wheel axle 38 to frame member 100. In use, wheel 40 (see Fig. 1) may be coupled to inner tube 28 by placing clamp system 34 in an open position as shown in Figs. 10 and 11. Although not shown, torsion springs may be provided about pivot pins 104 and 110 to hold clamp system 34 in the open position. Wheel axle 38 may then be moved vertically up and placed adjacent inner surface 102. This is made possible by locating cover plate 106 at the top end of inner surface 102. Lever 112 may then be operated to pivot cover plate 106 about the other half of wheel axle 38 and to place hook 120 into slot 124 so that the end of hook is beyond shoulder 122. Lever 112 is then rotated until pivot pin 114 moves to an over center position (i.e., past a line passing between pin 110 and hook 120) and locks cover plate 106 in place where wheel axle 38 is clamped in place by surfaces 102 and 108 as shown in Fig. 12. To adjust the clamping force, hook 120 may be screwed further into or out of housing 118. When ready to remove wheel 40, lever 112 is simply pulled and hook 120 is removed from slot 124. A similar process is used to operate clamp system 36.

Also coupled to frame member 100 is a mount 128 that may be employed to mount a disc brake caliper to clamp system 34. Such a disc brake caliper may be similar to those known in the art, e.g., as defined by the G-3 Shimano disc brake standard.

Fork 10 may be modified to include other types of damping systems. Two such examples are illustrated in Figs. 13 and 14. For convenience of discussion, the elements in Figs. 13 and 14 that are similar to those described in connection with fork 10 will be described using the same reference numerals. Fig. 13 illustrates a fork section 200 that is constructed of an outer tube 12 that may be connected to the outer tube of another fork section. For example, a fork may be constructed of fork section 200 that is coupled to the outer tube 12 of a fork section 204 (see Fig. 14) in a manner similar to the embodiment illustrated in Fig. 1. Outer tubes 12 may taper outwardly in a manner similar to that previously described.

Slidable within outer tube 12 is inner tube 28 (that is coupled to damper tube 52). In some cases, inner tube 28 and damper tube 52 may be the same tube. Damper tube 52 includes a closed end 206, and a sealed piston 208 is slidable within tube 52. A hollow rod 210 is connected to piston 208 at its bottom end and is coupled to the top of outer tube 12 at
its top end. The top end of outer tube 12 includes a valve region 212 into which a valve may
be disposed. This valve permits the gas pressure in the space between piston 208 and closed
end 206 to be adjusted.

[0067] Hence, fork section 200 functions as a damper to dampen a shock experienced by
the two wheeled vehicle. More specifically, as inner tube 28 slides into outer tube 12, the gas
in damper tube 52 is compressed to provide a damping effect.

[0068] Fork section 204 of Fig. 14 is essentially identical to that of fork section 200 but
includes a spring 216 that provides a biasing effect. Hence, fork section 204 may be used in
combination with fork section 200 to provide a fork having both a damping and biasing
effect. More specifically, after the fork experiences a shock and is compressed, spring 216
forces inner tube 28 out of outer tube 14.

[0069] The invention may also utilize alternative techniques for externally adjusting the
suspension travel. Such adjustments may be made using a travel adjustment mechanism on
the spring side of the fork to effectively shorten a rod that holds the spring piston. In turn, the
spring piston stops against the seal head to limit the amount of extension of the telescoping
tubes relative to each other. Hence, as the rod is shortened, the amount of total suspension
travel is limited.

[0070] Such a feature is illustrated generally in Figs. 15 and 16. Shown in Figs. 15 and
15A is a telescoping tube arrangement 200 that functions as the spring side leg of a
suspension system. Telescoping tube arrangement 200 is constructed of an outer telescoping
tube 202 that may be attached to a lower crown of a fork as described in connection with
other embodiments herein. Slidable within outer tube 202 is an inner tube 204. A bottom
end of inner tube 204 is coupled to a drop out assembly 206 that is employed to hold the front
wheel axle in a manner similar to that previously described in connection with other
embodiments.

[0071] Disposed at the top end of outer tube 202 is a top cap 208. Extending from top cap
208 is an adjustment knob 210 that may be rotated to adjust the amount of travel of inner tube
204 relative to outer tube 202 as described hereinafter. As such, the amount of suspension
travel may easily be adjusted externally by the user by simply rotating knob 210.

[0072] Referring also now to Figs. 16, 16A and 16B, operation of telescoping tube
arrangement 200 will be described in greater detail. As best shown in Fig. 15A, a single
bushing 212 is fixed to outer tube 202 and provides a low friction surface to facilitate sliding
of inner tube 204 relative to outer tube 202. Conveniently, bushing 212 may be constructed
in a manner similar to that described in connection with other embodiments. Extending from
inner tube 204 is a spring tube 214, which in some cases may be considered to be an extension of inner tube 204. Disposed in spring tube 214 is a piston 216. Spring tube 214 has a closed bottom end 218 and a top end 220 to which is coupled a seal head 222. A biasing material, such as a pressurized gas or a spring may optionally be disposed between piston 216 and bottom end 218 to upwardly bias piston 216. Coupled to piston 216 is a spring rod 224. Spring rod 224 is hollow and connects piston 216 to top cap 208, which in turn is fixed to the top of outer tube 202.

[0073] Disposed between seal head 222 and top cap 208 is a travel adjustment mechanism 226. As previously mentioned, adjustment of the length of travel adjustment mechanism 226 is accomplished by rotating adjustment knob 210 from outside of telescoping tube arrangement 200. As best shown in Fig. 16B, travel adjustment mechanism 226 comprises a housing 228 having an open end 230 that is capped with a sealing cover 232 that also attaches to spring rod 224. Housing 228 also includes a closed end 234 having a sealing arrangement 236. Disposed within housing 228 is a piston 238. Extending upwardly from piston 238 is a first shaft 240 that attaches to top cap 208. First shaft 240 also extends downwards from piston 238 and slides within sealing cover 232 and spring rod 224. Conveniently, first shaft 240 and spring rod 224 may be referred together as a rod unit. The inner bore of first shaft 240 that extends above piston 238 has a diameter that is larger than the diameter of the inner bore that extends below piston 238. Also, formed in first shaft 240 are orifices 242 and 244 that are positioned on opposite sides of piston 238. Further, first shaft 240 tapers from the top bore to the bottom bore to form a tapered seat 246. Disposed within first shaft 240 is a second shaft 248 that extends from adjustment knob 210 down to the tapered seat 246. Second shaft 248 is threadably engaged to top cap 208. Further, disposed within housing 228 is a pressurized gas, optionally in combination with a liquid. Also, it will be appreciated that other types of valve seats may be used to prevent fluid flow.

[0074] With this configuration, when adjustment knob 210 is turned, second shaft 248 is moved up and down within first shaft 240 depending on the direction of rotation of adjustment knob 210. The interface between second shaft 248 and the tapered seat 246 defines a valve that prevents fluid flow between an upper chamber 250 and a lower chamber 252 within housing 228 when the valve is closed. However, when adjustment knob is rotated to move second shaft 248 upwardly within first shaft 240, a space forms between the bottom end of second shaft 248 and the tapered seat 246 to open the valve and permit fluid to flow between chambers 250 and 252 through orifices 242 and 244. First shaft 240 also has an outer diameter above piston 238 that is larger than the outer diameter below piston 238.
Because the first shaft 240 has an outer diameter below piston 238 that is smaller than the outer diameter of the first shaft 240 above piston 238, the pressurized gas produces an upwardly directed biasing on piston 238. Hence, when adjustment knob 210 is rotated to open the valve, outer tube 202 and inner tube 204 will tend to extend relative to each other. To shorten the length of travel, the user may press down on the fork to force inner tube 204 within outer tube 202. In so doing, piston 238 is forced downward and the pressurized gas within lower chamber 252 passes through orifices 244 and 242 and into upper chamber 250. When adjustment knob 210 is rotated to close the valve, piston 238 generally remains in place. In effect, this shortens the length of spring rod 224. As such, the amount of travel of inner tube 204 out of outer tube 202 is limited because the distance between piston 216 and seal head 222 is reduced. As such, if the amount of extension of inner tube 204 out of outer tube 202 becomes too great, piston 216 will engage seal head 222 to limit the amount of extension. At any time, the amount of extension may be varied by simply rotating adjustment knob 210 in the opposite direction, adjusting the position of inner tube 204 relative to outer tube 202 and then readjusting knob 210 to close the valve. In an alternative embodiment, the diameter of first shaft 240 may be the same both above and below piston 238. In such cases, the housing may hold an incompressible liquid, such as oil.

Another feature of telescoping tube arrangement 200 is that a fluid channel may be provided through second shaft 248, through first shaft 240, through spring rod 224, through piston 216 and into spring tube 214. As such, a valve may be provided within adjustment knob 210 to allow fluids to be introduced into and be withdrawn from spring tube 214. In this way, an independent passage runs through the fork leg to permit the pressure of the air spring to be adjusted from outside of the suspension system and at the same location where the travel adjustment may be made. Further, although not shown, it will be appreciated that a damping system could also be incorporated into telescoping tube arrangement in a manner similar to that described herein. As another alternative, spring rod 224 could also be configured to move within spring tube 214.

Hence, telescoping tube arrangement 200 includes a travel adjustment mechanism that is located on the exterior of the suspension system to control the maximum extended length of inner tube 204 relative to outer tube 202. Conveniently, this may be accomplished by utilizing a housing having two chambers that are filled with a pressurized fluid. The transfer of the fluid between these two chambers changes the effective length of the travel adjustment mechanism. Further, using different inner bore diameters in the travel adjustment mechanism, a biasing effect is produced that tends to separate the inner tube from the outer
tube when the adjustment knob is rotated to open the valve. Conveniently, the valve may be configured as a tapered seat to control the transfer of fluids between the two chambers.

[0077] Referring now to Figs. 17 and 17A, an alternative telescoping tube arrangement 300 will be described. Telescoping tube arrangement 300 is similar to arrangement 200 except that the position of the inner and outer tubes have been swapped. Telescoping tube arrangement 300 comprises an inner tube 302 that is configured to be coupled to a fork crown and an outer tube having a connector 306 to permit a wheel axle to be coupled to outer tube 304. Disposed within outer tube 304 is a spring tube 308 that is coupled at its bottom end to outer tube 308. A seal head 310 is coupled to the top end of spring tube 308. Disposed within spring tube 308 is a piston 312 that is coupled to a hollow rod 314. In turn, rod 314 is coupled to a travel adjustment mechanism 316 that may be constructed essentially identical to travel adjustment mechanism 226. As such, travel adjustment mechanism will not be described in detail.

[0078] Coupled to the top end of inner tube 302 is a top cap 316 to which travel adjustment mechanism 316 is coupled in a manner similar to that previously described with other embodiments. Extending out of top cap 316 is an adjustment knob 318 that may be used to adjust the amount of travel of the suspension system in a manner similar to that described with previous embodiments.

[0079] In operation, inner tube 302 slides within outer tube 204. To limit the amount of extension of inner tube 302 out of outer tube 204, adjustment knob 318 may be used to effectively shorten the length of the rod unit in a manner similar to that previously described. In so doing, the distance between piston 312 and seal head 310 is adjusted to limit the amount of travel.

[0080] The invention has now been described in detail for purposes of clarity and understanding. However, it will be appreciated that certain changes and modifications may be practiced within the scope of the appended claims.
WHAT IS CLAIMED IS:

1. A telescoping fork for the front wheel of a two wheeled vehicle, the fork comprising:
   a pair of outer tubes that each have a top end and a bottom end;
   an upper structural member connecting the outer tubes; and
   a lower structural member connecting the outer tubes, wherein the lower structural member is spaced below the upper structural member, wherein the upper structural member and the lower structural member are configured to be connected to a steering mechanism;
   wherein each outer tube tapers outwardly, both externally and internally, in a direction from the bottom end toward the lower structural member and from the top end toward the lower structural member.

2. A fork as in claim 1, wherein the lower structural member has a hollow box sectional shape.

3. A fork as in claim 1, further comprising a pair of inner tubes disposed to slide within the pair of outer tubes, wherein the inner tubes each have a bottom end and a top end, and wherein the bottom ends of the inner tubes extend out of the bottom ends of the outer tubes and are configured to connect to a wheel axle.

4. A fork as in claim 3, further comprising a single bushing disposed between each outer tube and each inner tube, wherein the bushings are located at the bottom ends of the outer tubes, and wherein the bushings have a length that is longer than a diameter of the inner tube.

5. A fork as in claim 3, further comprising a bracket disposed at the bottom end of each inner tube, wherein the brackets are adapted to clamp a front wheel axle to the inner tubes.

6. A fork as in claim 5, wherein at least one of the brackets has a mount for receiving a disk brake caliper.

7. A fork as in claim 1, further comprising a handle bar clamping device coupled to the upper structural member.
8. A fork as in claim 1, wherein the upper structural member incorporates a handle bar clamping device.

9. A fork as in claim 3, further comprising a fluid damping system disposed within at least one of the inner tubes.

10. A fork as in claim 9, wherein the fluid damping system comprises a hollow damper rod coupled to the top end of the outer tube and extending into the inner tube, a sealing member disposed to create a seal between the inner tube and the damper rod near the top end of the inner tube; and a damper piston valve coupled to the damper rod that seals against the inner tube.

11. A fork as in claim 10, wherein the fluid damping system further comprises a lock tube disposed within the damper rod, wherein the damper rod has at least one upper orifice and one lower orifice, and wherein the lock tube is rotatable from the top end of the outer tube to close the lower orifice, and further comprising a sleeve disposed over a top portion of the damper rod and the lock tube, wherein the sleeve is configured to close the upper orifice as the upper tube extends relative to the lower tube, such that further extension is prevented if the lower orifice is closed by the lock tube.

12. A fork as in claim 11, wherein the damper piston valve is a one-way valve that permits fluid flow in an upward direction upon compression of the inner tube into the outer tube.

13. A fork as in claim 3, wherein at least one of the inner tubes has a closed end, and further comprising a sealed piston inside the inner tube that is connected to a rod that extends and attaches to the top end of the outer tube, and a gas within the inner tube that is compressed by the piston to provide a biasing effect.

14. A fork as in claim 13, further comprising a spring disposed between the bottom end of the inner tube and the piston to provide a biasing effect.

15. A fork as in claim 13, wherein the rod is hollow to permit the gas pressure in the inner tube to be adjusted by a valve at the top end of the outer tube.
16. A fork as in claim 10, further comprising a stop positioned between the top of the outer tube and the top of the inner tube to stop compression of the inner tube into the outer tube.

17. A fluid damping system, comprising:
   a tube member having a closed end and an open end;
   a hollow damper rod extending through the open end of the tube member;
   a damper piston valve coupled to the damper rod and movable within the tube member, wherein the damper piston valve comprises a one-way valve that permits fluid flow in an upward direction upon compression;
   a sealing member disposed to create a seal between the tube member and the damper rod near the top end of the tube member;
   a sleeve disposed over a top portion of the damper rod;
   wherein the damper rod includes at least an upper orifice and a lower orifice that are located between the sealing member and the piston valve to permit fluid flow past the piston valve by passing through the damper rod during extension of the damper rod out of the tube member, wherein the lower orifice is manually closable, and wherein the sleeve is configured to close the upper orifice upon extension such that further extension is limited if the lower orifice is closed.

18. A system as in claim 17, further comprising a lock tube disposed within the damper rod, and wherein the lock tube is manually rotatable externally of the tube member to close the lower orifice to limit the amount of extension.

19. A system as in claim 18, wherein the sleeve comprises an extension of the sealing member.

20. A releasable clamp system for clamping a wheel axle of a wheel to a two wheeled vehicle, comprising:
   a frame member defining a shape that is adapted to receive a portion of the wheel axle;
   a cover plate pivotally attached to the frame member that is adapted to receive another portion of the wheel axle, wherein the cover plate is movable between a closed position where the frame member and the cover plate generally encompass and clamp the wheel axle, and an open position that permits removal of the wheel axle;
a lever pivotally attached to the cover plate; and
a hook member pivotally attached to the lever, where the hook member is
configured to hook onto the frame member and be pulled by the lever to secure the cover
plate to the frame member when the cover plate is moved to the closed position.

21. A clamp system as in claim 20, wherein the cover plate is pivotally
attached to the top of the frame member to permit the wheel axle to be vertically released
downward from the frame member.

22. A clamp system as in claim 20, wherein the frame member and the
cover plate each have inner surfaces that are adjacent to the wheel axle when the cover plate
is in the closed position, and wherein the inner surfaces and the wheel axle are each semi-
circular in geometry.

23. A clamp system as in claim 20, wherein the hook member is T shaped
in geometry, and wherein the frame member includes a shoulder with a slot into which the
hook member is receivable.

24. A clamp system as in claim 23, wherein the hook member comprises
two pieces that are threadably connected together such that the clamping force applied to the
wheel axle is adjustable by rotating the two pieces relative to each other.

25. A clamp system as in claim 20, wherein the cover plate is pivotally
attached to the frame member at a pivot point, wherein the lever is pivotally attached to the
cover plate at a pivot point, and further comprising torsion springs at each of the pivot points
to hold the cover plate in the open position when not clamping the wheel axle.

26. A clamp system as in claim 20, further comprising a mount on the
frame member that is adapted to mount a disk brake caliper to the frame member.

27. A suspension system for a vehicle, comprising:
a tube member having a closed end and an open end;
a seal head disposed at the open end of the tube member;
a rod unit passing through the seal head, wherein the rod has a top end and a
bottom end;
a piston coupled to the bottom end of the hollow rod unit so as to be disposed in the tube member; and

a travel adjustment mechanism operably coupled to the rod unit, wherein the travel adjustment mechanism is operable to adjust the position of the effective length of the rod unit and thereby adjust the amount of extension of the suspension system.

28. A system as in claim 27, further comprising an adjustment knob that is manipulatable to adjust the effective length of the rod unit.

29. A system as in claim 27, further comprising a telescoping tube arrangement operably coupled to the tube member, wherein the travel adjustment mechanism is operable control the amount of extension of the telescoping tube arrangement.

30. A system as in claim 29, wherein the telescoping tube arrangement comprises an outer tube having a top end and a bottom end and an inner tube coupled to the tube member, wherein the top end of the outer tube is coupled to the travel adjustment mechanism with a top cap, and wherein the inner tube is movable within the outer tube.

31. A system as in claim 29, wherein the telescoping tube arrangement comprises an outer tube and an inner tube having a top end and a bottom end, wherein the top end of the inner tube is coupled to the travel adjustment mechanism with a top cap, wherein the inner tube is movable within the outer tube, and wherein the tube member is coupled to the outer tube.

32. A system as in claim 27, further comprising a biasing material disposed within the tube member between the closed end and the piston, wherein the biasing material is selected from a group consisting of a spring or a gas.

33. A system as in claim 27, wherein the travel adjustment mechanism comprises a housing containing at least an amount of a pressurized gas, a first shaft extending through the housing and having a pair of spaced apart orifices, a piston coupled to the first shaft between the orifices to define an upper chamber and a lower chamber within the housing, and a second shaft and a valve disposed between the two orifices, wherein the second shaft is movable to open the valve and permit the pressured gas to flow between the upper chamber and the lower chamber through the two orifices.

34. A system as in claim 27, wherein the travel adjustment mechanism extends at least partially outside of the suspension system to permit adjustments to be made from outside of the suspension system.
35. A system as in claim 33, wherein the first shaft has an outer diameter above the piston that is larger than the an outer diameter below the piston such that when the valve is opened, a biasing effect is produced to lengthen the travel adjustment mechanism.

36. A system as in claim 35, wherein the first shaft includes a tapered seat that is positioned between the two orifices, and wherein the second shaft includes a tapered bottom end that engages the tapered seat to form the valve.

37. A system as in claim 27, wherein the rod unit is hollow, and wherein the travel adjustment mechanism, the hollow rod unit and the piston define a fluid flow passage into the tube member to permit the pressure within the tube member to be adjusted at the travel adjustment mechanism.

38. A suspension travel adjustment mechanism, comprising:
   a housing containing a fluid;
   a first shaft extending through the housing and having a pair of spaced apart orifices;
   a piston coupled to the first shaft between the orifices to define an upper chamber and a lower chamber within the housing;
   a second shaft; and
   a valve disposed between the two orifices, wherein the second shaft is movable to open the valve and permit the fluid to flow between the upper chamber and the lower chamber through the two orifices.

39. A mechanism as in claim 38, wherein the fluid comprises a pressurized gas, and wherein the first shaft has an outer diameter above the piston that is larger than the an outer diameter below the piston such that when the valve is opened, a biasing effect is produced to lengthen the travel adjustment mechanism.

40. A mechanism as in claim 39, wherein the first shaft includes a seat that is positioned between the two orifices, and wherein the second shaft includes a bottom end that engages the seat to form the valve.

41. A telescoping suspension system for a vehicle, the system comprising:
   a telescoping tube arrangement;
   a tube member operably coupled to the telescoping tube arrangement, the tube member having a closed end and an open end;
   a seal head disposed at the open end of the tube member;
   a rod unit passing through the seal head, wherein the rod unit has a top end and a bottom end;
a piston coupled to the bottom end of the rod unit so as to be disposed in the tube member; and

a travel adjustment mechanism operably coupled to the rod unit, wherein the travel adjustment mechanism is operable from outside of the telescoping tube arrangement to adjust the effective length of the rod unit thereby adjust the amount of extension of the telescoping tube arrangement.

42. A system as in claim 41, wherein the travel adjustment mechanism, the rod unit and the piston define a gas flow passage into the tube member from outside of the telescoping tube arrangement to permit a fluid to be introduced into or withdrawn from the tube member from outside of the telescoping tube arrangement.

43. A system as in claim 39, wherein the travel adjustment mechanism comprises a housing containing at least an amount of a pressurized gas, a first shaft extending through the housing and having a pair of spaced apart orifices, a piston coupled to the first shaft between the orifices to define an upper chamber and a lower chamber within the housing, a second shaft and a valve disposed between the two orifices, wherein the second shaft is movable to open the valve and permit the pressurized fluid to flow between the upper chamber and the lower chamber through the two orifices.

44. A system as in claim 43, wherein the first shaft has an outer diameter above the piston that is larger than the an outer diameter below the piston such that when the valve is opened, a biasing effect is produced to lengthen the travel adjustment mechanism.

45. A suspension travel adjustment mechanism, comprising:
a housing containing a fluid;
a shaft extending through the housing;
a piston coupled to the shaft to define an upper chamber and a lower chamber within the housing;
a fluid passageway extending between the upper chamber and the lower chamber; and

a means for selectively opening and closing the fluid passageway from outside of the housing permit the fluid to flow between the upper chamber and the lower chamber when the fluid passageway is opened.
