[Continued on next page]

(54) Title: MOBILE COMMUNITY COMMUNICATION

(57) Abstract: A system and method for providing community services to mobile user terminals (14) including routing and translating messages. The service provision is performed by an application/server (10, 16) dependant on group context attributes (11) that may relate to group membership and availability of service features. The context attributes including the service features can be configured by users by sending messages to the application/server and by selecting templates. A cross-network subsystem (18) links instances of the application/server to a plurality of telecommunication networks (19) that route messages to mobile terminals.

1 **Mobile Community Communication**

2

3 The present invention relates to telecommunications and,  
4 in particular, to communication within mobile  
5 communities.

6

7 In the field of communication, people naturally organise  
8 themselves into groups. For instance, office co-workers,  
9 other company members, family, close friends, college  
10 friends, people at the rowing club, etc. This has been  
11 exploited by news groups, chat rooms and instant  
12 messaging services.

13

14 The group context is an important criterion in  
15 determining the subject and language of discourse amongst  
16 the group members. For example, John works with Jack,  
17 however John and Jack are also friends who regularly meet  
18 for a drink in their local pub. Their communications in  
19 the context of the 'work group' and their communications  
20 in the context of the 'pub group' differ both in subject  
21 and dialogue, despite the fact that in both cases it is  
22 still both John and Jack communicating.

23

1 The contextual nature of group discourse is very  
2 advantageous for the people involved. It allows the  
3 terminology to be very context dependent and therefore  
4 brief. People often use nicknames, and acronyms for  
5 people, places, activities and event. For instance "Who's  
6 going down the pub tonight, I hear FYC are playing?"  
7 requires the other group members to know which pub is  
8 'the pub' and what sort of music FYC play and what the  
9 acronym stands for.

10

11 An instance of group context based discourse is where one  
12 person is describing their own or other group member's  
13 locations. People describe locations in a group  
14 contextual terminology. One can use the term "place" as  
15 opposed to "location" to distinguish this usage. A  
16 location is a fixed point determined by geographical  
17 survey, an absolute description usually expressed in  
18 systematic manner such as lat/long, ordinance survey grid  
19 reference. Places are group contextual descriptions of  
20 locations. Some are translations to other systematic  
21 descriptions such as a postal address. For instance John  
22 might refer to his place of work as '35 Water Street,  
23 Leith'. However most groups for familiar places may  
24 abbreviate or use entirely group contextual place names.  
25 For instance John might refer to his place of work as  
26 'Yakara', or simply 'work'. All these place descriptions  
27 have meaning within the scope of the group (possibly only  
28 that group) and carries with it as a description a heavy  
29 dependence on the properties of the group members and,  
30 more specifically, the subject speaker.

31

32 Linguistics is the study of the structure of speech and  
33 language. Linguistics covers many study areas such as

1 syntax analysis, language parsing/semantic analysis. The  
2 study of the two or more speakers (inter-locutors)  
3 communicating is referred to as discourse analysis. The  
4 character of a discourse is that it consists of a series  
5 of short context dependent phrases passed back and forth  
6 between the speakers. Discourse requires an agreed  
7 context between the speakers, as most of the discourse is  
8 brief and refers (or even assumes reference) to a common  
9 context. This kind of communication is very different to  
10 that of 'email or news' where the software reflects all  
11 of the information in the sender's submission to the  
12 recipients, without applying any semantic analysis. If a  
13 discourse is held via email, news group, chat room or an  
14 instant messenger, the discourse context is applied  
15 purely by the people using the software. The software  
16 dumbly transports their messages without applying any  
17 semantic analysis or holding any contextual information  
18 about the nature of the discourse.

19  
20 Systems are known in the field of group messaging,  
21 location services, chat services and personalised  
22 services. Protocols and methods of establishing group  
23 calls and managing group calls are known. The use of a  
24 database configured with user profiles for maintaining a  
25 group call is known, and the use of location as an  
26 attribute to control group calls is known.

27  
28 United States Patent No US5,930,723 to Nokia relates to  
29 establishing an expanded group call in a mobile  
30 communication system. The network infrastructure  
31 receives a group call set-up request, checks whether an  
32 expanded group call set-up facility has been activated  
33 and initiates the call.

1

2 United States Patent No US6,032,051 to Ericsson relates  
3 to a wireless mobile communication device for group use.  
4 Mobile devices share information about their status. The  
5 system permits a group member to automatically monitor  
6 the status of any other group member, without manually  
7 establishing a call with other group members.

8

9 International Patent Application No WO01/31964 to  
10 Ericsson relates to dynamically controlled group call  
11 services to mobile subscribers. Mobile users can  
12 establish group call immediately when needed, and the  
13 group call area is dynamically modified during the call  
14 to accommodate location changes of group members. Mobile  
15 users can initiate and participate in group calls without  
16 having previous group call subscription and users or  
17 software can dynamically and on demand establish, modify  
18 group call attributes.

19

20 The known systems do not elaborate on further contextual  
21 information which is used for configuring and routing  
22 group calls. Such systems suffer from a variety of  
23 problems related to the narrow scope of their solutions,  
24 and the complexity of their set-up and configuration  
25 maintenance. In such systems, much of the information  
26 relating to the context of communication is lost,  
27 resulting in the recipients of communication losing  
28 visibility of that contextual information. Both senders  
29 and recipients of communications using such systems also  
30 lose control of the flow of information.

31

32 It would be advantageous to provide a more efficient and  
33 'natural' means for people to conduct their

1 communications, collaboration and co-ordination that  
2 preserves and uses the context of the communication,  
3 collaboration and co-ordination to enhance the utility of  
4 the communication, collaboration and co-ordination.

5

6 It would be further advantageous to provide a system that  
7 gives users control over the flow of information.

8

9 It would be further advantageous to provide a system that  
10 self-provisions and can be configured for the user by the  
11 user.

12

13 It would be further advantageous to provide group  
14 communication, collaboration and co-ordination accessible  
15 via a range of different input/output devices carried  
16 across a range of different communication networks.

17

18 It would be further advantageous to provide a system that  
19 allows service providers to deploy a range of services  
20 and to add and remove services without interrupting  
21 existing service provision.

22

23 In this document and claims, the term 'translate' is  
24 defined as acting on a message by one or a combination  
25 of:

- 26 • Leaving the information in the message as it is; or
- 27 • Replacing information in the message; or
- 28 • Tagging information in a message; or
- 29 • Adding new information to the message; or
- 30 • Re-formatting information in a message; or
- 31 • Formatting information in a message for presentation;
- 32 or

1 • Deleting information from a message; or

2 • Screening information from a message.

3

4 In this document and claims, the term 'group game  
5 service' is defined as a group available game or suite of  
6 games services, including the management within the  
7 context of the group of game score history, or re-useable  
8 points accrual.

9

10 It is an object of the present invention to provide group  
11 related services within communities while preserving and  
12 using the context of the group.

13

14 It is an object of the present invention to provide self-  
15 provisioned group related services within communities.

16

17 It is a further object of the present invention to  
18 provide group related services within communities  
19 accessed from a range of telecommunication networks.

20

21 According to a first aspect of the present invention,  
22 there is provided a mobile community system comprising:

23 • a plurality of mobile terminals;

24 • means for storing a group context attribute;

25 • a configuration means for configuring said group  
26 context attribute;

27 • an application server means for providing a  
28 plurality of group related services, wherein at  
29 least two of the services are different, in co-

1 operation with said mobile terminals responsive to  
2 said group context attribute;

3 • a communication means for connecting each of said  
4 terminals to the application server means.

5 Preferably said application server means further  
6 comprises:

7 • a means for translating a message responsive to a  
8 stored group context attribute; and

9 • a means for routing a message responsive to a  
10 stored group context attribute.

11 Preferably said configuration means is responsive to the  
12 selection of a template.

13 Preferably said configuration means is adapted to co-  
14 operate with a mobile terminal to configure a group  
15 context attribute.

16 Preferably said configuration means is responsive to the  
17 content of a message from a terminal.

18 Optionally said application server means is adapted to  
19 record system usage data and configure a group context  
20 attribute responsive to said stored system usage data.

21 According to a second aspect of the present invention,  
22 there is provided a cross-network system for connecting  
23 the application server means to a plurality of  
24 telecommunication networks, the cross-network system  
25 comprising:

26 • a means for storing routing rules;

- 1           • an in-bound message queue connected to said  
2           application server means;
- 3           • a connection agent means connected to each  
4           telecommunication network for:
- 5           selecting and routing messages to said in-bound  
6           message queue responsive to said stored routing  
7           rules; and
- 8           routing messages to a telecommunication network  
9           responsive to receiving a message from said  
10          application server means.

11 According to a third aspect of the present invention,  
12 there is provided a method for community communication  
13 from and to a plurality of mobile terminals comprising  
14 the steps of:

- 15          • storing a group context attribute;
- 16          • configuring said group context attribute;
- 17          • providing a plurality of group related services,  
18          wherein at least two of the services are  
19          different, in co-operation with said mobile  
20          terminals responsive to said group context  
21          attribute;

22 Preferably said method further comprises the steps of:

- 23          • translating a message responsive to a stored group  
24          context attribute; and
- 25          • routing a message responsive to a stored group  
26          context attribute.

1 Preferably said step of configuring is responsive to the  
2 selection of a template.

3 Preferably said step of configuring further comprises the  
4 step of co-operating with a mobile terminal to configure  
5 a group context attribute.

6 Preferably said step of configuring is responsive to the  
7 content of a message from a terminal.

8 Preferably said method further comprising the steps of  
9 recording method usage data and configuring a group  
10 context attribute responsive to said stored method usage  
11 data.

12 Typically said group context attribute relates to the  
13 availability of group related services to members of a  
14 group.

15 Alternatively said group context attribute relates to a  
16 user's membership of a group.

17 Alternatively said group context attribute relates to a  
18 user's role within a group.

19 Alternatively said group context attribute relates to a  
20 place.

21 Alternatively said group context attribute relates to a  
22 group related event.

23 Alternatively said group context attribute relates to a  
24 terminal status.

25 Alternatively said group context attribute relates to a  
26 terminal identifier.

1 Alternatively said group context attribute relates to a  
2 user account identifier.

3 Alternatively said group context attribute relates to a  
4 preferred network connection.

5 Typically said group related service is a chat service.

6 Optionally said group related service is a group decision  
7 making service.

8 Optionally said group related service is a group member  
9 finder service.

10 Optionally said group related service is a group event  
11 reminder service.

12 Optionally said group related service is a group content  
13 sharing service.

14 Optionally said group related service is a group game  
15 service.

16 According to a fourth aspect of the present invention,  
17 there is provided a method for connecting said  
18 application server means to a plurality of  
19 telecommunication networks, the method comprising the  
20 steps of:

- 21 • storing routing rules;
- 22 • selecting and routing messages to an in-bound  
23 message queue connected to said application server  
24 means responsive to said stored routing rules; and

1           • routing messages to a telecommunication network  
2           responsive to receiving a message from said  
3           application server means.

4 According to a fifth aspect of the present invention,  
5 there is provided a computer program comprising program  
6 instructions which when run on a computer constitute the  
7 system of the first aspect of the present invention.

8 According to a sixth aspect of the present invention,  
9 there is provided a computer program comprising program  
10 instructions which when run on a computer constitute the  
11 system of the second aspect of the present invention.

12 According to a seventh aspect of the present invention,  
13 there is provided a computer program comprising program  
14 instructions for causing a computer to perform the method  
15 of the third aspect of the present invention.

16 According to a eighth aspect of the present invention,  
17 there is provided a computer program comprising program  
18 instructions for causing a computer to perform the method  
19 of the fourth aspect of the present invention.

20 In order to provide a better understanding of the present  
21 invention, an embodiment will now be described by way of  
22 example only and with reference to the accompanying  
23 Figures, in which:

24

25 Figure 1 illustrates in schematic form a mobile community  
26 system, a cross-network sub-system and user terminals  
27 connected through telecommunication networks to the  
28 system, in accordance with a preferred embodiment of the  
29 present invention.

30

1 Figure 2 illustrates in schematic form stored group  
2 context attributes in accordance with a preferred  
3 embodiment of the present invention.

4

5 Figure 3 illustrates a flow chart representing the method  
6 of sending a message between terminals.

7

8 Figure 4 illustrates in schematic form several instances  
9 of the community communication system connected through a  
10 cross-network subsystem to multiple telecommunication  
11 networks.

12

13 Figure 5 illustrates the in-bound message flow to  
14 instances of the community communication system from  
15 telecommunication networks via connection agents.

16

17 Figure 6 illustrates a flow chart representing a method  
18 for connecting the community communication system with  
19 telecommunication networks while handling an in-bound  
20 message.

21

22 Figure 7 illustrates the out-bound message flow from  
23 instances of the community communication system to  
24 telecommunication networks via connection agents.

25

26 Figure 8 illustrates a flow chart representing a method  
27 for connecting a community communication system with  
28 telecommunication networks while handling an out-bound  
29 message.

30

31 Figure 9 illustrates in schematic form XML (eXtensible  
32 Markup Language) Parser technology used for message  
33 translation.

1

2 Table 1 illustrates XML document definitions.

3

4 Table 2 illustrates document translation definitions.

5

6 Table 3 illustrates service features available to each  
7 template.

8

9 The invention is a system that translates and routes  
10 messages according to context attributes associated with  
11 groups and users. A cross-network subsystem connects  
12 instances of the system to multiple telecommunication  
13 networks.

14

15 The preferred embodiment is a suite of mobile lifestyle  
16 applications that provide fun, easy and compelling ways  
17 to communicate with groups of friends, family and co-  
18 workers.

19

20 The preferred embodiment's applications enable private  
21 groups of people to vote, share, send reminders, chat,  
22 play games or find each other. Anyone can create a group  
23 and invite people they know to join their groups.

24

25 The preferred embodiment supports access via GSM (Global  
26 System for Mobile communications) / GPRS (General Packet  
27 Radio Service) and GPRS/EDGE (Enhanced Data-rate for Gsm  
28 Evolution) networks and handsets, and can provide a  
29 consistent service to users throughout migration to  
30 third-generation UMTS (Universal Mobile  
31 Telecommunications System) technologies.

32

1 The preferred embodiment is a white-label product. This  
2 means that a service operator can overlay their preferred  
3 branding on top of the functionality of the services.

4

5 The preferred embodiment is designed as a carrier-class  
6 solution, and supports a wide range of user-access means  
7 including messaging technologies such as GSM SMS (Short  
8 Messaging Service, MMS (Multimedia Messaging Service) and  
9 Email, as well as mobile browser technologies such as WAP  
10 (Wireless Application Protocol) and cHTML (compact  
11 Hypertext Mark-up language) and fixed line access via  
12 Internet browser and instant messenger technologies.

13

14 The preferred embodiment interfaces with operational  
15 support systems (OSS) such as Billing and CRM (Customer  
16 Relationship Management) systems.

17

18 The following parts of the preferred embodiment are  
19 described herein.

20

21 1. Message routing and translation.

22

23 2. Self-provisioning of multiple interactive group  
24 services.

25

26 3. Text expansion.

27

28 Although the embodiments of the invention described with  
29 reference to the drawings comprise computer apparatus and  
30 processes performed in computer apparatus, the invention  
31 also extends to computer programs, particularly computer  
32 programs on or in a carrier, adapted for putting the  
33 invention into practice. The program may be in the form

1 of source code, object code, a code of intermediate  
2 source and object code such as in partially compiled form  
3 suitable for use in the implementation of the processes  
4 according to the invention. The carrier may be any  
5 entity or device capable of carrying the program.

6

7 For example, the carrier may comprise a storage medium,  
8 such as ROM, for example a CD ROM or a semiconductor ROM,  
9 or a magnetic recording medium, for example, floppy disc  
10 or hard disc. Further, the carrier may be a  
11 transmissible carrier such as an electrical or optical  
12 signal that may be conveyed via electrical or optical  
13 cable or by radio or other means.

14

15 When the program is embodied in a signal that may be  
16 conveyed directly by a cable or other device or means,  
17 the carrier may be constituted by such cable or other  
18 device or means.

19

20 Alternatively, the carrier may be an integrated circuit  
21 in which the program is embedded, the integrated circuit  
22 being adapted for performing, or for use in the  
23 performance of, the relevant processes.

24

25 With reference to Figure 1, software stored and executed  
26 on a server is shown. The storage 10, which may be a  
27 hard disk, RAM or a network storage device, stores  
28 program modules and data. The data structures include  
29 group context attributes 11. The program modules include  
30 a service provision module 12 for providing a range of  
31 different services (including multiple copies of the same  
32 service), a configuration module 13 configuring the group  
33 context attributes, a translation module 14 that has

1 access to the group context attributes and a routing  
2 module 15 that also has access to the group context  
3 attributes.

4

5 A central processing unit (CPU) 16 accesses the storage  
6 and executes the program modules. The CPU can  
7 communicate through a communication unit 17 to a cross-  
8 network subsystem 18 that is further connected to several  
9 telecommunication networks 19 which in turn connect to  
10 user terminals 20. The terminals are typically mobile  
11 terminals, but may also be terminals at a fixed location.

12

13 Although in Figure 1 the server is shown as being in one  
14 CPU/Storage unit, it may be distributed across more than  
15 one platform, over more than one processor and storage  
16 medium.

17

18 With reference to Figure 2, the stored group context  
19 attributes 11 are shown. The group context attributes  
20 may be a data structure for storing such attributes that  
21 is empty.

22

23 With reference to Figure 3 that shows the flow chart 30  
24 of steps performed by the system, a group context  
25 attribute is stored 31, and the configuration module  
26 configures the group context attribute 32. On receiving  
27 a message 33 through the communication unit from a user  
28 terminal, the translation module translates the message  
29 34 using the stored group context attributes. Next the  
30 routing module routes the message 35 (using group context  
31 attributes) and the message is further transmitted 36 to  
32 the recipient terminal. In configuring the group context  
33 attribute, the configuration module can be triggered and

1 controlled by the content of a message from a terminal.  
2 The content of the message can indicate the selection of  
3 a template and the group context attributes can include a  
4 set of service features defined by the template.

5

#### 6 **Message routing and translation**

7

8 Effective message translation and routing are critical to  
9 the success of a mass-market message driven community  
10 service. The preferred embodiment is a system that hosts  
11 personal communities and supplies them with services. The  
12 system has two components associated with providing  
13 message translation and routing. These are the 'cross-  
14 network subsystem' and the 'content translation support  
15 components'.

16

#### 17 **Routing overview**

18

19 The system requires its services to be available to  
20 mobile telephone handset owners on a widespread easy  
21 access basis. To achieve this the routing of messages to  
22 and from various networks needs to be handled  
23 effectively. This is the role of the cross-network  
24 subsystem component. This level of accessibility is  
25 integral to the success of a mass-market message oriented  
26 product.

27

28 Furthermore the cross-network subsystem allows operators  
29 to easily introduce new or remove existing links to  
30 mobile telephone networks without interrupting the  
31 service to existing users. This feature is necessary  
32 also, as the users expect a very high level of service  
33 availability and the service operators need a quick and

1 cost effective means to increase or modify service  
2 connectivity.

3

#### 4 **Translation overview**

5

6 The system requires its services to be easy to use. The  
7 users must be able to interact with their personal  
8 communities and use the associated services without  
9 learning jargon, reading user literature, or memorising  
10 complex menu systems and usage practices.

11

12 The system needs to support a wide range of interaction  
13 terminals to achieve the level of accessibility  
14 necessary. Typically this includes: -

15

- 16 • Internet accessibility to/from both personal computer  
17 and interactive television Web browser.
- 18 • Mobile accessibility to/from mobile telephones and  
19 wired or wireless personal digital assistants (PDAs).
- 20 • Mobile telephone handset access can be sub-divided into  
21 messaging access, browser access and voice access.
- 22 • Messaging access can be via SMS messaging, and its  
23 successor technologies EMS (Electronic Messaging  
24 Service)/ MMS (Multimedia Messaging Service).
- 25 • Mobile telephone browser access via WAP/XHTML  
26 (eXtensible HyperText Markup Language) or i-mode™ by  
27 NTT DoCoMo (cHTML) enabled browsers.
- 28 • Mobile telephone voice access, using mixed audio and  
29 DTMF (Dual Tone MultiFrequency) key driven interaction  
30 via a computer telephony interface.

31

1 The above technologies are 2G (2<sup>nd</sup> Generation) and 2.5G  
2 service access mechanisms. The advent of 3G (3<sup>rd</sup>  
3 Generation) UMTS mobile telephone services will further  
4 expand the service access mechanisms required by users of  
5 the system.

6

7 These varied access mechanisms provide a challenge to  
8 achieving intuitive user interfaces, as information  
9 entered in an intuitive manner by one access mechanism  
10 such as SMS messaging can be viewed as garbled, low  
11 quality and even unintelligible when viewed via another  
12 access mechanism, such as Web browser access.

13

14 The system's content translation support components work  
15 to bridge this gap. They provide a means to expand user  
16 brevity or contract user verbosity to suit the target  
17 device the user is using to access the preferred  
18 embodiment.

19

#### 20 **Design of the cross-network subsystem**

21

22 The cross-network access subsystem gives personal  
23 communities the ability to communicate in both directions  
24 with the handsets registered and active on multiple  
25 networks. Each of the networks must be connected to the  
26 cross-network access subsystem either via a fixed link  
27 for instanced to a network's SMS message centre or via a  
28 mobile terminal registered on the network, such as a GSM  
29 modem.

30

31 The preferred embodiment can be viewed through the  
32 standard 4-layer application server provision (ASP)  
33 service model. This comprises of the service,

1 application, platform and integration layers of an ASP  
2 service. The cross-network subsystem is an integration  
3 layer component. It is one of several subsystems that  
4 link the first and second aspects of the present  
5 invention to peripheral systems that are necessary to  
6 support its function.

7

8 The design of the cross-network subsystem specifically  
9 allows multiple SMS links from many network operators to  
10 connect to a server farm. The server farm can host  
11 multiple unique instances of the preferred embodiment's  
12 application software. Each unique application software  
13 instance usually has a distinct brand and service  
14 specialisation and is operated by or on behalf of a  
15 distinct customer (service owner). It is usual for each  
16 service to be made available on distinct contact numbers  
17 (both standard telephone long codes or short codes)  
18 synonymous with the service, for messaging (SMS/EMS/MMS)  
19 and voice access. Similarly distinct URL (Uniform Resource  
20 Locator) / URI (Uniform Resource Identifier) are normally  
21 offered on a per service basis.

22

23 The diagram shown in Figure 4 illustrates the role played  
24 by the cross network subsystem 41 in linking  
25 heterogeneous 3rd party network messaging subsystems 42  
26 with specific link technologies 43 to multiple server  
27 installations 44 of the application software hosting in  
28 turn multiple branded services 45 for specific customers.  
29 There is a standard interface 46 between the  
30 platform/application layer 44 and the interface layer 41.

31

32 The internal structure of the cross network subsystem  
33 consists of three elements. A standard messaging plug, a

1 standard messaging socket (to accept the plug), and link  
2 in turn to the platform's hosted application software and  
3 the accompanying watcher component.

4

5 The standard messaging plug consists of a code base that  
6 can be easily modified by application developers to cater  
7 for each new network-messaging link that must be  
8 connected. The code base has been set up to cater for the  
9 four European Telecommunication Standards Institute  
10 (ETSI) approved SMSC protocols, SMPP (by Logica), CIMD  
11 (by Nokia), UCP/EMI (by CMG) and SMS2000 (by SEMA). The  
12 plug maintains a generic interface to the cross network  
13 subsystem socket code. This interface remains unchanged  
14 and together a customised plug and socket form and  
15 connection agent task. The connection agent task can read  
16 and write to Java Messaging Service (JMS) queues and  
17 thereby send and receive messages for transport to and  
18 from the SMSC link serviced by a specific connection  
19 agent task. The JMS queues link to the preferred  
20 embodiment's core and provide orderly transport between  
21 each connection agent task and each customer's  
22 application/server installation.

23

#### 24 **Connection agents and queues**

25

26 The cross network subsystem is a distinct integration  
27 layer component separated from the platform and  
28 application layer components by the JMS queues. Each  
29 customer application/server installation maintains an in-  
30 bound and out-bound JMS queue for that installation.

31

32 Figure 5 shows in-bound message flow from networks to  
33 applications via connection agents. With reference to

1 Figure 5, when a connection agent task 51 receives an in-  
2 bound message from the network 52 that it serves, it  
3 examines the called party number set by the sender (long  
4 code or short code) and thereby determines the customer  
5 application/server 53 that should receive that message  
6 and therefore which JMS queue 54 to write to. This is  
7 done by reference to routing rules 55 made available to  
8 the connection agent.

9

10 Figure 6 shows the flowchart 60 of the steps performed  
11 during the in-bound message flow. The routing rules are  
12 initially stored 61. On receiving 62 an in-bound  
13 message, the connection agent accesses the routing rules  
14 63 and selects an in-bound message queue 64. It then  
15 routes the message to the in-bound message queue 65.

16

17 Figure 7 shows out-bound message flow from networks to  
18 applications via connection agents. With reference to  
19 Figure 7, when a customer's application/server  
20 installation 71 prepares to send a message to a  
21 particular user, it resolves the appropriate connection  
22 agent 72 to send to by referencing routing rules 73. This  
23 establishes the JMS queue 74 the message must be written  
24 to in order to reach the connection agent for the network  
25 75 the user is a member of.

26

27 Figure 8 shows the flow chart 80 of the steps in the out-  
28 bound message flow. The customer application/server  
29 installation accesses routing rules 81 in order to select  
30 the connection agent 82 and send a message to the  
31 appropriate connection agent queue 83. The connection  
32 agent receives 84 the out-bound message and sends 85 the  
33 message to its linked telecommunication network.

1

2 Neither the core nor the cross-network subsystem has hard  
3 coded routing logic. Instead, the core and the cross  
4 network subsystem are made to be configurable so that  
5 administrators can instruct them to route messages  
6 according to an installation specific routing policy.

7

8 The following are two possible routing policies.

9

10 1. An administrator may decide on a per-customer per-  
11 service and least-cost basis which network a message  
12 should be routed through, trying to send messages  
13 out through the network that the recipient belongs  
14 to (in order to avoid charges for inter-network SMS  
15 transfer).

16

17 2. A customer may come to the provider of the system  
18 with a special commercial relationship with a  
19 Telecoms network operator already in place, and may  
20 wish to configure their system to route all out-  
21 bound messages through the one operator.

22

### 23 **Message routing**

24

25 A routing table holds all configuration data that allows  
26 an administrator to apply the message routing policies  
27 for a customer.

28

29 Sometimes a particular customer may have a special  
30 billing and charging relationship with a particular  
31 telecommunications network operator. In this case, the  
32 system must allow a routing override so that SMS messages  
33 for all networks can be transmitted through the preferred

1 operator. The routing table in the application/server  
2 installation customer database allows this. The table has  
3 five columns, and has an entry for each  
4 telecommunications network operator currently connected  
5 to.

6

7 The columns are defined as follows: GSM Country Code; GSM  
8 Network Code; Network ID; Link ID; and Reply-To Short  
9 Code.

10

11 The GSM Country Code and the GSM Network Code form the  
12 primary key.

13

14 When the application/server installation sends an SMS to  
15 a user, for instance as a response to a user submitted  
16 command such as 'WHO', it performs the following steps.  
17 The software looks up the user details in the member  
18 table in the customer database and identifies the network  
19 operator the user is contracted to. The value in the  
20 member table is a GSM Country and Network Code tuple. The  
21 software then runs a query on the routing table using the  
22 GSM Country and Network Code tuple. The query returns a  
23 Network Identifier and a Link Identifier. These are used  
24 to form a selector to place the message in the correct  
25 out-bound JMS queue to reach the network identified by  
26 the routing rule.

27

28 This mechanism is configured for 'normal' operation when  
29 each telecommunications network operator has its own  
30 Network Identifier against its own GSM Network Code and  
31 an appropriate Link Identifier. The Link Identifier must  
32 be a connection agent link that goes to the network in  
33 question.

1  
2 To achieve a policy override (that is when the customer  
3 has a special relationship with a particular  
4 telecommunications network operator), all Network  
5 Identifiers and Link Identifiers are stripped out and  
6 replaced with the details of the telecommunications  
7 network operator with whom the customer has a special  
8 relationship. In this way, the lookup always returns the  
9 same Network Identifier and Link Identifier, regardless  
10 of the user's contracted network. No special logic is  
11 required to achieve a policy override. Under this design  
12 it is a data-driven feature.

13

#### 14 **Design of the translation support components**

15

16 The translation support components consist of a set of  
17 XML document translation definitions. These define the  
18 valid form of an in-bound XML document to an XML parser  
19 and how the parser can translate a document provided in  
20 that form into a different out-bound well-formed  
21 document. This mechanism is public domain functionality  
22 of XML parser technology. The specifications of the XML  
23 document translation definitions are unique to the design  
24 of the preferred embodiment.

25

26 Figure 9 shows the application of XML parser technology  
27 to the preferred embodiment using document definitions.

28

29 The document definitions are described in Table 1.

30

31 With reference to Figure 9, when a user interacts with  
32 the system their in-bound command/message is converted to  
33 the appropriate document associated with their current

1 client access device type. Interaction by the system and  
2 others is subject to translation into a document 91  
3 associated with their current access device type, e.g.  
4 SMS. Information sent to other users 92 or retrieved by  
5 them is translated in accordance with their access device  
6 type, e.g. MMS, by the system.

7  
8 For instance, consider an SMS message user might send to  
9 his family group the message "Lets meet at the dead cow  
10 burger bar for lunch". Sending this as an in-bound chat  
11 message with the following SMS message "Chat Lets meet at  
12 the dead cow burger bar for lunch". If his wife received  
13 the message as a pushed MMS message, the message may well  
14 appear with her husband's avatar (appropriate to that  
15 family group alone), the text of the message, and perhaps  
16 a link to the map of the shopping mall in which the dead  
17 cow burger bar in question was situated.

18  
19 The translation definitions listed in Table 2 are  
20 developed as part of the Translation Service Components.  
21 These allow the system to convert information internally  
22 between any of the above document forms.

23

#### 24 **Responding to sender/recipient attributes**

25

26 The system discussed above applies translations to  
27 messages between users to make best use of the  
28 capabilities of the access mode they are using. Therefore  
29 for example, an SMS text originated vote set up by a  
30 group member will be sent to another group member with a  
31 WAP-Push capable handset as a WAP screen containing the  
32 voting options.

33

1 Each group member has a number of context attributes that  
2 are pertinent to their user profile, as well as further  
3 attributes relating to their membership of each group.  
4 Therefore, for a given group member there are attributes  
5 that are the group specific and user profile derived.  
6 Group attributes can be static, such as 'role' (for  
7 instance rowing club treasurer) and dynamic such as  
8 current place, presence (active recent communication/not  
9 recently communicated), group oriented state (not rowing,  
10 rowing) etc.

11

12 The translators make use of content from the message and  
13 content from the group context to create out-bound  
14 messages. These are passed through a filter so that the  
15 out-bound content is appropriate to the recipient's  
16 device.

17

18 Typical group context attributes are:

19

20 Place attributes: - Each group allows places to be  
21 registered and named (or names imported into the group  
22 from 3rd party data sources/databases). User locations  
23 provided to the system from a 3rd party location  
24 derivation technology can be imported and translated into  
25 the context of the group and published only to other  
26 group members as a group related place name. A group  
27 member's place is only released to other group members  
28 under the location conditions they have agreed to for  
29 that group. A place attribute may be a group member place  
30 name, derived from combination of group place context  
31 attributes held in a group and a group member location  
32 update.

33

1 If the user is a member of several groups each of which  
2 supports a different definition for a place that is  
3 geographically the same location, then each group will  
4 report the 'place' related to specifically that group for  
5 the same location.

6

7 The system supports place-oriented alerts, proximity  
8 alerts, non-proximity alerts, time-oriented alerts, and  
9 time-place-combined alerts. It can provide a sequence of  
10 place transit reports in real-time or captured and later  
11 reported.

12

13 Time based attributes:- The system can support time-based  
14 events such as timed alerts. It can integrate with client  
15 and Internet based diary applications, generating and  
16 importing definitions of alerts, meetings, and  
17 appointments between the system and 3rd party  
18 applications (such as PDA organisers or diary managers  
19 such as that built into Microsoft® Exchange™).

20

21 Communication and peer-action events: - The system  
22 supports events triggered from group peers performing an  
23 action, such as chatting, voting or using any of the  
24 services. For instance the user could register an event  
25 to notify them if another group member enters the group  
26 and downloads a ring-tone. The system as in this example  
27 allows the user to combine a response with the event to  
28 be triggered when the conditions that raise the event  
29 become true. These can be quite specific. For instance  
30 the event/action for a family group might be to let a  
31 parent group member know if a child group member leaves  
32 school premises within the hours of school by more than  
33 200 yards and if true to open a voice call between the

1 parent and the child, predicted with the alert text to  
2 the parent explaining to them the purpose of the  
3 spontaneous call.

4

5 **Self-provisioning of multiple interactive group services**

6

7 Two important aspects in establishing a successful  
8 community service are earning the trust of the user, and  
9 empowering them. For a user to use a personal community  
10 service they need to feel their communication space and  
11 activities are private to them and their co-group  
12 members. It is also important that they can rely on the  
13 service being accessible, highly available and reliable  
14 in doing what it has been instructed to do. In short the  
15 system must protect their privacy and provide a high  
16 quality of service. Without the trust of the user, the  
17 service will either not be used or infrequently used. The  
18 system has several design features to provide privacy  
19 control and ensure a high quality of service.

20

21 With trust established, the next important aspect of the  
22 system is the empowerment of the user. This involves  
23 receiving commands from the user (including commands in  
24 the content of messages to the system) to allow them to  
25 control the creation or removal of their groups, control  
26 group membership and direct the groups to their purpose.  
27 Furthermore, to control the services that are available  
28 to themselves and other group members, and to evict  
29 unruly members, or disband groups they own. These are  
30 important features of the design of a personal community  
31 service that differentiate a personal community system  
32 such as the preferred embodiment from a mediated public

1 chat forums. In the later the user is not empowered to a  
2 similar degree.

3

4 Self-provisioning, is an important aspect of the user  
5 empowerment. It allows users to create groups (including  
6 by sending messages) for their own purpose and invite  
7 users of their choice and control the membership during  
8 the group lifetime. Self-provisioning is also important  
9 to the operators of the system, as it removes the need to  
10 create groups, mediate, or control their membership on  
11 behalf of the users. Self-provisioning is also important  
12 as it by this means that the number of groups increase  
13 and the use of the system develops.

14

15 The system incorporates in its design user oriented  
16 privacy control, high quality of service features, and  
17 user empowerment features such as self-provisioning.

18

### 19 **Setting up a group**

20

21 The objective is to make setting up a group as simple as  
22 possible for a user, and yet to also make the group as  
23 useful as possible by capturing attributes of the group  
24 and its members. The user can create a group by clicking  
25 a 'create group' button on the Web/WAP (or cHTML) site  
26 pages. The user can also create a group by sending a  
27 message (SMS/MMS) containing the group creation command  
28 syntax. Although this description focuses on creating a  
29 group, it applies with little change to configuration of  
30 an existing group.

31

32 Any and all of the above user activities are translated  
33 from the specifics of the user input device into an

1 internal generic XML command for creating a group. This  
2 command captures the intent of creating a group, the name  
3 of the group to be created, and the identity of the group  
4 creator. The command also allows for an optional group  
5 template to be specified. The characteristics of the new  
6 group are based on properties specified at the time of  
7 the group creation. These are held as parameters  
8 associated with the group creator, in their personal  
9 profile, and in the group template if one was specified.  
10 For instance: Jack may be a user using the system as a  
11 facility made available to him via his employer. As such  
12 the employer may have specified that no location updates  
13 will be available in groups outside working hours, for  
14 any groups created by members of their staff through this  
15 facility. This restrictive parameter will pass through to  
16 Jack's personal profile and be a constraint on the  
17 properties of the groups he can create. The company may  
18 also have applied some positive parameters. For instance  
19 each person's employee contact details may be available  
20 in their personal profile. This allows Jack to create  
21 groups that use this information. If Jack specified a  
22 template for his group, he can further define the scope  
23 of use of his group. For instance, the template selected  
24 may restrict other members from deleting group assets,  
25 such as shared reports. The template may however allow  
26 group members to get work-time only place information to  
27 help colleagues find each other.

28

29 Processing the device access button click or in-bound  
30 message generates an internal generic XML command for  
31 group creation. This is received by the XML command  
32 processor and parsed by an XML parser such as Xalan-Java  
33 XSLT (an XSLT translator developed by the Apache Software

1 Foundation project of the same name, under the Apache XML  
2 initiative). The parsing triggers the group creation  
3 actions such as extracting personal profile parameters,  
4 and template related parameters. These parameters  
5 characterise the instance of the new group created. The  
6 new group is added to the groups owned by the creator (in  
7 this instance owned by Jack). Once the group is created,  
8 Jack can proceed to invite some colleagues. Some groups  
9 may be open, and not require an explicit  
10 invite/invitation response to join. These "open" groups  
11 simply allow people to join without an invite. This is an  
12 example of another parameter that can be specified by  
13 selecting the appropriate template for the style of group  
14 the creator intends. The template mechanism is a short  
15 hand. It allows a series of parameters to be collected  
16 that create a useful distinctive group type under a  
17 single template name. This makes creating groups with  
18 many detailed properties a simple matter of selecting the  
19 desired template by name. If no template is specified a  
20 default group template is assumed.

21

22 By processing the user interaction with the access device  
23 into an abstract command, expressed in XML (a World Wide  
24 Web Consortium (W3C) standard), the system can be further  
25 developed allowing modification of the user  
26 interaction/presentation layer without causing core  
27 system functionality update work. By using XML to express  
28 the command and its parameters, the system can make use  
29 of a flexible data description language to define all  
30 existing (and any future) commands, and readily available  
31 parsers to process the commands. Modifying core  
32 functionality similarly does not affect access device

1 handling code. This internal structure improves the ease  
2 of evolution of the system's services.

3

#### 4 **Privacy control and high quality of service**

5

6 Whilst the accessibility, availability and reliability  
7 aspects of a high quality of service are necessary along  
8 with privacy control to gaining user trust, the high  
9 quality of services features of the design of the system  
10 are aspects that are implemented using recognised  
11 industry standard techniques of system structure and  
12 software design to achieve the high quality of service  
13 goals.

14

#### 15 **Privacy control, and self-provisioning**

16

17 The user can interact with two different types of groups,  
18 public groups that are open to all to join and personal  
19 groups. A public group is generally not a forum in which  
20 you meet friends or work colleagues. The membership of a  
21 public group is generally strangers who have a common  
22 interest, such as a pop idol fanzine. The membership of a  
23 personal group is generally people you actually know. As  
24 a result the type of conversation and the frequency  
25 differ between public and personal groups. As public  
26 groups are open to anyone to join, the main privacy  
27 protection involved is protecting the users phone number  
28 from the group and allowing them to use a pseudonym. A  
29 user can leave a public group at anytime and if the owner  
30 of the group could disband the public group at anytime.  
31 The users of public groups apply their own filter to  
32 their dialogue and use of group services, as this is a  
33 public context.

1  
2 A user can only join a personal group if either they have  
3 created the group themselves and are therefore the group  
4 owner, or if they have received and responded to an  
5 invite to join another person's group. Therefore if a  
6 user creates a group they can control to whom invites are  
7 sent and whether or not anyone else in the group can also  
8 issue invites. The system also states in the invite, the  
9 identity of who is inviting you to join their group, the  
10 purpose (if appropriate) of the group, and the  
11 information the group needs from you (from your personal  
12 profile). A user, receiving an invite to join another's  
13 group, can therefore review the terms of joining the  
14 group and if satisfied can proceed and respond to the  
15 invite. Once they have joined the group, only the  
16 information stated in the invite will be open to that  
17 group. A user can maintain different nicknames for  
18 different groups if they wish.

19

#### 20 **User empowerment**

21

22 To empower the user a balance must be struck between  
23 power and easy of use. The design of the system supports  
24 features that provide the user great flexibility to  
25 control the types and features of the groups they create,  
26 without taxing them with too much detail.

27

28 The two key mechanisms that support user empowerment  
29 within the system are the service generation wizard and  
30 rapid service development.

31

#### 32 **Service generation wizard**

33

1 To set up a group and join a group must be easy for the  
2 system's usage to widespread. The system expedites the  
3 process of setting up groups by giving users template  
4 groups to create their own instances of. Each template  
5 has a set of group access and usage parameters and  
6 associated services. By selecting a template (including  
7 by sending a message to the system) the user can select a  
8 whole set of features by making a single option choice.

9

10 Table 3 shows examples of template selected service  
11 features. In Table 3, 'X' indicates the service feature  
12 is present in an instance of a group built from this  
13 template. The user can create a group of any of the  
14 types shown in the columns by selecting the optional  
15 group type in the 'create group' command. If the  
16 parameter is omitted, then the same group type as created  
17 last by that user is inherited. If this is the first  
18 group they have ever created then the system default  
19 group type is assumed.

20

21 The self-provisioning aspects of the system allows users  
22 to create their own groups of a specific type that  
23 inherit the properties related to that type, or fall  
24 through to a default group type.

25

26 The 'Chat' service feature enables group members to  
27 participate in group messaging. Chat relies on the  
28 concept of "presence" - defined as whether a given member  
29 has been active in a group. If a user is present when a  
30 chat message is sent to a group, they automatically  
31 receive the message. If a user isn't present when a chat  
32 message is sent to a group, they receive a one-off 'new  
33 chat in ur group' notification that details how they can

1 start chatting. This ensures that only those group  
2 members who are actively using the service receive group  
3 messages.

4

5 Users who have already received a chat notification (and  
6 not participated) will only receive a further  
7 notification after a minimum of 24 hours. The Service  
8 Manager can control the "presence" timeout (i.e. the  
9 length of time that a user is considered present), and  
10 the notification period if required.

11

12 The service features give the group tools for  
13 communication, collaboration and co-ordination.

14

15 The 'Vote' service feature acts as an enabler for making  
16 group decisions. Members can issue a time-limited  
17 vote that consists of a question and a series of options.  
18 Responses are automatically tallied by the system and the  
19 outcome is relayed to group members. Furthermore, members  
20 can track who's voted for what and monitor progress.

21

22 The 'Remind' service feature provides a simple calendar  
23 mechanism for group related events. When a reminder is  
24 triggered, group members receive a one-off "ur missing  
25 out" notification that details how they can check their  
26 reminders. Users who have already received a reminder  
27 notification (and haven't checked them) will only receive  
28 a further notification after a minimum of 24 hours.

29

30 The 'Play' service feature enables a group member to  
31 initiate a game with other members of a group. Each group  
32 member receives a message that asks whether or not they  
33 wish to play. Those members that respond within a time

1 window are considered participants and their details are  
2 forwarded to a 3rd party game. The 3rd party game now  
3 assumes control of the user dialog and initiates the  
4 game.

5

6 Draw is a simple game based on the notion of a 'Wild  
7 West' gunfight whereby participants draw by sending an  
8 SMS with the text 'draw'. The game is carried over three  
9 rounds and at the end of each round, players are awarded  
10 a point for each player that was slower to respond.

11

12 The 'Find' service feature provides the ability to  
13 discover the location of members within a group. Without  
14 a location feed, 'Find' operates a manual policy where  
15 group members are prompted to set their current location.

16

17 The 'Share' service feature enables group members to  
18 download shared items (e.g. operator logos, ring tones,  
19 pictures) onto their own, or another group member's  
20 compatible handset.

21

## 22 **Rapid service development**

23

24 The design of the system allows for rapid service  
25 development. It allows the service operator to introduce  
26 and brand new services into a deployed system. Rapid  
27 service development consists of the ability of operators  
28 of the system to easily introduce, modify or remove  
29 service definitions and the ability to easily add, or  
30 modify the branding of the service experience.

31

32 The structure of the system consists of a set of atomic  
33 service features that are linked to form the suite of

1 services that form the user experience. The user can  
2 select services available to their group at group  
3 creation time by selecting a template that incorporates  
4 the combination of desired service features. Some groups  
5 may allow the owner the power to make subsequent  
6 modifications of the service definition and add or remove  
7 services from the group.

8

9 The service operator can introduce new services to the  
10 users of the system by introducing new service features  
11 into the system. To add new services the operator:

12

- 13 1. Loads the new service features. This adds new  
14 entries in the service feature table (see Table 3).
- 15
- 16 2. Publish new template definitions that make use of  
17 the new service features.
- 18
- 19 3. User can create groups from this point of the new  
20 template type that make use of the new services.

21

22 The service operator can apply branding to the user  
23 experience of the system. This will then be made  
24 available via all supported access devices, SMS, WAP and  
25 Web etc. The second component of rapid service  
26 development is the support by the system of easy brand of  
27 services. The ability to add or modify service branding  
28 is called 'white labelling'.

29

30 The system has an XML based design for separation of  
31 service content and core functionality from presentation  
32 (i.e. branding). The design consists of XML translators

1 to apply branding to message oriented clients and XHTML  
2 support for browser based clients (Web/WAP/PDA).

3

4 **Text expansion**

5

6 Currently the text messaging service is the major part of  
7 the data services revenue earned by mobile operators.  
8 Text messaging at the moment consists of the SMS service.  
9 This is being augmented by both EMS and MMS services  
10 within the year in many European countries. Each of these  
11 messaging services will be interoperable. EMS and MMS  
12 services can transport a richer content and therefore  
13 between compatible handsets will provide a higher quality  
14 messaging service.

15

16 The system supports personal communities and provides  
17 them with a range of lifestyle assisting services. An  
18 expected component of any community is the basic chat  
19 service. The young have adopted SMS as an effective and  
20 entertaining communication medium. Their use of the  
21 service has led to the evolution of a slang/phonetics  
22 based language. This achieves two goals, that of  
23 increasing the level of expression between the  
24 interlocutors and reducing the amount of typing. The  
25 latter is important as the handsets are small and restrict  
26 the speed that the user can type.

27

28 As part of the translation capabilities of the system  
29 supporting the expansion or contraction of text and other  
30 content to reflect the access device capabilities, the  
31 'Text Expander' component provides the system with a  
32 translator between the SMS chat vernacular and full  
33 English, as might appear on a Web page.

1

**2 Design of the Text Expander**

3

4 Once again the system makes use of XML parser technology  
5 to achieve the translation of an input document and an  
6 output document. In this case the system uses a SMS Chat  
7 XML document that consists of a series of free text  
8 components interspersed with well know SMS chat  
9 contracted phrases and 'smilies'. This well formed  
10 document is constructed by the SMS client access  
11 component of the system that processes the in bound text  
12 message and converts it into an internal SMS XML  
13 document. This document can be translated using an XML  
14 parser to plain English, for use in the free text  
15 component of any of the documents supporting the various  
16 client access modes. The XML parser translation is  
17 applied to achieve this transformation.

18

19 The XML SMS Chat document is a definition for supporting  
20 SMS Chat messages alone, the XML SMS document supports  
21 the wider SMS mobile community messaging and includes all  
22 the commands a user can instruct the system with. An XML  
23 SMS Chat document is typically referred to from within  
24 and XML SMS document. The XML SMS Chat document describes  
25 the chat text being submitted. The XML SMS document  
26 describes the 'chat' command that and refers to the XML  
27 SMS Chat document for the submitted text from the user.

28

29 As with the Translation support components, the Text  
30 Expander consists of a set of an XML Char document  
31 translation definition. This defines the valid form of an  
32 in-bound XML Chat document to an XML parser and how the  
33 parser can translate a document provided in that formed

1 into a plain English or back again. This mechanism is  
2 public domain functionality of XML parser technology. The  
3 specifications of the XML Chat document translation  
4 definitions are unique to the design of the system.

5

6 Further modifications and improvements may be added  
7 without departing from the scope of the invention herein  
8 described.

1 **Claims**

2

3 1. A mobile community system comprising:

4 • a plurality of mobile terminals;

5 • means for storing a group context attribute;

6 • a configuration means for configuring said group  
7 context attribute;8 • an application server means for providing a  
9 plurality of group related services, wherein at  
10 least two of the services are different, in co-  
11 operation with said mobile terminals responsive to  
12 said group context attribute;13 • a communication means for connecting each of said  
14 terminals to the application server means.15 2. The system of Claim 1 wherein said application  
16 server means further comprises:17 • a means for translating a message responsive to a  
18 stored group context attribute; and19 • a means for routing a message responsive to a  
20 stored group context attribute.21 3. The system of any previous Claim wherein said  
22 configuration means is responsive to the selection  
23 of a template.24 4. The system of any previous Claim wherein said  
25 configuration means is adapted to co-operate with a

- 1 mobile terminal to configure a group context  
2 attribute.
- 3 5. The system of any previous Claim wherein said  
4 configuration means is responsive to the content of  
5 a message from a terminal.
- 6 6. The system of any previous Claim wherein said  
7 application server means is adapted to record system  
8 usage data and configure a group context attribute  
9 responsive to said stored system usage data.
- 10 7. The system of any previous Claim wherein said group  
11 context attribute relates to the availability of  
12 group related services to members of a group.
- 13 8. The system of any previous Claim wherein said group  
14 context attribute relates to a user's membership of  
15 a group.
- 16 9. The system of any previous Claim wherein said group  
17 context attribute relates to a user's role within a  
18 group.
- 19 10. The system of any previous Claim wherein said group  
20 context attribute relates to a place.
- 21 11. The system of any previous Claim wherein said group  
22 context attribute relates to a group related event.
- 23 12. The system of any previous Claim wherein said group  
24 context attribute relates to a terminal status.
- 25 13. The system of any previous Claim wherein said group  
26 context attribute relates to a terminal identifier.

- 1 14. The system of any previous Claim wherein said group  
2 context attribute relates to a user account  
3 identifier.
- 4 15. The system of any previous Claim wherein said group  
5 context attribute relates to a preferred network  
6 connection.
- 7 16. The system of any previous Claim wherein said group  
8 related service is a chat service.
- 9 17. The system of any previous Claim wherein said group  
10 related service is a group decision making service.
- 11 18. The system of any previous Claim wherein said group  
12 related service is a group member finder service.
- 13 19. The system of any previous Claim wherein said group  
14 related service is a group event reminder service.
- 15 20. The system of any previous Claim wherein said group  
16 related service is a group content sharing service.
- 17 21. The system of any previous Claim wherein said group  
18 related service is a group game service.
- 19 22. A cross-network system for connecting an application  
20 server means of any previous Claim to a plurality of  
21 telecommunication networks, the cross-network system  
22 comprising:
- 23 • a means for storing routing rules;
  - 24 • an in-bound message queue connected to said  
25 application server means;

- 1           • a connection agent means connected to each  
2           telecommunication network for:
- 3                 selecting and routing messages to said in-bound  
4                 message queue responsive to said stored routing  
5                 rules; and
- 6                 routing messages to a telecommunication network  
7                 responsive to receiving a message from said  
8                 application server means.

9   23. A method for facilitating mobile communities using a  
10   plurality of mobile terminals comprising the steps  
11   of:

- 12           • storing a group context attribute;
- 13           • configuring said group context attribute;
- 14           • providing a plurality of group related services,  
15           wherein at least two of the services are  
16           different, in co-operation with said mobile  
17           terminals responsive to said group context  
18           attribute;

19   24. The method of Claim 23 further comprising the steps  
20   of:

- 21           • translating a message responsive to a stored group  
22           context attribute; and
- 23           • routing a message responsive to a stored group  
24           context attribute.

- 1 25. The method of any previous Claim wherein step of  
2 configuring is responsive to the selection of a  
3 template.
- 4 26. The method of any previous Claim wherein said step  
5 of configuring further comprises the step of co-  
6 operating with a mobile terminal to configure a  
7 group context attribute.
- 8 27. The method of any previous Claim wherein said step  
9 of configuring is responsive to the content of a  
10 message from a terminal.
- 11 28. The method of any previous Claim further comprising  
12 the steps of recording method usage data and  
13 configuring a group context attribute responsive to  
14 said stored method usage data.
- 15 29. The method of any previous Claim wherein said group  
16 context attribute relates to the availability of  
17 group related services to members of a group.
- 18 30. The method of any previous Claim wherein said group  
19 context attribute relates to a user's membership of  
20 a group.
- 21 31. The method of any previous Claim wherein said group  
22 context attribute relates to a user's role within a  
23 group.
- 24 32. The method of any previous Claim wherein said group  
25 context attribute relates to a place.
- 26 33. The method of any previous Claim wherein said group  
27 context attribute relates to a group related event.

- 1 34. The method of any previous Claim wherein said group  
2 context attribute relates to a terminal status.
- 3 35. The method of any previous Claim wherein said group  
4 context attribute relates to a terminal identifier.
- 5 36. The method of any previous Claim wherein said group  
6 context attribute relates to a user account  
7 identifier.
- 8 37. The method of any previous Claim wherein said group  
9 context attribute relates to a preferred network  
10 connection.
- 11 38. The method of any previous Claim wherein said group  
12 related service is a chat service.
- 13 39. The method of any previous Claim wherein said group  
14 related service is a group decision making service.
- 15 40. The method of any previous Claim wherein said group  
16 related service is a group member finder service.
- 17 41. The method of any previous Claim wherein said group  
18 related service is a group event reminder service.
- 19 42. The method of any previous Claim wherein said group  
20 related service is a group content sharing service.
- 21 43. The method of any previous Claim wherein said group  
22 related service is a group game service.
- 23 44. A method for connecting an application server means  
24 of any previous Claim to a plurality of  
25 telecommunication networks, the method comprising  
26 the steps of:

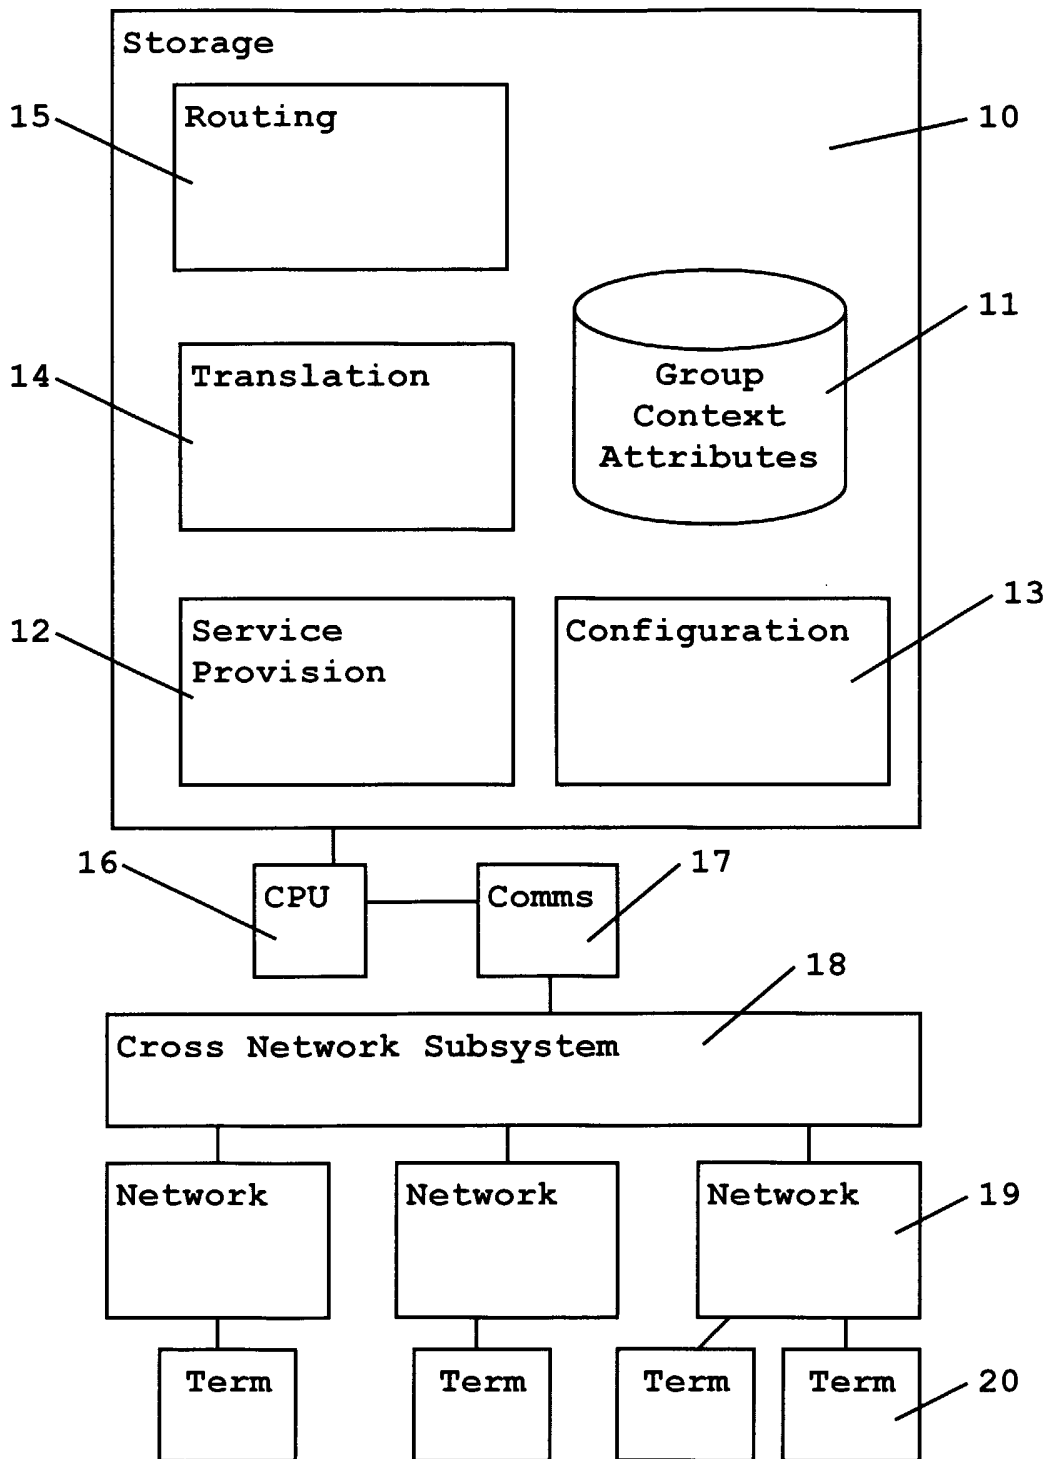

- 1       • storing routing rules;
- 2       • selecting and routing messages to an in-bound
- 3       message queue connected to said application server
- 4       means responsive to said stored routing rules; and
- 5       • routing messages to a telecommunication network
- 6       responsive to receiving a message from said
- 7       application server means.

8   45. A computer program comprising program instructions  
9       which when run on a computer constitute the system  
10      of Claims 1 to 21.

11 46. A computer program comprising program instructions  
12      which when run on a computer constitute the system  
13      of Claim 22.

14 47. A computer program comprising program instructions  
15      for causing a computer to perform the method of  
16      Claims 23 to 43.

17 48. A computer program comprising program instructions  
18      for causing a computer to perform the method of  
19      Claim 44.

10/12

	Description
1	SMS interaction document. Embodies both the existing command structure and the pro-forma for future command extension and refers to plain text sections that are subject to the 'TextExpander' processing.
2	MMS interaction document. Embodies both existing command structure and the pro-forma for future command extensions. Typically can carry content inserts derived from the sender (for instance senders avatar, the group avatar or audio sting) or other derived content driven at the instruction of the sender.
3	Voice interaction document. Embodies both existing command structure and the pro-forma for future command extensions. Typically can carry sender recorded and service generated audio prompts, along with derived content such as the group audio sting or other derived content driven at the instruction of the sender.
4	Web interaction document. Embodies both the existing command structure and the pro-forma for future command extension. Typically can carry sender-generated content such as audio or video clips, include linked content such as Java Applets derived from the Internet (for instance a map). This multimedia document follows a specific message structure and so can be generated from other client types and is not a generic multi-media document. The document can be constructed from the sender content and other group related content such as the sender avatar, group avatar or audio sting, group assets such as access to 3 <sup>rd</sup> party Java Applet mapping service.
5	WAP/XHTML for mobile phone and on-air PDA. . Embodies both the existing command structure and the pro-forma for future command extension. Similar to Web documents, these documents are specialised to link to recognise the existence of local PDA services such as diary, rolodex, document and spreadsheet applications. Also these documents are aware of device display parameters and are sensitive to making the most of them.
