(57) **ABSTRACT**

A system and method for automatically executing a participating application upon insertion of a removable media into a computing device. When the computing device detects that the removable media containing has been inserted, a task disk control file is read from the removable media. The task disk control file contains all of the configuration information necessary to run the participating application from the removable media. The participating application is then launched for use by a user. After the user is finished using the participating application, the removable disk is automatically ejected. In addition to monitoring for insertion of the removable media, events such as a completion of the self-contained application and a request to eject the media are monitored. When a completion event is encountered, all data files are saved, temporary files deleted and configuration information removed prior to the removable disk ejection. When an ejection event is encountered, the computing device is instructed to wait until the completion events are executed prior to actual ejection of the removable media.

AUTOMATICALLY LAUNCHING APPLICATION
SOFTWARE OR STARTING DEVICES AND
PERIPHERALS**

FIELD OF THE INVENTION

[0001] The present invention relates to application software contained on removable storage media. In particular, the present invention relates to a system wherein instructions to configure operating system environmental variables and to load predetermined application software are stored on removable media such that the application and its associated data files are automatically launched for use upon insertion of the removable disk into a removable media drive.

BACKGROUND OF THE INVENTION

[0002] In the beginning of the personal computing era, software applications were simple and small mainly because of limitations in storage and computing power. For example, one of the first widely used software applications, VisiCalc, was only 25 kB in size and was typically run from a floppy disk. Because of these limitations, data files created by VisiCalc were often stored on the same floppy disk as the program file. However, as processing power and capabilities of personal computers increased, additional features were added to software applications to take advantage of the increased processing power. These features have led to a tremendous increase in the size of software applications. For example, Microsoft® Excel97 now has an executable file that is approximately 5.4 MB, which is an increase of 21,600% over the early VisiCalc spreadsheet software. In addition, this figure fails to account for the shared files that Microsoft® Excel97 requires for proper execution. Because of the increase in size and complexity of modern software, applications are no longer developed to be executed from a single piece of removable media, and at a minimum, must be partially installed to the computer's hard disk drive for use.

[0003] While modern software applications have greater functionality and are easier to use than their early counterparts, they have created usability problems for end users. A first problem is that managing data files has become increasingly difficult. With personal computer hard drives exceeding 20 GB in storage capacity, users can store almost everything they generate and download. Naming, organizing and differentiating between data files is extremely difficult, particularly in view of the common practice of users to name and save files using cryptic or uninformative names (e.g., today.doc, temp.xls, or junk.txt).

[0004] Another problem has been created by the sheer number of personal computers and peripherals devices. A typical user may have a computer at home, a computer at work, and a portable computer (e.g., notebook) that he or she uses every day. Thus, if a user wants to use a particular data file(s) on more than one computer, the user must manually copy the data file(s) to a removable disk and either access the data file(s) from the removable disk or copy them to the other computer. In addition, each computer that the user wants to use must have the particular piece of software that generated the data file(s) installed thereon in order to properly access the data. Inevitably, as users move data from one computer to another, data is lost as newer files are overwritten by older versions. Further complicating file management

tasks is when the user creates several pieces of removable media containing several versions of the data files and then must figure out which version is the correct version by looking at the time stamps or inspecting the contents of each of the data files. Peripheral devices and their associated software have become numerous and are in many cases difficult to use. In addition, many peripheral devices create data files that must be saved for use by other application software.

[0005] There have been some advances in file management. These include file managers and applications that synchronize files between computers to reduce the effort necessary to maintain current versions of data files on multiple computers. However, these programs are severely limited because they typically cannot synchronize files between more than two computers. In addition, the files to be synchronized are often manually selected by the users. Thus, if a particular piece of software creates and access multiple data files, the user must manually select all of the data files for synchronization between two computers, otherwise errors may occur. Often users forget to select a particular data file for synchronization and later find that they are unable to utilize any of the data on another computer. This problem not only affects synchronization programs, but also occurs when users manually copy data files to removable media, in the scenario noted above.

[0006] There have been other advances in making computers easier use, such as graphical user interfaces and applications that automatically launch programs contained on removable media. An example of an application that automatically launches another application upon insertion of the removable media into a computer and include the Windows® "Autorun" feature which automatically runs an application contained on, e.g., a CD-ROM. When the CD-ROM is inserted into the drive, the operating system checks for a file named "autorun.inf" in the root directory of the CD. Within the autorun.inf file is a pointer to an executable file named "autorun.exe" which launches the software on the CD. Typically, the Autorun feature is used to launch software setup/install routines to install software contained on the CD to the hard drive. However, the Autorun feature is limited in that it does not configure a computer to run application software based on instructions contained on the removable media, nor does the Autorun feature have the ability to manage events such as ejection of the removable media, closing of the application running from the removable media, and storage of data files to the removable media.

[0007] However even with the above advancements, computers remain difficult for many people to use. For example, when a user turns on the computer, he or she is most often presented with the graphical user interface. At this point, it is up to the user to navigate to and launch the application software that he or she desires to use. Although this task seems relatively easy, it is not for many users as there is no standardization on where a particular application software is located on the computer. Clearly, the personal computer has failed to achieve the simplicity of other home appliances, which has prevented large numbers of people from accepting and using computers.

[0008] In view of the above, there is a need for a method and apparatus for facilitating the maintenance and use of a user's data, application software and computer devices.

Further, there is a need for a method and apparatus that performs these functions automatically with little or no input from the user in order to prevent accidental loss of data and to provide ease of application use. Such a need would be solved by a self-contained application stored on removable media that is adapted to automatically start devices or launch application software from the removable media or the computer's hard drive upon insertion into the computer, while also saving the data files to the removable media or other predetermined location. The present invention provides such a solution.

SUMMARY OF THE INVENTION

[0009] In view of the above, the present invention, through one or more of its various aspects and/or embodiments is thus presented to accomplish many advantages, such as those noted below.

[0010] In accordance with the present invention, there is provided an application or service that resides on a computer that automatically, and without requiring any user intervention, recognizes the insertion of a piece of removable media. The removable media contains a task disk control file that contains all of the configuration information necessary to run participating applications from the removable media. In particular, the task disk control file contains three sections of configuration information as follows: pre-run, application run, and clean-up. The pre-run section configures registry information such that the operating system is aware of the path, environmental variables and command line to launch the participating application. Optionally, the pre-run section may specify files (e.g., executable files, DLLs, device drivers, etc.) that are to be copied to the hard drive to properly execute the participating application. The application run section instructs the operating system to load the participating application, which launches the participating application for use by a user. The clean-up section removes all registry information added by the pre-run section. Optionally, the clean-up section may remove from the hard drive the files copied thereto to execute the participating application.

[0011] After reading the task disk control file and configuring the computing device, the participating application is then launched for use by a user. Once the user is finished using the participating application, the removable disk is automatically ejected. In addition to monitoring for insertion of the removable media, events such as a completion of the self-contained application and a request to eject the media are monitored. When a completion event is encountered, all data files are saved, temporary files are deleted and configuration information is removed prior to the removable disk ejection. When an ejection event is encountered, the computing device is instructed to wait until the completion events are executed prior to actual ejection of the removable media.

[0012] The system of the present invention serves to greatly simplify the use and operation of computer application software, devices and peripherals because users are not required to have any knowledge of how to launch the application or start the devices and peripherals they wish to use other than such applications, devices and peripherals will be launched/started automatically upon insertion of the removable media. Other features of the invention are described below.

BRIEF DESCRIPTION OF THE DRAWINGS

[0013] The foregoing summary, as well as the following detailed description of the preferred embodiments, is better understood when read in conjunction with the appended drawings. For the purpose of illustrating the invention, there is shown in the drawings an embodiment that is presently preferred, in which like reference numerals represent similar parts throughout the several views of the drawings, it being understood, however, that the invention is not limited to the specific methods and instrumentalities disclosed. In the drawings:

[0014] **FIG. 1** is a block diagram of the components of a personal computer in which the present invention is embodied;

[0015] **FIG. 2** is a block diagram of the components of a preferred removable media drive shown in **FIG. 1**;

[0016] **FIG. 3** is a flow chart illustrating an overview of the processes performed by the present invention; and

[0017] **FIG. 4** is an exemplary task disk control file in accordance with the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

[0018] The present invention provides a novel application on a removable disk used within a computing environment to maintain application software, data and devices. In accordance with the present invention, a user inserts the removable disk containing the application software to be executed into the personal computer, and the software application or device is automatically launched/started and readied for use. The present invention advantageously allows a user to maintain everything he or she needs using a removable disk.

[0019] Referring now to **FIGS. 1-2**, exemplary hardware in which the present invention may be embodied will be described. As illustrated, the preferred platform is a personal computer (PC) **20**, which may comprise Windows® 95/98 or Windows NT® Workstation-based personal computer having, e.g., an Intel Pentium® processor or higher, a long-term non-removable storage device (e.g., a IDE or SCSI hard disk), a removable media drive (e.g., CD-R, CD-RW, DVD, or other removable floppy or hard disk drive), random access memory (RAM), communication peripherals (e.g., network interface card, modem, and/or terminal adapter), and suitable application programs (e.g., Dial-up networking software and a Web Browser).

[0020] As shown, the PC **20** may be divided between internal and external components. The internal components include a Basic Input/Output System (BIOS) **70** and a processor (CPU) **66** that control the overall functioning of the PC **20**. Memory **64**, a hard disk drive **76**, a floppy disk drive **74**, a tape drive **78**, a CD-ROM drive **80**, a MODEM/Terminal Adaptor/Network Interface Card **82**, and a removable media drive **52a** are also connected to the CPU **66**. The removable media drive **52a** or **52b** operates to read and/or write to a storage media contained within a removable storage cartridge **28**. The exemplary PC **20** of **FIG. 1** is configured with two removable media drives **52a** and **52b** to emphasize that a removable media drive can be implemented in either internal or external form.

[0021] By way of a non-limiting example, the removable media **28** may comprise a ZIP® disk manufactured by Iomega Corporation, Roy, Utah. Each Iomega ZIP® disk contains a unique serial number that is written to a predetermined track during the formatting process which may be used as the unique identifier. The serial number is preferably created by but not limited to a pseudo random number generator. Further, while the media **28** has been described in terms of a ZIP® disk, it is not limited to the ZIP® disk, as the use of other removable media types having a unique serial number is within the scope and spirit of the present invention such as CD-R, DVD-RAM, and other removable floppy and hard disks.

[0022] The MODEM/Terminal Adaptor/Network Interface Card **82** may comprise individual cards performing communications-related functions, as known in the art. The MODEM/Terminal Adaptor/Network Interface Cards **82** are included within PC **20** to provide communications to external networks to which the PC **20** is connected. In particular, the MODEM/Terminal Adaptor/Network Interface Card **82** may be used to access LAN **14**, ISP **18** and network infrastructure **12**.

[0023] Communications between internal and external devices may be accomplished via controllers provided within the PC **20**. A serial/parallel/USB port controller (which may comprise separate controllers) **58**, a monitor controller (video card) **60**, and a keyboard and mouse controller **62** each provide an interface between the CPU **66** and an external removable media drive **52b** (or printer), monitor **54**, and keyboard and mouse device **56**, respectively. A hard disk and floppy disk controller **72** serves as an interface between the CPU **66** and the hard disk **76** and the CD-ROM drive **80**, and the floppy disk **74** and tape drive **78**, respectively. It will be appreciated by those skilled in the art that the disk controller **72** may comprise separate floppy and hard disk controllers (e.g., IDE or SCSI controller).

[0024] A removable media controller **68** serves as an interface between the removable media drive **52a** and the CPU **66**. For example, the removable disk controller **68** may comprise a Small Computer System Interface (SCSI) or Integrated Drive Electronics (IDE) interface controller. A hard disk and floppy disk controller **72** serves as an interface between the CPU **66** and the hard disk **76** and the CD-ROM drive **80**, and the floppy disk **74** and tape drive **78**, respectively. Alternatively, the removable media drive **52a** may utilize the disk controller **72** as an interface to the CPU **66**.

[0025] Referring now to FIG. 2, there is illustrated a block diagram of an exemplary media drive **52** having a SCSI interface to the PC **20** (via controller **68**). The media drive **52** preferably comprises, a ZIP® drive, manufactured by Iomega Corporation, Roy, Utah; however, the present invention is not limited to such removable media drives and other media drives may be used as media drive **52**. The media drive **52** includes components that provide for communication between the read/write channel for the media (lower right side of diagram) and the PC **20** (upper left side of diagram). The media drive **52** includes an AIC chip **101** which performs the SCSI **102**, the direct memory access (DMA) **103**, and disk formatter **104** functions. The interface also includes a PHAEDRUS **105** which includes an 8032 microcontroller **106**, a 1 kbyte RAM **107** and an application specific integrated circuit (ASIC) **108**. The ASIC **108** may

perform various functions, such as servo sequencing, data splitting, EOC, ENDEC, A-to-D, and D-to-A conversion. The communication between the media drive **52** and the PC **20** is accomplished through transfers of data between the input/output channel of the media drive **52** and the media controller **68** (e.g., SCSI controller) of the PC **20**.

[0026] Referring now to FIG. 3, there is a flow chart illustrating the processes performed by the present invention. As will become evident to those of ordinary skill in the art, the features and aspects of the present invention discussed below may be implemented by any suitable combination of hardware, software and/or firmware. Preferably, the present invention runs as a background task or service that recognizes and reads a task disk control file stored on the removable media upon detection of insertion of the removable media into the computer. The task disk control file includes instructions to configure the computer operating environment and launch application software resident on the removable media or the computer's hard disk (or on both). Also, the task disk control file may be used to start application software that controls computer devices and/or the devices themselves. Upon closing the predetermined application software or device, data files are saved in accordance with instructions in the control file, the computer's environment is cleaned-up and the removable media is ejected. As will be described below, the system of the present invention serves to greatly simplify the use and operation of computer application software, devices and peripherals because users are not required to have any knowledge of how to launch the application or start the device or peripheral they wish to use. In other words, all the user needs to know is that the application, device or peripheral he or she wants to use will be automatically launched/started upon insertion of the removable media.

[0027] The details of the present invention will now be described with reference to FIG. 3. An application or system service running on the PC **20** monitors device commands to and from the removable media drive **52** (step **200**). It is preferable that this be a background application or service that is loaded when the computer is booted-up. An example of such an application to monitor device commands to the removable media drive **52** is IOWatch, available from Iomega Corporation, Roy, Utah. The application or service resides on the computer **20** and automatically, and without requiring any user intervention, recognizes the insertion of a piece of removable media.

[0028] At step **202** it is determined if a monitored device command is "a media change condition." Media change conditions indicate that removable media **28** has been inserted in to the removable media drive **52** or that some action has occurred with regard to the removable media **28** currently in the drive **52**. If no media change condition is present at step **202**, then processing returns to step **200** to monitor for subsequent device commands.

[0029] If a media change condition is present at step **202**, then the present invention begins its processing by identifying an event type associated with the media change condition. Events that may be identified and routed at step **204** include, but are not limited to: device events and events resulting from calls from a "participating application" **201**. A "participating application" **201** is defined herein as a software application that has knowledge of, and cooperates

with, the present invention by making and accepting event calls to and from the present invention. The participating application may be located on, e.g., the hard disk **76**, the removable media **28**, a CD-ROM, or network location. In addition, participating applications may control peripherals and devices attached to or within the computer (e.g., tape drives, scanners, etc.). Media change conditions are provide to the present invention by known mechanisms such as inter-application messages, program calls, and event notifications.

[**0030**] A first identified event may be a media insertion event (step **206**), which is a condition that exists when the removable media **28** is inserted into the removable media drive **52**. The media may be detected as inserted by the drive in accordance with the method of U.S. Pat. No. 5,854,719, to Ginosar et al., which is incorporated herein by reference in its entirety. At step **208**, the system then checks for the presence of a task disk control file (TDCF) **220** on the media **28**.

[**0031**] An exemplary task disk control file **220** is illustrated in **FIG. 4**, and contains configuration and execution information and regarding the participating application. For example the TDCF **220** may contain information such as the executable filename, path information, and Windows® registry data, including the identification of necessary device drivers, Dynamic Link Libraries, VxDs, etc. The contents of the TDCF will be discussed in greater detail below.

[**0032**] If a valid task disk control file (TDCF) **220** does not exist (step **210**), the disk is mounted for use, however, the system returns to step **200** to monitor for subsequent device commands, as the disk cannot be used to configure and launch an application or device. Alternatively, a message may be generated and displayed to the user indicating the TDCF **220** is not valid. If a valid TDCF **220** exists, then at step **212**, a unique identifier (e.g., serial number) of the media **28** is read. In accordance with a feature of the present invention, the TDCF **220** may be encrypted using the media serial number as an encryption key to provide an added measure of security and to prevent the application software from being copied and run from another piece of media. For the purposes of the present invention, any encryption algorithm may be used.

[**0033**] The media serial number may be obtained by an application running on the PC **20** that reads the unique identifier and authentication code. This is performed by querying the media using an application programming interface (API) such as the Iomega Ready API, or other suitable method.

[**0034**] The Iomega Ready API when invoked causes the media drive to read the unique serial number from the predetermined track by using the SCSI 0x06 Non-Sense Command. In particular, by invoking the Disk Status Page (page 0x02) of the Non-Sense Command, the media serial number may be determined by reading offset bytes **20-59** of the returned data structure. Exemplary source code for

reading the serial number of an Iomega ZIP® drive and disk is as follows:

```

void CClientApp::GetZipDrive( )
{
    int j,k;
    m_DriveNum = 0;
    for(j = 0;j < 26;j++)
        // scan the drives and find the IOMEGA drives
        {
            if(IsIomegaDrive(j))
            {
                k = GetGeneralDevType(j);
                if( k == DRIVE_IS_ZIP)
                {
                    m_DriveNum = j;
                    j = 26;
                }
            }
        }
}

void CClientApp::GetSerialNumber( )
{
    unsigned char szBuffer[1024];
    memset(szBuffer,0,sizeof(szBuffer));
    memset(&m_SerialNumber,0,40);
    GetInfoNonSense(m_DriveNum,0x02,szBuffer);
    memcpy(&m_SerialNumber,&szBuffer[22],39);
}

```

[**0035**] It can be appreciated that the unique serial number should contain a sufficient number of bits (length) to ensure that no two pieces of media have the same identifier. For example, each Iomega ZIP® disk contains a unique **39** byte (312 bits) serial number, and other bit lengths may be utilized.

[**0036**] Once the media serial number is read, the task disk control file (TDCF) **220** is processed at step **214**, where it is decrypted using the media serial number as a decryption key. It is noted that encryption of the TDCF **220** is not necessary for the operation of the present invention, and is provided as a security feature to prevent, e.g., illegal copying of copyrighted program files on the removable media **28**. Accordingly, step **210** may be provided with a mechanism to determine if the TDCF is encrypted, and if not, jump to step **216**.

[**0037**] At step **216**, the unencrypted TDCF **220** is read and the system environment is configured in accordance with information contained in the TDCF **220** prior to launching the participating application.

[**0038**] Referring to **FIG. 4**, the TDCF **220** contains three sections of configuration information labeled as follows: pre-run, application run, and clean-up. The pre-run section configures registry information such that the operating system is aware of the path, environmental variables and commands to launch the participating application. Optionally, the pre-run section may specify files (e.g., executable files, DLLs, device drivers, etc.) that are to be copied to the hard drive to properly execute the participating application. The application run section instructs the operating system to load the participating application, which launches the participating application for use by a user (see, step **218**, below). The clean-up section removes all registry information added by the pre-run section (see, step **224**, below). Optionally, the clean-up section may remove from the hard

drive the files (e.g., executable files, DLLs, device drivers, etc.) copied thereto to execute the participating application.

[0039] In accordance with the present invention, the TDCF 220 may configure the system environment to run applications in several modes. In a first mode of operation, the participating application is stored on, and run from, the removable media 28 upon insertion. In this first mode of operation, everything necessary to run the participating application is maintained and executed from the removable media 28. Thus, no files are copied to the hard drive, nor are any files required to be on the hard drive to run the participating application.

[0040] In a second mode of operation, the participating application cannot be run from the removable media 28 alone. In this mode, certain files are copied to the hard disk as specified in the pre-run section of the TDCF 220. These files may include, but are not limited to the above-mentioned executable files, DLLs, device drivers, etc. It may be necessary to copy files to the hard disk because of limitations in speed or size of the removable media 28. In the second mode, when the participating application is closed or the removable disk 28 ejected, the previously copied files are removed from the hard drive in accordance with the clean-up section such that the hard disk is returned to essentially the same state it was in prior to the insertion of the removable media 28.

[0041] In a third mode, the participating application cannot be run from the removable media 28 alone, as in the second mode. However, in this mode when the participating application is closed or the disk ejected, the files are not removed from the hard drive. In the third mode, the previously copied files remain on the hard disk in accordance with the clean-up section, such that any subsequent insertion of the removable media 28 would not require copying of the specified files to the hard drive. This third mode of operation speeds up the launching of the participating application for second and subsequent insertions of the removable disk 28 into the removable media drive 52.

[0042] In a fourth mode, the participating application is installed to, and stored on, the computer's hard drive. The participating application's installation program preferably includes an option to make it "participating" in accordance with the present invention. Optionally, a plug-in may be used to hook into the participating application to make it "participating" in accordance with the present invention. The pre-run section of the TDCF contains all of the instructions necessary to automatically launch the participating application from the hard drive and, optionally, load data files as the participating application is launched. The data files are preferably on the removable media 28, but also may reside on the hard disk. In this fourth mode, the TDCF 220 contains a list of instructions to open and close the participating application, such that the removable media acts as a "key" to automatically open the participating application upon insertion into the removable media drive 52.

[0043] It is noted that the TDCF 220 of FIG. 4 is provided herein for exemplary purposes only. Further, the TDCF 220 may contain additional or fewer instructions to configure the computer 20, copy files to the computer 20, etc. than illustrated. Further, additional or few modes of operation are possible. In accordance with the present invention, the TDCF 220 contains the instructions necessary to properly

configure and launch the participating application upon insertion of the removable media 28, and gracefully remove configuration settings and save data files without the need for user intervention.

[0044] Returning again to FIG. e, at step 218, once the PC 20 is configured in accordance with the TDCF 220, the participating application is launched for use and the system returns to step 200 to monitor for new events.

[0045] Returning again to step 204, if an event identified is a Save/Close Complete event, then processing continues at step 222. A Save/Close Complete event occurs when the user has finished using the participating application and either selects exit or clicks the "π" box (i.e., close window box) in the application window. At step 222 the participating application saves all data files, deletes all temporary files and indicates to the system that it is ready to terminate. The data files may be saved in accordance with a predetermined file path set by the TDCF 220. At step 224 all configuration information is removed from the PC 20 in accordance with the clean-up section of the TDCF 220. The clean-up section will perform certain clean-up functions based on a mode of operation, as noted above. Next, at step 226, the participating application terminates and the removable media 28 is ejected by the present invention from the media drive 52. Processing then continues at step 200.

[0046] Again returning to step 240, if an event detected a Media Eject Request Event, then processing continues at step 228. A Media Eject Request Event is a condition that exists when the user has initiated an eject function by pressing an eject button provided on the drive 52 or through a provide software eject feature. At step 230, the participating application is notified via inter-application mechanisms, such as a message, that a "request for media eject" was detected. Next, at step 232, the system executes steps 222-226 as discussed above to complete. Once the present invention is notified of a completion at step 234, processing returns to step 200 to monitor for new events.

[0047] Thus, as described above, the present invention provides a new and improved system for managing data files and applications that requires very little, if any, user attention. In accordance with the present invention, the user need only know that insertion of a particular piece of removable media launches a particular application or starts a particular device or peripheral that he or she wants to use. The user's data files are saved to the same piece of removable media or other specified location for easy retrieval, therefore, the user's data is easily obtainable for use when the application is launched. When the user has completed using the application and exits, the removable media is ejected from the computer to be placed away for safekeeping.

[0048] It is noted that the foregoing examples have been provided merely for the purpose of explanation and are in no way to be construed as limiting of the present invention. While the invention has been described with reference to preferred embodiments, it is understood that the words which have been used herein are words of description and illustration, rather than words of limitations. Further, although the invention has been described herein with reference to particular means, materials and embodiments, the invention is not intended to be limited to the particulars disclosed herein; rather, the invention extends to all functionally equivalent structures, methods and uses, such as are

within the scope of the appended claims. Those skilled in the art, having the benefit of the teachings of this specification, may effect numerous modifications thereto and changes may be made without departing from the scope and spirit of the invention in its aspects.

What is claimed is:

1. A method of managing a participating application or device in accordance with a task disk control file contained on removable media, said participating application or device being run with a computing device having a removable media drive, said method comprising:

detecting an insertion of said removable media into said removable media drive;

configuring said computing device in accordance with said task disk control file contained on said removable media;

launching said participating application in accordance with information in said task disk control file;

monitoring events in said removable media drive and said participating application until execution of said participating software application is completed, and thereafter;

ejecting said removable media from said removable media drive.

2. The method as recited in claim 1, wherein said configuring said computing device in accordance with said task disk control file further comprises:

determining a unique identifier of said removable media; accessing said task disk control file in accordance with said unique identifier; and

configuring said computing device by providing at least one of executable files, linked library files, device drivers, path information, environmental information, and registry entries to said computing device.

3. The method as recited in claim 2, wherein accessing said task disk control file comprises decrypting said task disk control file using said unique identifier as a decryption key.

4. The method as recited in claim 1, wherein said monitoring events in said removable media drive comprises monitoring for an application save/close completion event.

5. The method as recited in claim 4, further comprising:

saving all data files to a predetermined location specified in said task disk control file;

deleting temporary files; and

unconfiguring said computing device in accordance with said task disk control file.

6. The method as recited in claim 5, wherein said unconfiguring comprises removing at least one of executable files, linked library files, device drivers, path information, environmental information, and registry entries from said computing device.

7. The method as recited in claim 1, wherein said monitoring includes monitoring for a request to eject said removable media.

8. The method as recited in claim 7, further comprising:

saving all data files to said removable media;

deleting any temporary files;

unconfiguring said computing device in accordance with said task disk control file; and

ejecting said removable media once said unconfiguring has completed.

9. The method as recited in claim 8, wherein said unconfiguring comprises removing at least one of executable files, linked library files, device drivers, path information, environmental information, and registry entries.

10. The method as recited in claim 1, wherein said participating application is adapted to be stored on said removable media or on non-removable storage media, and

wherein said launching said participating application in accordance with information in said task disk control file comprises launching said participating application from said removable media, said non-removable storage media, or both said removable media and said non-removable media.

11. A computer-readable medium containing instructions executed by a computing device having a removable media drive that receives said computer-readable medium, said instructions for performing:

configuring said computing device in accordance with a task disk control file contained on said computer-readable media;

launching a participating application in accordance with information in said task disk control file;

monitoring events in said removable media drive and said participating application until execution of said participating software application is completed, and thereafter;

ejecting said computer-readable media from said removable media drive.

12. The computer-readable medium as recited in claim 11, wherein said configuring said computing device in accordance with said task disk control file further comprises:

determining a unique identifier of said computer-readable medium;

accessing said task disk control file in accordance with said unique identifier; and

configuring said computing device by providing at least one of executable files, linked library files, device drivers, path information, environmental information, and registry entries to said computing device.

13. The computer-readable medium as recited in claim 12, wherein accessing said task disk control file comprises decrypting said task disk control file using said unique identifier as a decryption key.

14. The computer-readable medium as recited in claim 11, wherein said monitoring events in said removable media drive comprises monitoring for an application save/close completion event.

15. The computer-readable medium as recited in claim 14, further comprising:

saving all data files to a predetermined location specified in said task disk control file;

deleting temporary files; and

unconfiguring said computing device in accordance with said task disk control file.

16. The computer-readable medium as recited in claim 15, wherein said unconfiguring comprises removing at least one of executable files, linked library files, device drivers, path information, environmental information, and registry entries from said computing device.

17. The computer-readable medium as recited in claim 11, wherein said monitoring includes monitoring for a request to eject said computer-readable medium.

18. The computer-readable medium as recited in claim 17, further comprising:

saving all data files to said computer-readable medium;

deleting any temporary files;

unconfiguring said computing device in accordance with said task disk control file; and

ejecting said computer-readable medium once said unconfiguring has completed.

19. The computer-readable medium as recited in claim 18, wherein said unconfiguring comprises removing at least one of executable files, linked library files, device drivers, path information, environmental information, and registry entries.

20. The computer-readable medium as recited in claim 11, wherein said participating application is adapted to be stored on said computer-readable medium or on non-removable storage media, and

wherein said launching said participating application in accordance with information in said task disk control file comprises launching said participating application from said computer-readable medium, said non-remov-

able storage media, or both said computer-readable medium and said non-removable storage medium.

21. A computer-readable medium having stored thereon a task list control file comprising:

a pre-run section containing instructions to be executed by a computer-implemented device prior to launching a predetermined participating application;

an application run section data containing instructions to launch said participating application; and

a clean-up section containing instructions to be executed upon closing said participating application.

22. The task list control file of claim 21, wherein said pre-run section comprises

instructions to configure registry information such that the operating system is aware of at least one of a path, environmental variables and commands to launch said participating application.

23. The task list control file of claim 22 further comprising instructions to specify files to be copied to a hard drive of said computer-implemented device to execute said participating application.

24. The task list control file of claim 21, wherein said application run section comprises instructions for the operating system to load said participating application for use.

25. The task list control file of claim 21, wherein said clean-up section removes all registry information added by the pre-run section.

26. The task list control file of claim 25, wherein said clean-up section removes from the hard drive the files copied thereto to execute the participating application as specified by said pre-run section.
