WO 2006/138373 A2

MODULATORS OF GLUCOCORTICOID RECEPTOR, AP-1, AND/OR NF-κB ACTIVITY, AND USE THEREOF

[0001] This application claims priority from U.S. Provisional Applications Serial Nos.60/690,355 and 60/782,636 filed June 14, 2005 and March 15, 2006, respectively.

FIELD OF THE INVENTION

[0002] The present invention relates to new non-steroidal compounds which are effective modulators of the glucocorticoid receptor, AP-1, and/or NF-κB activity and thus are useful in treating diseases such as obesity, diabetes and inflammatory or immune associated diseases, and to a method for using such compounds to treat these and related diseases.

BACKGROUND OF THE INVENTION

[0003] The transcription factors NF-κB and AP-1 are involved in regulating the expression of a number of genes involved in mediating inflammatory and immune responses. NF-κB regulates the transcription of genes including TNF-α, IL-1, IL-2, IL-6, adhesion molecules (such as E-selectin) and chemokines (such as Rantes), among others. AP-1 regulates the production of the cytokines TNF- α, IL-1, IL-2, as well as, matrix metalloproteases. Drug therapies targeting TNF- α, a gene whose expression is regulated by both NF-κB and AP-1, have been shown to be highly efficacious in several inflammatory human diseases including rheumatoid arthritis and Crohn's disease. Accordingly, NF-κB and AP-1 play key roles in the initiation and perpetuation of inflammatory and immunological disorders. *See* Baldwin, AS, *Journal of Clin. Investigation,* 107, 3 (2001); Firestein, G.S., and Manning, A.M., *Arthritis and Rheumatism*, 42, 609 (1999); and Peltz, G., *Curr. Opin, in Biotech.* 8, 467 (1997).

[0004] There are many signaling molecules (kinases and phosphatases) upstream of AP-1 and NF-κB which are potential therapeutic drug targets. The kinase JNK plays an essential role in regulating the phosphorylation and subsequent activation of c-jun, one of the subunits which constitute the AP-1 complex (fos/c-jun). Compounds

which inhibit JNK have been shown to be efficacious in animal models of inflammatory disease. *See* Manning AM and Davis RJ, *Nature Rev. Drug Disc.*, V. 2, 554 (2003). A kinase critical to the activation of NF-κB is the IκB kinase (IKK). This kinase plays a key role in the phosphorylation of IκB. Once IκB is phosphorylated it undergoes degradation leading to the release of NF-κB which can translocate into the nucleus and activate the transcription of the genes described above. An inhibitor of IKK, BMS-345541, has been shown to be efficacious in animal models of inflammatory disease. *See* Burke JR., *Curr Opin Drug Discov Devel.*, Sep;6(5), 720-8, (2003).

[0005] In addition to inhibiting signaling cascades involved in the activation of NF-κB and AP-1, the glucocorticoid receptor has been shown to inhibit the activity of NF-κB and AP-1 via direct physical interactions. The glucocorticoid receptor (GR) is a member of the nuclear hormone receptor family of transcription factors, and a member of the steroid hormone family of transcription factors. Affinity labeling of the glucocorticoid receptor protein allowed the production of antibodies against the receptor which facilitated cloning the glucocorticoid receptors. For results in humans seeWeinberger, et al., *Science* 228, 640-742, (1985); Weinberger, et al., *Nature*, 318, 670-672 (1986) and for results in rats see Miesfeld, R., *Nature*, 312, 779-781, (1985).

[0006] Glucocorticoids which interact with GR have been used for over 50 years to treat inflammatory diseases. It has been clearly shown that glucocorticoids exert their anti-inflammatory activity via the inhibition by GR of the transcription factors NF-κB and AP-1. This inhibition is termed transrepression. It has been shown that the primary mechanism for inhibition of these transcription factors by GR is via a direct physical interaction. This interaction alters the transcription factor complex and inhibits the ability of NF-κB and AP-1 to stimulate transcription. *See* Jonat, C., et al., *Cell*, 62, 1189 (1990); Yang-Yen, H.F., et al,. *Cell*, 62, 1205 (1990); Diamond, M.I., et al., *Science* 249, 1266 (1990); and Caldenhoven, E,. et al., *Mol. Endocrinol.*, 9, 401 (1995). Other mechanisms such as sequestration of co-activators by GR have also been proposed. *See* Kamer Y., et al., *Cell*, 85, 403 (1996); and Chakravarti, D., et al., *Nature*, 383, 99 (1996).

[0007] In addition to causing transrepression, the interaction of a glucocorticoid with GR can cause GR to induce transcription of certain genes. This induction of

transcription is termed transactivation. Transactivation requires dimerization of GR and binding to a glucocorticoid response element (GRE).

[0008] Recent studies using a transgenic GR dimerization defective mouse which cannot bind DNA have shown that the transactivation (DNA binding) activities of GR could be separated from the transrepressive (non-DNA binding) effect of GR. These studies also indicate that many of the side effects of glucocorticoid therapy are due to the ability of GR to induce transcription of various genes involved in metabolism, whereas, transrepression, which does not require DNA binding leads to suppression of inflammation. *See* Tuckermann, J. et al., *Cell*, 93, 531 (1998) and Reichardt, HM, *EMBO J.*, 20, 7168 (2001).

[0009] PCT application WO 2004/009017 published January 29, 2004, assigned to Applicant and incorporated herein by reference in its entirety, describes substituted bicyclooctane compounds useful in treating diseases such as obesity, diabetes and inflammatory or immune associated diseases.

[0010] In addition, a number of patent applications, including WO 03/086294 and WO04/075840, published October 23, 2003 and September 10, 2004, respectively, both assigned to Merck and Co., Inc, as well as WO 03/061651, published July 31, 2003 and assigned to The Regents of the U. of CA, describe compounds having a fused tricyclic ring system that are said to be useful in treating diseases associated with binding to the glucocorticoid receptor, including autoimmune and inflammatory diseases and conditions.

[0011] Compounds that modulate AP-1 and/or NF-κB activity would be useful as such compounds would be useful in the treatment of inflammatory and immune diseases and disorders such as osteoarthritis, rheumatoid arthritis, multiple sclerosis, asthma, inflammatory bowel disease, transplant rejection and graft vs. host disease.

[0012] Also, with respect to the glucocorticoid receptor pathway, it is known that glucocorticoids are potent anti-inflammatory agents, however their systemic use is limited by side effects. Compounds that retain the anti-inflammatory efficacy of glucocorticoids while minimizing the side effects such as diabetes, osteoporosis and glaucoma would be of great benefit to a very large number of patients with inflammatory diseases.

[0013] Additionally concerning GR, the art is in need of compounds that antagonize transactivation. Such compounds may be useful in treating metabolic diseases associated with increased levels of glucocorticoid, such as diabetes, osteoporosis and glaucoma.

[0014] Additionally concerning GR, the art is in need of compounds that cause transactivation. Such compounds may be useful in treating metabolic diseases associated with a deficiency in glucocorticoid. Such diseases include Addison's disease.

[0015] Also, there is a need for new compounds with improved activity compared with known modulators of GR, AP-1, and/or NF-κB activity. It is also desirable and preferable to find compounds with advantageous and improved characteristics in one or more categories, which may be, but are not limited to, the following: (a) pharmaceutical properties; (b) dosage requirements; (c) factors which decrease blood concentration peak-to-trough characteristics; (d) factors that increase the concentration of active drug at the receptor; (e) factors that decrease the liability for clinical drug-drug interactions; (f) factors that decrease the potential for adverse side-effects; (g) factors that improve manufacturing costs or feasibility and (h) factors leading to desirable physical characteristics.

DESCRIPTION OF THE INVENTION

[0016] The present invention relates to new non-steroidal compounds which are which are particularly effective modulators of the glucocorticoid receptor, AP-1, and/or NF-κB activity and thus are useful in treating diseases such as obesity, diabetes and inflammatory or immune associated diseases, and to a method and composition for using such compounds to treat these and related diseases.

METHODS OF SYNTHESIS

[0032] The compounds of the present invention may be synthesized by many methods available to those skilled in the art of organic chemistry. General synthetic schemes, in accordance with the present invention, for preparing compounds of the present invention are described below. These schemes are illustrative and are not meant to limit the possible techniques one skilled in the art may use to prepare the compounds disclosed herein. Different methods to prepare the compounds of the

present invention will be evident to those skilled in the art. Additionally, the various steps in the synthesis may be performed in an alternate sequence in order to give the desired compound or compounds. Examples of compounds of the present invention prepared by methods described in the general schemes are given in the preparations and examples section set out hereinafter.

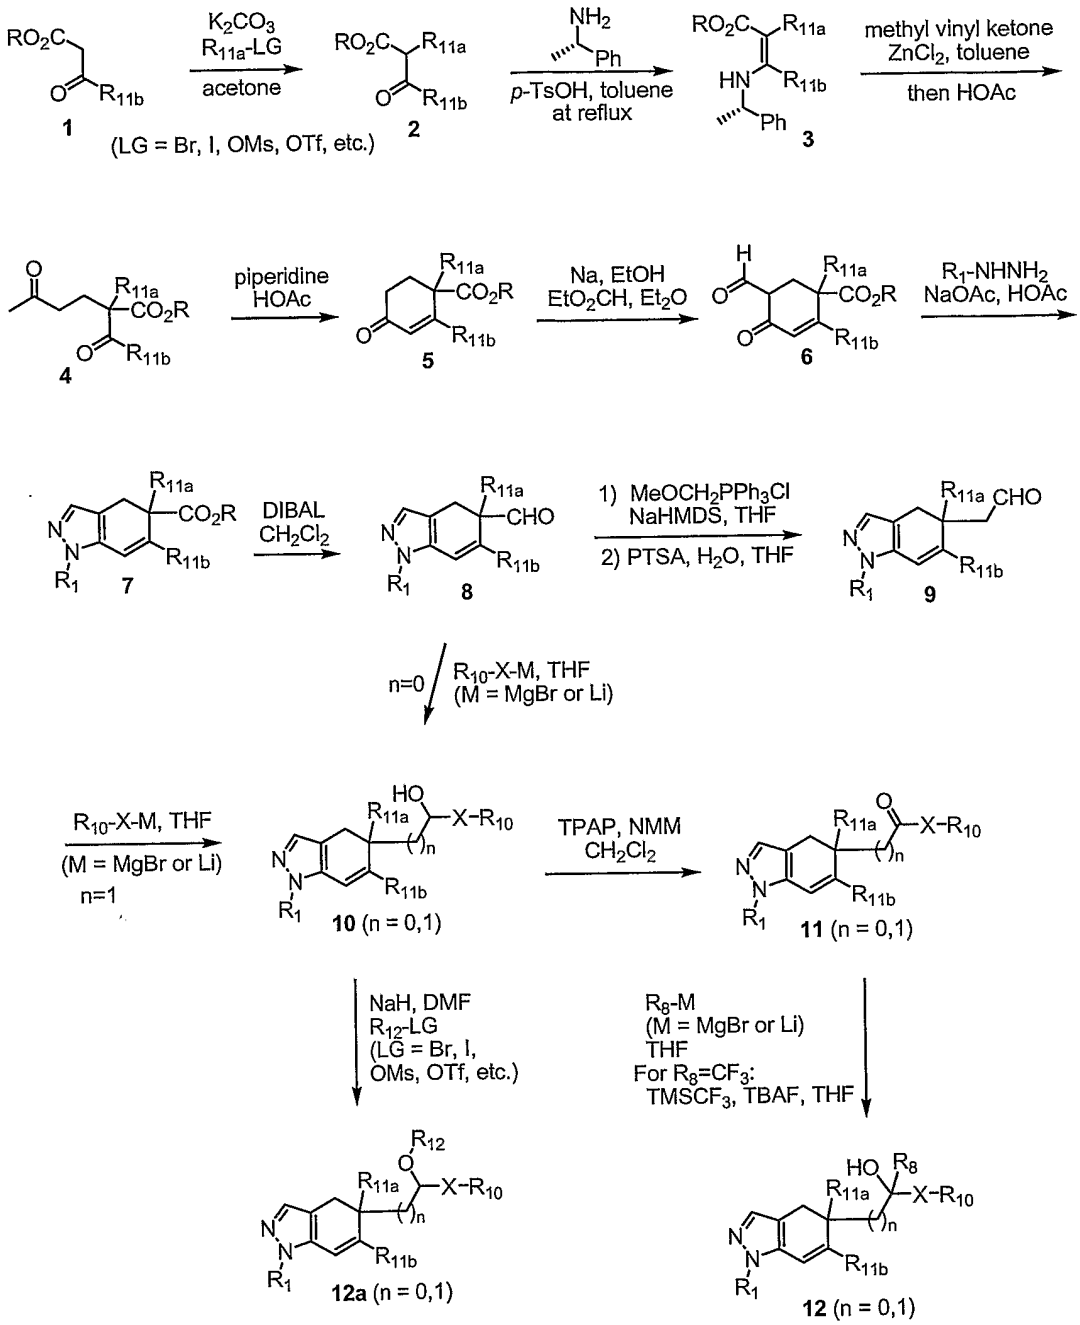
[0033] Scheme 1 outlines a general synthesis for a series of 4,5-dihydroindazoles. Many of the starting β-keto esters **1** are commercially available. Others are prepared following well known literature procedures, such as reaction of acid chlorides (R_{11b}-COCl) with potassium methyl malonate (Clay et al. *Synthesis* **1993**, 290).

[0034] The alkylation of **1** may be effected with mild bases such as potassium carbonate. A wide variety of alkylating reagents (R_{11a}-LG) may be used for this reaction. The leaving group (LG) may be a halogen or sulfonate. After condensation of malonates **2** with (*S*)-alpha-methylbenzylamine, the stereoselective Michael reaction of enamine intermediates **3** with methyl vinyl ketone may be achieved under conditions reported by Nour et al. (Nour et al *Tetrahedron Asymmetry* **2001**, *12*, 765). After hydrolysis of the chiral amine auxiliary, diketones **4** can be obtained in enantiomerically enriched form. The antipodes of **4** may be synthesized from **2** using the other α-methylbenzylamine enantiomer. Alternative syntheses of diketones **4** include enantioselective Michael reaction to methyl vinyl ketone with a palladium catalyst (Hamashima et al. *J. Am. Chem. Soc.* **2002**, *124*, 11240), La-Na-BINOL complex (Sasai et al *Tetrahedron Lett.* **1996**, *37*, 5561), and copper catalyst (Christoffers et al *Chem. Eur. J.* **2001**, *7*, 1014). Diketones **4** can also be synthesized in racemic form from **2** and methyl vinyl ketone in the presence of catalytic amount of bases, such as sodium hydride (Begue et al *Synth. Commun.* **1992**, *22*, 573), or Lewis acids, such as ytterbium(III) trifluoromethanesulfonate (Keller et al *Tetrahedron Lett.* **1996**, *37*, 1879). The resolution of **4** or subsequent intermediates may be achieved using a variety of chiral HPLC columns.

[0035] Intramolecular aldol condensation of **4**, in the presence of piperidine and acetic acid gives Hagemann's esters **5**, which, in turn, can be converted to keto aldehydes **6** with ethyl formate, sodium in ethanol and ether. Treatment of **6** with hydrazines (R_1-$NHNH_2$), sodium acetate and acetic acid would yield 4,5-

dihydroindazole intermediates **7**, which may then be reduced to aldehydes **8** with diisobutylaluminum hydride. Reaction of **8** with organo lithium or magnesium reagents (R_{10}-X-M) would give the corresponding alcohols **10** (n=0). Alternatively, **8** may be elongated to aldehydes **9** via reaction with (methoxymethylene)triphenylphosphorane followed by acid hydrolysis. Aldehydes **9** can react with R_{10}-X-M to provide **10** (n=1). Alcohols **10** may then be oxidzed to ketones **11** under oxidation conditions, such as tetrapropylammonium perruthenate (TPAP) or Dess-Martin periodinane. Tertiary alcohols **12** may be obtained from **11** using organolithium or magnesium reagents (R_8-M). Analogues of **12** where R_8 is trifluoromethyl group may be prepared with (trifluoromethyl)trimethylsilane and tetrabutylammonium fluoride. Alcohols **10** can also be converted to variety of ethers (**12a**) with alkylating reagents (R_{12}-LG) under basic conditions such as sodium hydride in N,N-dimethyl formamide.

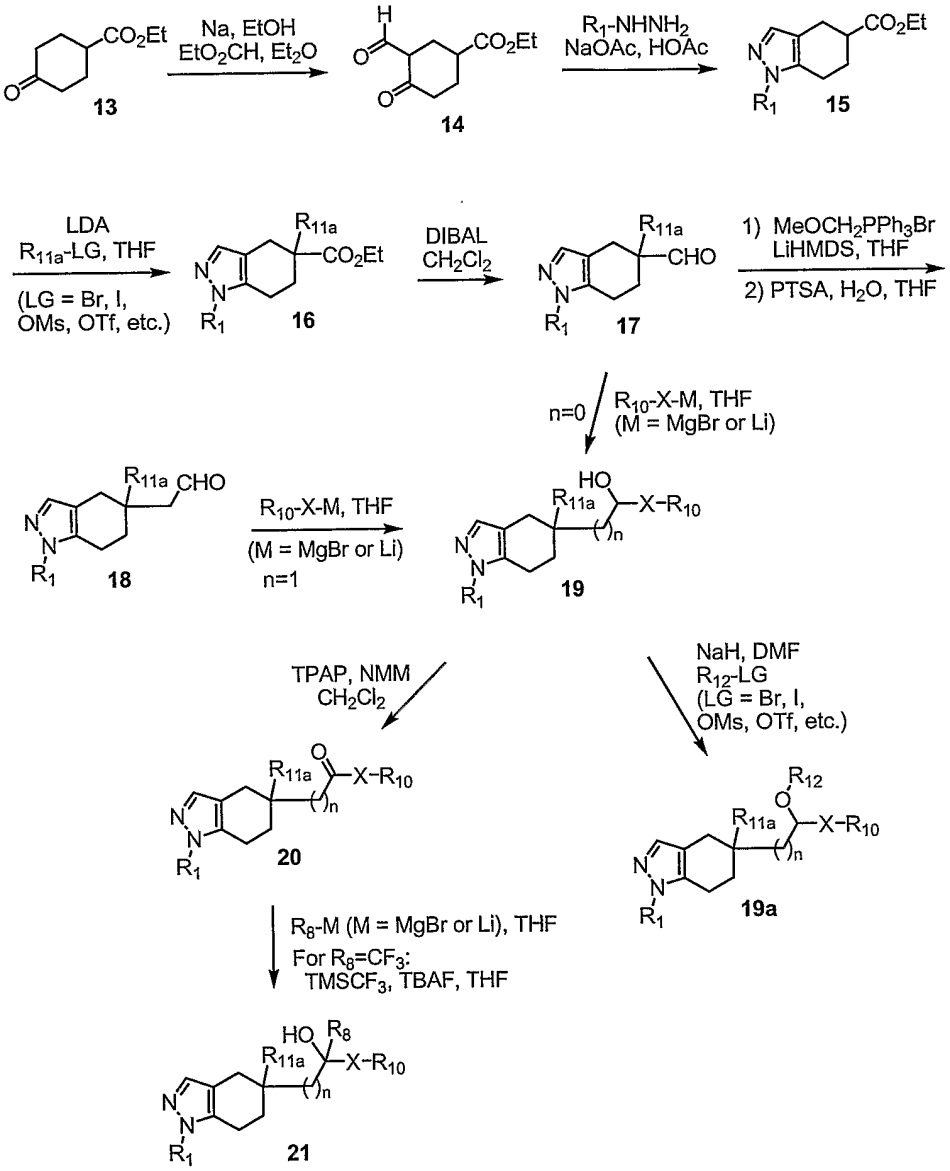
Scheme 1



[0036] Scheme 2 outlines a general synthesis for a series of 4,5,6,7-tetrahydroindazoles. Treatment of ethyl 4-oxocyclohexanecarboxylate (**13**) with sodium ethoxide and ethyl formate would provide keto aldehydes **14**, which can be converted to 4,5,6,7-tetrahydroindazoles **15** with hydrazines (R_1-$NHNH_2$), sodium acetate and acetic acid. Incorporation of R_{11a} can be achieved by alkylation with LDA

and R_{11a}-LG. Addition of hexamethylphosphoramide (HMPA) may improve the efficiency of reaction. Subsequent transformations are analogous to those described above for the 4,5-dihydroindazole series. Various secondary alcohols (**19**), ketones (**20**), tertiary alcohols (**21**) and ethers (**19a**) of the 4,5,6,7-tetrahydroindazoles can be synthesized using this route.

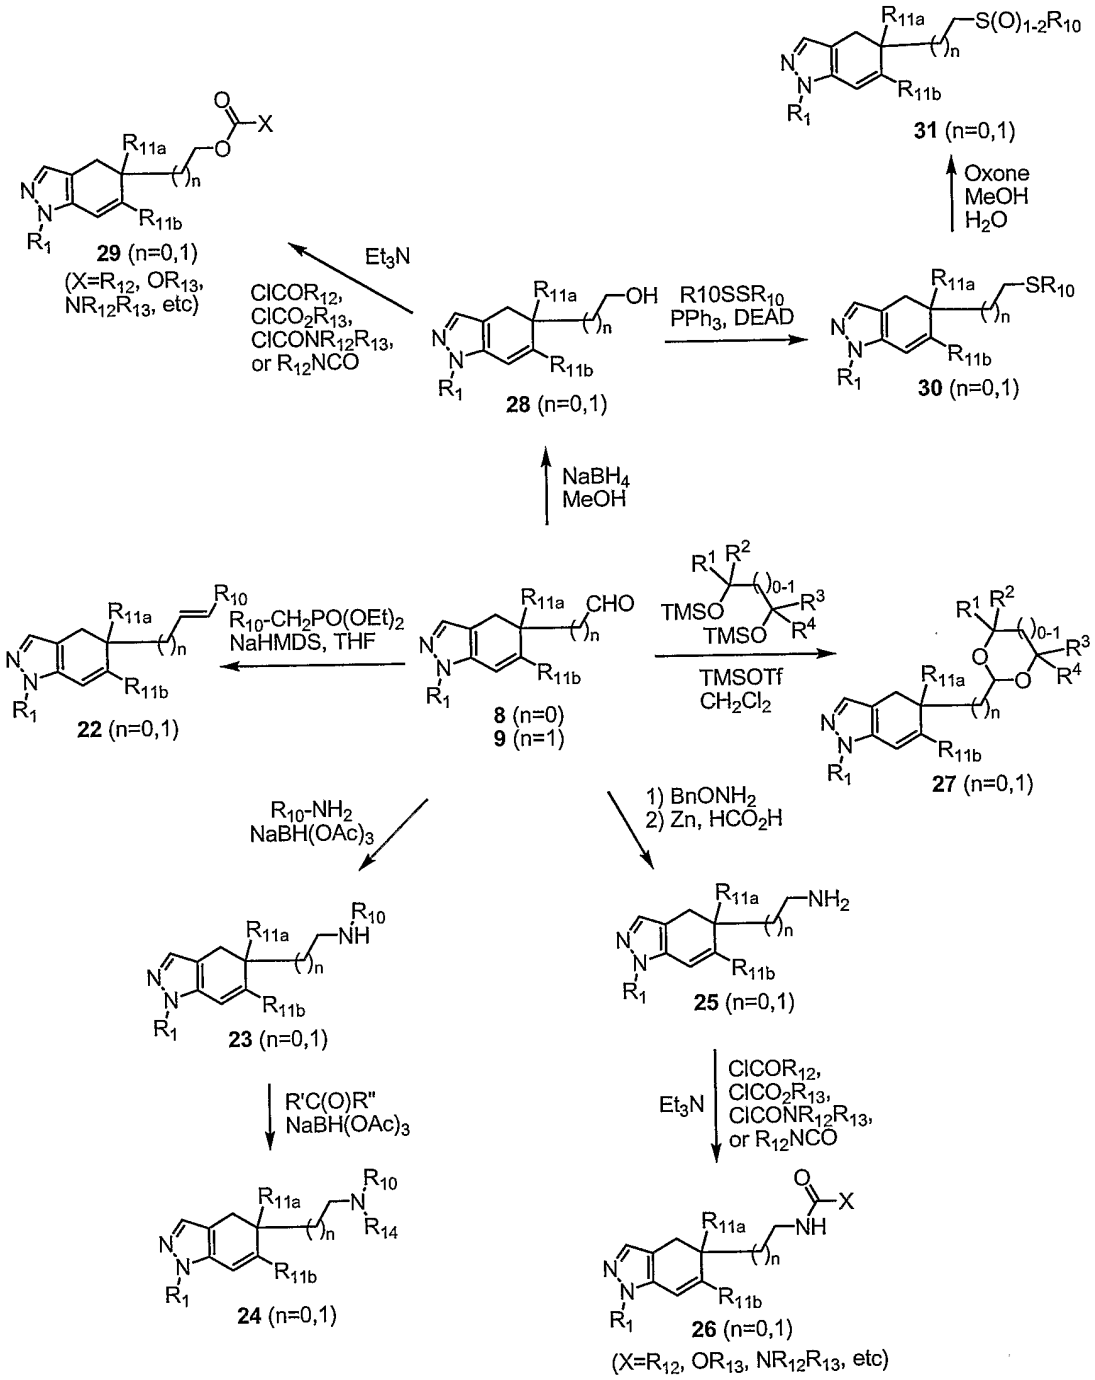
Scheme 2



Aldehydes **8** and **9** from Scheme 1 can be useful intermediates for diversification. They can be reacted under Horner-Emmons or Wittig conditions to

yield olefins **22** (Scheme 3). They can be reacted with amines (R_{10}-NH_2) under reductive conditions such as sodium triacetoxyborohydride to give secondary amines **23**, which can be further derivatized to tertiary amines **24** under similar conditions. Alternatively, they can be converted to primary amines **25** by reaction with O-benzylhydroxylamine (NH_2OBn) to form oximes and reduction using conditions such as zinc in formic acid at elevated temperature. These primary amines can be converted to amides, carbamates and ureas (**26**) by reaction with acid chlorides, chloroformates, carbamoyl chlorides and isocyanates. Aldehydes **8** and **9** can also be converted to acetals **27** using trimethylsilyl trifluoromethanesulfonate (TMSOTf) conditions reported by Tsunoda et al (*Tetrohedron Lett.* **1980**, *21*, 1357). Furthermore, aldehydes **8** and **9** can be reduced with sodium borohydride, diisobutylaluminum hydride or lithium aluminum hydride to give alcohols **28**, another useful intermediate for diversification. For example, **28** can react with acid chlorides, chloroformates, carbamoyl chloride and isocyanates to yield esters, carbonates and carbamates (**29**). **28** can also react with disulfide ($R_{10}SSR_{10}$) under Mitsunobu conditions to give sulfides **30**, which can be oxidized to sulfoxides and sulfones **31** using oxone or meta-chloroperbenzoic acid.

Scheme 3



A series of amide derivatives **35** can be prepared following a sequence outlined in Scheme 4. Esters **7** can be converted to acids **32** using saponification conditions such as sodium hydroxide in methanol and water (for methyl or ethyl esters) or acidic conditions such as hydrogen chloride or trifluoroacetic acid (for *t*-butyl esters). Oxidation of aldehydes **9** under Sharpless sodium chlorite conditions

will give acids **33**. For preparation of acids **34**, aldehydes **8** can be treated with stabilized Wittig ylide (Ph_3PCHCO_2Me). The resulting enoates could be selectively reduced with magnesium in methanol (Hudlicky et al. *Tetrahedron Lett.* **1987**, *28*, 5287). Subsequent hydrolysis with lithium hydroxide can provide the desired acids **34**. DEFINITION OF TERMS

[0037] The following are definitions of terms used in this specification and appended claims. The initial definition provided for a group or term herein applies to that group or term throughout the specification and claims, individually or as part of another group, unless otherwise indicated.

[0038] The term "alkyl" refers to straight or branched chain hydrocarbon groups having 1 to 12 carbon atoms, preferably 1 to 6 carbon atoms. Lower alkyl groups, that is, alkyl groups of 1 to 4 carbon atoms, are most preferred. When numbers appear in a subscript after the symbol "C", the subscript defines with more specificity the number

of carbon atoms that a particular group may contain. For example, "C_{1-6}alkyl" refers to straight and branched chain alkyl groups with one to six carbon atoms, such as methyl, ethyl, n-propyl, isopropyl, n-butyl, t-butyl, n-pentyl, and so forth. The subscript "0" refers to a bond. Thus, the term hydroxy(C_{0-2})alkyl or (C_{0-2})hydroxyalkyl includes hydroxy, hydroxymethyl and hydroxyethyl.

[0039] The term "substituted alkyl" refers to an alkyl group as defined above having one, two, or three substituents selected from the group consisting of halo (*e.g.*, trifluoromethyl), alkenyl, substituted alkenyl, alkynyl, nitro, cyano, oxo (=O), OR_a, SR_a, (=S), $-NR_aR_b$, $-N(alkyl)_3^+$, $-NR_aSO_2$, $-NR_aSO_2R_c$, $-SO_2R_c$ $-SO_2NR_aR_b$, $-SO_2NR_aC(=O)R_b$, SO_3H, $-PO(OH)_2$, $-C(=O)R_a$, $-CO_2R_a$, $-C(=O)NR_aR_b$, $-C(=O)(C_{1-4}alkylene)NR_aR_b$, $-C(=O)NR_a(SO_2)R_b$, $-CO_2(C_{1-4}alkylene)NR_aR_b$, $-NR_aC(=O)R_b$, $-NR_aCO_2R_b$, $-NR_a(C_{1-4}alkylene)CO_2R_b$, =N-OH, =N-O-alkyl, aryl, cycloalkyl, heterocyclo, and/or heteroaryl,wherein R_a and R_b are selected from hydrogen, alkyl, alkenyl, CO_2H, CO_2(alkyl), C_{3-7}cycloalkyl, phenyl, benzyl, phenylethyl, napthyl, a four to seven membered heterocylo, or a five to six membered heteroaryl, or when attached to the same nitrogen atom may join to form a heterocyclo or heteroaryl, and R_c is selected from same groups as R_a and R_b but is not hydrogen. Each group R_a and R_b when other than hydrogen, and each R_c group optionally has up to three further substituents attached at any available carbon or nitrogen atom of R_a, R_b, and/or R_c, said substituent(s) being selected from the group consisting of (C_{1-6})alkyl, (C_{2-6})alkenyl, hydroxy, halogen, cyano, nitro, CF_3, $O(C_{1-6}alkyl)$, OCF_3, C(=O)H, $C(=O)(C_{1-6}alkyl)$, CO_2H, $CO_2(C_{1-6}alkyl)$, $NHCO_2(C_{1-6}alkyl)$, $-S(C_{1-6}alkyl)$, $-NH_2$, $NH(C_{1-6}alkyl)$, $N(C_{1-6}alkyl)_2$, $N(CH_3)_3^+$, $SO_2(C_{1-6}alkyl)$, $C(=O)(C_{1-4}alkylene)NH_2$, $C(=O)(C_{1-4}alkylene)NH(alkyl)$, $C(=O)(C_{1-4}alkylene)N(C_{1-4}alkyl)_2$, C_{3-7}cycloalkyl, phenyl, benzyl, phenylethyl, phenyloxy, benzyloxy, napthyl, a four to seven membered heterocylo, or a five to six membered heteroaryl. When a substituted alkyl is substituted with an aryl, heterocyclo, cycloalkyl, or heteroaryl group, said ringed systems are as defined below and thus may have zero, one, two, or three substituents, also as defined below.

[0040] One skilled in the field will understand that, when the designation "CO_2" is used herein, this is intended to refer to the group $-\overset{O}{\overset{\|}{C}}-O-$.

[0041] When the term "alkyl" is used together with another group, such as in "arylalkyl", this conjunction defines with more specificity at least one of the substituents that the substituted alkyl will contain. For example, "arylalkyl" refers to a substituted alkyl group as defined above where at least one of the substituents is an aryl, such as benzyl. Thus, the term aryl(C_{0-4})alkyl includes a substituted lower alkyl having at least one aryl substituent and also includes an aryl directly bonded to another group, *i.e.*, aryl(C_0)alkyl.

[0042] The term "alkenyl" refers to straight or branched chain hydrocarbon groups having 2 to 12 carbon atoms and at least one double bond. Alkenyl groups of 2 to 6 carbon atoms and having one double bond are most preferred.

[0043] The term "alkynyl" refers to straight or branched chain hydrocarbon groups having 2 to 12 carbon atoms and at least one triple bond. Alkynyl groups of 2 to 6 carbon atoms and having one triple bond are most preferred.

[0044] The term "alkylene" refers to bivalent straight or branched chain hydrocarbon groups having 1 to 12 carbon atoms, preferably 1 to 6 carbon atoms, *e.g.*, $\{-CH_2-\}_n$, wherein *n* is 1 to 12, preferably 1-6. Lower alkylene groups, that is, alkylene groups of 1 to 4 carbon atoms, are most preferred. The terms "alkenylene" and "alkynylene" refer to bivalent radicals of alkenyl and alkynyl groups, respectively, as defined above.

[0045] When reference is made to a substituted alkenyl, alkynyl, alkylene, alkenylene, or alkynylene group, these groups are substituted with one to three substitutents as defined above for substituted alkyl groups.

[0046] The term "heteroalkylene" is used herein to refer to saturated and unsaturated bivalent straight or branched chain hydrocarbon groups having 2 to 12 carbon atoms, preferably 2 to 8 carbon atoms, wherein one or two carbon atoms in the straight chain are replaced by heteroatom(s) selected from –O–, –S–, –S(=O)–, $–SO_2–$, –NH–, and $–NHSO_2–$. Thus, the term "heteroalkylene" includes bivalent alkoxy, thioalkyl, and aminoalkyl groups, as defined below, as well as alkylene and alkenylene groups having a combination of heteroatoms in the alkyl chain. As an illustration, a "heteroalkylene" herein may comprise groups such as $–S-(CH_2)_{1-5}NH-CH_2-$, $–O-(CH_2)_{1-5}S(=O)-CH_2–$, $–NHSO_2-CH_2–$, $–CH_2-NH–$, and so forth. Preferably,

a heteroalkylene does not have two adjacent atoms simultaneously selected from –O- and –S-. When a subscript is used with the term heteroalkylene, *e.g.*, as in $|C_{2-3}$heteroalkylene, the subscript refers to the number of carbon atoms in the group in addition to heteroatoms. Thus, for example, a C_{1-2}heteroalkylene may include groups such as –NH-CH_2-, -CH_2-NH-CH_2-, -CH_2-CH_2-NH-, -S-CH_2-, -CH_2-S-CH_2-, -O-CH_2-NH-CH_2-, CH_2-O-CH_2 and so forth.

[0047] The term "substituted heteroalkylene" refers to a heteroalkylene group as defined above wherein at least one of the nitrogen or carbon atoms in the heteroalkylene chain is bonded to (or substituted with) a group other than hydrogen. Carbon atoms in the heteroalkylene chain may be substituted with a group selected from those recited above for substituted alkyl groups, or with a further alkyl or substituted alkyl group. Nitrogen atoms of the heteroalkylene chain may be substituted with a group selected from alkyl, alkenyl, alkynyl, cyano, or A_1-Q-A_2-R_h, wherein A_1 is a bond, C_{1-2}alkylene, or C_{2-3}alkenylene; Q is a bond, -C(=O)-, -C(=O)NR_d-, -C(=S)NR_d-, -SO_2-, -SO_2NR_d-, –CO_2-, or – NR_dCO_2-; A_2 is a bond, C_{1-3}alkylene, C_{2-3}alkenylene, -C_{1-4}alkylene-NR_d-, -C_{1-4}alkylene-NR_dC(=O)-, -C_{1-4}alkylene-S-, -C_{1-4}alkylene-SO_2-, or -C_{1-4}alkylene-O-, wherein said A_2 alkylene groups are branched or straight chain and optionally substituted as defined herein for substituted alkylene; R_h is hydrogen, alkyl, substituted alkyl, alkenyl, substituted alkenyl, aryl, heteroaryl, heterocyclo, or cycloalkyl; and R_d is selected from hydrogen, alkyl, and substituted alkyl, as defined herein, provided, however, that for a substituted heteralkylene R_h is not hydrogen when A_1, Q and A_2 are each bonds. When R_h is aryl, heteroaryl, cycloalkyl, or heterocyclo, these rings are, in turn, optionally substituted with one to three groups as defined below in the definitions for these terms.

[0048] The term "alkoxy" refers to an alkyl or substituted alkyl group as defined above having one or two oxygen atoms (-O-) in the alkyl chain. For example, the term "alkoxy" includes the groups -O-C_{1-12}alkyl, –(C_{1-6}alkylene)-O-C_{1-6}alkyl, –(C_{1-4}alkylene-O-C_{1-4}alkylene)-O-C_{1-4}alkyl, and so forth.

[0049] The term "thioalkyl" or "alkylthio" refers to an alkyl or substituted alkyl group as defined having one or two sulfur atoms in the alkyl chain. For example, the

term "thioalkyl" or "alkylthio" includes the groups -S-C_{1-12}alkyl, –(S-C_{1-6}alkylene)-S-C_{1-6}alkyl, and so forth.

[0050] The terms "aminoalkyl" or "alkylamino" refer to an alkyl or substituted alkyl group as defined above having one or two nitrogen (-NR-) atoms in the alkyl chain. For example, the term "aminoalkyl" includes the groups -NR-C_{1-12}alkyl, –NR-C_{1-6}alkylene-NR-C_{1-6}alkyl, etc. (where R is preferably hydrogen but may include alkyl or substituted alkyl as defined above.) When a subscript is used with reference to an alkoxy, thioalkyl or aminoalkyl, the subscript refers to the number of carbon atoms that the group may contain in addition to heteroatoms. Thus, for example, monovalent C_{1-2}aminoalkyl includes the groups -CH_2-NH_2, -NH-CH_3, -$(CH_2)_2$-NH_2, -NH-CH_2-CH_3, -CH_2-NH_2- CH_3, and -N-$(CH_3)_2$. A lower aminoalkyl comprises an aminoalkyl having one to four carbon atoms. "Amino" refers to the group NH_2. The alkoxy, thioalkyl, or aminoalkyl groups may be monovalent or bivalent. By "monovalent" it is meant that the group has a valency (*i.e.*, ability to combine with another group), of one, and by "bivalent" it is meant that the group has a valency of two. Thus, for example, a monovalent alkoxy includes groups such as -O-C_{1-12}alkyl, –C_{1-6}alkylene-O-C_{1-6}alkyl, –C_{1-4}alkylene-O-C_{1-4}alkylene-O-C_{1-4}alkyl, whereas a bivalent alkoxy includes groups such as -O-C_{1-12}alkylene-, –C_{1-6}alkylene-O-C_{1-6}alkylene-, –C_{1-4}alkylene-O-C_{1-4}alkylene-O-C_{1-4}alkylene-, and so forth. Where a bivalent group is specified, attachment may occur at either end of the bivalent group. For example bivalent groups such as -Oalkylene-, -N(R_{14})-C(O)-, -N(R_{14})-C(O)O-, and -NR_{15}C(O)NR_{16}-, are also intended to include -alkyleneO-, -C(O)-N(R_{14})-, -OC(O)N(R_{14})-, and -NR_{16}C(O)NR_{15}-. Accordingly a compound having an asymmetric bivalent group indicates two compounds having differing attachment.

[0051] It should be understood that the selections for alkoxy, thioalkyl, and aminoalkyl will be made by one skilled in the field to provide stable compounds. Thus, for example, in compounds of formula (I), when G is attached to a nitrogen atom (N*) of ring A and is selected from an alkoxy or alkylthio group, the alkoxy and alkylthio groups will have at least one carbon atom bonded directly to ring A (at N*), with the oxygen or sulfur atoms being at least one atom away from said nitrogen atom.

[0052] The term "acyl" refers to a carbonyl group linked to an organic radical, more particularly, the group $C(=O)R_e$, as well as the bivalent groups $-C(=O)-$ or $-C(=O)R_e-$, which are linked to organic radicals or ring A in compounds of formula (I). The group R_e can be selected from alkyl, alkenyl, alkynyl, aminoalkyl, substituted alkyl, substituted alkenyl, or substituted alkynyl, as defined herein, or when appropriate, the corresponding bivalent group, *e.g.*, alkylene, alkenylene, etc. Accordingly, in compounds of formula (I), the groups $-C(=O)R_e-$ or $-R_eC(=O)-$, wherein in this instance, the group R_e will be selected from bivalent groups, *e.g.*, alkylene, alkenylene, alkynylene, bivalent aminoalkyl, substituted alkylene, substituted alkenylene, or substituted alkynylene.

[0053] The term "alkoxycarbonyl" refers to a carboxy group ($-\overset{\overset{O}{\|}}{C}-O-$ or $-O-\overset{\overset{O}{\|}}{C}-$) linked to an organic radical (CO_2R_e), as well as the bivalent groups $-CO_2-$, $-CO_2R_e-$ which are linked to organic radicals in compounds of formula (I), wherein R_e is as defined above for acyl. The organic radical to which the carboxy group is attached may be monovalent (*e.g.*, $-CO_2$-alkyl or $-OC(=O)$alkyl), or bivalent (*e.g.*, $-CO_2$-alkylene, $-OC(=O)$alkylene, etc.) Accordingly, in compounds of formula (I), when it is recited that G can be "alkoxycarbonyl," this is intended to encompass a selection for G of $-CO_2-$ and also the groups $-CO_2R_e-$ or $-R_eCO_2-$, wherein in this instance, the group R_e will be selected from bivalent groups, *e.g.*, alkylene, alkenylene, alkynylene, bivalent aminoalkyl, substituted alkylene, substituted alkenylene, or substituted alkynylene.

[0054] The term "amide" or "amidyl" refers to the group $C(=O)NR_aR_b$, wherein the groups R_a and R_b are defined as recited above in the definition for substituted alkyl groups.

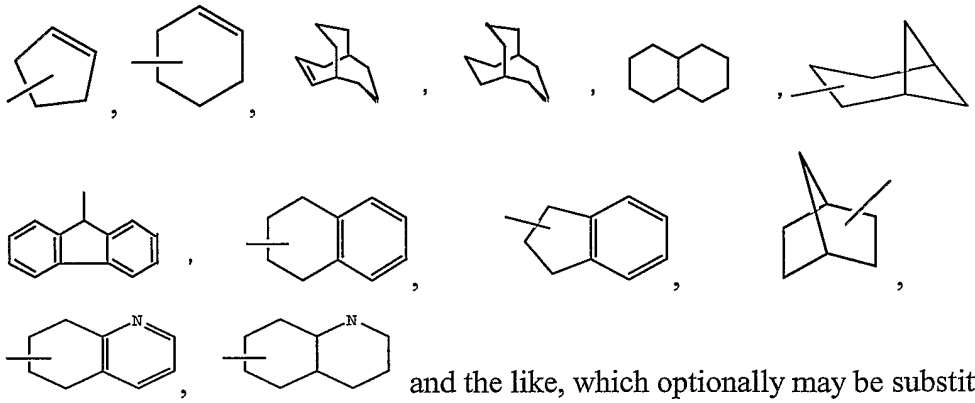
[0055] The term "sulfonyl" refers to a sulphoxide group linked to an organic radical in compounds of formula (I), more particularly, the monovalent group $S(O)_{1-2}$-R_e, or the bivalent group $-S(O)_{1-2}-$ linked to organic radicals in compounds of formula (I). Accordingly, in compounds of formula (I), when it is recited that G can be "sulfonyl," this is intended to encompass a selection for G of $-S(=O)-$ or $-SO_2-$ as well as the groups $-S(=O)R_e-$, $-R_eS(=O)-$, $-SO_2R_e-$, or $-R_eSO_2-$, wherein in this

instance, the group R_e will be selected from those recited above for acyl and alkoxycarbonyl groups.

[0056] The term "sulfonamidyl" refers to the group $-S(O)_2NR_aR_b$, wherein R_a and R_b are as defined above for substituted alkyl groups. Additionally, the sulfonamidyl group may be bivalent, in which case one of the groups R_a and $R_b$will be a bond. Thus, in compounds of formula (I), when it is stated that G may be sulfonamidyl, it is intended to mean that G is a group $-S(O)_2NR_a-$.

[0057] The term "cycloalkyl" refers to fully saturated and partially unsaturated hydrocarbon rings of 3 to 9, preferably 3 to 7 carbon atoms. The term "cycloalkyl" includes such rings having zero, one, two, or three substituents selected from the group consisting of halogen, trifluoromethyl, trifluoromethoxy, alkyl, substituted alkyl, alkenyl, substituted alkenyl, alkynyl, nitro, cyano, oxo (=O), OR_a, SR_a, (=S), $-NR_aR_b$, $-N(alkyl)_3^+$, $-NR_aSO_2$, $-NR_aSO_2R_c$, $-SO_2R_c$ $-SO_2NR_aR_b$, $-SO_2NR_aC(=O)R_b$, SO_3H, $-PO(OH)_2$, $-C(=O)R_a$, $-CO_2R_a$, $-C(=O)NR_aR_b$, $-C(=O)(C_{1-4}alkylene)NR_aR_b$, $-C(=O)NR_a(SO_2)R_b$, $-CO_2(C_{1-4}alkylene)NR_aR_b$, $-NR_aC(=O)R_b$, $-NR_aCO_2R_b$, $-NR_a(C_{1-4}alkylene)CO_2R_b$, =N-OH, =N-O-alkyl, aryl, cycloalkyl, heterocyclo, and/or heteroaryl, wherein R_a, R_b and R_c are as defined above for substituted alkyl groups, and are also in turn optionally substituted as recited above in the definition for substituted alkyl groups. The term "cycloalkyl" also includes such rings having a second ring fused thereto (*e.g.*, including benzo, heterocyclo, or heteroaryl rings) or having a carbon-carbon bridge of 3 to 4 carbon atoms. When a cycloalkyl is substituted with a further ring (or has a second ring fused thereto), said ring in turn is optionally substituted with one to two of (C_{1-4})alkyl, (C_{2-4})alkenyl, halogen, hydroxy, cyano, nitro, CF_3, $O(C_{1-4}alkyl)$, OCF_3, C(=O)H, $C(=O)(C_{1-4}alkyl)$, CO_2H, $CO_2(C_{1-4}alkyl)$, $NHCO_2(C_{1-4}alkyl)$, $-S(C_{1-4}alkyl)$, $-NH_2$, $NH(C_{1-4}alkyl)$, $N(C_{1-4}alkyl)_2$, $N(C_{1-4}alkyl)_3^+$, $SO_2(C_{1-4}alkyl)$, $C(=O)(C_{1-4}alkylene)NH_2$, $C(=O)(C_{1-4}alkylene)NH(alkyl)$, and/or $C(=O)(C_{1-4}alkylene)N(C_{1-4}alkyl)_2$.

[0058] Accordingly, in compounds of formula (I), the term "cycloalkyl" includes cyclopropyl, cyclobutyl, cyclopentyl, cyclopentenyl, cyclohexyl, cyclohexenyl, cycloheptyl, cyclooctyl, etc., as well as the following ring systems,



and the like, which optionally may be substituted at any available atoms of the ring(s). Preferred cycloalkyl groups include cyclopropyl, cyclobutyl, cyclopentyl, cyclohexyl,  .and  .

[0059] The term "halo" or "halogen" refers to chloro, bromo, fluoro and iodo.

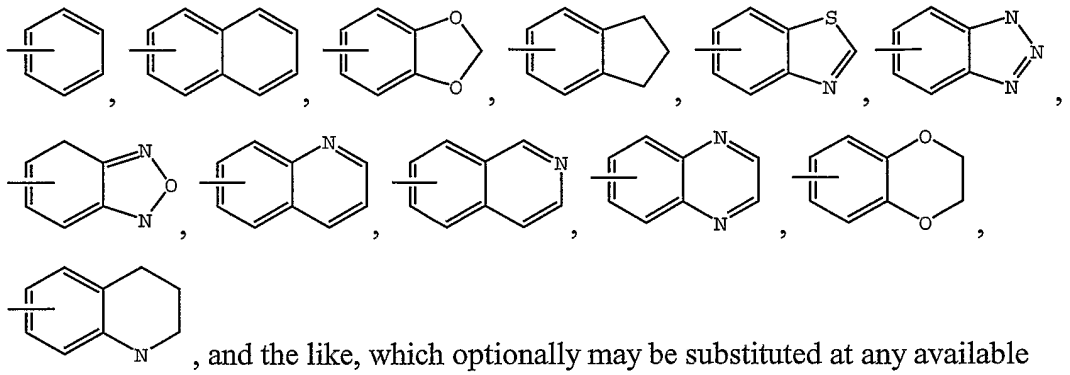
[0060] The term "haloalkyl" means a substituted alkyl having one or more halo substituents. For example, "haloalkyl" includes mono, bi, and trifluoromethyl.

[0061] The term "haloalkoxy" means an alkoxy group having one or more halo substituents. For example, "haloalkoxy" includes OCF_3.

[0062] The term "aryl" refers to phenyl, biphenyl, 1-naphthyl and 2-naphthyl. The term "aryl" includes such rings having zero, one, two or three substituents selected from the group consisting of halogen, trifluoromethyl, trifluoromethoxy, alkyl, substituted alkyl, alkenyl, substituted alkenyl, alkynyl, nitro, cyano, OR_a, SR_a, (=S), -NR_aR_b, -$N(alkyl)_3^+$, -NR_aSO_2, -$NR_aSO_2R_c$, -SO_2R_c -$SO_2NR_aR_b$, -$SO_2NR_aC(=O)R_b$, SO_3H, -$PO(OH)_2$, -$C(=O)R_a$, -CO_2R_a, -$C(=O)NR_aR_b$, -$C(=O)(C_{1-4}alkylene)NR_aR_b$, -$C(=O)NR_a(SO_2)R_b$, -$CO_2(C_{1-4}alkylene)NR_aR_b$, -$NR_aC(=O)R_b$, -$NR_aCO_2R_b$, -$NR_a(C_{1-4}alkylene)CO_2R_b$, aryl, cycloalkyl, heterocyclo, and/or heteroaryl, wherein R_a, R_b and R_c are as defined above for substituted alkyl groups, and are also in turn optionally substituted as recited above. Additionally, two substituents attached to an aryl, particularly a phenyl group, may join to form a further ring such as a fused or spiro-ring, *e.g.*, cyclopentyl or cyclohexyl, or fused heterocyclo or heteroaryl. When an aryl is substituted with a further ring (or has a second ring fused thereto), said ring in turn is optionally substituted with one to two of (C_{1-4})alkyl, (C_{2-4})alkenyl, halogen, hydroxy, cyano, nitro, CF_3, $O(C_{1-4}alkyl)$, OCF_3, C(=O)H, $C(=O)(C_{1-4}alkyl)$, CO_2H,

$CO_2(C_{1-4}alkyl)$, $NHCO_2(C_{1-4}alkyl)$, $-S(C_{1-4}alkyl)$, $-NH_2$, $NH(C_{1-4}alkyl)$, $N(C_{1-4}alkyl)_2$, $N(C_{1-4}alkyl)_3^+$, $SO_2(C_{1-4}alkyl)$, $C(=O)(C_{1-4}alkylene)NH_2$, $C(=O)(C_{1-4}alkylene)NH(alkyl)$, and/or $C(=O)(C_{1-4}alkylene)N(C_{1-4}alkyl)_2$.

[0063] Thus, examples of aryl groups include:



, and the like, which optionally may be substituted at any available carbon or nitrogen atom. A preferred aryl group is optionally-substituted phenyl.

optionally may be substituted at any available carbon or nitrogen atom.

CAS Registry Number refers to the unique identifier number assigned to chemical compounds by the Chemical Abstracts Service, a division of the American Chemical Society.

[0072] Unless otherwise indicated, when reference is made to a specifically-named aryl (*e.g.*, phenyl), cycloalkyl (*e.g.*, cyclohexyl), heterocyclo (*e.g.*, pyrrolidinyl) or heteroaryl (*e.g.*, imidazolyl), unless otherwise specifically indicated the reference is intended to include rings having 0 to 3, preferably 0-2, substituents selected from those recited above for the aryl, cycloalkyl, heterocyclo and/or heteroaryl groups, as appropriate.

[0073] The term "heteroatoms" shall include oxygen, sulfur and nitrogen.

[0074] The term "carbocyclic" means a saturated or unsaturated monocyclic or bicyclic ring in which all atoms of all rings are carbon. Thus, the term includes cycloalkyl and aryl rings. The carbocyclic ring may be substituted in which case the substituents are selected from those recited above for cycloalkyl and aryl groups.

[0075] The term "optionally substituted" is intended to include both unsubstituted and substituted groups.

[0076] When the term "unsaturated" is used herein to refer to a ring or group, the ring or group may be fully unsaturated or partially unsaturated.

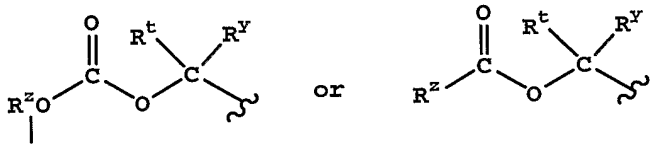
[0077] Throughout the specification, groups and substituents thereof may be chosen by one skilled in the field to provide stable moieties and compounds and compounds useful as pharmaceutically-acceptable compounds and/or intermediate compounds useful in making pharmaceutically-acceptable compounds.

[0078] The term "prodrug" denotes a compound which, upon administration to a subject, undergoes chemical conversion by metabolic or chemical processes to yield a compound of the formula (I), and/or a salt and/or solvate thereof. For example,

compounds containing a carboxy group can form physiologically hydrolyzable esters which serve as prodrugs by being hydrolyzed in the body to yield formula (I) compounds *per se*. Such prodrugs are preferably administered orally since hydrolysis in many instances occurs principally under the influence of the digestive enzymes. Parenteral administration may be used where the ester *per se* is active, or in those instances where hydrolysis occurs in the blood. Examples of physiologically hydrolyzable esters of compounds of formula (I) include C_{1-6}alkylbenzyl, 4-methoxybenzyl, indanyl, phthalyl, methoxymethyl, C_{1-6}alkanoyloxy-C_{1-6}alkyl, *e.g.* acetoxymethyl, pivaloyloxymethyl or propionyloxymethyl, C_{1-6}alkoxycarbonyloxy-C_{1-6}alkyl, *e.g.* methoxycarbonyl-oxymethyl or ethoxycarbonyloxymethyl, glycyloxymethyl, phenylglycyloxymethyl, (5-methyl-2-oxo-1,3-dioxolen-4-yl)-methyl and other well known physiologically hydrolyzable esters used, for example, in the penicillin and cephalosporin arts. Such esters may be prepared by conventional techniques known in the art.

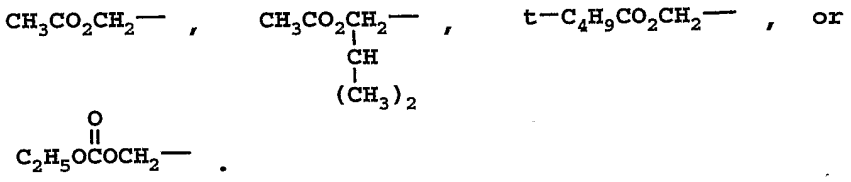
[0079] Prodrug ester examples include the following groups:

(1-alkanoyloxy)alkyl such as,

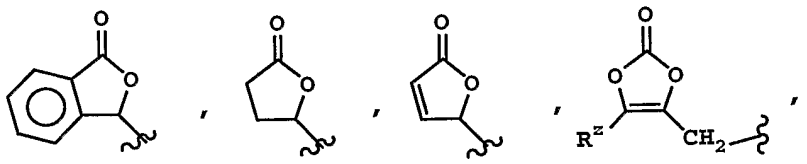


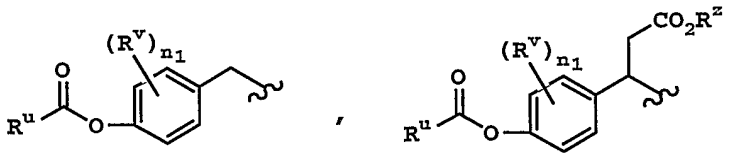
wherein R^z, R^t and R^y are H, alkyl, aryl or arylalkyl; however, R^zO cannot be HO.

[0080] Examples of such prodrug esters include



[0081] Other examples of suitable prodrug esters include





wherein R^Z can be H, alkyl (such as methyl or t-butyl), arylalkyl (such as benzyl) or aryl (such as phenyl); R^V is H, alkyl, halogen or alkoxy, R^U is alkyl, aryl, arylalkyl or alkoxyl, and n_1 is 0, 1 or 2.

[0083] The term tautomer refers to compounds of the formula (I) and salts thereof that may exist in their tautomeric form, in which hydrogen atoms are transposed to other parts of the molecules and the chemical bonds between the atoms of the molecules are consequently rearranged. It should be understood that the all tautomeric forms, insofar as they may exist, are included within the invention.

[0084] The terms pharmaceutically acceptable "salt" and "salts" refer to basic salts formed with inorganic and organic bases. Such salts include ammonium salts; alkali metal salts, such as lithium, sodium and potassium salts (which are preferred); alkaline earth metal salts, such as calcium and magnesium salts; salts with organic bases, such as amine like salts (e.g., dicyclohexylamine salt, benzathine, N-methyl-D-glucamine, and hydrabamine salts); and salts with amino acids like arginine, lysine and the like; and zwitterions, the so-called "inner salts". Nontoxic, pharmaceutically acceptable salts are preferred, although other salts are also useful, e.g., in isolating or purifying the product.

[0085] The term pharmaceutically acceptable "salt" and "salts" also includes acid addition salts. These are formed, for example, with strong inorganic acids, such as

mineral acids, for example sulfuric acid, phosphoric acid or a hydrohalic acid such as HCl or HBr, with strong organic carboxylic acids, such as alkanecarboxylic acids of 1 to 4 carbon atoms which are unsubstituted or substituted, for example, by halogen, for example acetic acid, such as saturated or unsaturated dicarboxylic acids, for example oxalic, malonic, succinic, maleic, fumaric, phthalic or terephthalic acid, such as hydroxycarboxylic acids, for example ascorbic, glycolic, lactic, malic, tartaric or citric acid, such as amino acids, (for example aspartic or glutamic acid or lysine or arginine), or benzoic acid, or with organic sulfonic acids, such as (C_1-C_4) alkyl or arylsulfonic acids which are unsubstituted or substituted, for example by halogen, for example methanesulfonic acid or p-toluenesulfonic acid.

[0086] All stereoisomers of the compounds of the instant invention are contemplated, either in admixture or in pure or substantially pure form. The compounds of the present invention can have asymmetric centers at any of the carbon atoms including any one or the R substituents. Consequently, compounds of formula I can exist in enantiomeric or diastereomeric forms or in mixtures thereof. The processes for preparation can utilize racemates, enantiomers or diastereomers as starting materials. When diastereomeric or enantiomeric products are prepared, they can be separated by conventional methods for example, chromatographic or fractional crystallization.

[0087] The inventive compounds may be in the free or solvate (e.g. hydrate) form.

It will be understood that the specific dose level and frequency of dosage for any particular subject may be varied and will depend upon a variety of factors including the activity of the specific compound employed, the metabolic stability and length of action of that compound, the species, age, body weight, general health, sex and diet of the subject, the mode and time of administration, rate of excretion, drug combination, and severity of the particular condition. Preferred subjects for treatment include animals, most preferably mammalian species such as humans, and domestic animals such as dogs, cats and the like.

[00185] A typical capsule for oral administration contains compounds of structure I (250 mg), lactose (75 mg) and magnesium stearate (15 mg). The mixture is passed through a 60 mesh sieve and packed into a No. 1 gelatin capsule.

[00186] A typical injectable preparation is produced by aseptically placing 250 mg of compounds of structure I into a vial, aseptically freeze-drying and sealing. For use, the contents of the vial are mixed with 2 mL of physiological saline, to produce an injectable preparation.

[00187] The compounds of formula (I) of the invention are glucocorticoid receptor modulators as shown either by their ability to bind glucocorticoid receptors in GR

binding assays, or by their ability to inhibit AP-1 activity as indicated in cellular transrespressional assays, and cause none to minimal transactivation as indicated in cellular transscriptional assays.

[00188] Examples of the invention have been tested in at least one of the assays described below and have glucocorticoid receptor (GR)/Dexamethasone (Dex) inhibition activity (>25%, preferably >95% at 10 μM) and/or AP-1 inhibition activity (EC_{50} less than 15 μM).

[00189] Identical and/or similar assays are described in copending provisional application No. 60/396,907, filed July 18, 2002 which is incorporated in its entireity herein by reference.

GR (Dex) Binding Assay

[00190] In order to measure the binding of compounds to Site I on the glucocorticoid receptor a commercially available kit was used (Glucocorticoid receptor competitor assay kit, Panvera Co., Madison, WI). Briefly, a cell lysate containing recombinantly expressed human full-length glucocorticoid receptor was mixed with a fluorescently labeled glucocorticoid (4nM FITC-dexamethasone) plus or minus test molecule. After one hour at room temperature, the fluorescence polarization (FP) of the samples were measured. The FP of a mixture of receptor, fluorescent probe (i.e. FITC-dexamethasone) and 1mM dexamethasone represented background fluorescence or 100% inhibition, whereas, the FP of the mixture without dexamethasone was taken to be 100% binding. The percentage inhibition of test molecules were then compared to the sample with 1mM dexamethasone and expressed as % relative binding activity with dexamethasone being 100% and no inhibition is 0%. Test molecules were analyzed in the concentration range from 0.1nM to 40 μM.

[00191] Site I binding assays for any NHR (Nuclear Hormone Receptor) are conducted similarly to the above. An appropriate cell lysate or purified NHR is used as the source of the NHR. The fluorescent probe and unlabeled competitor are appropriate for the specific NHR, i.e. are ligands for the specific NHR.

Cellular Transrepressional Assay

[00192] To measure the ability of test molecules to inhibit AP-1 induced transcriptional activity we utilized an A549 cell which was stably transfected with a plasmid containing 7x AP-1 DNA binding sites (pAP-1-Luc plasmid , Stratagene Co. La Jolla, CA) followed by the gene for luciferase. Cells were activated with 10ng/ml of phorbol myristic acid (PMA) plus or minus test molecules for 7 hours. After 7 hours a luciferase reagent was added to measure luciferase enzymatic activity in the cell. After a 10 minute incubation of luciferase reagent with cells, luminescence was measured in a TopCount luminescence counter. Repression of AP-1 activity was calculated as the percentage decrease in the signal induced by PMA alone. Test molecules were analyzed in the concentration range from 0.1nM to 40 μM. EC50s were determined by using standard curve fitting methods such as Excel fit (Microsoft Co.). An EC50 is the test molecule concentration at which there is a 50% repression of the maximal inhibition of transcription, i.e. a 50% reduction of AP-1 activity.

[00193] Other reporters and cell lines also may be used in a cellular transrepressional assay. A similar assay may be performed in which NF-κB activity can be measured. A plasmid containing NF-κB DNA binding sites, such as pNF-κB-Luc, (Stratagene, LaJolla CA), and PMA, or another stimulus, such as TNF-α or lipopolysaccharide, is used to activate the NF-κB pathway. NF-κB assays similar to that described in Yamamoto K., et al., *J Biol Chem* Dec 29;270(52):31315-20 (1995) may be used.

[00194] The cellular transrepressional assays described above may be used to measure transrepression by any NHR. One of skill in the art will understand that assays may require the addition of components, such as a stimulus (eg. PMA, lipopolysaccharide, TNF-α, etc) which will induce transcription mediated by AP-1 or NF-κB. Additionally, AR mediated transrepression may be measured by the assay described in Palvimo JJ, et al. *J Biol Chem Sep* 27;271(39):24151-6 (1996), and PR mediated transrepression may be measured by the assay described in Kalkhoven E., et al. *J Biol Chem* Mar 15;271(11):6217-24 (1996).

The mixture was heated to reflux for 18 h, cooled to room temperature, and carefully quenched with 1 N HCl (50 mL). After stirring for 30 min, the mixture was diluted with brine (200 mL) and extracted with EtOAc (3x300 mL). The combined extracts were washed with saturated $NaHCO_3$ (10 mL), brine (10 mL), dried ($MgSO_4$) and concentrated. HPLC and LCMS analysis indicated that the desired ketone is the minor product while most of the material is the imine intermediate. The crude material was stirred in THF (150 mL) and 2 N HCl (100 mL) at room temperature for 15 h. The reaction was incomplete. Concentrated HCl (35 mL) was added. The mixture was stirred at room temperature for 1 h and at reflux for 1 h, then concentrated *in vacuo*. The residue was taken up in EtOAc (300 mL), washed with saturated $NaHCO_3$ (2x10 mL), brine (10 mL), dried ($MgSO_4$) and concentrated. Silica gel chromatography (EtOAc-hexanes, 0% to 10% gradient) gave the desired methyl ketone as a colorless liquid (2.18 g, 68%). MS found: $(M+Na)^+$=297.

[00453] *(230b)* To a solution of the ketone (2.15 g, 7.85 mmol) from reaction *230a* in *N,N*-dimethylacetamide (100 mL) and water (15 mL) were added $PdCl_2$ (278 mg, 0.2 eq) and $Cu(OAc)_2$ (695 mg, 0.5 eq). The mixture was stirred under balloon pressure oxygen for three days, diluted with brine (100 mL) and 1 N HCl (100 mL), and extracted with EtOAc (4x100 mL). Upon heating to reflux, the resulting solid became a homogeneous solution. After 20 h at reflux, the mixture was filtered through a silica gel pad. The pad was rinsed with ether. The filtrate was concentrated. Silica gel chromatography (EtOAc-hexanes, 5% to 25% gradient) separated the desired cyclohexenone (a mixture of two diastereomers) from unreacted starting material (592 mg, 29%). The product mixture was further separated using Sunfire reverse phase HPLC (60% to 90% solvent B

gradient) to give a fast eluting isomer (556.9 mg, 29%) and a slow eluting isomer (476.2 mg, 25%). MS found: $(M\text{-}EtOH+H)^+$=227 for both isomers.
