Introduction

Infections caused by or related to bacteria are a major cause of human illness worldwide, and the frequency of resistance to standard antibiotics has risen dramatically over the last decade. Hence, there exists an unmet medical need and demand for new agents acting against bacterial targets.

Examples of potential bacterial targets are those enzymes involved in fatty acid biosynthesis. While the overall pathway of saturated fatty acid biosynthesis is similar in all organisms, the fatty acid synthase (FAS) systems vary considerably with respect to their structural organization. It is believed that vertebrates and yeast possess a FAS in which all the enzymatic activities are encoded on one or two polypeptide chains, respectively, and the acyl carrier protein (ACP) is an integral part of the complex. In contrast, in bacterial FAS, it is known that each of the reactions is catalyzed by a distinct, mono-functional enzyme and the ACP is a discrete protein. Therefore, it may be possible to achieve selective inhibition of the bacterial system by appropriate agents.

One such potential bacterial target is the FabI protein. FabI (previously designated EnvM) is believed to function as an enoyl-ACP reductase in the final step of the four reactions involved in each cycle of bacterial fatty acid biosynthesis. It is believed that in this pathway, the first step is catalyzed by β-ketoacyl-ACP synthase, which condenses malonyl-ACP with acetyl-CoA (FabH, synthase III). It is believed that in subsequent rounds, malonyl-ACP is condensed with the growing-chain acyl-ACP (FabB and FabF, synthases I and II, respectively). The second step in the elongation cycle is thought to be ketoester reduction by NADPH-dependent β-ketoacyl-ACP reductase (FabG). Subsequent dehydration by β-hydroxyacyl-ACP dehydrase (either FabA or FabZ) leads to trans-2-enoyl-ACP. Finally, in step four, trans-2-enoyl-ACP is converted to acyl-ACP by an NADH (or NADPH)-dependent enoyl-ACP reductase (FabI). Further rounds of this cycle, adding two carbon atoms per cycle, would eventually lead to palmitoyl-ACP (16C), where upon
the cycle is stopped largely due to feedback inhibition of FabI by palmitoyl-ACP. Thus, FabI is believed to be a major biosynthetic enzyme and is a key regulatory point in the overall synthetic pathway of bacterial fatty acid biosynthesis.

In some bacteria it is believed that the final step of fatty acid biosynthesis is catalyzed by FabI only, in others by FabK, an NADH and FMN dependent reductase, still others utilize both FabI and FabK.

The present invention provides, in part, compositions with FabI inhibiting properties.

**Summary of Invention**

In part, the present invention is directed towards compositions comprising a FabI inhibitor and at least one other antibiotic agent. The ratio between the FabI inhibitor and the at least one other antibacterial agent may vary within relatively broad ranges and will be dependent on the intended use. It is contemplated that the compositions of the present invention may comprise a ratio in the range of about 0.01:1 to 1:100 between the FabI inhibitor and the antibiotic agent. In certain embodiments, the two or more agents in the subject compositions work synergistically.

In one embodiment, the present invention relates to antibacterial compositions comprising a compound of formulas I-III and at least one other antibacterial compound. In certain embodiments, the compound of formulas I-III and the at least one other antibacterial compound exhibit a synergistic antibacterial effect. That is, fractional amounts of the MIC of each compound are combined such that the total amount is still less than one times the MIC of either compound, and the antibacterial composition of the present invention still inhibits bacterial growth. As a non-limiting example, the antibacterial compositions of the present invention may comprise a compound of formula I at half its MIC and another antibacterial compound at a quarter of its MIC, with the combined composition inhibiting bacterial growth. Other examples using other fractional amounts can be envisioned by of ordinary skill in the art.

In one embodiment, the dosage amount of the at least one other antibiotic agent in the compositions of the present invention is about half the dosage amount when the FabI inhibitor is absent. In another embodiment, the amount of the at least one other antibiotic agent is less than about half of the amount in the dosage when the FabI inhibitor is absent. In another embodiment, the amount of the at least one other antibiotic agent is less than about a quarter of the amount in the dosage when the FabI inhibitor is absent. In another
embodiment, the amount of the at least one other antibiotic agent is less than about a tenth of the amount in the dosage when the FabI inhibitor is absent.

In part, the present invention is directed towards compositions that will affect multiple species, so-called “wide spectrum” anti-bacterials. Alternatively, subject compositions that are selective for one or more bacterial or other non-mammalian species, and not for one or more mammalian species (especially human), may be identified.

In one embodiment, the dosage amount of the FabI inhibitor in the compositions of the present invention is about half the dosage amount when the at least one other antibiotic agent is absent. In another embodiment, the amount of the FabI inhibitor is less than about half of the amount in the dosage when the at least one other antibiotic agent is absent. In another embodiment, the amount of the FabI inhibitor is less than about a quarter of the amount in the dosage when the at least one other antibiotic agent is absent. In another embodiment, the amount of the FabI inhibitor is less than about a tenth of the amount in the dosage when the at least one other antibiotic agent is absent.

The subject compositions may be administered by one of a variety of means known to those of skill in the art.

Whole-cell antimicrobial activity for the antibacterial compositions of the present invention may be determined by broth microdilution using the National Committee for Clinical Laboratory Standards (NCCLS) recommended procedure, Document M7-A4, “Methods for Dilution Susceptibility Tests for Bacteria that Grow Aerobically”. The compositions of the present invention may be tested in serial two-fold dilutions ranging from, for example, 0.06 to 64 mcg/mL. A panel of up to 12 or more bacterial strains may be evaluated in the assay. A panel may consist of, for example, the following laboratory strains: *Staphylococcus aureus* Oxford, *Streptococcus pneumoniae* R6, *Streptococcus pyogenes* CN10, *Enterococcus faecalis* I, *Haemophilus influenzae* Q1, *Escherichia coli* DC0, *E. coli* ESS, *E. coli* 7623 (AcrAB<sup>T</sup>) *E. coli* 120 (AcrAB<sup>−</sup>) *Klebsiella pneumoniae* E70, *Pseudomonas aeruginosa* K799wt and *Candida albicans* GRI 681. The minimum inhibitory concentration (MIC) may then be determined as the lowest concentration of the subject composition that inhibited visible growth. A mirror reader may be used to assist in determining the MIC endpoint.

In one embodiment, the antibacterial compositions of the present invention have a MIC of less than 256 µg/mL. In other embodiments, the antibacterial compositions of the
present invention may have a MIC value of less than 128 μg/mL, or even less than 64 μg/mL.

_Detailed Description of Invention_

_Introduction_

The present invention is directed in part towards novel compositions that inhibit bacterial enzymes, and methods of making and using the same. In certain aspects, inhibitors and other compounds of the invention may be found by a structure-guided medicinal chemistry effort.

Bacterial fatty acid biosynthesis is believed to proceed via a Type II or dissociated fatty acid synthase system, in contrast to the mammalian Type I system. The overall process is believed to proceed in two stages — initiation and cyclic elongation. Enoyl-ACP reductase is part of the elongation cycle, in which malonyl-ACP is condensed with a growing acyl chain by β-ketoacyl-ACP synthase (FabB, FabF, FabH). The β-ketoester is reduced by β-ketoacyl-ACP reductase, which is then dehydrated to the trans-unsaturated acyl-ACP. The trans-unsaturated acyl-ACP is then reduced by enoyl-ACP reductase. (See Figure 1).

The enoyl-ACP reductase step is believed to be accomplished by FabI in _E. coli_ and other gram negative organisms and _Staphylococci_. In certain gram-positive organisms, FabI paralogs exist. In _Streptococcus pneumoniae_, the enzymatic step is believed to be accomplished by the FabK protein. In _B. subtilis_ and _E. faecalis_, genes encoding both FabI and FabK exist. In _Mycobacterium tuberculosis_ a FabI paralog termed InhA exists.
Enoyl-ACP reductase is believed to be the enzymatic target of the antimicrobial product triclosan.

In certain embodiments, the design of new analogs having FabI inhibiting properties is based on viewing the analogs as consisting of a central acrylamide flanked by two relatively hydrophobic groups, conveniently denoted as left-hand side (LHS) and right-hand side (RHS). Schematically this is depicted in Figure 2, where a dumbbell like structure provides one way of viewing certain of the subject compositions (the central bond disconnections that is envisioned in a retrosynthetic sense are shown with dashed lines).

If, for instance, a particular enantiomer of compound of the present invention is desired, it may be prepared by asymmetric synthesis, or by derivation with a chiral auxiliary, where the resulting diastereomeric mixture is separated and the auxiliary group cleaved to provide the pure desired enantiomers. Alternatively, where the molecule contains a basic functional group, such as amino, or an acidic functional group, such as carboxyl, diastereomeric salts are formed with an appropriate optically-active acid or base, followed by resolution of the diastereomers thus formed by fractional crystallization or chromatographic means well known in the art, and subsequent recovery of the pure enantiomers.

It will be understood that “substitution” or “substituted with” includes the implicit proviso that such substitution is in accordance with permitted valence of the substituted atom and the substituent, and that the substitution results in a stable compound, e.g., which does not spontaneously undergo transformation such as by rearrangement, cyclization, elimination, or other reaction.

The term “substituted” is also contemplated to include all permissible substituents of organic compounds. In a broad aspect, the permissible substituents include acyclic and cyclic, branched and unbranched, carbocyclic and heterocyclic, aromatic and nonaromatic substituents of organic compounds. For purposes of this invention, the heteroatoms such as nitrogen may have hydrogen substituents and/or any permissible substituents of organic compounds described herein which satisfy the valences of the heteroatoms. The term “electron-withdrawing group” is art-recognized, and refers to the tendency of a substituent to attract valence electrons from neighboring atoms, i.e., the substituent is electronegative with respect to neighboring atoms. A quantification of the level of electron-withdrawing capability is given by the Hammett sigma (σ) constant. This well known constant is described in many references, for instance, March, Advanced Organic Chemistry 251-59 (McGraw Hill Book Company: New York, 1977). The Hammett constant values are generally negative for electron donating groups (σ(P) = -0.66 for NH₂) and positive for electron withdrawing groups (σ(P) = 0.78 for a nitro group), σ(P) indicating para substitution. Exemplary electron-withdrawing groups include nitro, acyl, formyl, sulfonyl, trifluoromethyl, cyano, chloride, and the like. Exemplary electron-donating groups include amino, methoxy, and the like.

The term “amino acid” is art-recognized and refers to all compounds, whether natural or synthetic, which include both an amino functionality and an acid functionality, including amino acid analogs and derivatives.

The term “amino acid residue” further includes analogs, derivatives and congeners of any specific amino acid referred to herein, as well as C-terminal or N-terminal protected amino acid derivatives (e.g. modified with an N-terminal or C-terminal protecting group).

The names of the natural amino acids are abbreviated herein in accordance with the recommendations of IUPAC-IUB.

A “reversed” or “retro” peptide sequence as disclosed herein refers to that part of an overall sequence of covalently-bonded amino acid residues (or analogs or mimetics thereof) wherein the normal carboxyl-to amino direction of peptide bond formation in the amino
acid backbone has been reversed such that, reading in the conventional left-to-right
direction, the amino portion of the peptide bond precedes (rather than follows) the carbonyl

The reversed orientation peptides described herein include (a) those wherein one or
more amino-terminal residues are converted to a reversed ("rev") orientation (thus yielding
a second "carboxyl terminus" at the left-most portion of the molecule), and (b) those
wherein one or more carboxyl-terminal residues are converted to a reversed ("rev")
orientation (yielding a second "amino terminus" at the right-most portion of the molecule).
A peptide (amide) bond cannot be formed at the interface between a normal orientation
residue and a reverse orientation residue.

Therefore, certain reversed peptide compounds of the invention may be formed by
utilizing an appropriate amino acid mimic moiety to link the two adjacent portions of the
sequences depicted above utilizing a reversed peptide (reversed amide) bond.

The reversed direction of bonding in such compounds will generally, in addition,
require inversion of the enantiomeric configuration of the reversed amino acid residues in
order to maintain a spatial orientation of side chains that is similar to that of the non-
reversed peptide. The configuration of amino acids in the reversed portion of the peptides is
usually (D), and the configuration of the non-reversed portion is usually (L). Opposite or
mixed configurations are acceptable when appropriate to optimize a binding activity.

The term “nucleic acid” is art-recognized and refers to polynucleotides such as
deoxyribonucleic acid (DNA), and, where appropriate, ribonucleic acid (RNA). The term
should also be understood to include, as equivalents, analogs of either RNA or DNA made

genome or the like which includes an “coding sequence” for a polypeptide or which is
otherwise transcribable to a biologically active RNA (e.g., antisense, decoy, ribozyme, etc),
can transfecct cells, in certain embodiments mammalian cells, and may cause expression of
the coding sequence in cells transfected with the construct.
The term “homology” is art-recognized and refers to sequence similarity between two peptides or between two nucleic acid molecules.

The term “operably linked” is art-recognized and refers to the relationship between two nucleic acid regions, means that they are functionally related to each other.

The term “antisense” nucleic acid is art-recognized and refers to oligonucleotides which specifically hybridize (e.g., bind) under cellular conditions with a gene sequence, such as at the cellular mRNA and/or genomic DNA level, so as to inhibit expression of that gene, e.g., by inhibiting transcription and/or translation. The binding may be by conventional base pair complementarily, or, for example, in the case of binding to DNA duplexes, through specific interactions in the major groove of the double helix.

The term “host cell” is art-recognized and refers to a cell transduced with a specified transfer vector. The cell is optionally selected from in vitro cells such as those derived from cell culture, ex vivo cells, such as those derived from an organism, and in vivo cells, such as those in an organism. “Recombinant host cells” refers to cells which have been transformed or transfected with vectors constructed using recombinant DNA techniques.

The terms “recombinant protein,” “heterologous protein” and “exogenous protein” are art-recognized and are used interchangeably to refer to a polypeptide which is produced by recombinant DNA techniques, wherein generally, DNA encoding the polypeptide is inserted into a suitable expression vector which is in turn used to transform a host cell to produce the heterologous protein. That is, the polypeptide is expressed from a heterologous nucleic acid.

The term “regulatory element” is art-recognized and refers to nucleotide sequences (such as DNA sequences) that induce or control transcription of protein coding sequences with which they are operably linked. Examples of regulatory elements categorized by function include initiation signals, enhancers, promoters and the like. Exemplary regulatory elements are described in Goeddel; Methods in Enzymology 185 (1990). In certain embodiments, transcription of a gene or other DNA is under the control of a promoter sequence (or other regulatory element) which controls the expression of a coding sequence in a cell-type in which expression is intended. A variety of promoters categorized by function are known. The term “tissue-specific promoter” means a DNA sequence that serves as a promoter, i.e., regulates expression of a selected DNA sequence operably linked to the promoter, and which effects expression of the selected DNA sequence in specific cells of a tissue, such as cells of a urogenital origin, e.g., renal cells, or cells of a neural
origin, e.g., neuronal cells. The term also covers so-called “leaky” promoters, which regulate expression of a selected DNA primarily in one tissue, but cause expression in other tissues as well. The term “inducible” promoter refers to a promoter which is under environmental or developmental regulation. The term “constitutive” promoter refers to a promoter which is active under most environmental and developmental conditions.

The term “transfection” is art-recognized and refers to the introduction of a nucleic acid, e.g., an expression vector, into a recipient cell, which in certain embodiments may be by nucleic acid-mediated gene transfer. “Transformation,” as used with respect to transfected nucleic acid, is an art-recognized term and refers to a process in which a cell’s genotype is changed as a result of the cellular uptake of exogenous nucleic acid.

The term “transfer vector” is art-recognized and refers to a first nucleic acid molecule to which a second nucleic acid has been linked, and includes for example plasmids, cosmids or phages (as discussed in greater detail below). In certain embodiments of the present invention, the therapeutic agent is the second nucleic acid. One type of transfer vector is an episome, i.e., a nucleic acid capable of extra-chromosomal replication.

In certain embodiments, a transfer vector may be an “expression vector,” which refers to a replicable DNA construct used to express DNA which encodes the desired protein and which includes a transcriptional unit comprising an assembly of (i) genetic element(s) having a regulatory role in gene expression, for example, promoters, operators, or enhancers, operatively linked to (ii) a DNA sequence encoding a desired protein which is transcribed into mRNA and translated into protein, and (iii) appropriate transcription and translation initiation and termination sequences. In certain embodiments, the therapeutic agent is the DNA sequence. The choice of promoter and other regulatory elements generally varies according to the intended host cell. In general, expression vectors of utility in recombinant DNA techniques are often in the form of “plasmids,” which refer to circular double stranded DNA loops which, in their vector form are not bound to the chromosome. The invention is intended to include such other forms of expression vectors which serve equivalent functions and which become known in the art subsequently hereto.

Certain transfer vectors may contain regulatory elements for controlling transcription or translation, which may be generally derived from mammalian, microbial, viral or insect genes. The ability to replicate in a host, usually conferred by an origin of replication, and a selection gene to facilitate recognition of transformants, may additionally be incorporated.
The design of any transfer vector may depend on such factors as the choice of the 
host cell to be transformed and/or the type of protein desired to be expressed. Moreover, 
the vector’s copy number, the ability to control that copy number and the expression of any 
other proteins encoded by the vector, such as antibiotic markers (e.g., ampicillin), may also 
be considered.

The term “transgenic animal” is art-recognized and refers to any animal, often a 
non-human mammal, a bird or an amphibian, in which one or more of the cells of the 
animal contain nucleic acid introduced by way of human intervention, such as by transgenic 
techniques well known in the art. Such nucleic acid may be referred to as a “transgene.” 
The nucleic acid is introduced into the cell, directly or indirectly by introduction into a 
precursor of the cell, by way of deliberate genetic manipulation, such as by microinjection 
or by infection with a recombinant virus. The term genetic manipulation does not include 
classical cross-breeding, or in vitro fertilization, but rather is directed to the introduction of 
a recombinant DNA molecule. This molecule may be integrated within a chromosome, or 
it may be extrachromosomally replicating DNA. A transgene may be partly or entirely 
heterologous, i.e., foreign, to the transgenic animal or cell into which it is introduced, or, is 
homologous to an endogenous gene of the transgenic animal or cell into which it is 
introduced, but which is designed to be inserted, or is inserted, into the animal’s genome in 
such a way as to alter the genome of the cell into which it is inserted (e.g., it is inserted at a 
location which differs from that of the natural gene or its insertion results in a knockout). A 
transgene may also be present in a cell in the form of an episome. A transgene may include 
one or more regulatory elements and any other nucleic acid, such as introns, that may be 
necessary for optimal expression of a selected nucleic acid. In certain embodiments, a 
transgene comprises a nucleic acid sequence of interest and one or more regulatory 
elements for controlling transcription of the nucleotide sequence encoded by such nucleic 
acid sequence, e.g., the regulatory element is operably linked to a nucleic acid.

In certain embodiments, the transgene or other therapeutic agent may be a “gene 
therapy construct,” which is an expression vector which may alter the phenotype of a cell 
when taken up by the cell, or a gene construct. In certain embodiments, the gene therapy 
construct may be a “recombinant coding sequence” which encodes a polypeptide, or is 
transcribable to an antisense nucleic acid, a ribozyme, or any other RNA product which 
alters the phenotype of the cell in which it is produced. “Recombinant gene” refers to a 
genetic construct including a “recombinant coding sequence.”
The term "antibody" is art-recognized and refers to whole antibodies, e.g., of any isotype (IgG, IgA, IgM, IgE, etc.), and includes fragments thereof which are also specifically reactive with a vertebrate, e.g., mammalian, protein. Antibodies may be fragmented using conventional techniques and the fragments screened for utility in the same manner as described above for whole antibodies. Thus, the term includes segments of proteolytically-cleared or recombinantly-prepared portions of an antibody molecule that are capable of selectively reacting with a certain protein. Non-limiting examples of such proteolytic and/or recombinant fragments include Fab, F(ab')2, Fab', Fv, and single chain antibodies (scFv) containing a V[L] and/or V[H] domain joined by a peptide linker. The scFv's may be covalently or non-covalently linked to form antibodies having two or more binding sites. The subject invention includes polyclonal, monoclonal or other purified preparations of antibodies and recombinant antibodies.

"Human monoclonal antibodies" or "humanized" murine antibodies, as the terms are used herein, refer to murine monoclonal antibodies "humanized" by genetically recombing the nucleotide sequence encoding the murine Fv region (i.e., containing the antigen binding site) or the complementarity-determining regions thereof with the nucleotide sequence encoding at least a human constant domain region and an Fc region, e.g., in a manner similar to that disclosed in European Patent Application Publication No. 0,411,893 A3. Some additional murine residues may also be retained within the human variable region framework domains to ensure proper target site binding characteristics. In certain embodiments, humanized antibodies may decrease the immunoreactivity of the antibody or polypeptide in the host recipient, permitting an increase in the half-life and a reduction in the possibility of adverse immune reactions.

The term "small molecule" is art-recognized and refers to a composition which has a molecular weight of less than about 2000 amu, or less than about 1000 amu, and even less than about 500 amu. Small molecules may be, for example, nucleic acids, peptides, polypeptides, peptide nucleic acids, peptidomimetics, carbohydrates, lipids or other organic (carbon containing) or inorganic molecules. Many pharmaceutical companies have extensive libraries of chemical and/or biological mixtures, often fungal, bacterial, or algal extracts, which can be screened with any of the assays of the invention. The term "small organic molecule" refers to a small molecule that is often identified as being an organic or medicinal compound, and does not include molecules that are exclusively nucleic acids, peptides or polypeptides.
A “target” shall mean a site to which targeted constructs bind. A target may be either in vivo or in vitro. In certain embodiments, a target may be a tumor (e.g., tumors of the brain, lung (small cell and non-small cell), ovary, prostate, breast and colon as well as other carcinomas and sarcomas). In other embodiments, a target may be a site of infection (e.g., by bacteria, viruses (e.g., HIV, herpes, hepatitis) and pathogenic fungi (Candida sp.). In still other embodiments, a target may refer to a molecular structure to which a targeting moiety binds, such as a hapten, epitope, receptor, dsDNA fragment, carbohydrate or enzyme. Additionally, a target may be a type of tissue, e.g., neuronal tissue, intestinal tissue, pancreatic tissue etc.

The term “targeting moiety” refers to any molecular structure which assists the construct in localizing to a particular target area, entering a target cell(s), and/or binding to a target receptor. For example, lipids (including cationic, neutral, and steroidal lipids, virosomes, and liposomes), antibodies, lectins, ligands, sugars, steroids, hormones, nutrients, and proteins may serve as targeting moieties.

The term “modulation” is art-recognized and refers to up regulation (i.e., activation or stimulation), down regulation (i.e., inhibition or suppression) of a response, or the two in combination or apart.

The term “treating” is art-recognized and refers to curing as well as ameliorating at least one symptom of any condition or disease.

The term “prophylactic” or “therapeutic” treatment is art-recognized and refers to administration to the host of one or more of the subject compositions. If it is administered prior to clinical manifestation of the unwanted condition (e.g., disease or other unwanted state of the host animal) then the treatment is prophylactic, i.e., it protects the host against developing the unwanted condition, whereas if administered after manifestation of the unwanted condition, the treatment is therapeutic (i.e., it is intended to diminish, ameliorate or maintain the existing unwanted condition or side effects therefrom).

A “patient,” “subject” or “host” to be treated by the subject method may mean either a human or non-human animal.

The term “mammal” is known in the art, and exemplary mammals include humans, primates, bovines, porcines, canines, felines, and rodents (e.g., mice and rats).

The term “bioavailable” is art-recognized and refers to a form of the subject invention that allows for it, or a portion of the amount administered, to be absorbed by,
incorporated to, or otherwise physiologically available to a subject or patient to whom it is administered.

The term “pharmaceutically-acceptable salts” is art-recognized and refers to the relatively non-toxic, inorganic and organic acid addition salts of compounds, including, for example, those contained in compositions of the present invention.

The term “pharmaceutically acceptable carrier” is art-recognized and refers to a pharmaceutically-acceptable material, composition or vehicle, such as a liquid or solid filler, diluent, excipient, solvent or encapsulating material, involved in carrying or transporting any subject composition or component thereof from one organ, or portion of the body, to another organ, or portion of the body. Each carrier must be “acceptable” in the sense of being compatible with the subject composition and its components and not injurious to the patient. Some examples of materials which may serve as pharmaceutically acceptable carriers include: (1) sugars, such as lactose, glucose and sucrose; (2) starches, such as corn starch and potato starch; (3) cellulose, and its derivatives, such as sodium carboxymethyl cellulose, ethyl cellulose and cellulose acetate; (4) powdered tragacanth; (5) malt; (6) gelatin; (7) talc; (8) excipients, such as cocoa butter and suppository waxes; (9) oils, such as peanut oil, cottonseed oil, safflower oil, sesame oil, olive oil, corn oil and soybean oil; (10) glycols, such as propylene glycol; (11) polyols, such as glycerin, sorbitol, mannitol and polyethylene glycol; (12) esters, such as ethyl oleate and ethyl laurate; (13) agar; (14) buffering agents, such as magnesium hydroxide and aluminum hydroxide; (15) alginic acid; (16) pyrogen-free water; (17) isotonic saline; (18) Ringer’s solution; (19) ethyl alcohol; (20) phosphate buffer solutions; and (21) other non-toxic compatible substances employed in pharmaceutical formulations.

The terms “systemic administration,” “administered systemically,” “peripheral administration” and “administered peripherally” are art-recognized and refer to the administration of a subject composition, therapeutic or other material other than directly into the central nervous system, such that it enters the patient’s system and, thus, is subject to metabolism and other like processes, for example, subcutaneous administration.

The terms “parenteral administration” and “administered parenterally” are art-recognized and refer to modes of administration other than enteral and topical administration, usually by injection, and includes, without limitation, intravenous, intramuscular, intraarterial, intrathecal, intracapsular, intraorbital, intracardiac, intradermal,
intraperitoneal, transtracheal, subcutaneous, subcuticular, intra-articular, subcapsular, subarachnoid, intraspinal, and intratrernal injection and infusion.

Contemplated equivalents of the compositions described herein include compositions which otherwise correspond thereto, and which have the same general properties thereof (such as other compositions comprising FabI/Fab K inhibitors), wherein one or more simple variations of substituents or components are made which do not adversely affect the characteristics of the compositions of interest. In general, the components of the compositions of the present invention may be prepared by the methods illustrated in the general reaction schema as, for example, described below, or by modifications thereof, using readily available starting materials, reagents and conventional synthesis procedures. In these reactions, it is also possible to make use of variants which are in themselves known, but are not mentioned here.

Also included in the antibacterial compositions of the present invention are pharmaceutically acceptable addition salts and complexes of the FabI inhibitors. In cases wherein the inhibitors may have one or more chiral centers, unless specified, the present
invention comprises each unique racemic compound, as well as each unique nonracemic compound.

In cases in which the inhibitors have unsaturated carbon-carbon double bonds, both the cis (Z) and trans (E) isomers are within the scope of this invention. In cases wherein inhibitors may exist in tautomeric forms, such as keto-enol tautomers, such as \( \text{OR}' \), each tautomeric form is contemplated as being included within this invention, whether existing in equilibrium or locked in one form by appropriate substitution with \( R' \). The meaning of any substituent at any one occurrence is independent of its meaning, or any other substituent's meaning, at any other occurrence.

Also included in the antibiotic compounds of the present invention are prodrugs of the FabI inhibitors.

It is believed that the compositions of the present invention comprising compounds of formulas I-III are antibacterial because the compounds inhibit FabI, FabK, or both. It may be, however, that for some or all of the compounds, they inhibit other enzymes in addition or inhibit completely different enzymes. The exact mechanism by which the compositions of the present invention achieve their antibacterial properties is not meant to be limiting.

A variety of subject compounds and intermediates of them may be made by a person of ordinary skill in the art using conventional reaction techniques. Non-limiting examples of compounds and methods of making them may be found in U.S. Patent Application Nos. 08/790,043, 10/009,219, 10/089,019, 09/968,129, 09/968,123, 09/968,236, 09/959,172, 09/979,560, 09/980,369, 10/089,755, 10/089,739, 10/089,740, PCT Published Patent Application Nos. Synthetic Routes to Compounds of Formula I

A generalized chemical approach to assembling compounds of formula I is based on viewing the analogs as consisting of a central ene-amide flanked left-hand side (LHS) and right-hand side (RHS) moieties. Schematically, this is depicted in Figure 2. Two possible bond disconnections envisioned in a retrosynthetic sense are shown with dashed lines.

Schemes I to XXXV illustrate some of the general methods that can be used in the synthesis of compounds of formula I. It will be recognized by one skilled in the art that other
disconections are possible resulting in alternative modes of assembly of the compounds of the invention.

Schemes I to VIII disclose the basic chemistry involved in the synthesis of the left hand side moieties of formula I wherein the requisite LHS coupling partners are amines and the late stage chemistry involves formation of the amide linkage. The amines are typically arylalkyl-amines which are most conveniently prepared from commercially available arylicarbaldehydes by the action of a reducing agent such as sodium borohydride in the presence of an alkyl amine such as methyl amine (Scheme I).

(a) i. MeNH\textsubscript{2}, MeOH; ii. NaBH\textsubscript{4}, EtOH
When the arylicarbaldehydes are not commercially available their synthesis can be effected by a number of general methods including the action of dimethylformamide on the lithium salt of aryl anions (Scheme IIa and IIIa).

Other methods of obtaining the desired arylcarbaldehydes include the widely employed oxidation of alcohols (Scheme IVb) and a variety of miscellaneous methods (Scheme Va and Via).

During the course of these syntheses it may be desirable to alkylate indole-like nitrogens. This can be accomplished either prior to (Scheme IIa) or after formation of said carbaldehydes (Scheme Ivc) by the action of strong bases such as sodium hydride and the addition of alkylating agents such as alkyl halides. Likewise oxygen atoms appended to the aromatic systems (e.g. phenols) can be alkylated by the action of base (potassium carbonate) and an alkylhalide (Scheme VIIa).

Scheme VII

(a) Iodoethane, K₂CO₃, DMF; (b) i. MeNH₂, MeOH; ii. NaBH₄, EtOH
Yet another approach to the formation of the desired amines can be from the reduction of precursor amides (Scheme VIII)

Scheme VIII

Scheme IX describes the basic chemistry involved in the synthesis of the left hand side moieties of formula I wherein the requisite LHS coupling partners are ene-amides and the late stage chemistry involves formation of a carbon-carbon bond. The carbon-carbon bond formation is usually accomplished by Heck type chemistry which will be described subsequently. The ene-amide is prepared by activation of acrylic acid to undergo coupling reaction (with an amine) by any one of the known methods for amide bond formation. One typically used procedure is to treat acrylic acid with a solution of a tertiary amine in DMF followed by the addition of 1-hydroxybenzotriazole hydrate and a carbodiimide such as 1-(3-dimethylaminopropyl)-3-ethyl-carbodiimide hydrochloride. The reaction mixture is then treated with the desired arylalkylamine such as methyl-(1-methyl-1H-indol-3-ylmethyl)-amine (Scheme IX).

Schemes X to XXIV disclose the basic chemistry involved in the synthesis of the right hand side moieties of formula I wherein the requisite RHS coupling partners are carboxylic acids and the late stage chemistry involves formation of the amide linkage. The carboxylic acids are typically arylalkenyl carboxylic acids whose preparation is illustrated by the schemes described below. A common starting material, 5-bromo-3-bromomethyl-pyridin-2-ylamine hydrobromide, is used in the construction of the right hand side moieties described in Schemes X-XVII. In some embodiments of the invention, this material is reacted with a commercial secondary amine (Schemes X-XII) or reacted with a secondary amine which is prepared in the manner illustrated (Schemes XIII-XIV). In either case, a
tertiary base is employed. A common feature of the resultant products are compounds incorporating a pendent alkyl ester and an aminopyridine moiety which react in the presence of a base like sodium hydride to form the pyridodiazepinone bicyclic unit.

The pyridodiazepinones prepared in this manner have in common a bromine substitution in the pyridine ring. As will be seen from inspection of the Schemes X-XIV synthesis of arylalkenyl acids proceeds from intermediary bromo-pyridodiazepinones via Heck chemistry (e.g. Scheme Xc). Heck chemistry is carried out by admixture of an arylbromide with an alkylacrylate, such as tert-butylacrylate, in the presence of a palladium catalyst (Pd(OAc)$_2$, P(o-tol)$_3$) and a tertiary base such as di-(isopropyl)ethylamine in an appropriate solvent or solvents (e.g. DMF and EtCN). The desired carboxylic acid is obtained by acid-catalysed hydrolysis of the tert-butyl ester (e.g. SchemeXd).

In an analogous way to the chemistry described above, 5-bromo-3-bromomethylpyridin-2-ylamine hydrobromide, may be reacted with primary amines (Scheme XVI, XVII, XVIII); subsequent cyclization with sodium hydride yields a pyridodiazepinone in which the nitrogen at the four position is unsubstituted. In Scheme XVI the final product represents a right hand side moiety of formula I wherein the requisite RHS coupling partners is an aryl bromide and the late stage chemistry involves formation of a carbon-carbon bond via Heck chemistry. One skilled in the art will recognize that the intermediate aryl bromides described in Schemes X-XX may also be used in late stage carbon-carbon bond forming chemistry.

Alternatively, the nitrogen at position four may be derivatized by reaction with alkylation (Scheme XVIIc) or acylating agents (Scheme XVIIIc). In the former case, further elaboration (Scheme XVIIId,e) yields a derivatized bromopyridodiazepinone which is subjected to standard Heck coupling/deprotection sequence to give the desired acid. In the latter case, the CBz-protected pyridodiazepinone is similarly treated (Scheme XVIII).

Schemes XXI-XXIV are illustrative of methods use for preparing RHS moieties wherein 3,4-dihydro-1H-pyrido[2,3-d]pyrimidin-2-ones are incorporated as RHS moieties. Schemes XXI-XXIII show preparations wherein carboxylic acids are prepared and end stage chemistry involves amide bond formation, scheme XXIV shows preparation of an aryl bromide employed in carbon-carbon bond forming end stage chemistry.

In each case an intermediate aminomethyl aminopyridine is prepared by amide bond reduction (Scheme XXI), reductive amination of aldehydes (Scheme XXII and Scheme XXIV) or, as described above in Scheme XVII, by displacement of an benzylic bromide with the desired primary amine. The latter method yields the starting material for Scheme
XXIII. The subsequent step, common to all cases, is cyclization using carbonyl diimidazole to form the 3,4-dihydro-1H-pyrimidin-2-one ring. Other activated carbonyl equivalents are expected to affect a similar cyclization. In Schemes XXI-XXIII further elaboration using Heck coupling and hydrolysis gives the desired carboxylic acid RHS moieties.

Schemes XXVII describes a specific example of a general method for assembly of compounds of formula I wherein the LHS coupling partners are amines, the RHS coupling partners are acids and the late stage chemistry involves formation of the amide linkage. There are many common methods for formation of amide linkages. In the example depicted in Scheme XXVII an acid ((E)-3-(4-methyl-2-oxo-2,3,4,5-tetrahydro-1H-pyrido[2,3-e][1,4]diazepin-7-yl)-acrylic acid) is activated by treatment with a carbodiimide (EDC) and hydroxybenzotriazole (HOBt) in the presence of a polar aprotic solvent (DMF) and reacted with a suitable amine (N-methyl-N-(1-methyl-1H-indol-3-ylmethyl)amine) in the presence of a tertiary amine base like diisopropylethylamine.

**Scheme XXVII**

(a) N-methyl-N-(1-methyl-1H-indol-3-ylmethyl)amine, (i-Pr)$_2$EtN, EDC, HOBt, DMF

An alternative method for assembling compounds of formula I, generally referred to as Heck coupling, is depicted in Scheme XVIII. An acrylic amide such as N-methyl-N-(3-methyl-benzo[b]thiophen-2-ylmethyl)-acylamide is treated with an aryl bromide such as 7-bromo-3,3-dimethyl-1,3,4,5-tetrahydro-pyrido[2,3-e][1,4]diazepin-2-one in the presence of a palladium catalyst (Pd(OAc)$_2$, P(o-tol)$_3$), a tertiary amine ((i-Pr)$_2$EtN) and an aprotic solvent or solvents (EtCN, DMF).

To access certain compounds of the invention it may be necessary to perform synthetic manipulations after the right hand side and left hand side units have been assembled. Scheme XXIX for example outlines the conversion of an aminopyridine moiety to a cyclic imide followed by ring opening with ammonia.

Scheme XXIX

(a) succinic anhydride, 1,4-dioxane; (b) \(\text{NH}_3\), 1,4-dioxane.

Additional examples of aminopyridine derivatization are given in Schemes XXX and XXXI which describe the acylation of the amine moiety to form amide linkages.

In certain aspects of the invention it is desirable to have pyridodiazepinones in place on the right hand side with unsubstituted 4-position nitrogen. In these instances a suitable protecting group such as methoxybenzyl can temporarily mask the nitrogen. This protecting group may be removed in a two-step procedure by treatment with 1-chloroethyl chloroformate followed by hydrolysis of the intermediate carbamate. The hydrochloride salt may be prepared, if desired, through treatment with dilute acid (HCl) in an aprotic solvent such as ether (Scheme XXXII).

Schemes XXXIII and XXXIV respectively show methods for conversion of ester and dimethylether ether groups pendent on a 3,4-dihydro-1H-pyrido[2,3-d]pyrimidin-2-one right hand side to piperidine-containing tethers. These chemical manipulations are carried out after the standard coupling reactions described above are applied (e.g. Scheme XXVII or XXVIII).

Synthetic Routes to Compounds of Formulas II and III

Examples of the compounds of formulas II and III in the antibacterial compositions of the present invention may be prepared by the general methods described in the Schemes hereinafter.

Scheme XXXVI

(a) benzyl acrylate, Pd(OAc)$_2$, P(o-tol)$_3$, (i-Pr)$_2$NEt, propionitrile; (b) 1.0 N NaOH, MeOH; (c) 1-methyl-2-(methylaminomethyl)indole, EDC, HOBT H$_2$O, Et$_3$N, DMF.

A suitable haloaromatic derivative, for instance 2-amino-5-bromopyridine (XXXVI-1), reacts with an appropriate $\alpha$, $\beta$-unsaturated ester, for example benzyl acrylate, in a Heck-type reaction to afford XXXVI-2. The reaction is mediated by a palladium(0) species, and generally is conducted in an inert solvent, such as CH$_3$CN, propionitrile, or toluene, in the presence of an appropriate acid scavenger, such as triethylamine (Et$_3$N) or diisopropylethylamine ((i-Pr)$_2$NEt). Typical sources of the palladium(0) species include palladium (II) acetate (Pd(OAc)$_2$) and palladium(II) chloride (PdCl$_2$), and oftentimes
phosphine ligands, for instance triphenylphosphine (PPh₃) or tri-ortho-tolylphosphine (P(tol)₃), are included. The ethyl ester of XXXVI-2 is hydrolyzed using aqueous base, for example, LiOH in aqueous THF or NaOH in aqueous methanol or ethanol, and the intermediate carboxylate salt is acidified with a suitable acid, for instance TFA or HCl, to afford the carboxylic acid XXXVI-3. The carboxylic acid of XXXVI-3 is converted to an activated form using, for example, EDC and HOBT, or SOCl₂, and the activated form is subsequently reacted with an appropriate amine, for instance 1-methyl-2-(methylaminomethyl)indole, in a suitable solvent such as DMF, CH₂Cl₂, or CH₃CN, to afford XXXVI-4. Depending on whether acid neutralization is required, an added base, such as triethylamine (Et₃N), diisopropylethylamine ((i-Pr)₂NEt), or pyridine, may be used. Many additional methods for converting a carboxylic acid to an amide are known, and can be found in standard reference books, such as “Compendium of Organic Synthetic Methods”, Vol. I - VI (published by Wiley-Interscience), or Bodansky, “The Practice of Peptide Synthesis” (published by Springer-Verlag).

Scheme XXXVII

(a) NaH, Mel, DMF; (b) CH₃NH₂, H₂O, MeOH; (c) LiAlH₄, THF.

The amine coupling partners used in the present invention were prepared by established methods well-known to those of skill in the art. For example, amine XXXVII-4 is prepared by the straightforward procedure outlined in Scheme II. Commercially available ethyl indole-2-carboxylate (XXXVII-1) is deprotonated with a suitable base, generally sodium hydride (NaH), and the intermediate sodium salt is reacted with an appropriate alkylating agent, for instance methyl iodide, to afford XXXVII-2. Polar solvents such as DMF, THF, or mixtures thereof are generally preferred for this reaction. Compound XXXVII-2 can be conveniently converted to XXXVII-3 by reaction with an
excess of an amine, such as methylamine, in a polar solvent, generally H₂O or a mixture of H₂O and methanol. Alternatively, the ester of XXXVII-2 can be saponified under standard conditions, typically with an alkali metal hydroxide such as LiOH, NaOH, or KOH, in an aqueous solvent, such as THF, ethanol, or methanol, and the resulting carboxylic acid can be converted to the desired amide. Typical methods for forming amides are described in Scheme I. Reduction of the amide XXXVII-3 to the amine XXXVII-4 is typically accomplished with lithium aluminum hydride (LiAlH₄) in refluxing THF, although many other methods can be used to reduce amides to amines. Such methods are well-known to those of skill in the art, and can be found in standard reference volumes, such as “Compendium of Organic Synthetic Methods” (published by Wiley-Interscience).

Scheme XXXVIII

![Diagram showing chemical reactions](image)

(a) CH₃NH₂, MeOH; (b) NaBH₄, EtOH.

The amine coupling partners used in the present invention can also be prepared by the reductive amination of an appropriate aldehyde (Scheme III). This method, which is well-known to those of skill in the art, involves the initial conversion of an aldehyde to an intermediate imine, which is subsequently reduced, oftentimes in situ, to afford the amine. For example, the commercially-available aldehyde XXXVIII-1 reacts with an appropriate amine, for instance methylamine, in a suitable solvent, typically methanol, to afford the imine XXXVIII-2. Reaction of XXXVIII-2 with a suitable reducing agent, for example sodium borohydride, sodium cyanoborohydride or sodium (triacetoxy)borohydride, gives the amine XXXVIII-3.
Scheme XXXIX

(a) LiAlH₄, THF; (b) Br₂, AcOH; (c) 48% HBr; (d) (MeO₂C)₂CH₂, NaH, DMF, THF; (e) NaOH, H₂O, MeOH; (f) HCl, H₂O, MeOH; (g) acryloyl chloride, Et₃N, CH₂Cl₂; (h) Pd(OAc)₂, P(o-tol)₃, (i-Pr)₂NEt, propionitrile.

Commercially available 2-aminonicotinic acid (XXXIX-1) is reduced to alcohol XXXIX-2 under standard conditions (LiAlH₄, THF), and the aromatic ring of XXXIX-2 is brominated using, for example, bromine or N-bromosuccinimide (NBS), in a suitable solvent such as CH₂Cl₂, acetic acid (AcOH), or mixtures thereof, to afford XXXIX-3. On reaction with 48% aqueous HBr, XXXIX-3 is converted to bromide XXXIX-4, which reacts with a diester of malonic acid, for instance dimethyl malonate, under basic conditions, to afford the naphthyridone derivative XXXIX-5. Typical basic conditions include an alkali metal hydride, for instance sodium hydride, in a neutral solvent such as DMF, THF, or mixtures thereof, or an alkali metal alkoxide, such as sodium methoxide or sodium ethoxide, in an alcoholic solvent such as with methanol or ethanol. Saponification and neutralization under standard conditions affords an intermediate carboxylic acid (not shown), which is typically not isolated, but is subject to decarboxylation on gentle warming.
to afford the naphthyridone XXXIX-6. This compound reacts with acrylamide XXXIX-8 in a Heck-type reaction as described in Scheme I to afford XXXIX-9. Alternatively, XXXIX-6 might be converted to XXXIX-9 according to the general procedure described in Scheme I for the conversion of XXXVI-1 to XXXVI-4. The acrylamide XXXIX-8 is conveniently prepared by reaction of amine XXXIX-7 (see Scheme I) with an activated form of acrylic acid in an amide bond-forming reaction. Typical conditions for the formation of amides are described in Scheme I, and are well-known to those of skill in the art.

15 Benzyllic bromide XL-1, prepared as described in Scheme XXXIX, reacts with an amine, for example aqueous methylamine, to afford benzyllic amine XL-2. Polar solvents such as THF, DMF, DMSO, or mixture thereof, are generally preferred for this reaction. XL-2 reacts with a dialkyl carbonate, preferably dimethyl carbonate, in the presence of a suitable base, typically sodium methoxide, in an alcoholic solvent, generally methanol, to afford the cyclic urea derivative XL-3. This compound is converted to XL-4 by reaction with compound XXXIX-8 as described in Scheme XXXIX.

The nitro group of commercially available 2-amino-5-bromo-3-nitropyridine (XLI-1) is reduced under standard conditions using, for example, tin (II) chloride in EtOH. The resulting diamine, XLI-2, reacts with formic acid, or an appropriate equivalent, to afford the imidazopyridine derivative XLI-3. This compound is converted to a suitably protected derivative, for instance the N-trityl protected derivative XLI-4, by reaction with trityl chloride in the presence of an appropriate base, typically triethylamine or diisopropylethylamine. Typical solvents for this reaction include CH₂Cl₂, DMF, or mixtures thereof. The protecting group for the amine must be compatible with subsequent chemistry, and must be readily removable when desired. Methods for the protection of amines are well-known to those of skill in the art, and are described in standard reference volumes, such as Greene "Protective Groups in Organic Synthesis" (published by Wiley-Interscience). XLI-4 is converted to XLI-5 according to the general procedure described in Scheme I. The trityl protecting group is removed under standard acidic conditions (see Greene above), and the ester is saponified as in Scheme I to afford XLI-6.

Commercially-available tetrahydroquinoline (XLII-1) is condensed with an appropriate aldehyde, typically benzaldehyde (PhCHO), under standard conditions to afford the olefinic derivative XLII-2. Oxidative cleavage of the exocyclic olefin affords ketone XLII-3. Generally, ozonolysis in a neutral solvent, such as methylene chloride (CH₂Cl₂), methanol (MeOH), or mixtures thereof, followed by in situ reduction of the intermediate ozonide with an appropriate reducing agent, usually dimethylsulfide, is the method of choice for this transformation. Compound XLII-3 is converted to the 7-membered lactam derivative XLII-6 as described by Jøssang-Yanagida and Gansser. This procedure involves conversion of the ketone of XLII-3 to the corresponding oxime XLII-4, which is subsequently converted to the O-tosyl derivative XLII-5. A Beckmann-type rearrangement of XLII-5 affords the lactam XLII-6. Bromination of XLII-6 with a suitable brominating agent, such as bromine (Br₂) or N-bromosuccinimide (NBS), affords the bromo derivative.
XLII-7. Typical solvents for a bromination reaction include CH₂Cl₂, CCl₄, MeOH, AcOH, or mixtures thereof. Bromide VII-7 reacts with an appropriate α,β-unsaturated ester, for example tert-butyl acrylate, in a Heck-type reaction as described in Scheme I to afford XLII-8. The tert-butyl ester of XLII-8 is cleaved to the corresponding carboxylic acid XLII-9 under standard acidic conditions. Typical conditions for this transformation are described in standard reference volumes, such as Greene "Protective Groups in Organic Synthesis" (published by Wiley-Interscience). XLII-9 is converted to XLII-10 by the general method described in Scheme I.

Compound XLIII-1, prepared as described in Scheme XL, reacts with two equivalents of an appropriate acylating agent, preferably di-tert-butyl dicarbonate, to afford XLIII-2. As discussed in Scheme XLI, the protecting group for the amines must be compatible with subsequent chemistry, and must be readily removable when desired. XLIII-2 is deprotonated with a suitable base, generally sodium hydride (NaH), and the intermediate sodium salt is reacted with an appropriate alkylating agent, for instance ethyl bromoacetate, to afford XLIII-3. Polar solvents such as DMF, THF, or mixtures thereof are generally preferred for this reaction. The Boc protecting groups are removed under
standard acidic conditions (see Greene above) to afford XLIII-4, which undergoes cyclization to compound XLIII-5 on exposure to a suitable base, typically triethylamine (Et$_3$N) or diisopropylethylamine ((i-Pr)$_2$NEt). An inert solvent, such as toluene, is preferred. XLIII-5 is converted to XLIII-6 by the general method described in Scheme XXXIX.

Commercially available 2,5-dibromopyridine (XLIV-1) reacts with 2-aminopyridine in the presence of a suitable base, typically sodium tert-butoxide, to afford the dipyrindylamine derivative XLIV-2. The reaction is mediated by a suitable palladium (0) catalyst, such as tris(dibenzylideneacetone)dipalladium(0), in the presence of an appropriate ligand, for example 1,3-bis(diphenylphosphino)propane. A neutral solvent such as toluene is preferred.

Benzylic bromide XLV-1, prepared as described in Scheme XXXIX, reacts with an appropriate a-aminoester equivalent, for example N-(diphenylmethylene)glycine ethyl ester, under basic conditions, to provide XLV-2. A polar, aprotic solvent, such as DMF, THF, DME, or mixtures thereof, is generally preferred, and sodium hydride is typically the base of choice, although LDA or LiN(TMS)₂ might also be used. Alternatively, the reaction might be conducted in an alcoholic solvent, such as methanol or ethanol, with an alkali metal alkoxide, for example sodium methoxide or sodium ethoxide, as the base. The diphenylmethylene group is conveniently removed under acidic conditions, such as HCl in aqueous dioxane. Other conditions for the removal of a diphenylmethylene group are known to those of skill in the art, and can be found in the chemical literature or in standard reference volumes, such as Greene (see above).

It will be recognized by one skilled in the art that other methods of LHS and RHS synthesis can be employed in the preparation of said intermediates. Likewise other methods of amide and/or carbon-carbon bond formation may be used to assemble the compounds of the invention. It is also apparent that combinations of LHS and RHS other than those described above can be envisioned to prepare compounds falling within the scope of the invention as represented by formulas I-III. These possibilities are further detailed in the preparations and examples section to follow.

Acid addition salts of the compounds of formulas I-III can be prepared in a standard manner in a suitable solvent from the parent compound and an excess of an acid, such as hydrochloric, hydrobromic, hydrofluoric, sulfuric, phosphoric, acetic, trifluoroacetic, maleic, succinic or methanesulfonic. Certain of the compounds form inner salts or zwitterions which may be acceptable. Cationic salts may be prepared by treating the parent compound with an excess of an alkaline reagent, such as a hydroxide, carbonate or alkoxide, containing the appropriate cation; or with an appropriate organic amine. Cations such as Li⁺, Na⁺, K⁺, Ca⁡⁺⁺, Mg⁡⁺⁺ and NH₄⁺ are some non-limiting examples of cations present in pharmaceutically acceptable salts.

Toxicology of Compounds

Acute toxicity can be assessed using increasing doses in mice and rodents. Exploratory acute toxicity in mice and/or rats after single dose may be undertaken to begin estimation of the therapeutic window of inhibitors and to identify the potential target organ of toxicity. As candidate selection nears, these studies may provide guidance for
the selection of proper doses in multi-dose studies, as well as establish any species specific
differences in toxicities. These studies may be combined with routine PK measurements to
assure proper dosages were achieved. Generally 3-4 doses will be chosen that are estimated
to span a range having no effect through to higher doses that cause major toxic, but non-
lethal, effects. Animals will be observed for effects on body weight, behavior and food
consumption, and after euthanasia, hematology, blood chemistry, urinalysis, organ weight,
gross pathology and histopathology will be undertaken.

Resistance Frequencies and Mechanisms of Compounds

In vitro resistance frequencies in bacteria of interest can be estimated for
compounds of formula I. Experiments can determine whether resistant isolates arise when
challenged to grow on solid media at 1X, 2X and 4XMIC concentrations. For example
with respect to S. aureus or E. Coli, the experiments may use several recent clinical isolates
of methicillin-sensitive and methicillin-resistant S. aureus and a laboratory strain of E. coli
with acrA efflux pump defect. In addition, experiments may use several characterized
triclosan-resistant S. aureus strains. The MICs of resistant strains isolated in this manner
can then be determined. Subsequent experiments can determine whether resistant strains
arise after serial passage of the strains in 0.5XMIC concentrations of each lead compound.

Mechanism of resistance may be determined in S. aureus laboratory strain, RN450
and in an E. coli laboratory strain carrying an acrA efflux pump mutation. Both high dose
challenge (4XMIC) and sub-MIC serial passage may be used to obtain spontaneously
arising resistant isolates. If no isolates are obtained with reasonable frequencies, chemical
and physical mutagenesis methods can be used to obtain resistant isolates. The fabI gene
from the chromosome of resistant isolates may be PCR amplified, then may be sequenced
to determine whether changes in the FabI protein caused resistance. Triplicate PCR
amplifications and sequences may be performed to assure that the observed sequence
changes are correct, and did not arise from PCR errors during amplification. Strains
carrying resistance mutations outside of the gene of interest may be documented and saved,
characterized for their effects on susceptibilities of other antibiotics as evidence of possible
efflux-mediated resistance mechanisms, characterized for their ability to alter compounds
characterized for their effects on the expression of the specific mRNA and FabI protein.

Cloning of S. aureus FabI

The fabI gene was cloned from the chromosomal DNA of S. aureus strain WCUH29
using the polymerase chain reaction. Amplification was performed using Taq DNA
polymerase (BRL) and the following primers: 5'-
CGCCTCGAGATGTTAAATCTTTGAAAAACAAAAACATATGTC-3' and 5'-
CGCGGATCCATCAAGTCAAGGTGTAATATCCA-3' (XhoI and BamHI sites
underlined). The resulting fragment was then digested with XhoI and BamHI and ligated
into XhoI- and BamHI-digested expression vector pET-16b (Novagen), producing pET-
His10-fabI. The gene sequence of fabI was confirmed by automated cycle sequencing
using an Applied Biosystems model 377 machine. The untagged version of pET-fabI was
constructed by digesting pET-His10-fabI with NcoI and NdeI to remove a 97 bp fragment
encoding the His 10 tag, the factor Xa cleavage site and the first 8 amino acids of FabI, and
replacing it with a linker encoding the first 8 amino acids of FabI plus a glycine residue
between the initiator methionine and the lysine at position 2. This plasmid was called pET-
fabI. The linker was made by annealing the following two oligonucleotides: 5'-
CATGGGCTTAAATCTTTGAAAAACAAAAAC-3' and 5'-
TATGTTTTGTTTTCAAGATTTAAGGC-3'. The linker sequence in pET-fabI was
confirmed by dideoxy sequencing. Only native FabI was used for compound evaluation.
For overproduction of native FabI, plasmid pET-fabI was transformed into BL21(DE3)
(Novagen) cells, to form strain BL21(DE3):pET-fabI.

Purification of S. aureus FabI

S. aureus FabI was expressed as soluble protein to 10% of total cell protein, 400g
cells being recovered from 15L fermentation in tryptone phosphate medium. The cells
were lysed and the sample centrifuged. The resulting supernatant was filtered and purified
using three consecutive chromatography columns: ion-exchange (Sourse 15Q), dye-affinity
(Blue sepharose), and size exclusion chromatography columns (Superose 12). After each
column the FabI containing fractions were pooled, concentrated, and checked for purity and
biological activity.

Cloning/Expression Haemophilus influenzae FabI

The FabI gene was PCR amplified from Haemophilus influenzae (Q1) genomic
DNA. Oligonucleotide primers were designed with unique restriction sites at both the N'
and C' terminal ends of the gene to allow efficient sub-cloning into the expression vector

PCR amplification was performed using *Pfu* Turbo DNA polymerase as per the instructions of the manufacturer (Stratagene). The following cycling conditions were used: 95 °C for 3 minutes followed by 30 cycles of 94 °C 1 minute, 55 °C 1 minute and 72 °C 3 minutes. A final extension at 72 °C for 5 minutes was carried out. PCR products of expected size for *Haemophilus influenzae* FabI were cloned into the PCR cloning vector TOPO TA 2.1 as per instructions of the manufacturer (Invitrogen). The fidelity of the presumptive PCR amplified *Haemophilus influenzae* FabI gene was confirmed by DNA sequencing on both strands using an ABI 377 Automated DNA Sequencer (Applied Biosystems). pPROLar was digested with *KpnI* and *NotI* restriction endonucleases using conditions as recommended by the supplier (New England Biolabs). Purification of the linear plasmid, was achieved using agarose gel purification and the Qia-quick gel purification kit as per the protocol supplied by the manufacturer (Qiagen). The *Haemophilus influenzae* FabI gene was excised from TOPO TA 2.1 by *KpnI* and *NotI* restriction endonuclease digestion and purified as above. Subsequent fragment/vector ligations were carried out using T4 DNA ligase, using conditions supplied by the manufacturer (Promega).

Transformations into *E. coli* TOP 10 competent cells were performed using the protocol as supplied by the manufacturer (Invitrogen). Verification of the resultant clones was carried out using colony PCR and restriction endonuclease digestion. Positive clones were then transformed into the expression strain *E. coli* DH5αPRO, which expresses *AraC* in addition to the *lac* repressor.

Subsequent clones were then evaluated for expression at small-scale using the conditions as recommended by the manufacturer (Clontech). Expression analysis showed over-expressed protein bands of correct size for *Haemophilus influenzae* FabI clearly visible by SDS PAGE. Protein identity was further confirmed by peptide mass fingerprinting. Further analysis by N-terminal Amino Acid sequencing of the purified protein showed that the N-terminus starts 35 residues downstream of the presumptive initiation codon. DNA sequence analysis also highlighted the presence of a ribosome binding site upstream and correctly spaced from the new initiation codon. These findings match perfectly with *E. coli* FabI and the protein is also now a similar size to other FabIs.
The over-expression construct has managed to use the correct ribosome binding site and start at the correct ATG to give the correct protein.

**Purification of *H. influenzae* FabI**

One liter of cells containing the *H. influenzae* FabI expression construct were grown to an OD600 of 0.6. Expression was induced as described above and the cells were grown for a further 3 h and then harvested. The cell pellet was re-suspended in 10 ml 50 mM Tris pH 7.5, 1 mM PMSF, 1 mM benzamidine, 1 mM DTT (buffer A) and lysed by sonication. Cell debris was removed by centrifugation. The supernatant was loaded onto a Hi-load Q (16/10) column (Pharmacia) equilibrated in buffer A. Protein was eluted over a 200 mL gradient of 0-100% buffer B, where buffer B is buffer A + 1 M KCl. Fractions containing FabI were identified by SDS PAGE and by their FabI activity and pooled. 1.5 M ammonium sulfate was added to the pooled fractions and these were then loaded onto a Hi-load phenyl sepharose (16/10) column (Pharmacia) equilibrated in 50 mM Tris pH 7.5, 1 mM PMSF, 1 mM benzamidine, 1 mM DTT, 1.5 M ammonium sulfate.

Proteins were eluted with a gradient of ammonium sulfate (1.5 to 0 M) over 200 mL. Fractions containing FabI were identified as above and pooled. The pooled fractions were buffer exchanged into 100 mM Tris, pH 7.5, 2 mM DTT and glycerol was then added to 50%. The protein was stored at -20 °C. The identity of the protein was confirmed by N-terminal sequencing and MALDI mass spectrometry.

**Cloning of *E. coli* FabI**

A PCR fragment of correct size for *E. coli* FabI was PCR amplified from *E. coli* chromosomal DNA, subcloned into the TOPO TA cloning vector, and verified by colony PCR + restriction endonuclease analysis. The presumptive *E. coli* FabI PCR fragment was subcloned into the expression vector pBluePet. The FabI clone was transformed into *E. coli* strain BL21(DE3). Small Scale expression studies show an over-expressed protein band of correct molecular weight (~28 Kda) for *E. coli* FabI clearly visible following Coomassie staining of SDS PAGE gels. DNA sequencing of the *E. coli* FabI expression constructs illustrated that no errors were apparent. N’ terminal amino acid sequencing has confirmed the over-expressed protein band to be *E. coli* FabI.

**Purification of *E. coli* FabI**

*E. coli* FabI was expressed as soluble protein to 15% of total cell protein, 120g cells being recovered from 3L fermentation in shake flasks in modified terrific broth. The cells were lysed and the sample centrifuged. The resulting supernatant was filtered and purified.
using three consecutive chromatography columns: ion-exchange (Sourse 15Q), dye-affinity (blue sepharose), and size exclusion (superose 12). After each column the FabI containing fractions were pooled, concentrated and checked for purity and biological activity.

Antimicrobial Activity Assay

Whole-cell antimicrobial activity was determined by broth microdilution using the National Committee for Clinical Laboratory Standards (NCCLS) recommended procedure, Document M7-A4, “Methods for Dilution Susceptibility Tests for Bacteria that Grow Aerobically". The compound was tested in serial two-fold dilutions ranging from 0.06 to 64 mcg/mL. A panel of 12 strains were evaluated in the assay. This panel consisted of the following laboratory strains: Staphylococcus aureus Oxford, Streptococcus pneumoniae R6, Streptococcus pyogenes CN10, Enterococcus faecalis I, Haemophilus influenzae Q1, Escherichia coli DC0, E. coli ESS, E. coli 7623 (AcrAB') E. coli 120 (AcrAB") Klebsiella pneumoniae E70, Pseudomonas aeruginosa K799 wt and Candida albicans GRI 681. The minimum inhibitory concentration (MIC) was determined as the lowest concentration of compound that inhibited visible growth. A mirror reader was used to assist in determining the MIC endpoint.

One skilled in the art would consider any antibacterial compositions of the present invention with a MIC of less than 256 μg/mL to be a potential lead composition. The antibacterial compositions used in the antimicrobial assays may have a MIC value of less than 128 μg/mL. Said compositions may have a MIC value of less than 64 μg/mL.

Method for Checkerboard Combination Studies

The combination experiments were performed and the results were interpreted using the checkerboard method as described in Eliopoulos, G. M., and R. C. Moellering, 1996, Antimicrobial combinations, p. 330-396, In V. Lorian (ed.), Antibiotics in laboratory medicine, 4th ed., The Williams & Wilkins Co., Baltimore, Md., in 96-well microtiter
plates. Compound A was serially diluted along the x-axis of the test plate to a final volume of 50 µl, and compound B was serially diluted in a separate transfer plate. Dilutions in both plates were made in CAMHB (cation-adjusted Mueller Hinton broth) for *Staphylococci* and in CAMHB + 5% sheep blood for *Streptococci*. Aliquots (50 µl) of Compound B were transferred to the test plate along the y-axis thereby achieving a checkerboard matrix of antimicrobial combinations (100 µl total volume) as in Figure 4. The first column and last row (shaded in Figure 4) contained only compound B or compound A, respectively. Plates were then inoculated with 10 µl of the test microorganism and MICs were determined according to NCCLS guidelines (see National Committee for Clinical Laboratory Standards, 2000, Methods for Dilution Antimicrobial Susceptibility Tests for Bacteria That Grow Aerobically - Fifth Edition, Approved Standard M7-A5, NCCLS, Wayne, PA, USA.)

Data analysis was performed as follows and according to Eliopoulos, G. M., and R. C. Moellering, 1996, Antimicrobial combinations, p. 330–396, in V. Lorian (ed.), Antibiotics in laboratory medicine, 4th ed., The Williams & Wilkins Co., Baltimore, Md.

First individual FIC values for each combination in a plate were calculated:

FIC (Fractional Inhibitory Concentration) = FICA + FICB

FICA = MIC A+B / MIC A i.e. the MIC of combination of compound A + compound B divided by the MIC of compound A alone.

FICB = MICB+A / MICB i.e. the MIC of combination of compound B + compound A divided by the MIC of compound B alone.

FIC values were calculated only for combinations that enabled determination of a true MIC (e.g. not > or <= values). FIC indexes were then calculated as the average of individual FIC values for each combination plate. FIC index interpretation is:

<0.5 = synergy;

≥0.5 < 2 = additivity or indifference; and

>2 = antagonism.

A summary of the FIC index values is presented below in Table 1. Please see Figure 5 for the identity of compounds A, B, C, D, E, and F.

**Dosages**

The dosage of any compositions of the present invention will vary depending on the symptoms, age and body weight of the patient, the nature and severity of the disorder to be treated or prevented, the route of administration, and the form of the subject composition. Any of the subject formulations may be administered in a single dose or in divided doses. Dosages for the compositions of the present invention may be readily determined by techniques known to those of skill in the art or as taught herein.
In certain embodiments, the dosage of the subject compounds will generally be in the range of about 0.01 ng to about 10 g per kg body weight, specifically in the range of about 1 ng to about 0.1 g per kg, and more specifically in the range of about 100 ng to about 10 mg per kg.

An effective dose or amount, and any possible affects on the timing of administration of the formulation, may need to be identified for any particular composition of the present invention. This may be accomplished by routine experiment as described herein, using one or more groups of animals (preferably at least 5 animals per group), or in human trials if appropriate. The effectiveness of any subject composition and method of treatment or prevention may be assessed by administering the composition and assessing the effect of the administration by measuring one or more applicable indices, and comparing the post-treatment values of these indices to the values of the same indices prior to treatment.

The precise time of administration and amount of any particular subject composition that will yield the most effective treatment in a given patient will depend upon the activity, pharmacokinetics, and bioavailability of a subject composition, physiological condition of the patient (including age, sex, disease type and stage, general physical condition, responsiveness to a given dosage and type of medication), route of administration, and the like. The guidelines presented herein may be used to optimize the treatment, e.g., determining the optimum time and/or amount of administration, which will require no more than routine experimentation consisting of monitoring the subject and adjusting the dosage and/or timing.

While the subject is being treated, the health of the patient may be monitored by measuring one or more of the relevant indices at predetermined times during the treatment period. Treatment, including composition, amounts, times of administration and formulation, may be optimized according to the results of such monitoring. The patient may be periodically reevaluated to determine the extent of improvement by measuring the same parameters. Adjustments to the amount(s) of subject composition administered and possibly to the time of administration may be made based on these reevaluations.

Treatment may be initiated with smaller dosages which are less than the optimum dose of the compound. Thereafter, the dosage may be increased by small increments until the optimum therapeutic effect is attained.
The use of the subject compositions may reduce the required dosage for any
individual agent contained in the compositions (e.g., the FabI inhibitor) because the onset
and duration of effect of the different agents may be complimentary.

Toxicity and therapeutic efficacy of subject compositions may be determined by
standard pharmaceutical procedures in cell cultures or experimental animals, e.g., for
determining the LD$_{50}$ and the ED$_{50}$.

The data obtained from the cell culture assays and animal studies may be used in
formulating a range of dosage for use in humans. The dosage of any subject composition
lies preferably within a range of circulating concentrations that include the ED$_{50}$ with little
or no toxicity. The dosage may vary within this range depending upon the dosage form
employed and the route of administration utilized. For compositions of the present
invention, the therapeutically effective dose may be estimated initially from cell culture
assays.

Formulation

The antibacterial compositions of the present invention may be administered by
various means, depending on their intended use, as is well known in the art. For example,
if compositions of the present invention are to be administered orally, they may be
formulated as tablets, capsules, granules, powders or syrups. Alternatively, formulations of
the present invention may be administered parenterally as injections (intravenous,
intramuscular or subcutaneous), drop infusion preparations or suppositories. For
application by the ophthalmic mucous membrane route, compositions of the present
invention may be formulated as eyedrops or eye ointments. These formulations may be
prepared by conventional means, and, if desired, the compositions may be mixed with any
conventional additive, such as an excipient, a binder, a disintegrating agent, a lubricant, a
corriger, a solubilizing agent, a suspension aid, an emulsifying agent or a coating agent.

In formulations of the subject invention, wetting agents, emulsifiers and lubricants,
such as sodium lauryl sulfate and magnesium stearate, as well as coloring agents, release
agents, coating agents, sweetening, flavoring and perfuming agents, preservatives and
antioxidants may be present in the formulated agents.

Subject compositions may be suitable for oral, nasal, topical (including buccal and
sublingual), rectal, vaginal, aerosol and/or parenteral administration. The formulations may
conveniently be presented in unit dosage form and may be prepared by any methods well
known in the art of pharmacy. The amount of composition that may be combined with a
carrier material to produce a single dose vary depending upon the subject being treated, and
the particular mode of administration.

Methods of preparing these formulations include the step of bringing into
association compositions of the present invention with the carrier and, optionally, one or
more accessory ingredients. In general, the formulations are prepared by uniformly and
intimately bringing into association agents with liquid carriers, or finely divided solid
carriers, or both, and then, if necessary, shaping the product.

Formulations suitable for oral administration may be in the form of capsules,
cachets, pills, tablets, lozenges (using a flavored basis, usually sucrose and acacia or
tragacanth), powders, granules, or as a solution or a suspension in an aqueous or non-
aqueous liquid, or as an oil-in-water or water-in-oil liquid emulsion, or as an elixir or syrup,
or as pastilles (using an inert base, such as gelatin and glycerin, or sucrose and acacia), each
containing a predetermined amount of a subject composition thereof as an active ingredient.
Compositions of the present invention may also be administered as a bolus, electuary, or
paste.

In solid dosage forms for oral administration (capsules, tablets, pills, dragees,
powders, granules and the like), the subject composition is mixed with one or more
pharmacologically acceptable carriers, such as sodium citrate or dicalcium phosphate, and/or
any of the following: (1) fillers or extenders, such as starches, lactose, sucrose, glucose,
mannitol, and/or silicic acid; (2) binders, such as, for example, carboxymethylcellulose,
alginates, gelatin, polyvinyl pyrrolidone, sucrose and/or acacia; (3) humectants, such as
glycerol; (4) disintegrating agents, such as agar-agar, calcium carbonate, potato or tapioca
starch, alginic acid, certain silicates, and sodium carbonate; (5) solution retarding agents,
such as paraffin; (6) absorption accelerators, such as quaternary ammonium compounds; (7)
wetting agents, such as, for example, acetyl alcohol and glycerol monostearate; (8)
absorbents, such as kaolin and bentonite clay; (9) lubricants, such a talc, calcium stearate,
magnesium stearate, solid polyethylene glycols, sodium lauryl sulfate, and mixtures
thereof; and (10) coloring agents. In the case of capsules, tablets and pills, the
compositions may also comprise buffering agents. Solid compositions of a similar type
may also be employed as fillers in soft and hard-filled gelatin capsules using such
excipients as lactose or milk sugars, as well as high molecular weight polyethylene glycols
and the like.
A tablet may be made by compression or molding, optionally with one or more accessory ingredients. Compressed tablets may be prepared using binder (for example, gelatin or hydroxypropylmethyl cellulose), lubricant, inert diluent, preservative, disintegrant (for example, sodium starch glycolate or cross-linked sodium carboxymethyl cellulose), surface-active or dispersing agent. Molded tablets may be made by molding in a suitable machine a mixture of the subject composition moistened with an inert liquid diluent. Tablets, and other solid dosage forms, such as dragees, capsules, pills and granules, may optionally be scored or prepared with coatings and shells, such as enteric coatings and other coatings well known in the pharmaceutical-formulating art.

Liquid dosage forms for oral administration include pharmaceutically acceptable emulsions, microemulsions, solutions, suspensions, syrups and elixirs. In addition to the subject composition, the liquid dosage forms may contain inert diluents commonly used in the art, such as, for example, water or other solvents, solubilizing agents and emulsifiers, such as ethyl alcohol, isopropyl alcohol, ethyl carbonate, ethyl acetate, benzyl alcohol, benzyl benzoate, propylene glycol, 1,3-butylene glycol, oils (in particular, cottonseed, groundnut, corn, germ, olive, castor and sesame oils), glycerol, tetrahydrofuryl alcohol, polyethylene glycols and fatty acid esters of sorbitan, and mixtures thereof.

Suspensions, in addition to the subject composition, may contain suspending agents as, for example, ethoxylated isostearyl alcohols, polyoxyethylene sorbitol and sorbitan esters, microcrystalline cellulose, aluminum metahydroxide, bentonite, agar-agar and tragacanth, and mixtures thereof.

Formulations for rectal or vaginal administration may be presented as a suppository, which may be prepared by mixing a subject composition with one or more suitable non-irritating excipients or carriers comprising, for example, cocoa butter, polyethylene glycol, a suppository wax or a salicylate, and which is solid at room temperature, but liquid at body temperature and, therefore, will melt in the body cavity and release the active agent. Formulations which are suitable for vaginal administration also include pessaries, tampons, creams, gels, pastes, foams or spray formulations containing such carriers as are known in the art to be appropriate.

Dosage forms for transdermal administration of a subject composition includes powders, sprays, ointments, pastes, creams, lotions, gels, solutions, patches and inhalants. The active component may be mixed under sterile conditions with a pharmaceutically
acceptable carrier, and with any preservatives, buffers, or propellants which may be required.

The ointments, pastes, creams and gels may contain, in addition to a subject composition, excipients, such as animal and vegetable fats, oils, waxes, paraffins, starch, tragacanth, cellulose derivatives, polyethylene glycols, silicones, bentonites, silicic acid, talc and zinc oxide, or mixtures thereof.

Powders and sprays may contain, in addition to a subject composition, excipients such as lactose, talc, silicic acid, aluminum hydroxide, calcium silicates and polyamide powder, or mixtures of these substances. Sprays may additionally contain customary propellants, such as chlorofluorohydrocarbons and volatile unsubstituted hydrocarbons, such as butane and propane.

Compositions of the present invention may alternatively be administered by aerosol. This is accomplished by preparing an aqueous aerosol, liposomal preparation or solid particles containing the compound. A non-aqueous (e.g., fluorocarbon propellant) suspension could be used. Sonic nebulizers may be used because they minimize exposing the agent to shear, which may result in degradation of the compounds contained in the subject compositions.

Ordinarily, an aqueous aerosol is made by formulating an aqueous solution or suspension of a subject composition together with conventional pharmaceutically acceptable carriers and stabilizers. The carriers and stabilizers vary with the requirements of the particular subject composition, but typically include non-ionic surfactants (Tweens, Pluronics, or polyethylene glycol), innocuous proteins like serum albumin, sorbitan esters, oleic acid, lecithin, amino acids such as glycine, buffers, salts, sugars or sugar alcohols. Aerosols generally are prepared from isotonic solutions.

Pharmaceutical compositions of this invention suitable for parenteral administration comprise a subject composition in combination with one or more pharmaceutically-acceptable sterile isotonic aqueous or non-aqueous solutions, dispersions, suspensions or emulsions, or sterile powders which may be reconstituted into sterile injectable solutions or dispersions just prior to use, which may contain antioxidants, buffers, bacteriostats, solutes which render the formulation isotonic with the blood of the intended recipient or suspending or thickening agents.

Examples of suitable aqueous and non-aqueous carriers which may be employed in the pharmaceutical compositions of the invention include water, ethanol, polyols (such as
glycerol, propylene glycol, polyethylene glycol, and the like), and suitable mixtures thereof, vegetable oils, such as olive oil, and injectable organic esters, such as ethyl oleate. Proper fluidity may be maintained, for example, by the use of coating materials, such as lecithin, by the maintenance of the required particle size in the case of dispersions, and by the use of surfactants.

Efficacy of treatment

The efficacy of treatment with the subject compositions may be determined in a number of fashions known to those of skill in the art.

In one exemplary method, the median survival rate of the bacteria or bacteria median survival time or life span for treatment with a subject composition may be compared to other forms of treatment with the particular FabI inhibitor or antibiotic agent contained in the subject composition, or with other antibiotic agents. The decrease in median bacteria survival rate or time or life span for treatment with a subject composition as compared to treatment with another method may be 10, 25, 50, 75, 100, 150, 200, 300, 400% less or even more. The period of time for observing any such decrease may be about 3, 5, 10, 15, 390, 60 or 90 or more days. The comparison may be made against treatment with the particular FabI inhibitor or antibiotic agent contained in the subject composition, or with other antibiotic agents, or administration of the same or different agents by a different method, or administration as part of a different drug delivery device than a subject composition. The comparison may be made against the same or a different effective dosage of the various agents. The different regiments compared may use bacterial levels.

Alternatively, a comparison of the different treatment regimens described above may be based on the effectiveness of the treatment, using standard indices for bacterial infections known to those of skill in the art. One method of treatment may be 10%, 20%, 30%, 50%, 75%, 100%, 150%, 200%, 300% more effective, than another method.

Alternatively, the different treatment regimens may be analyzed by comparing the therapeutic index for each of them, with treatment with a subject composition as compared to another regimen having a therapeutic index two, three, five or seven times that of, or even one, two, three or more orders of magnitude greater than, treatment with another method using the same or different FabI inhibitor, antibiotic agent or combinations thereof.

Kits

This invention also provides kits for conveniently and effectively implementing the methods of this invention. Such kits comprise any subject composition, and a means for
facilitating compliance with methods of this invention. Such kits provide a convenient and effective means for assuring that the subject to be treated takes the appropriate active in the correct dosage in the correct manner. The compliance means of such kits includes any means which facilitates administering the actives according to a method of this invention. Such compliance means include instructions, packaging, and dispensing means, and combinations thereof. Kit components may be packaged for either manual or partially or wholly automated practice of the foregoing methods. In other embodiments involving kits, this invention contemplates a kit including compositions of the present invention, and optionally instructions for their use.

The solution was concentrated in vacuo, and the residue was dissolved in H_2O. The pH was adjusted to 6 with dilute HCl, and the solid precipitate was collected by suction filtration and dried to give the title compound (0.6 g, 72%) as a white solid: MS (ES) \text{m/e 165 (M} + \text{H)}^+.

**Preparation 2**

**Preparation of (E)-3-(6-aminopyridin-3-yl)acrylic acid (Method B)**

a) (E)-3-(6-Aminopyridin-3-yl)acrylic acid

Acrylic acid (23 mL, 0.33 mole) was added carefully to a solution of 2-amino-5-bromopyridine (25.92 g, 0.15 mole) and Na_2CO_3 (55.64 g, 0.53 mole) in H_2O (600 mL). PdCl_2 (0.53 g, 0.003 mole) was then added, and the mixture was heated at reflux. After 24 hr, the reaction was cooled to RT and filtered, and the filtrate was adjusted to pH 6 with
aqueous HCl. Additional H₂O (0.5 L) was added to improve mixing, and the mixture was stirred for 1 hr. The pH was readjusted to 6, then the solid was collected by suction filtration. The filter pad was washed sequentially with H₂O (2 x 0.5 L), cold absolute EtOH (100 mL), and Et₂O (2 x 250 mL). Drying in high vacuum at elevated temperature gave the title compound (15.38 g, 62%) as a tan solid: 1H NMR (300 MHz, D₆SO-d₆) δ 8.11 (d, J = 2.0 Hz, 1 H), 7.75 (dd, J = 8.7, 2.0 Hz, 1 H), 7.43 (d, J = 15.8 Hz, 1 H), 6.53 (s, 2 H), 6.45 (d, J = 8.7 Hz, 1 H), 6.22 (d, J = 15.8 Hz, 1 H); MS (ES) m/e 165 (M + H)⁺.

Preparation 3
Preparation of (E)-3-(2-aminopyrimidin-5-yl)acrylic acid

a) Benzyl (E)-3-(2-aminopyrimidin-5-yl)acrylate

According to the procedure of Preparation 1 (a), except substituting 5-bromo-2-aminopyrimidine (1.95 g, 11.2 mmole) for 2-amino-5-bromopyridine, the title compound (2.25 g, 79%) was prepared as a light orange solid: MS (ES) m/e 256 (M + H)⁺.

b) (E)-3-(2-Aminopyrimidin-5-yl)acrylic acid

According to the procedure of Preparation 1 (b), except substituting benzyl (E)-3-(2-aminopyrimidin-5-yl)acrylate (2.93 g, 11.5 mmole) for benzyl (E)-3-(6-aminopyridin-3-yl)acrylate, the title compound (1.71 g, 90%) was prepared as an off-white solid: MS (ES) m/e 166 (M + H)⁺.
Preparation 4

Preparation of 6-bromo-3,4-dihydro-1H,1,8-naphthyridin-2-one

a) 2-Amino-3-(hydroxymethyl)pyridine

Solid 2-aminonicotinic acid (199 g, 1.44 mole) was added in portions over 4 hr to 1.0 M LiAlH₄ in THF (3 L, 3 mole) with stirring under Argon. An ice-bath was applied to control the temperature below 30 °C. After the addition was complete, the reaction was heated at reflux for 16 hr, then was cooled to 0 °C and carefully quenched by sequential addition of H₂O (120 mL), 15% NaOH in H₂O (120 mL), and H₂O (350 mL). The resulting thick suspension was stirred for 1 hr, then was filtered through a pad of celite®. The filter pad was rinsed with THF (1 L), and the filtrate was concentrated to dryness to give the title compound (156 g, 87%) as a pale yellow waxy solid: MS (ES) m/e 125.1 (M + H)⁺; ¹H NMR (400 MHz, DMSO-d₆) δ 7.84 (dd, 1 H), 7.37 (m, 1 H), 6.53 (dd, 1 H), 5.65 (br s, 2 H), 5.16 (t, 1 H), 4.34 (d, J = 4.6 Hz, 2 H).

b) 2-Amino-5-bromo-3-(hydroxymethyl)pyridine hydrobromide

To a stirred solution of 2-amino-3-(hydroxymethyl)pyridine (156 g, 1.257 mole) in HOAc (2.5 L) at ambient temperature was added bromine (64.1 mL, 1.257 mole) dropwise over 1 hr. A suspension began to form during the addition. An exotherm to 36 °C was controlled with an ice bath. After the addition, the reaction mixture was stirred at ambient temperature overnight. The yellow precipitate was filtered, washed with ether and air-dried to give the title compound (289 g, 81%): MS (ES) m/e 203.2 (M + H)⁺; ¹H NMR (400 MHz, DMSO-d₆, free base) δ 7.89 (d, J = 2.3 Hz, 1 H), 7.52 (s, 1 H), 5.92 (br s, 2 H), 5.29 (br s, 1 H), 4.30 (s, 2 H).

c) 2-Amino-5-bromo-3-(bromomethyl)pyridine hydrobromide

A suspension of 2-amino-5-bromo-3-(hydroxymethyl)pyridine hydrobromide (289 g, 1.02 mole) in 48% aqueous HBr (2.9 L) was heated at reflux for 12 hrs. Complete solution occurred during heating. The reaction mixture was cooled and a crystalline precipitate formed. This was filtered and washed with ethyl acetate and air dried to give the title compound (305 g, 86%).

d) Methyl (±)-6-bromo-2-oxo-1,2,3,4-tetrahydro-1H,1,8-naphthyridine-3-carboxylate

Solid ethyl indole-2-carboxylate (25.29 g, 133.66 mmole) was added portionwise over 5 - 10 min, allowing gas evolution to subside between additions. When the addition was complete, the yellow mixture was stirred for 15 min, then methyl iodide (42 mL, 668.3 mmole) was added all at once. The reaction was exothermic, and the internal temperature rose to 40 - 45°C. After 1 hr, the reaction was quenched with 10% NH\(_4\)Cl (100 mL) and concentrated on the rotavap (high vacuum). The residue was partitioned between Et\(_2\)O(500 mL) and H\(_2\)O (100 mL), and the layers were separated. The Et\(_2\)O layer was washed with H\(_2\)O (100 mL), dried (MgSO\(_4\)), and concentrated to leave the title compound (27.10 g, quantitative) as a light yellow solid.
