(54) Title: CIRCULAR STAPLER AND STAPLE HEAD ASSEMBLY THEREOF

(57) Abrégé/Abstract:

A circular stapler and a staple head assembly thereof are disclosed, and pertain to the technical field of medical instruments. The staple barrel of the staple head assembly comprises a tubular housing and an anti-expansion tube disposed in the housing, and the housing is provided with a first cavity for accommodating to-be-excised tissues, wherein, at least one opening communicating with the first cavity is arranged on the sidewall of the housing of staple barrel, and a distance from a distal end of the anti- expansion tube to the staple cartridge surface is larger than that from a distal end of the opening to the staple cartridge surface; and at least a part of the first cavity is exposed from the opening. Thus, the staple head assembly of present invention not only provides a larger view window during surgery, but also facilitates the pulling-in operation and accommodates more to-be-excised tissues.

ABSTRACT

A circular stapler and a staple head assembly thereof are disclosed, and pertain to the technical field of medical instruments. The staple barrel of the staple head assembly comprises a tubular housing and an anti-expansion tube disposed in the housing, and the housing is provided with a first cavity for accommodating to-be-excised tissues, wherein, at least one opening communicating with the first cavity is arranged on the sidewall of the housing of staple barrel, and a distance from a distal end of the anti-expansion tube to the staple cartridge surface is larger than that from a distal end of the opening to the staple cartridge surface; and at least a part of the first cavity is exposed from the opening. Thus, the staple head assembly of present invention not only provides a larger view window during surgery, but also facilitates the pulling-in operation and accommodates more to-be-excised tissues.

CIRCULAR STAPLER AND STAPLE HEAD ASSEMBLY THEREOF

Technical Field

The invention relates to a circular stapler and, more particularly, to a staple head
5 assembly of a circular stapler, which belongs to the technical field of medical instrument.

Background

It has been a history of more than 4,000 years for people to get the cognition of
hemorrhoid. Up to now, the conventional methods for treating internal hemorrhoid include
10 injection sclerotherapy, rubber band ligation and various kinds of surgical excisions. All these
methods are treatments against the hemorrhoid per se and intended to make the hemorrhoid
dwindled or disappeared. Among surgical excisions of hemorrhoid, a method named PPH
surgery is to perform a procedure for prolapse and hemorrhoids with the assistance of a
circular stapler.

15 US patent US6083241 discloses a circular stapler, as shown in Fig. 1, its staple head
assembly 40 includes an anvil 60 and a staple barrel 41 provided with a staple cartridge, a
staple pusher and staples inside, and the anvil 60 and the staple barrel 41 are disposed
oppositely. During surgery, the hemorrhoidal mucosa is pulled into the staple barrel 41, and is
cut annularly while the anastomosis is performed between the anvil 60 and staple barrel 41.
20 The opening on the housing of staple barrel 41 is significantly small, which can only be
served to form a passageway 42 for string guiding instrument 140 to pass through the staple
barrel 41 and to pull the purse-string sutured tissue into the staple barrel 41.

Currently, the staple barrel of commonly-used circular stapler, as the limitations in its
structure, may provide limited viewing window and operating space for surgeon during the
25 using process in surgery, which is bad for pulling-in operation on tissues. Besides, the
accommodating space of staple barrel is also too limited to accommodate more to-be-excised
tissues, which has great limitations, while a plurality of hemorrhoids need to be cut at one
time in surgery (such as TST surgery against a plurality of hemorrhoids).

In addition, according to the clinical experience of surgeons, if an overlong tissue is
30 pulled into the staple barrel, the postoperative performance may be not well. For example, it
can be

learned from medical knowledge that: a dentate annular line which can be seen at the commissure of anal canal skin and rectal mucosa and is enclosed by the edge of anal valves and the lower end of anal columns, is named dentate line. As the tissue structure above and below the dentate line are different, more than 85% of rectum and anus diseases occur near the dentate line. The dentate line is an induction area of defecation reflex, so when the excrement arrives at the anal canal via the rectum, the nerve terminal receptor at dentate line area will be stimulated and then make the anal canal open reflectively to discharge the excrement. If the tissues pulled in are too long to lead to excise dentate line in surgery, it will cause decreased defecation reflex on postoperative patient, which may make some adverse reactions such as constipation or sensory fecal incontinence occurred.

However, the conventional circular stapler only has scale indication for indicating the depth of stapler into anus on the outer surface of staple barrel (such as reference numeric 49 in Fig. 1), which can't provide criterion for surgeon to estimate the amount of hemorrhoid mucosa tissues pulled into staple barrel. As a result, the amount and depth of mucosa tissues pulled into staple barrel cannot be determined, which may cause too many tissues pulled into staple barrel to make poor postoperative performance on patients.

Summary

An object of the invention is to provide a circular stapler and the staple head assembly thereof, which can obtain large view window, large capacity and high operation convenience.

Another object of the invention is to provide a circular stapler and the staple head assembly thereof, which have the indicator function for indicating the depth of to-be-excised tissues pulled in to avoid too many tissues to be pulled in.

The object of the invention is realized by the technical solutions as follows:

A staple head assembly of circular stapler, comprising:

a staple barrel assembly including a staple barrel, a staple pusher arranged inside said staple barrel and a staple cartridge fixed at a distal end of said staple barrel; the distal end of said staple barrel assembly being a staple cartridge surface; said staple barrel comprising a tubular housing, an anti-expansion tube disposed in said housing and a stiffener connected between said housing and said anti-expansion tube; said housing being provided with a first

cavity for accommodating to-be-excised tissues, and a proximal end of said housing being configured for connecting with a body of said circular stapler, and a distal end of said housing being configured for mounting said staple cartridge; wherein, at least one opening communicating with said first cavity is arranged on sidewall of said housing of staple barrel, and a distance from a distal end of said anti-expansion tube to said staple cartridge surface is larger than that from a distal end of said opening to said staple cartridge surface, and at least a part of said first cavity is exposed from said opening; and

an anvil assembly including an anvil ring and an anvil shaft which are fixedly connected to each other, said anvil shaft being capable of sliding in said anti-expansion tube along a longitudinal direction .

Preferably, said housing comprises a first part with the distal end of housing and a second part with the proximal end of housing, and a diameter of said first part is larger than that of said second part, and a proximal end of said first part is connecting to a distal end of said second part in a tapered way.

Preferably, said housing of staple barrel is provided with a plurality of openings symmetrical about the longitudinal axis of said housing, and one said stiffener is correspondingly disposed between every two adjacent openings.

Preferably, in the cross-section of said housing of staple barrel, a circular arc length of said opening is larger than that of a connecting portion between two adjacent openings.

Preferably, the proximal end of said anti-expansion tube extends to be close to the proximal end of said housing, and the proximal end of said anvil shaft which is adaptable with said anti-expansion tube also extends to be close to the proximal end of said housing.

Preferably, the distance from the distal end of said anti-expansion tube to said staple cartridge surface is less than that from the proximal end of said opening to said staple cartridge surface, and the distance from the proximal end of said anti-expansion tube to said staple cartridge surface is larger than that from the proximal end of the opening to said staple cartridge surface.

Preferably, at least one guiding slot is arranged in a through-hole of said anti-expansion tube, and said anvil shaft is provided with at least one guiding rib accordingly, which is capable of sliding in said guiding slot.

Preferably, said stiffener extends along the longitudinal direction from the proximal end of said anti-expansion tube to beyond the distal end of said anti-expansion tube and to be close to said staple cartridge.

Preferably, the shape of said staple pusher is made to be adaptable with said staple barrel,
5 and a second cavity arranged inside said staple pusher is aligned with said first cavity of said staple barrel.

Preferably, said staple pusher comprises: a pusher ring at the distal end; a plurality of supporting plates extending along the longitudinal direction from said pusher ring to the proximal end in a tapered way; and a plurality of insertion sheets in long-stripe shape which are
10 connected between two adjacent supporting plates and separated from each other; wherein said plurality of supporting plates are engaged with the corresponding said stiffeners and arranged to form said second cavity, and said plurality of insertion sheets in long-stripe shape are respectively inserted to an insertion space which is enclosed by said anti-expansion tube, said housing and two adjacent stiffeners.

15 Preferably, the distance from the distal end of said insertion sheets to said staple cartridge surface is larger than that from the distal end of said opening to said staple cartridge surface, and at least a part of second cavity is exposed from said opening.

Preferably, the distance from the distal end of said opening to said staple cartridge surface is less than or equal to 32mm.

20 Preferably, the distance from the distal end of said opening to said staple cartridge surface is larger than or equal to 20mm, and less than or equal to 32mm.

Preferably, the distance from the distal end of said opening to said staple cartridge surface is 30mm.

Preferably, the distal end of said opening is provided with an indicator line.

25 A circular stapler, comprising a body and a staple head assembly connected with the distal end of said body, where the staple head assembly is as above described.

Compared with the prior art, beneficial effects of the embodiments of the invention mainly include:

1) by arranging opening(s) which can be communicating with the first cavity of the staple
30 barrel in the staple barrel, with the distance from the distal end of the anti-expansion tube to the

staple cartridge surface being larger than that from the distal end of the opening(s) to the staple cartridge surface, at least a part of first cavity can be exposed from the opening(s), which can thusly not only provide a larger view window during surgery, but also facilitate the pulling-in operation on tissues and accommodate more to-be-excised tissues;

- 5 2) the distance from the distal end of the opening(s) of the staple barrel to the staple cartridge surface is less than or equal to 32mm, which can thusly allow the surgeon to take the distal end of the opening(s) as a criterion determining the depth of tissues pulled in during surgery to avoid too long tissues pulled in to affect the surgery effect.

Detailed description

Hereinafter, embodiments are described in detail with reference to the accompanying drawings. The term “distal end” and “proximal end” used in the description are described
20 relative to the position of surgeon, wherein, the “distal end” is the end away from surgeon, and the “proximal end” is the end close to surgeon, which is opposite to the distal end.

The first embodiment

As shown in Fig. 2, Fig. 3A and Fig. 3B, a circular stapler, provided by the embodiment of the present invention, comprises a body 1, a first actuating mechanism (not shown) and a second
25 actuating mechanism (not shown) which are arranged on the body 1, and a staple head assembly 2 connected to the distal end of body 1.

The staple head assembly 2 of the embodiment of the invention at least includes a staple barrel assembly 3 and an anvil assembly 5 which are disposed oppositely. The anvil assembly 5 includes an anvil ring 51 and an anvil shaft 52 which are fixedly connected to each other. The
30 anvil assembly 5 may be driven by the first actuating mechanism (not shown) to move along the

longitudinal direction of circular stapler relative to the staple barrel assembly 3, between a first position away from the staple barrel assembly 3 and a second position close to the staple barrel assembly 3. When the anvil assembly 5 is in the first position, it is convenient for pulling the to-be-excised tissues into the staple barrel 31, and when the anvil assembly 5 is in the second position, the tissues in the staple barrel 31 can be stapled and excised.

The staple barrel assembly 3 at least includes a staple barrel 31, a staple cartridge 32 fixed at the distal end of staple barrel 31, and a staple pusher 33 arranged inside the staple barrel 31. The staple pusher 33 moves along the longitudinal direction of circular stapler with the function of the second actuating mechanism, to fire the staples in staple cartridge 32 to the to-be-excised tissues in staple barrel 31, which can get the tissues stapled and sutured. The staple cartridge 32 is fixed at the distal end of staple barrel 31, thereby the distal end surface of the staple barrel assembly 3 is the staple cartridge surface 320, which is disposed oppositely as to the anvil ring 51.

As shown in FIG. 4A to Fig. 4F, the staple barrel 31 includes a tubular housing 311, an anti-expansion tube 315 disposed in the tubular housing 311 and a stiffener 316 connected between the tubular housing 311 and the anti-expansion tube 315. Preferably, in this embodiment, the tubular housing 311, the anti-expansion tube 315 and the stiffener 316 are integrally molded.

The housing 311 includes a first cavity 310 for accommodating the to-be-excised tissues. The distal end 311c of housing 311 is configured for mounting the staple cartridge 32, and the proximal end 311d of housing 311 is configured for connecting the body 1 of circular stapler. Preferably, in this embodiment, the housing 311 includes a first part 311a provided with the distal end 311c of housing and a second part 311b provided with the proximal end 311d of housing. The diameter of the first part 311a is larger than that of the second part 311b, and the proximal end of the first part 311a is connected to the distal end of the second part 311b in a tapered way.

At least one opening 313 communicating with the first cavity 310 is arranged on the sidewall of said housing 311, which is for surgeons to observe the situation of tissues pulled-in. Preferably, in this embodiment, the sidewall of housing 311 of staple barrel 31 is provided with four openings 313 symmetrical about the longitudinal axis of housing 311, as a result that the

openings 313 in four directions may provide better multi-direction windows for medical workers during surgery. Of course, the amount of openings 313 are not limited thereof, and it may also be one, two, three or more. In the cross-section of the housing of the staple barrel 31, the circumferential arc length 313a corresponding to the opening 313 is larger than the circumferential arc length 314a corresponding to the connecting portion 314 between two adjacent openings. Thus, such large openings may provide the surgeon excellent viewing angle during surgery. Preferably, in this embodiment, as shown in Fig. 4B and Fig. 4D, the circumferential arc length corresponding to each opening 313 is roughly equal to 1/4 of circumferential length of the housing 311.

The anti-expansion tube 315 includes a through-hole 3151 to allow the anvil shaft 52 of anvil assembly 5 to slide through. In a preferred embodiment, the through-hole 3151 of anti-expansion tube 315 is disposed with two guiding slots 3152 therein (as shown in Fig. 4D and Fig. 4E), and the anvil shaft 52 is provided with two guiding ribs 521 (as shown in Fig. 2), each of which may slide in the corresponding guiding slots 3152. The number of pairs of guiding slot and guiding rib may be not limited to two, and it can be one or more than two. To accommodate more to-be-excised tissues within the housing 311 and provide larger operating space for the instruments such as the string guiding instrument to facilitate the pulling-in operation of tissues, the distance from the distal end 315c of anti-expansion tube 315 to the staple cartridge surface 320 is larger than that from the distal end 313c of opening 313 to the staple cartridge surface 320, that is to say, the distance from the distal end 315c of anti-expansion tube 315 to the proximal end 311d of housing 311 is less than that between the farthest edge (that is the distal end) 313c of opening 313 and the proximal end 311d of housing 311, thus at least a part of first cavity 310 is exposed from the opening 313. Preferably, in this embodiment, the distance from the distal end 315c of anti-expansion tube 315 to the staple cartridge surface 320 is less than that from the proximal end 313d of opening 313 to the staple cartridge surface 320, and the distance from the proximal end 315d of anti-expansion tube 315 to the staple cartridge surface 320 is larger than that from the proximal end 313d of opening 313 to the staple cartridge surface 320. Such structure is benefit for the sliding stability of the anvil shaft 52 sliding in the anti-expansion tube 315 along a longitudinal direction. However, the invention is not limited thereto, for example, the anti-expansion tube in whole may also

correspond to the second part of the housing, that is the distance from the distal end of anti-expansion tube to the staple cartridge surface is larger than that from the proximal end of opening to the staple cartridge surface.

Both the distal ends of the stiffener 316 and the anti-expansion tube 315 in present invention are relatively lower than those in prior art in which both the distal ends of stiffener and anti-expansion tube are close to the staple cartridge surface. To compensate for shortage in axial and circumferential strength resulted by lowering of anti-expansion tube 13, the proximal end 315d of anti-expansion tube 315 in the invention is made to extend as compared with that in prior art, and also the anvil shaft 52 is lengthened (which equals to an extension of proximal end) to increase the adaption and connection between the anvil shaft 52 and the anti-expansion tube 315. To be specific, the proximal end 315d of anti-expansion tube 315 extends to be close to the proximal end 311d of housing 311, and the proximal end of anvil shaft 52 being adaptable with the anti-expansion tube 315 also extends to be close to the proximal end 311d of the housing 311.

The stiffener 316 is mainly served for connecting the tubular housing 311 and the anti-expansion tube 315. In this preferred embodiment, since the housing 311 is provided with a plurality of openings 313, a long-plane-shaped stiffener 316 can be arranged correspondingly on the inner wall of the connecting portion 314 which is mounted between two adjacent openings on the housing 311, to fix the anti-expansion tube 315 in the housing 311 correspondingly. Among the anti-expansion tube 315, the housing 311 and two adjacent stiffeners 316, there is an insertion space 317 enclosed (as shown in Fig. 4C) for the insertion sheet 333 of the staple pusher 33 (illustrated hereinafter) to insert into. In this preferred embodiment, the stiffener 316 extends from the proximal end 315d of the anti-expansion tube 315 along the longitudinal direction to beyond the distal end 315c of anti-expansion tube 315, and to get close to the staple cartridge 32. That is, the proximal end of stiffener 316 is basically aligned with the proximal end 315d of anti-expansion tube 315, however the distal end of the stiffener 316 extends to be more close to the staple cartridge surface 320 than the distal end 313c of the opening 313. Such arrangement is benefit for improving the strength of the housing 311 of staple barrel 31. The amount, length and placement of the stiffeners may be varied in many ways. For example, each stiffener may be placed on the outer wall of the anti-expansion tube continuously or

discontinuously.

As shown in Fig. 5A to Fig. 5C, the shape of staple pusher 33 may be made to match with the staple barrel 31. Specifically, the staple pusher 33 includes: a pusher ring 331 at the distal end, a plurality of supporting plates 332 extending from the pusher ring 331 to the proximal end along the longitudinal direction in a tapered way, and a plurality of long-striped insertion sheet 333 connected between two adjacent supporting plates 332 and separated from each other. In the staple pusher 33, there is a second cavity 330 (that is an inner space which is formed by being embraced with a plurality of supporting plates 332), which is aligned to the first cavity 310 of staple barrel 31. A plurality of long-striped insertion sheet 333 are inserted into the insertion space 317 of staple barrel 31 to form a tubular like structure surrounding around the periphery of anti-expansion tube 315. In this preferred embodiment, to accommodate more to-be-excised tissues and provide larger operating space for the instrument such as the string guiding instrument to facilitate the pulling-in operation of tissues, similar with the corresponding structure of anti-expansion tube 315, the distance from the distal end of insertion sheet 333 to the staple cartridge surface 320 is larger than that from the distal end of opening 313 to the staple cartridge surface 320, and at least a part of second cavity 330 is exposed from the opening 313.

Each supporting plate 332 corresponds to each stiffener 316 in the staple barrel 31, and each supporting plate 332 is provided with a slot 3321 capable of engaging on the outside surface of the stiffener 316 correspondingly. The engaging way between the stiffener and the supporting plate may be changed to: the stiffener of the staple barrel is provided with a slot, and the supporting plate of staple pusher can be engaged into the slot of the stiffener. The engaging fixation way between the stiffener and the supporting plate is benefit for improving the stableness of the staple pusher 33 in the staple barrel 31. Obviously, the stiffener and the supporting plate may employ other fixation way. In addition, in this embodiment, after the supporting plate 332 of staple pusher 33 and the stiffener 316 of staple barrel 31 are assembled, the proximal edge 3322 of the supporting plate 332 abuts against the inner side of the housing 311 of staple barrel 31.

Hereinafter, taking the surgery of excising hemorrhoid tissues for example, the operating method of the circular stapling instrument in this embodiment of the invention will be illustrated

with Fig. 6 as: after a purse-string suture is performed on the to-be-excised hemorrhoid tissues 7, place the circular stapler which is under the condition that the anvil ring 51 and the staple cartridge 32 are far away from each other into an anoscope 8; afterwards, apply the string guiding instrument to insert into the space between the anvil ring 51 and the staple cartridge 32 from the opening 313 of staple barrel 31 and to pull the purse string to get the to-be-excised hemorrhoid tissues 7 pulled into the accommodating space (the first cavity and the second cavity) of circular stapler; and then, adjust the first actuating mechanism of circular stapler to make the distance from the staple cartridge 32 to the anvil ring 51 reduced until the anvil ring 51 and the staple cartridge 32 clap the to-be-excised hemorrhoid tissues 7 tightly; subsequently, operate the second actuating mechanism of circular stapler and fire the staple in the staple cartridge 32 to the tissues by using the staple pusher 33 to perform stapling and suturing and to excise the tissues at the same time. The application of the circular stapler in this embodiment of the invention is not limited to excise the hemorrhoid tissues, but also may be used to excise other tissues in the anorectal surgery.

15 **Second embodiment**

As shown in Fig. 7, one difference from the first embodiment is, in the staple barrel 31' of second embodiment, one end of opening 313 (the distal end or edge of opening) close to the staple cartridge surface 320 is provided with an indicator line 9, which is convenient for the surgeon with different models of circular stapler to get to know the value of distance L from the distal end of opening to the staple cartridge surface. The distance L from the indicator line 9 to the staple cartridge surface 320 may be, for example, greater than or equal to 20mm, and less than or equal to 32mm, and preferable it can be 30mm to obtain the best clinical effect. The indicator line 9 may be realized in various ways, which includes directly printing the indicator line at the opening of the staple barrel 31' and marking the corresponding distance value such as 20mm, 30mm or 32mm and so on. Thusly, before the surgery, the surgeon may know the distance from the opening to the staple cartridge surface in such stapler according to the value indicated by the indicator line 9. During the operation process of surgery, the doctor may take the distal end of opening in the staple barrel as a criterion determining the depth of tissues pulled in to avoid too long tissues pulled in to affect the surgery effect.

30 The other difference from the first embodiment is, the proximal edge 3322' of supporting

plate 332' of staple pusher 33' may not abut against the housing 311 of staple barrel 31'.

The above description only illustrates preferred embodiments of the invention, which can't be used for limiting the scope of the invention. Therefore, any other equivalent deformations or modifications without departing from the spirit of the invention are intended to be included in
5 the scope of invention.

CLAIMS:

1. A staple head assembly of circular stapler, comprising:

5 a staple barrel assembly including a staple barrel, a staple pusher arranged inside said staple barrel and a staple cartridge fixed at a distal end of said staple barrel; the distal end of said staple barrel assembly being a staple cartridge surface; said staple barrel comprising a tubular housing, an anti-expansion tube disposed in said housing and a stiffener connected between said housing and said anti-expansion tube; said housing being provided with a first cavity for accommodating to-be-excised tissues, and a proximal end of said housing being configured for connecting with a body of said circular stapler, and a distal end of said housing
10 being configured for mounting said staple cartridge; wherein, at least one opening communicating with said first cavity is arranged on sidewall of said housing of staple barrel, and a distance from a distal end of said anti-expansion tube to said staple cartridge surface is larger than that from a distal end of said opening to said staple cartridge surface, and at least a part of said first cavity is exposed from said opening; and

15 an anvil assembly including an anvil ring and an anvil shaft which are fixedly connected to each other, and said anvil shaft is configured for sliding in said anti-expansion tube along a longitudinal direction .

2. The staple head assembly of circular stapler according to claim 1, wherein said housing comprises a first part with the distal end of housing and a second part with the proximal end of housing, and a diameter of said first part is larger than that of said second
20 part, and a proximal end of said first part is connecting to a distal end of said second part in a tapered way.

3. The staple head assembly of circular stapler according to claim 1, wherein said housing of staple barrel is provided with a plurality of openings symmetrical about the longitudinal axis of said housing, and one said stiffener is correspondingly disposed between
25 every two adjacent openings.

4. The staple head assembly of circular stapler according to claim 3, wherein, in the

cross-section of said housing of staple barrel, a circular arc length of said opening is larger than that of a connecting portion between two adjacent openings.

5 5. The staple head assembly of circular stapler according to claim 1, wherein a proximal end of said anti-expansion tube extends to be close to the proximal end of said housing, and the proximal end of said anvil shaft which is adaptable with said anti-expansion tube also extends to be close to the proximal end of said housing.

10 6. The staple head assembly of circular stapler according to claim 1, wherein the distance from the distal end of said anti-expansion tube to said staple cartridge surface is less than that from the proximal end of said opening to said staple cartridge surface, and the distance from the proximal end of said anti-expansion tube to said staple cartridge surface is larger than that from the proximal end of the opening to said staple cartridge surface.

7. The staple head assembly of circular stapler according to claim 1, wherein at least one guiding slot is arranged in a through-hole of said anti-expansion tube, and said anvil shaft is provided with at least one guiding rib for sliding in said guiding slot.

15 8. The staple head assembly of circular stapler according to claim 1, wherein said stiffener extends along the longitudinal direction from a proximal end of said anti-expansion tube to beyond the distal end of said anti-expansion tube and to be close to said staple cartridge.

20 9. The staple head assembly of circular stapler according to claim 1, wherein the shape of said staple pusher is made to be adaptable with said staple barrel, and a second cavity arranged inside said staple pusher is aligned with said first cavity of said staple barrel.

25 10. The staple head assembly of circular stapler according to claim 9, wherein said staple pusher comprises: a pusher ring at the distal end; a plurality of supporting plates extending along the longitudinal direction from said pusher ring to the proximal end in a tapered way; and a plurality of insertion sheets in long-stripe shape which are connected between two adjacent supporting plates and separated from each other; wherein said plurality of supporting plates are engaged with the corresponding said stiffeners and arranged to form said second

cavity, and said plurality of insertion sheets in long-stripe shape are respectively inserted to an insertion space which is enclosed by said anti-expansion tube, said housing and two adjacent stiffeners.

11. The staple head assembly of circular stapler according to claim 10, wherein a
5 distance from a distal end of said insertion sheets to said staple cartridge surface is larger than that from the distal end of said opening to said staple cartridge surface, and at least a part of second cavity is exposed from said opening.

12. The staple head assembly of circular stapler according to claim 1, wherein the
distance from the distal end of said opening to said staple cartridge surface is less than or
10 equal to 32mm.

13. The staple head assembly of circular stapler according to claim 12, wherein the
distance from the distal end of said opening to said staple cartridge surface is larger than or
equal to 20mm, and less than or equal to 32mm.

14. The staple head assembly of circular stapler according to claim 13, wherein the
15 distance from the distal end of said opening to said staple cartridge surface is 30mm.

15. The staple head assembly of circular stapler according to claim 1, wherein the distal
end of said opening is provided with an indicator line for indicating a distance value from the
distal end of said opening to said staple cartridge surface.

16. A circular stapler, comprising: a body; and a staple head assembly according to any
20 one of claims 1-15, connected with the distal end of said body.
