Title: SEALING MEMBER FOR USE WITH PIPE COUPLINGS

Abstract: A sealing member is disclosed having an outer surface that supports segments of a pipe coupling for joining pipe elements in end to end relation. The segments are supported in spaced relation to permit the pipe elements to be inserted into the coupling without disassembly. The sealing member is a flexible ring that has conical lips around its inner circumference to engage and guide the pipe elements into the coupling. A tongue extends radially inwardly between the lips, the tongue having conical shoulders which engage and guide the pipe ends. The tongue locates the coupling segments relatively to the pipe elements.

SEALING MEMBER FOR USE WITH PIPE COUPLINGS

Field of the Invention

This invention relates to flexible seals for use with mechanical pipe couplings to ensure a fluid-tight joint.

Background of the Invention

Mechanical couplings for joining pipe elements together end-to-end comprise interconnectable segments that are positionable circumferentially surrounding the end portions of co-axially aligned pipe elements. The term "pipe element" is used herein to describe any pipe-like item or component having a pipe like form. Pipe elements include pipe stock, pipe fittings such as elbows, caps and tees as well as fluid control components such as valves, reducers, strainers, restrictors, pressure regulators and the like.

Each mechanical coupling segment comprises a housing having arcuate surfaces which project radially inwardly from the housing and engage plain end pipe elements or circumferential grooves that extend around each of the pipe elements to be joined. Engagement between the arcuate surfaces and the pipe elements provides mechanical restraint to the joint and ensures that the pipe elements remain coupled even under high internal pressure and/or external forces. The housings define an annular channel that receives a sealing member, typically an elastomeric ring which engages the ends of each pipe element and cooperates with the segments to provide a fluid tight seal. The segments have connection members, typically in the form of lugs which project outwardly from the housings. The lugs are adapted to receive fasteners, such as nuts and bolts, which are adjustably tightenable to draw the segments toward one another.
To ensure a good fit between the couplings and the pipe elements, the arcuate surfaces on prior art couplings have a radius of curvature that is substantially matched to the radius of curvature of the outer surface of the pipe element that it is intended to engage. For couplings used with grooved pipe elements, the radii of curvature of the arcuate surfaces are smaller than the radii of curvature of the outer surfaces of the pipe elements outside of the grooves so that the arcuate surfaces fit within and engage the grooves properly.

This geometrical relation between the arcuate surfaces of the couplings and the outer surfaces of the pipe elements in prior art couplings results in a tedious and time consuming installation process when mechanical couplings are used. Typically, the coupling is received by the technician with the segments bolted together and the ring seal captured within the segments' channels. The technician first disassembles the coupling by unbolting it, removes the ring seal, lubricates it (if not pre-lubricated) and places it around the ends of the pipe elements to be joined. Installation of the ring seal requires that it be lubricated and stretched to accommodate the pipe elements, an often difficult and messy task, as the ring seal is usually stiff and the lubrication makes manual manipulation of the seal difficult. With the ring seal in place on both pipe elements, the segments are then placed one at a time straddling the ends of the pipe elements and capturing the ring seal against them. During placement, the segments engage the seal, the arcuate surfaces are aligned with the grooves, the bolts are inserted through the lugs, the nuts are threaded onto the bolts and tightened, drawing the coupling segments toward one another, compressing the seal and engaging the arcuate surface within the grooves.

As evident from the previous description, installation of mechanical pipe couplings according to the prior art
requires that the technician typically handle at least seven individual piece parts (and more when the coupling has more than two segments), and must totally disassemble and reassemble the coupling. Significant time, effort and expense would be saved if the technician could install a mechanical pipe coupling without first totally disassembling it and then reassembling it, piece by piece.

**Summary of the Invention**

The invention concerns a sealing member positionable between segments of a coupling having a plurality of segments. The coupling is for securing pipe elements together in end to end relationship. The pipe elements have an outer surface of substantially cylindrical profile. The segments have arcuate surfaces facing inwardly, the arcuate surfaces being engageable with the pipe element outer surfaces. The segments have adjustably tightenable connection members for drawing the segments together. The sealing member comprises a flexible, resilient ring having a ring inner surface adapted to engage the outer surfaces of the pipe elements. The ring inner surface has a diameter sized to receive the pipe elements upon insertion of the pipe elements between the segments. The ring has a ring outer surface with a diameter sized to support the segments in spaced apart relation sufficient to allow the pipe elements to be inserted therebetween. Tightening of the connection members move the segments toward one another, compressing the ring. The ring is deformable upon motion of the segments to permit engagement of the arcuate surfaces with the pipe elements.

Preferably, the ring inner surface comprises first and second lips extending circumferentially around the ring. The lips are positioned on opposite sides of the ring in spaced apart relation and project substantially inwardly toward one another. The lips are adapted to engage the outer surfaces
of the pipe elements and form a fluid tight seal when the ring is compressed by the segments.

The first and second lips each have a conical surface facing outwardly from the ring. The conical surfaces have a width sized to engage and guide the pipe elements between the segments when the pipe elements are inserted therebetween.

The sealing member may also have a backwall that forms the ring outer surface. First and second sidewalls are positioned in spaced apart relation on opposite sides of the ring. The sidewalls extend substantially radially inwardly from the backwall. The first lip is attached to the first sidewall, and the second lip is attached to the second sidewall. A tongue is attached to the backwall and extends circumferentially around the ring. The tongue is positioned between the first and the second lips and projects substantially radially inwardly. The tongue engages ends of the pipe elements upon insertion thereof between the segments. The tongue facilitates positioning the segments relatively to the pipe elements.

Preferably, the tongue comprises a root portion attached to the backwall, and a tip portion extending from the root portion. The tip portion has a smaller thickness than the root portion, and a pair of shoulders are formed on opposite sides of the tongue between the root portion and the tip portion. Each of the shoulders has a conical profile shape for engaging and guiding the pipe elements upon insertion thereof between the segments.

Detailed Description of the Embodiments

Figure 1 shows a perspective view of a sealing member 10 according to the invention. Sealing member 10 comprises a flexible, resilient ring 12 having a ring inner surface 14. Preferably, ring inner surface 14 is formed of a pair of lips 16 and 18 that are attached to respective sidewalls 20 and 22 that extend from a backwall 24. Backwall 24 provides a ring outer surface 26 that extends circumferentially around the ring. The sidewalls and the lips are positioned in spaced apart relation on opposite sides of the ring 12. Lips 16 and 18 project substantially inwardly toward one another and have respective conical surfaces 28 and 30 that slope inwardly toward the center of ring 12 to act as a lead-in to guide pipe elements into engagement with the sealing member as described below.

In a preferred embodiment 32 of the sealing member, shown in Figure 2, ring 12 further includes a tongue 34. Tongue 34 is positioned between lips 16 and 18 and has a root portion 36 that is attached to the backwall 24 opposite to the ring outer surface 26. Tongue 34 projects substantially radially inwardly from the backwall 24 and extends circumferentially around ring 12. The tongue may be substantially continuous, as shown in Figure 2, or may comprise a plurality of sections 34a in spaced apart relation to one another around the ring as shown in Figure 2A. In another embodiment, shown in Figure 2B, the root portion 36 of tongue 34 is not attached to the backwall 24, but has a flared base 36a that engages the backwall and side walls 20 and 22 to maintain the tongue in position between lips 16 and 18.

In a preferred embodiment 32, best shown in Figure 3, tongue 34 has a tip portion 38 extending from the root portion 36. The thickness 40 of tip portion 38 is smaller than the thickness 42 of the root portion 36. This
dimensional relation results in a pair of shoulders 44 and 46 being formed between the root and tip portions. Preferably, the shoulders 44 and 46 have conical profile shapes for engaging and guiding pipe elements as described below. Cone angles 48 up to about 30° are advantageous for the functioning of the tongue 34.

As shown in Figure 4, sealing members such as 10 and 32 are used with mechanical couplings 50 for securing pipe elements together in end to end relation, the sealing members ensuring a fluid tight joint. (Hereinafter, sealing member embodiment 32 is described, it being understood that the description applies to all sealing member embodiments according to the invention.)

Coupling 50 comprises a plurality of coupling segments, in this example, two segments 52 and 54. The coupling segments are connected to one another by adjustably tightenable connection members 56, which preferably comprise lugs 58 that extend outwardly from the ends of each segment and are positioned in facing relation to one another to receive fasteners 60, such as bolts 62 and nuts 64. Each segment also has a pair of arcuate surfaces 66 that are positioned in spaced relation to one another and face inwardly for engagement with the outer surfaces of respective pipe elements as described below.

Figure 4 further shows the coupling 50 in a preassembled state, with segments 52 and 54 supported on the ring outer surface 26, the segments being held together in the preassembled state by the fasteners 60. The coupling 50 is preassembled under controlled conditions at the manufacturing facility and arrives on site in the preassembled state, ready for immediate use. As shown in Figure 5, sealing member 32 is designed so that the ring outer surface 26 has a diameter 68 sized to maintain the segments 52 and 54 in spaced
relation with sufficient clearance to allow pipe elements 70 and 72 to be inserted between the segments 52 and 54 without disassembling the coupling. Use of seals according to the invention thus provides significant advantage in reducing the labor required for assembly of the pipe joint as the coupling does not require total or even partial disassembly prior to the installation. Sealing member 32 also has sufficient stiffness to maintain the coupling segments in spaced apart relation through shipping and handling during installation, but is resilient and flexible, allowing it to deform as required when the fasteners 60 are tightened to draw the coupling segments 52 and 54 toward one another and engage the coupling arcuate surfaces 66 with the pipe elements as shown in Figures 6 and 7 to secure the pipe elements 70 and 72 in end to end relation and provide a fluid tight joint.

Note that the conical surfaces 28 and 30 of lips 16 and 18 each have a width 74 (see Figure 3) that is sized so that the pipe elements engage the lips on the conical surfaces as they are inserted into coupling 50 (see Figure 5). This conical lip geometry facilitates assembly of the pipe joint with the preassembled coupling. The lips serve as a lead in to guide the pipe elements into proper engagement with the seal, and also eliminate the need to remove the seal from the coupling and manually stretch and deform it to enable it to receive the pipe elements, as must be done for prior art seals.

Tongue 34 also enhances the ability to quickly and conveniently install pipe elements into the preassembled coupling 50. The conical profile of shoulders 44 and 46 further serve as a lead-in to guide the pipe elements into proper engagement with the sealing member 32. The shoulders 44 and 46 engage the ends of the pipe elements and limit the tongue's extension into the bore of the pipe elements where it might impede fluid flow and increase the head loss. Head
loss due to resistance in joints becomes significant for long pipe runs having many joints, and is to be avoided. The tongue itself further serves as a stop to align the arcuate surfaces 66 of segments 52 and 54 with a desired target on the outer surface of the pipe elements, in the example shown in Figures 5 and 6, circumferential grooves 74 and 76. Engagement between the grooves and the arcuate surfaces provide mechanical restraint to secure the pipe elements to the coupling.

Virtually any type of pipe element will benefit from the use of seals according to the invention. If plain end pipe elements are used (not shown), the target may be witness marks formed on the outer surface to indicate proper engagement depth between pipe element and coupling. As shown in Figures 8 and 9, pipe elements having shoulders 78 (Figure 8) or pipe elements having flared ends 80 (Figure 9) may be used with the sealing member according to the invention, the sealing member being readily geometrically adaptable to receive the various types of pipe elements.

Sealing members according to the invention may also be used with any type of multi-segment coupling where a seal is used to maintain separation between the segments in a preassembled state. The couplings themselves may have enhancements that provide additional clearance for insertion of the pipe elements, allowing the segments to be closer to one another in the preassembled state and still permit direct insertion of the pipe elements without any disassembly. To this end, the coupling shown in Figure 4 is deformable as shown by a comparison of Figures 4 and 7. In the undeformed state, the arcuate surfaces 66 have a greater radius of curvature than the pipe elements that they are joining, and the surfaces 66 also subtend an arc of less than 180°. This geometry provides clearance at the 3 o'clock and 9 o'clock positions on the coupling (for a two segment coupling)
allowing pipe element insertion. The coupling segments are
deformed by tightening fasteners 60, which draw the segments
52 and 54 toward each other and force the arcuate surfaces 66
to engage the pipe elements and conform to its radius of
curvature.

Figure 10 illustrates a pipe coupling 82 having segments
84 with cut-outs 86 at opposite ends of the arcuate surfaces
66. The cut-outs provide the desired clearance enhancement
for the coupling. Figure 11 shows a hinged coupling 88
wherein a sealing member 32 is used to maintain the segments
90 and 92 open to permit pipe element insertion. In Figure
12 the sealing member 94 has one sidewall 96 that is wider
than its other sidewall 98. This geometry positions the lip
15 100 attached to sidewall 96 at a smaller diameter than lip
102 attached to sidewall 98. The different diameter lips
allow the seal to be used to couple pipe elements 104 and 106
having different diameters.

Sealing members according to the invention used with
multi-segment couplings provide a significant advantage in
assembly of pipe joints because they permit the couplings to
be maintained in spaced relation in a preassembled state that
facilitates assembly of the joint without the need to first
disassemble the couplings.
CLAIMS

What is claimed is:

1. A sealing member positionable between segments of a coupling having a plurality of said segments, said coupling for securing pipe elements together in end to end relationship, said pipe elements having an outer surface of substantially cylindrical profile, said segments having arcuate surfaces facing inwardly and engageable with said pipe element outer surfaces, said segments having adjustably tightenable connection members for drawing said segments together, said sealing member comprising:
   a flexible, resilient ring having a ring inner surface adapted to engage said outer surfaces of said pipe elements, said ring inner surface having a diameter sized to receive said pipe elements upon insertion of said pipe elements between said segments, said ring having a ring outer surface having a diameter sized to support said segments in spaced apart relation sufficient to allow said pipe elements to be inserted therebetween; and wherein upon tightening of said connection members said segments being movable toward one another compressing said ring, said ring being deformable upon motion of said segments to permit engagement of said arcuate surfaces with said pipe elements.

2. A sealing member according to Claim 1, wherein said ring inner surface comprises first and second lips extending circumferentially around said ring, said lips being positioned on opposite sides of said ring in spaced apart relation and projecting substantially inwardly toward one another, said lips being adapted to engage said outer surfaces of said pipe elements and form a fluid tight seal when said ring is compressed by said segments.
3. A sealing member according to Claim 2, wherein said first and second lips each have a conical surface facing outwardly from said ring, said conical surfaces having a width sized to engage and guide said pipe elements between said segments when said pipe elements are inserted therebetween.

4. A sealing member according to Claim 2, wherein said sealing member comprises a backwall and first and second sidewalks positioned in spaced apart relation on opposite sides of said ring, said sidewalks extending substantially radially inwardly from said backwall, said first lip being attached to said first sidewalk, said second lip being attached to said second sidewalk, said first sidewalk being wider than said second sidewalk, resulting in said first lip having a smaller diameter than said second lip permitting said ring to seal pipes having different diameters in end to end relationship.

5. A sealing member according to Claim 2, wherein said sealing member comprises:
   a backwall forming said ring outer surface;
   first and second sidewalks positioned in spaced apart relation on opposite sides of said ring, said sidewalks extending substantially radially inwardly from said backwall, said first lip being attached to said first sidewalk, said second lip being attached to said second sidewalk; and
   a tongue attached to said backwall and extending circumferentially around said ring, said tongue being positioned between said first and said second lips and projecting substantially radially inwardly, said tongue engaging ends of said pipe elements upon insertion thereof between said segments, said tongue positioning said segments relatively to said pipe elements.
6. A sealing member according to Claim 5, wherein said tongue comprises a root portion attached to said backwall and a tip portion extending from said root portion, said tip portion having a smaller thickness than said root portion, a shoulder being formed between said root portion and said tip portion.

7. A sealing member according to Claim 6, wherein said shoulder has a conical profile shape for receiving and guiding said pipe elements upon insertion thereof between said segments.

8. A sealing member according to Claim 5, wherein said tongue comprises a root portion attached to said backwall and a tip portion extending from said root portion, said tip portion having a smaller thickness than said root portion, a pair of shoulders being formed on opposite sides of said tongue between said root portion and said tip portion.

9. A sealing member according to Claim 8, wherein each of said shoulders has a conical profile shape for engaging and guiding said pipe elements upon insertion thereof between said segments.

10. A sealing member according to Claim 9, wherein said conical profile of said shoulders has a cone angle up to about 30°.

11. A sealing member according to Claim 2, wherein said sealing member comprises:
   a backwall forming said ring outer surface;
   first and second sidewalls positioned in spaced apart relation on opposite sides of said ring, said sidewalls extending substantially radially inwardly from said backwall, said first lip being attached to said first sidewall, said second lip being attached to said second sidewall; and
a tongue attached to a base and extending circumferentially around said ring; said base being engaged with said backwall and said sidewalls for positioning said tongue between said first and said second lips, said tongue projecting substantially radially inwardly, said tongue engaging ends of said pipe elements upon insertion thereof between said segments, said tongue positioning said segments relatively to said pipe elements.

12. A sealing member according to Claim 3, wherein said sealing member comprises:
   a backwall forming said ring outer surface;
   first and second sidewalls positioned in spaced apart relation on opposite sides of said ring, said sidewalls extending substantially radially inwardly from said backwall, said first lip being attached to said first sidewall, said second lip being attached to said second sidewall; and
   a tongue attached to said backwall and extending circumferentially around said ring, said tongue being positioned between said first and said second lips and projecting substantially radially inwardly, said tongue engaging ends of said pipe elements upon insertion thereof between said segments, said tongue positioning said segments relatively to said pipe elements.

13. A sealing member according to Claim 12, wherein said tongue comprises a root portion attached to said backwall and a tip portion extending from said root portion, said tip portion having a smaller thickness than said root portion, a pair of shoulders being formed on opposite sides of said tongue between said root portion and said tip portion.

14. A sealing member according to Claim 13, wherein said shoulders have a conical profile shape for engaging and guiding said pipe elements upon insertion thereof between said segments.
15. A sealing member according to Claim 14, wherein said conical profile of said shoulders has a cone angle up to about 30°.

16. A sealing member according to Claim 5, wherein said tongue extends substantially continuously around said ring.

17. A sealing member according to Claim 5, wherein said tongue comprises a plurality of sections positioned in spaced apart relation around said ring.

18. A sealing ring positionable between segments of a coupling having a plurality of said segments, said coupling for securing pipe elements together in end to end relationship, said pipe elements having an outer surface of substantially cylindrical profile, said segments having arcuate surfaces facing inwardly and engageable with said pipe element outer surfaces, said segments having adjustably tightenable connection members for drawing said segments together, said sealing ring comprising:

   a radially facing backwall having a ring outer surface having a diameter sized to support said segments in spaced apart relation sufficient to allow said pipe elements to be inserted therebetween;

   first and second sidewalls extending substantially radially inwardly from said backwall, said sidewalls being in spaced apart relation on opposite sides of said ring;

   first and second lips attached respectively to said first and second sidewalls, said lips projecting inwardly toward one another, and each having a conical surface facing outwardly and adapted to engage and guide said pipe elements inserted between said segments;

   a tongue attached to said backwall and extending circumferentially around said ring, said tongue being positioned between said first and said second lips and projecting substantially radially inwardly, said tongue being
engageable with said pipe elements upon insertion thereof for positioning said segments relatively to said pipe elements; and wherein

upon tightening of said connection members said segments being movable toward one another compressing said ring, said ring being deformable upon motion of said segments to permit engagement of said arcuate surfaces with said pipe elements.

19. A sealing member according to Claim 18, wherein said tongue comprises a root portion attached to said backwall and a tip portion extending from said root portion, said tip portion having a smaller thickness than said root portion, a pair of shoulders being formed on opposite sides of said tongue between said root portion and said tip portion.

20. A sealing member according to Claim 19, wherein said shoulders have a conical profile shape for engaging and guiding said pipe elements upon insertion thereof between said segments.

21. A sealing member according to Claim 20, wherein said conical profile of said shoulders has a cone angle up to about 30°.
