Description

TECHNICAL FIELD

[0001] The technical field relates to mobile radio communications, and in particular, to uplink communications involving mobile radio terminals in a mobile radio communications system.

BACKGROUND

[0002] Universal Mobile Telecommunications System (UMTS) is a 3rd Generation (3G) asynchronous mobile communication system operating in Wideband Code Division Multiple Access (WCDMA) based on European systems, Global System for Mobile communications (GSM) and General Packet Radio Services (GPRS). The Long Term Evolution (LTE) of UMTS is under development by the 3rd Generation Partnership Project (3GPP) which standardized UMTS. There are many technical specifications hosted at the 3GPP website relating to Evolved Universal Terrestrial Radio Access (E-UTRA) and Evolved Universal Terrestrial Radio Access Network (E-UTRAN), e.g., 3GPP TS 36.300. The objective of the LTE work is to develop a framework for the evolution of the 3GPP radio-access technology towards a high-data-rate, low-latency and packet-optimized radio-access technology. In particular, LTE aims to support services provided from the packet switched (PS)-domain. A key goal of the 3GPP LTE technology is to enable high-speed packet communications at or above about 100 Mbps.

[0003] Figure 1 illustrates an example of an LTE type mobile communications system 10. An E-UTRAN 12 includes E-UTRAN NodeB (eNodeBs or eNBs) 18 that provide E-UTRA user plane and control plane protocol terminations towards the user equipment (UE) 20 over a radio interface. Although an eNB is a logical node, often but not necessarily implemented by a physical base station, the term base station is used here to generally cover both logical and physical nodes. A UE is sometimes referred to as a mobile radio terminal and in an idle state monitors system information broadcast by eNBs within range to inform itself about "candidate" base stations in the service area. When a UE needs access to services from a radio access network, it sends a request over a random access channel (RACH) to a suitable eNB, typically an eNB with the most favorable radio conditions. The eNBs are interconnected with each other by means of an X2 interface. The eNBs are also connected by means of the S1 interface to an Evolved Packet Core (EPC) 14 which includes a Mobility Management Entity (MME) by an S1-MME and to a System Architecture Evolution (SAE) Gateway by an S1-U. The MME/SAE Gateway are referenced as a single node 22 in this example. The S1 interface supports a many-to-many relation between MMEs / SAE Gateways and eNBs. The E-UTRAN 12 and EPC 14 together form a Public Land Mobile Network (PLMN). The MMEs / SAE Gateways 22 are

connected to directly or indirectly to the Internet 16 and to other networks.

[0004] In order to enable operation in different spectrum allocations, for example to have a smooth migration from existing cellular systems to the new high capacity high data rate system in existing radio spectrum, operation in a flexible bandwidth is necessary, e.g., bandwidths ranging from 1.25 MHz to 20 MHz for downlink transmissions from network to UE. Both high rate data services low rate services like voice must be supported, and because 3G LTE is designed for TCP/IP, VoIP will likely be the service carrying speech.

[0005] LTE uplink transmission is based on so-called Discrete Fourier Transform Spread-OFDM (DFTS-OFDM) transmission, a low-peak to average power ratio (PAPR), single-carrier (SC) transmission scheme that allows for flexible bandwidth assignment and orthogonal multiple access not only in the time domain but also in the frequency domain. Thus, the LTE uplink transmission scheme is also often referred to as Single-Carrier FDMA (SC-FDMA).

[0006] The LTE uplink transport-channel processing is outlined in Figure 2. A transport block of dynamic size is delivered from the media access control (MAC) layer. A cyclic redundancy code (CRC) to be used for error detection at the base station receiver is calculated for the block and appended thereto. Uplink channel coding is then performed by a channel encoder which may use any suitable coding technique. In LTE, the code may be a turbo code that includes a Quadratic Permutation Polynomial (QPP)-based internal interleaver for performing block interleaving as part of the turbocoder. The LTE uplink hybrid-Automatic Repeat Request (ARQ) extracts, from the block of coded bits delivered by the channel coder, the exact set of bits to be transmitted at each transmission/retransmission instant. A scrambler scrambles the coded bits on the LTE uplink (e.g., bit-level scrambling) in order to randomize the interference and thus ensure that the processing gain provided by the channel code can be fully utilized.

[0007] To achieve this randomization of the interference, the uplink scrambling is mobile terminal-specific, i.e., different mobile terminals (UEs) use different scrambling sequences. Terminal-specific scrambling also provides the scheduler the freedom to schedule multiple users on the same time-frequency resource and rely on base station receiver processing to separate the transmissions from the multiple users. Terminal-specific scrambling randomizes the interference from other mobile terminals in the same cell that happen to be scheduled on the same resource and improves the performance.

[0008] After scrambling, the data is modulated to transform a block of coded/scrambled bits into a block of complex modulation symbols. The set of modulation schemes supported for the LTE uplink example include QPSK, 16QAM, and 64QAM, corresponding to two, four, and six bits per modulation symbol, respectively. The block of

modulation symbols is then applied to a DFTS-OFDM modulator, which also maps the signal to an assigned radio resource, e.g., a frequency sub-band.

[0009] Together with the modulated data symbols, the signal mapped to the assigned frequency band also contains demodulation reference signals. Reference signals known in advance by both the mobile terminal (UE) and the base station (eNodeB) and are used by the receiver for channel estimation and demodulation of the data symbols. Different reference signals can be assigned to a user terminal for similar reasons terminal-specific scrambling codes may be used, i.e., to intelligently schedule multiple users on the same time-frequency resource and thereby realize so-called multi-user MIMO. In case of multi-user MIMO, it is up to the eNodeB processing to separate the signals transmitted from the two (or more) UEs simultaneously scheduled on the same frequency resource in the same cell. Terminals simultaneously scheduled on the same frequency resource are typically assigned different (e.g., orthogonal) reference signal sequences in order for the eNodeB to estimate the radio channels to each of those UEs.

[0010] A basic requirement for any cellular or other radio communications system is providing a user terminal the capability to request a connection setup. This capability is commonly known as random access and serves two main purposes in LTE, namely, establishment of uplink synchronization with the base station timing and establishment of a unique user terminal identity, e.g., a cell radio network temporary identifier (C-RNTI) in LTE, known to both the network and the user terminal that is used in communications to distinguish the user's communication from other communications.

[0011] But during the (initial) random access procedure, uplink transmissions from the user terminal cannot employ terminal-specific scrambling sequences or reference numbers to randomize interference because the initial random access request message from the user terminal has just started communicating with the network and neither a terminal-specific scrambling code nor a terminal-specific reference number has not been assigned to that user terminal. What is needed is a mechanism that permits random access messages sent over a shared uplink channel to be scrambled until a terminal-specific scrambling code can be assigned to the user terminal. One reason to scramble random access messages is to randomize inter-cell interference, which is also the case for scrambling during "normal" uplink data transmission. In the latter case, scrambling can also be used to suppress intra-cell interference in case of multiple UEs being scheduled on the same time-frequency resource). Similarly, it would also be desirable to be able to have user terminals transmit known reference signals during random access to allow the base station receiver to estimate the uplink channel. Reference signals need to be included in the random access messages as well as in "normal" uplink data transmissions to enable channel estimation at the eNodeB and corresponding coher-

ent demodulation.

[0012] EP0565507 A2 describes a mobile station having means for selecting a scrambling code from a list of available scrambling codes broadcast from another radio station to generate a random access message, see page 3, lines 30-32.

SUMMARY

[0013] The technology described below facilitates random access by a user terminal with a radio base station. This advantage among others are according to one aspect of the present disclosure solved by a method in a user terminal according to claim 1 and a user terminal according to claim 6 as well as a method in a base station according to claim 5 and a radio base station according to claim 10.

A user terminal determines one of a first type of uplink scrambling sequences and generates a random access message using the determined one of the first type of uplink scrambling sequences. Its transmitter transmits the random access message to the radio base station. The user terminal receiver then receives from the base station a second different type of uplink scrambling sequence. The terminal uses that second different type of uplink scrambling sequence for subsequent communication with the radio base station. In one non-limiting example embodiment, the first type of uplink scrambling sequences may be specifically associated with the radio base station's cell area or a random access radio channel associated with the radio base station, but they are not specifically assigned to any user terminal, and the second different type of uplink scrambling sequence may be selected from a second set of uplink scrambling sequences specifically assignable to user terminals. Using these two different types of scrambling sequences permits user terminals to scramble their uplink signal transmissions even though terminal-specific scrambling codes cannot be used in the uplink during random access by user terminals.

[0014] The user terminal transmits a first random access request message including a random access preamble to the radio base station using a random access channel radio resource. A second random access response message is then received from the radio base station indicating a timing change, an identified radio resource, and a temporary user terminal identifier. The terminal adjusts a timing at the user terminal for transmitting signals to the radio base station based on information received in the random access response message, and based on the adjusted timing, transmits a third message corresponding to the generated random access message including the user's full terminal identity to the radio base station over the identified radio resource. The third message is scrambled using the determined one of the first type of uplink scrambling sequence, modulated, and mapped to a radio channel resource. The terminal receives a fourth contention resolution message from the

radio base station to complete the random access procedures and normal communications follow.

[0015] Various non-limiting embodiments map the first set of uplink scrambling sequences to some other parameter known by the user terminal and the base station. For example, the first set of uplink scrambling sequences may be mapped to corresponding random access preamble sequences. One of the first set of uplink scrambling sequences may then be selected based on the random access preamble included in the first random access request message and the mapping. Another example maps the first set of uplink scrambling sequences to corresponding user terminal identifiers and selects one of the first set of uplink scrambling sequences based on the user terminal identifier included in the second random access response message and the mapping. A third example maps the first set of uplink scrambling sequences to corresponding radio resources used for transmitting the random access request message and selects one of the first set of uplink scrambling sequences based on the random access channel radio resource used to send a first random access request message including a random access preamble to the radio base station and the mapping.

[0016] The two type scrambling sequence approach also may be used for reference signals embedded in uplink random access messages sent to the base station which are used by the base station to estimate the uplink channel, e.g., for equalization purposes, etc. One of a first set of uplink reference sequences is selected, e.g., uplink reference sequences specifically associated with a radio base station's cell area or random access channel but which are not specifically assigned to any user terminal. A random access message is generated using the selected one of the first set of uplink scrambling sequences and the selected one of the first set of uplink reference sequences. The user terminal transmits the random access message to the radio base station. Thereafter, the base station informs the user terminal of a second different type of reference sequence to use in subsequent uplink communications, e.g., a reference number assigned specifically to that user terminal.

[0017] In one non-limiting example implementation, the user terminal and base station are configured to communicate with a long term evolution (LTE) radio communications network with the user terminal transmitting the first random access request message over a random access channel (RACH) and the third message over an uplink-shared channel (UL-SCH). The user terminal identifier sent by the base station in the second message may be a temporary user terminal identifier used until a radio network terminal identifier (RNTI) is assigned to the user terminal.

BRIEF DESCRIPTION OF THE DRAWINGS

[0018]

Figure 1 an example LTE mobile radio communications system;

Figure 2 is a flow diagram illustrating non-limiting, example procedures for preparing a transport block delivered from the media access layer of a user terminal for transmission over the radio interface to the network in an LTE mobile radio communications system;

Figure 3 is flow diagram illustrating non-limiting, example procedures for a user terminal to make a random access to the radio network;

Figure 4 is flow diagram illustrating non-limiting, example procedures for a base station to receive and process a user terminal's random access to the radio network;

Figure 6 is a diagram illustrating three basic states of a user terminal;

Figure 7 is a signaling diagram illustrating a non-limiting example random access procedure;

Figure 8 illustrates a non-limiting example of a random access preamble transmission; and

Figure 9 is a non-limiting, example function block diagram of a user terminal and an eNode B base station.

DETAILED DESCRIPTION

[0019] In the following description, for purposes of explanation and non-limitation, specific details are set forth, such as particular nodes, functional entities, techniques, protocols, standards, etc. in order to provide an understanding of the described technology. In other instances, detailed descriptions of well-known methods, devices, techniques, etc. are omitted so as not to obscure the description with unnecessary detail. Individual function blocks are shown in the figures. Those skilled in the art will appreciate that the functions of those blocks may be implemented using individual hardware circuits, using software programs and data in conjunction with a suitably programmed microprocessor or general purpose computer, using applications specific integrated circuitry (ASIC), programmable logic arrays, and/or using one or more digital signal processors (DSPs).

[0020] It will be apparent to one skilled in the art that other embodiments may be practiced apart from the specific details disclosed below. The technology is described in the context of an evolved 3GPP UMTS system such as LTE in order to provide an example and non-limiting context for explanation. See for example the LTE system diagram shown in Figure 1. But this technology is not limited to LTE and may be used in any modern radio communications system. Moreover, the approach below which employs two different types of scrambling sequences—one for purposes of random access and one for communications after random access is completed—may

also be applied to known channel estimation reference signals (sometimes called pilot signals). However, the detailed explanation is provided using scrambling sequences with the understanding that similar details apply to reference signals. For ease of description, a user equipment (UE) is often referred to without limitation as a user terminal or a mobile terminal, and an eNodeB is referred to using the more general and familiar term base station.

[0021] Figure 3 is flow diagram illustrating non-limiting, example procedures for a user terminal to make a random access to the radio network using an uplink scrambling code that is generally available to all user terminals desiring to randomly access service in a particular cell. The user terminal detects a first type of uplink scrambling sequences, e.g., uplink scrambling sequences specifically associated with a radio base station's cell area or random access channel but which are not specifically assigned to any user terminal (step S1). A selected one of the first type of uplink scrambling sequences is determined (step S2), and a random access message is generated using the selected one of the first type of uplink scrambling sequences (step S3). The user terminal transmits the random access message to the radio base station (step S4). After transmitting the random access message, the user terminal receives from the radio base station a second, different type of uplink scrambling sequence, e.g., an uplink scrambling sequence selected from a second set of uplink scrambling sequences specifically assignable to user terminals (step S5). The user terminal uses the second type of uplink scrambling sequence for subsequent communication with the radio base station. Similar procedures can be used for known uplink reference signals.

[0022] Figure 4 is flow diagram illustrating non-limiting, example counterpart procedures for a base station to receive and process a user terminal's random access to the radio network. Each base station in the network has its own set of preamble sequences, reference signals, and non-terminal specific scrambling codes or sequences. The base station broadcasts, implicitly or explicitly, over a broadcast channel, e.g., BCH, its set of preambles and uplink scrambling sequences (step S10). If the base station does not explicitly broadcast the scrambling sequence to use, the identity of the cell from which the scrambling sequence to use may be derived for example via a mapping between sequence and cell identifier. The uplink scrambling sequences may be, for example, specifically associated with a radio base station's cell area or random access channel and are not specifically assigned to any user terminal. The base station then waits to receive a first random access request message from a user terminal that includes one of the base station's preambles. In response, the base station transmits a second random access response message to the one user terminal indicating a timing change, an identified radio resource, and a user terminal identifier. A third message corresponding to the generated random access mes-

sage that includes the user terminal identity is descrambled using the selected one of the first set of uplink scrambling sequences (step S11). Thereafter, the base station transmits to the user terminal a fourth message including a second different type of uplink scrambling sequence selected from a second set of uplink scrambling sequences, e.g., uplink scrambling sequences that are specifically assignable to user terminals (step S12). The user terminal uses the second uplink scrambling sequence for subsequent communication with the radio base station. Similar procedures can be applied for known uplink reference signals.

[0023] To better understand the following example and non-limiting LTE random access procedure, reference is made to Figures 5A and 5B which illustrate a mapping between transport and physical channels in the downlink and uplink, respectively. The following are downlink transport channels: the broadcast channel (BCH), the paging channel (PCH), the downlink shared channel (DL-SCH), and the multi-cast channel (MCH). The BCH is mapped to the Physical Broadcast Channel (PBCH), and the PCH and the DL-SCH are mapped to the Physical Downlink Shared Channel (PDSH). The uplink transport channels include the random access channel (RACH) and the uplink shared channel (UL-SCH). The RACH maps to the Physical Random Access Channel (PRACH), and the UL-SCH maps to the Physical Uplink Shared Channel (PUSCH).

[0024] In LTE, as in other mobile radio communication systems, a mobile terminal can be in several different operational states. Figure 6 illustrates those states for LTE. At power-up, the mobile terminal enters the LTE_DETACHED state. In this state, the mobile terminal is not known to the network. Before any further communication can take place between the mobile terminal and the network, the mobile terminal needs to register with the network using the random access procedure to enter the LTE_ACTIVE state. The LTE_DETACHED state is mainly a state used at power-up. Once the mobile terminal registers with the network, it is typically in one of the other states: LTE_ACTIVE or LTE_IDLE.

[0025] LTE_ACTIVE is the state used when the mobile terminal is active with transmitting and receiving data. In this state, the mobile terminal is connected to a specific cell within the network. One or several Internet Protocol (IP) or other type data packet addresses have been assigned to the mobile terminal, as well as an identity of the terminal, a Cell Radio Network Temporary Identifier (C-RNTI), used for signaling purposes between the mobile terminal and the network. The LTE_ACTIVE state includes two substates, IN_SYNC and OUT_OF_SYNC, depending on whether the uplink is synchronized to the network or not. As long as the uplink is in IN_SYNC, uplink transmissions of user data and lower layer control signaling are possible. If no uplink transmission has taken place within a given time window, the uplink is declared to be out-of-sync, in which case, the mobile terminal must perform a random access procedure to restore uplink

synchronization.

[0026] LTE_IDLE is a low activity state in which the mobile terminal sleeps most of the time in order to reduce battery consumption. Uplink synchronization is not maintained, and hence, the only uplink transmission activity that may take place is random access to move to LTE_ACTIVE. The mobile terminal keeps its IP address(es) and other internal information in order to rapidly move to LTE_ACTIVE when necessary. The position of the mobile terminal is partially known to the network such that the network knows at least the group of cells in which paging of the mobile terminal is to be done.

[0027] A non-limiting example random access procedure is illustrated in Figure 7 and includes four steps referred to as steps 1-4 with four associated signaling messages referred to as messages 1-4. The base station transmits a set of preambles associated with that base station, RACH resource information, and other information in a broadcast message sent regularly over a broadcast channel that active mobile terminals regularly scan. In step one, after the user terminal receives and decodes the information broadcast by the base station (eNodeB), selects one of the base station's random access preambles and transmits it over the RACH. The base station monitors the RACH and detects the preamble which allows the base station to estimate the transmission timing of the user terminal. Uplink synchronization is necessary in order to permit the terminal to transmit uplink data to the base station.

[0028] The random access preamble includes a known sequence, randomly selected by the mobile terminal from a set of known preamble sequences available for random access purposes with a particular base station. When performing a random access attempt, the terminal selects one preamble sequence at random from the set of preamble sequences allocated to the cell that the terminal is trying to access. As long as no other terminal is performing a random access attempt using the same preamble sequence at the same time instant, no collisions will occur, and the random access request will very likely be detected by the base station. The preamble is transmitted by a user terminal on a radio channel resource, e.g., a time/frequency resource, assigned for random access purposes, e.g., a RACH.

[0029] Figure 8 illustrates conceptually a random access preamble transmission according to the LTE specification as of this writing. One non-limiting example for generating suitable preambles is based on Zadoff-Chu (ZC) sequences and cyclic shifted sequences thereof. Zadoff-Chu sequences may also be used, for example, to create the uplink reference signals included in each data frame for channel estimation purposes.

[0030] A user terminal carrying out a random-access attempt has, prior to the transmission of the preamble, obtained downlink synchronization from a cell search procedure using timing information broadcast by the base station. But as explained above, the uplink timing is not yet established. The start of an uplink transmission

frame at the terminal is defined relative to the start of the downlink transmission frame at the terminal. Due to the propagation delay between the base station and the terminal, the uplink transmission will be delayed relative to the downlink transmission timing at the base station. Because the distance between the base station and the terminal is not known, there is an uncertainty in the uplink timing corresponding to twice the distance between the base station and the terminal. To account for this uncertainty and avoid interference with subsequent subframes not used for random access, a guard time is used.

[0031] Returning to the second random access signaling step shown in Figure 7, in response to the detected random access attempt, the base station transmits a random access request response message 2 on the downlink-shared channel (DL-SCH). Message 2 contains an index or other identifier of the random access preamble sequence the base station detected and for which the response is valid, an uplink timing correction or timing advance command calculated by the base station after processing the received random-access preamble, a scheduling grant indicating resources the user terminal shall use for the transmission of the message in the third message sent from the mobile terminal to the base station, and a temporary user terminal identity used for further communication between the user terminal and the base station. After step 2 is completed, the user terminal is time synchronized.

[0032] If the base station detects multiple random access attempts (from different user terminals), then the random access request response messages 2 to multiple mobile terminals can be combined in a single transmission. Therefore, the random access request response message 2 is scheduled on the DL-SCH and indicated on the Physical Downlink Control Channel (PDCCH) using a common identity reserved for random access response. The PDCCH is a control channel used to inform the terminal if there is data on the DL-SCH intended for that terminal and, if so, on which time-frequency resources to find the DL-SCH. All user terminals that transmitted a preamble monitor the PDCCH for a random access response transmitted using the predefined common identity used by the base station for all random access responses.

[0033] In the third step 3, the user terminal transmits the necessary information in message 3 to the network using the scheduled uplink resources assigned in the random access response message 2 and synchronized in the uplink. Transmitting the uplink message in step 3 in the same manner as "normal" scheduled uplink data, i.e., on the UL-SCH, instead of attaching it to the preamble in the first step, is beneficial for several reasons. First, the amount of information transmitted in absence of uplink synchronization should be minimized as the need for large guard time makes such transmissions relatively costly. Secondly, the use of a "normal" uplink transmission scheme for message transmission allows the grant size and modulation scheme to be adjusted to, for exam-

ple, different radio conditions. Third, it allows for hybrid ARQ with soft combining for the uplink message which may be valuable, especially in coverage limited scenarios, as it allows relying on one or several retransmissions to collect sufficient energy for the uplink signaling to ensure a sufficiently high probability of successful transmission. The mobile terminal transmits its temporary mobile terminal identity, e.g., a temporary C-RNTI, in the third step to the network using the UL-SCH. The exact content of this signaling depends on the state of the terminal, e.g., whether it is previously known to the network or not.

[0034] As long as the terminals which performed random access at the same time use different preamble sequences, no collision occurs. But there is a certain probability of contention where multiple terminals use the same random access preamble at the same time. In this case, multiple terminals react to the same downlink response message in step 2 and a collision occurs in step 3. Collision or contention resolution is performed in step 4.

[0035] In step 4, a contention-resolution message is transmitted from the base station to the terminal on the DL-SCH. This step resolves the contention in case multiple terminals tried to access the system on the same resource, by identifying which user terminal that was detected in the third step. Multiple terminals performing simultaneous random access attempts using the same preamble sequence in step 1 listen to the same response message in the step 2, and therefore, have the same temporary user terminal identifier. So in step 4, each terminal receiving the downlink message compares the user terminal identity in the message with the user terminal identity they transmitted in the third step. Only a user terminal that observes a match between the identity received in the fourth step and the identity transmitted as part of the third step determines the random access procedure as successful. If the terminal is not yet assigned a C-RNTI, the temporary identity from the second step is promoted to the C-RNTI; otherwise, the user terminal keeps its already-assigned C-RNTI. Terminals which do not find a match with the identity received in the fourth step must restart the random access procedure from the first step.

[0036] As explained above, the user terminal identity included in message 3 is used as part of the contention resolution mechanism in the fourth step. Continuing in the LTE non-limiting example, if the user terminal is in the LTE_ACTIVE state, i.e., is connected to a known cell and therefore has a C-RNTI assigned, this C-RNTI is used as the terminal identity in the uplink message. Otherwise, a core network terminal identifier is used, and the base station needs to involve the core network prior to responding to the uplink message in step three.

[0037] In this non-limiting LTE example, only the first step uses physical layer processing specifically designed for random access. The last three steps use the same physical layer processing as for "normal" uplink and downlink data transmission, which simplifies the imple-

mentation of both the terminal and the base station. Because the transmission scheme used for data transmission is designed to ensure high spectral flexibility and high capacity, it is desirable to benefit from these features also when exchanging random access messages.

[0038] In the example non-limiting LTE context, the general processing steps described in Figure 2 including CRC, coding, HARQ, scrambling, modulation, and DFT-S-OFDM modulation are applied by the user terminal to message 3 in Figure 7 and subsequent uplink transmissions from that user terminal to the base station (there is no scrambling in the initial uplink random access message in step 1). Different uplink scrambling sequences in the terminal depend on the type of uplink transmission. For the random access message 3, a first type of scrambling sequence is used, e.g., a cell-specific or random access channel-specific scrambling code. For subsequent "normal" data transmissions in the uplink, i.e., when the base station has assigned a non-temporary identity to the terminal, a second type of scrambling sequence is used, e.g., a terminal-specific scrambling code. A similar two-type approach may be used for uplink reference signals used by the base station for channel estimation: a first type, e.g., a cell- or random-access-specific reference signal for random access message 3, followed by a second type, e.g., a base station-assigned or associated uplink reference signal sequence for following "normal" data transmissions.

[0039] When the base station assigns a scrambling sequence and/or reference sequence to the mobile terminal, that terminal-specific scrambling sequence and/or reference sequence is(are) used for all subsequent uplink data transmissions for that particular uplink connection. The scrambling sequence and/or reference sequence to be used can either be explicitly configured in the mobile terminal or tied to the terminal identity (e.g., a C-RNTI) that the base station assigns to a mobile terminal.

[0040] In the above, the user terminal uses a cell-specific scrambling sequence to scramble message 3 because prior to performing random access, the user terminal has decoded the base station's/cell's broadcast information and therefore knows the identity of the cell it is accessing, the random access preambles associated with that cell, and cell-specific scrambling sequences and/or reference numbers. As long as multiple terminals performing random access at the same time are assigned different time/frequency resources for their respective uplink random access message 3, there is no interference between these users and the lack of inter-user randomization is not a problem.

[0041] In a non-limiting embodiment, a one-to-one mapping is introduced between the random access preamble sequence used in the random access request message sent in step 1 of Figure 7 and the scrambling sequence used for scrambling the random access message sent in step 3. Because both the base station and the user terminal know the preamble used for the random

access request message sent in step 1 by the time message 3 is to be transmitted, both know which scrambling sequence to use.

[0042] In another non-limiting embodiment, the base station assigns the scrambling sequence for the user terminal to use for scrambling message 3 as a part of the random access request response transmitted in step 2 of Figure 7, (i.e., before the transmission of message 3). As one example, this may be done by establishing a one-to-one mapping between the temporary user identifier sent in message 2, e.g., a temporary C-RNTI, and the scrambling sequence to use.

[0043] Yet another non-limiting embodiment links the scrambling sequence to be used by the user terminal to scramble message 3 to the time-frequency resource(s) used by the user terminal to transmit the random access preamble (message 1). In this case, the scrambling sequence will be known to both the base station and the user terminal because both know the time-frequency resources used for the first random access request message. For this embodiment, the scrambling sequence will be shared between all user terminals transmitting a random access request preamble on the same time-frequency resource (s). But as long as all those terminals are assigned different time/frequency resources for their own random access message 3, there is no interference between these users and the lack of inter-user randomization is not a problem.

[0044] Combinations of one or more of the four different example embodiments may also be used. Again, the principles described in the above scrambling sequence example and the four embodiments may also be used to uplink reference numbers used for uplink channel estimation. In other words, one general or shared type of reference number may be used for uplink random access message 3, and another terminal specific type reference number may be used for subsequent uplink communications associated with the connection.

[0045] There may be situations when the user terminal already has been assigned a identity but will still need to perform a random access. One example is when the terminal registers with the network, but loses synchronization in the uplink, and consequently, needs to perform a random access attempt to regain uplink synchronization. Although the user terminal has an identity assigned, terminal-specific scrambling cannot be used for message 3 in this case as the network does not know why the terminal is performing the random access attempt until message 3 is received. As a result, a cell-associated scrambling sequence rather than an outdated terminal-specific scrambling sequence needs to be used.

[0046] Accordingly, the benefits of terminal-specific scrambling for normal data transmission are kept without impacting the functionality of the random access procedure. As described above, terminal-specific scrambling randomizes interference which improves uplink transmission performance and provides additional flexibility in the scheduling design.

Claims

1. A method implemented in a user terminal for requesting service from a base station having a cell area where the base station offers radio communications service, the method comprising:

- determining (S1, S2) one of a first type of uplink scrambling sequences, wherein said first type of uplink scrambling sequences are cell-specific or random access channel-specific scrambling sequences, and
- generating (S3) a random access message using the determined one of the first type of uplink scrambling sequence, and
- transmitting (S4) the random access message to a radio base station, and
- receiving (S5) from the base station an assignment of a second different type of uplink scrambling sequence, wherein said second different type of uplink scrambling sequence is a terminal-specific scrambling sequence, and
- using (S5) the second different type of uplink scrambling sequence for subsequent communication with the radio base station.

2. The method in claim 1, wherein the generating step includes scrambling information in the random access message using the determined one of the first type of uplink scrambling sequences.
3. The method in claim 1, wherein the transmitting includes modulating the scrambled random access message and mapping the modulated message to a radio channel resource.
4. The method in claim 1, wherein the first set of uplink scrambling sequences are cell-specific scrambling sequences corresponding to a cell associated with the radio base station.
5. A method implemented in a base station for responding to user terminals requesting service from the base station over a radio channel, comprising:

- broadcasting (S10) a first type of uplink scrambling sequence specifically associated with a radio base station's cell area or random access channel but which are not specifically assigned to any user terminal;
- receiving (S11) from one of the user terminals a random access message using the one of the first type of uplink scrambling sequences;
- assigning (S12) to the one user terminal a user terminal-specific uplink scrambling sequence selected from a second type of uplink scrambling sequences specifically assignable to user terminals; and

receiving (S12) a subsequent communication from the one user terminal scrambled with the selected user terminal-specific uplink scrambling sequence for subsequent communication with the radio base station.

6. A user terminal (20) for requesting service from a base station (18) having a cell area where the base station offers radio communications service, comprising electronic processing circuitry (30) configured to:

determine one of a first type of uplink scrambling sequences wherein said first type of uplink scrambling sequences are cell-specific or random access channel-specific scrambling sequences, and
generate a random access message using the determined one of the first type of uplink scrambling sequences, and
radio transmission circuitry (32) for transmitting the random access message to the radio base station, and
radio receiving circuitry (36) for receiving from the radio base station an assignment of a second different type of uplink scrambling sequence, wherein said second different type of uplink scrambling sequence is a terminal-specific scrambling sequence,
wherein the electronic processing circuitry (30) is configured to use the second different type of uplink scrambling sequence for subsequent communication with the radio base station.

7. The user terminal in claim 6, wherein the first type of uplink scrambling sequences are specifically associated with the radio base station's cell area or a random access radio channel associated with the radio base station but which are not specifically assigned to any user terminal, and the second different type of uplink scrambling sequence is selected from a set of uplink scrambling sequences specifically assignable to user terminals.

8. The user terminal in claim 6, wherein the electronic processing circuitry is configured to scramble information in the random access message using the determined one of the first type of uplink scrambling sequences.

9. The user terminal in claim 8, wherein the transmitter is configured to modulate the scrambled random access message and map the modulated message to a radio channel resource.

10. A radio base station (18) for responding to user terminals (20) requesting service from the base station over a radio channel, comprising circuitry (40) con-

figured to:

broadcast a first type of uplink scrambling sequence specifically associated with a radio base station's cell area or random access channel but which are not specifically assigned to any user terminal;

receive from one of the user terminals a random access message using one of the first type of uplink scrambling sequences;

assign to the one user terminal a user terminal-specific uplink scrambling sequence selected from a second type of uplink scrambling sequences specifically assignable to user terminals; and

receive a subsequent communication from the one user terminal scrambled with the selected user terminal-specific uplink scrambling sequence for subsequent communication with the radio base station.

Patentansprüche

1. Verfahren, das in einem Benutzerendgerät implementiert wird, zum Anfordern eines Dienstes von einer Basisstation mit einem Zellbereich, in welchem die Basisstation Funkkommunikationsdienst anbietet, wobei das Verfahren umfasst:

- Bestimmen (S1, S2) einer von einem ersten Typ von Aufwärtsstreckenverwürfelungsfolgen, wobei es sich bei dem ersten Typ von Aufwärtsstreckenverwürfelungsfolgen um zellspezifische oder direktzugriffskanalspezifische Verwürfelungsfolgen handelt, und

- Erzeugen (S3) einer Direktzugriffsnachricht unter Verwendung der bestimmten einen des ersten Typs von Aufwärtsstreckenverwürfelungsfolge, und

- Senden (S4) der Direktzugriffsnachricht an eine Funkbasisstation, und

- Empfangen (S5) von der Basisstation einer Zuweisung eines zweiten, verschiedenen Typs von Aufwärtsstreckenverwürfelungsfolge, wobei der zweite, verschiedene Typ von Aufwärtsstreckenverwürfelungsfolge eine endgerätespezifische Verwürfelungsfolge ist, und

- Verwenden (S5) des zweiten, verschiedenen Typs von Aufwärtsstreckenverwürfelungsfolge zur anschließenden Kommunikation mit der Funkbasisstation.

2. Verfahren nach Anspruch 1, wobei der Erzeugungsschritt ein Verwürfeln von Informationen in der Direktzugriffsnachricht unter Verwendung der bestimmten einen des ersten Typs von Aufwärtsstreckenverwürfelungsfolgen umfasst.

3. Verfahren nach Anspruch 1, wobei das Senden ein Modulieren der verwürfelten Direktzugriffsnachricht und Zuordnen der modulierten Nachricht zu einer Funkkanalressource umfasst.
4. Verfahren nach Anspruch 1, wobei es sich bei dem ersten Satz von Aufwärtsstreckenverwürfelungsfolgen um zellspezifische Verwürfelungsfolgen handelt, die einer Zelle entsprechen, die mit der Funkbasisstation assoziiert ist.
5. Verfahren, das in einer Basisstation implementiert wird, zum Antworten auf Benutzerendgeräte, die über einen Funkkanal einen Dienst von der Basisstation anfordern, umfassend:

Senden per Broadcast (S10) eines ersten Typs von Aufwärtsstreckenverwürfelungsfolge, die speziell mit einem Zellbereich oder Direktzugriffskanal einer Funkbasisstation assoziiert ist, die aber nicht speziell zu einem Benutzerendgerät zugewiesen ist;
 Empfangen (S11) von einem der Benutzerendgeräte einer Direktzugriffsnachricht unter Verwendung der einen des ersten Typs von Aufwärtsstreckenverwürfelungsfolgen;
 Zuweisen (S12) zu dem einen Benutzerendgerät einer benutzerendgerätespezifischen Aufwärtsstreckenverwürfelungsfolge, die aus einem zweiten Typ von Aufwärtsstreckenverwürfelungsfolgen ausgewählt ist, die speziell zu Benutzerendgeräten zugewiesen werden können; und
 Empfangen (S12) einer anschließenden Kommunikation von dem einen Benutzerendgerät, die mit der ausgewählten benutzerendgerätespezifischen Aufwärtsstreckenverwürfelungsfolge verwürfelt ist, zur anschließenden Kommunikation mit der Funkbasisstation.

6. Benutzerendgerät (20) zum Anfordern eines Dienstes von einer Basisstation (18) mit einem Zellbereich, in welchem die Basisstation Funkkommunikationsdienst anbietet, umfassend elektronische Verarbeitungsschaltungsanordnung (30), die konfiguriert ist zum:

Bestimmen einer von einem ersten Typ von Aufwärtsstreckenverwürfelungsfolgen, wobei es sich bei dem ersten Typ von Aufwärtsstreckenverwürfelungsfolgen um zellspezifische oder direktzugriffskanalspezifische Verwürfelungsfolgen handelt, und
 Erzeugen einer Direktzugriffsnachricht unter Verwendung der bestimmten einen des ersten Typs von Aufwärtsstreckenverwürfelungsfolgen, und

Funkübertragungsschaltungsanordnung (32) zum Senden der Direktzugriffsnachricht an die Funkbasisstation, und
 Funkempfangsschaltungsanordnung (36) zum Empfangen von der Basisstation einer Zuweisung eines zweiten, verschiedenen Typs von Aufwärtsstreckenverwürfelungsfolge, wobei der zweite, verschiedene Typ von Aufwärtsstreckenverwürfelungsfolge eine endgerätespezifische Verwürfelungsfolge ist,
 wobei die elektronische Verarbeitungsschaltungsanordnung (30) so konfiguriert ist, dass sie den zweiten, verschiedenen Typ von Aufwärtsstreckenverwürfelungsfolge zur anschließenden Kommunikation mit der Funkbasisstation verwendet.

7. Benutzerendgerät nach Anspruch 6, wobei der erste Typ von Aufwärtsstreckenverwürfelungsfolgen speziell mit einem Zellbereich der Funkbasisstation oder einem mit der Funkbasisstation assoziierten Direktzugriffskanal assoziiert ist, der aber nicht speziell zu einem Benutzerendgerät zugewiesen ist, und der zweite, verschiedene Typ von Aufwärtsstreckenverwürfelungsfolgen aus einem Satz von Aufwärtsstreckenverwürfelungsfolgen ausgewählt ist, die speziell zu Benutzerendgeräten zugewiesen werden können.
8. Benutzerendgerät nach Anspruch 6, wobei die elektronische Verarbeitungsschaltungsanordnung so konfiguriert ist, dass sie Informationen in der Direktzugriffsnachricht unter Verwendung der bestimmten einen des ersten Typs von Aufwärtsstreckenverwürfelungsfolgen verwürfelt.
9. Benutzerendgerät nach Anspruch 8, wobei der Sender so konfiguriert ist, dass er die verwürfelte Direktzugriffsnachricht moduliert und die modulierte Nachricht zu einer Funkkanalressource zuordnet.
10. Funkbasisstation (18) zum Antworten auf Benutzerendgeräte (20), die einen Dienst von der Basisstation anfordern, umfassend Schaltungsanordnung (40), die konfiguriert ist zum:

Senden per Broadcast eines ersten Typs von Aufwärtsstreckenverwürfelungsfolge, die speziell mit einem Zellbereich oder einem Direktzugriffskanal der Funkbasisstation assoziiert ist, die aber nicht speziell zu einem Benutzerendgerät zugewiesen ist;
 Empfangen von einem der Benutzerendgeräte einer Direktzugriffsnachricht unter Verwendung einer des ersten Typs von Aufwärtsstreckenverwürfelungsfolgen;
 Zuweisen zu dem einen Benutzerendgerät einer benutzerendgerätespezifischen Aufwärtsstreckenverwürfelungsfolge, die aus einem zweiten

Typ von Aufwärtsstreckenverwürfelungsfolgen ausgewählt ist, der speziell zu Benutzerendgeräten zugewiesen werden kann; und Empfangen einer anschließenden Kommunikation von dem einen Benutzerendgerät, die mit der ausgewählten benutzerendgerätespezifischen Aufwärtsstreckenverwürfelungsfolge verwürfelt ist, zur anschließenden Kommunikation mit der Funkbasisstation.

Revendications

1. Procédé mis en oeuvre dans un terminal d'utilisateur pour demander un service à une station de base ayant une zone de cellule où la station de base propose un service de radiocommunications, le procédé comprenant :

- la détermination (S1, S2) de l'une d'un premier type de séquences de brouillage de liaison montante, dans lequel ledit premier type de séquences de brouillage de liaison montante sont des séquences de brouillage spécifiques à la cellule ou spécifiques au canal d'accès aléatoire, et
- la génération (S3) d'un message d'accès aléatoire en utilisant la séquence déterminée du premier type de séquences de brouillage de liaison montante, et
- la transmission (S4) du message d'accès aléatoire à une station de base radio, et
- la réception (S5), à partir de la station de base, d'une attribution d'un deuxième type différent de séquences de brouillage de liaison montante, dans lequel ledit deuxième type différent de séquences de brouillage de liaison montante est une séquence de brouillage spécifique au terminal, et
- l'utilisation (S5) du deuxième type différent de séquences de brouillage de liaison montante pour une communication ultérieure avec la station de base radio.

2. Procédé selon la revendication 1, dans lequel l'étape de la génération comprend le brouillage d'informations dans le message d'accès aléatoire en utilisant la séquence déterminée du premier type de séquences de brouillage de liaison montante.
3. Procédé selon la revendication 1, dans lequel la transmission comprend la modulation du message d'accès aléatoire brouillé et le mappage du message modulé sur une ressource de canal radio.
4. Procédé selon la revendication 1, dans lequel le premier ensemble de séquences de brouillage de liaison montante sont des séquences de brouillage spécifiques à la cellule correspondant à une cellule

associée à la station de base radio.

5. Procédé mis en oeuvre dans une station de base pour répondre à des terminaux d'utilisateur demandant un service à la station de base sur un canal radio, comprenant :

- la diffusion (S10) d'un premier type de séquences de brouillage de liaison montante associées spécifiquement à une zone de cellule d'une station de base radio ou à un canal d'accès aléatoire mais qui ne sont pas spécifiquement attribuées à un terminal d'utilisateur ;
- la réception (S11), à partir de l'un des terminaux d'utilisateur, d'un message d'accès aléatoire en utilisant la séquence du premier type de séquences de brouillage de liaison montante ;
- l'attribution (S12), au terminal d'utilisateur, d'une séquence de brouillage de liaison montante spécifique au terminal d'utilisateur sélectionnée parmi un deuxième type de séquences de brouillage de liaison montante pouvant être spécifiquement attribuées à des terminaux d'utilisateur ; et
- la réception (S12) d'une communication ultérieure, provenant du terminal d'utilisateur, brouillée avec la séquence de brouillage de liaison montante spécifique au terminal d'utilisateur sélectionnée pour une communication ultérieure avec la station de base radio.

6. Terminal d'utilisateur (20) pour demander un service à une station de base (18) ayant une zone de cellule où la station de base propose un service de radiocommunications, comprenant une circuiterie de traitement électronique (30) configurée pour effectuer :

- la détermination de l'une d'un premier type de séquences de brouillage de liaison montante, dans lequel ledit premier type de séquences de brouillage de liaison montante sont des séquences de brouillage spécifiques à la cellule ou spécifiques au canal d'accès aléatoire, et
- la génération d'un message d'accès aléatoire en utilisant la séquence déterminée du premier type de séquences de brouillage de liaison montante, et

- une circuiterie de radiotransmission (32) pour effectuer la transmission du message d'accès aléatoire à la station de base radio, et
- une circuiterie de réception radio (36) pour effectuer la réception, à partir de la station de base, d'une attribution d'un deuxième type différent de séquences de brouillage de liaison montante, dans lequel ledit deuxième type différent de séquences de brouillage de liaison montante est une séquence de brouillage spécifique au terminal,

dans lequel la circuiterie de traitement électronique (30) est configurée pour utiliser le deuxième type différent de séquences de brouillage de liaison montante pour une communication ultérieure avec la station de base radio.

5

7. Terminal d'utilisateur selon la revendication 6, dans lequel les séquences du premier type de séquences de brouillage de liaison montante sont spécifiquement associées à la zone de cellule de la station de base radio ou à un canal radio d'accès aléatoire associé à la station de base radio mais elles ne sont pas spécifiquement attribuées à un terminal d'utilisateur, et la séquence du deuxième type différent de séquences de brouillage de liaison montante est sélectionnée parmi un ensemble de séquences de brouillage de liaison montante pouvant être spécifiquement attribuées à des terminaux d'utilisateur. 10
8. Terminal d'utilisateur selon la revendication 6, dans lequel la circuiterie de traitement électronique est configurée pour effectuer le brouillage d'informations dans le message d'accès aléatoire en utilisant la séquence déterminée du premier type de séquences de brouillage de liaison montante. 15
9. Terminal d'utilisateur selon la revendication 8, dans lequel l'émetteur est configuré pour effectuer la modulation du message d'accès aléatoire brouillé et le mappage du message modulé sur une ressource de canal radio. 20
10. Station de base radio (18) pour répondre à des terminaux d'utilisateur (20) demandant un service à la station de base sur un canal radio, comprenant une circuiterie (40) configurée pour effectuer : 25

la diffusion d'un premier type de séquences de brouillage de liaison montante associées spécifiquement à une zone de cellule d'une station de base radio ou à un canal d'accès aléatoire mais qui ne sont pas spécifiquement attribuées à un terminal d'utilisateur ; 40

la réception, à partir de l'un des terminaux d'utilisateur, d'un message d'accès aléatoire en utilisant la séquence du premier type de séquences de brouillage de liaison montante ; 45

l'attribution, au terminal d'utilisateur, d'une séquence de brouillage de liaison montante spécifique au terminal d'utilisateur sélectionnée parmi un deuxième type de séquences de brouillage de liaison montante pouvant être spécifiquement attribuées à des terminaux d'utilisateur ; et 50

la réception d'une communication ultérieure, provenant du terminal d'utilisateur, brouillée avec la séquence de brouillage de liaison montante spécifique au terminal d'utilisateur sélectionnée pour une communication ultérieure avec la station de base radio. 55

tionnée pour une communication ultérieure avec la station de base radio.

FELFELÉ IRÁNYÚ KAPCSOLAT TITKOSÍTÁSA VÉLETLEN HOZZÁFÉRÉS KÖZBEN

Szabadalmi igénypontok

1. Felhasználói végberendezésben megvalósított eljárás olyan bázisállomástól való szolgáltatás kéréséhez, amelynek olyan cellaterülete van, ahol a bázisállomás rádiós kommunikációs szolgáltatást kínál, az eljárás a következőket tartalmazza:
 - felfelé irányú kapcsolat titkosítási sorozatai egyik első típusának meghatározása (S1, S2), ahol a felfelé irányú kapcsolat titkosítási sorozatainak első típusa cellára jellemző vagy véletlen hozzáférésű csatornára jellemző titkosítási sorozatok, és
 - véletlen hozzáférési üzenet előállítás (S3) a felfelé irányú kapcsolat egyik meghatározott titkosítási sorozata segítségével, és
 - a véletlen hozzáférési üzenet adása (S4) egy rádiós bázisállomáshoz, és
 - felfelé irányú kapcsolati titkosítási sorozat második különböző típusa kijelölésének a vétele (S5) a bázisállomástól, ahol a felfelé irányú kapcsolati titkosítási sorozat végberendezésre jellemző titkosítási sorozat, és
 - a felfelé irányú kapcsolati titkosítási sorozat második különböző típusának használata (S5) a rádiós bázisállomással való további kommunikációhoz.
2. Az 1. igénypont szerinti eljárás, ahol az előállító lépés tartalmazza a véletlen hozzáférési üzenetben lévő titkosítási információt a felfelé irányú kapcsolati titkosítási sorozatok egyik meghatározott első típusa segítségével.
3. Az 1. igénypont szerinti eljárás, ahol az adás tartalmazza a titkosított véletlen hozzáférési üzenet modulálását és a modulált üzenetnek egy rádiócsatornás erőforrásra való leképezését.
4. Az 1. igénypont szerinti eljárás, ahol a felfelé irányú kapcsolati titkosít első titkosítási sorozatainak első készlete cellára jellemző titkosítási sorozatok, amelyek megfelelnek a rádiós bázisállomással társított cellának.
5. Bázisállomásban megvalósított eljárás a bázisállomástól szolgáltatást kérő felhasználói végberendezéseknek való válaszoláshoz, amely a következőket tartalmazza:

- olyan felfelé irányú kapcsolati titkosítási sorozat első típusának adatszórása (S10), amely kifejezetten társítva van egy rádiós bázisállomás cellaterületével vagy véletlen hozzáférési csatornájával, de nincs kifejezetten hozzárendelve felhasználói végberendezéshez;
- véletlen hozzáférési üzenet vétele (S11) az egyik felhasználói végberendezéstől a felfelé irányú kapcsolati titkosítási sorozatok egyik első típusa segítségével;
- felhasználói végberendezésre jellemző olyan felfelé irányú kapcsolati titkosítási sorozat hozzárendelése (S12) az egyik felhasználói végberendezéshez, amely felhasználói végberendezésekhez kifejezetten hozzárendelhető felfelé irányú kapcsolati titkosítási sorozatok második típusából van kiválasztva; és
- további kommunikáció vétele (S12) a kiválasztott felhasználói végberendezésre jellemző felfelé irányú kapcsolati titkosítási sorozattal titkosított felhasználói végberendezéstől a rádiós bázisállomással való további kommunikációhoz.

6. Felhasználói végberendezés (20) bázisállomástól (18) való szolgáltatás kéréséhez, amelynek van egy cellaterülete, ahol a bázisállomás rádiós kommunikációs szolgáltatást kínál, amely elektronikus feldolgozó áramkört (30) tartalmaz, amely a következőkre van kialakítva:

- felfelé irányú kapcsolat titkosítási sorozatai egyik első típusának meghatározása, ahol a felfelé irányú kapcsolat titkosítási sorozatainak első típusa cellára jellemző vagy véletlen hozzáférésű csatornára jellemző titkosítási sorozatok, és
- véletlen hozzáférési üzenet előállítás a felfelé irányú kapcsolat egyik meghatározott titkosítási sorozata segítségével, és
- rádióadás áramkör (32) a véletlen hozzáférési üzenetnek a rádiós bázisállomáshoz való adására, és
- rádióvétele áramkör (36) felfelé irányú kapcsolati titkosítási sorozat második különböző típusa hozzárendelésének a rádiós bázisállomástól való vételéhez, ahol a felfelé irányú kapcsolati titkosítási sorozat második különböző típusa egy végberendezésre jellemző titkosítási sorozat,
- ahol az elektronikus feldolgozó áramkör (30) arra van kialakítva, hogy a felfelé irányú kapcsolati titkosítási sorozat második típusát használja a rádiós bázisállomással való további kommunikációra.

7. A 6. igénypont szerinti felhasználói végberendezés, ahol a felfelé irányú kapcsolati titkosítási sorozatok első típusa kifejezetten társítva van a rádiós bázisállomás cellaterületével vagy egy véletlen hozzáférési rádiócsatornával, amelyek társítva vannak

a rádiós bázisállomással de amelyek nincsenek kifejezetten hozzárendelve felhasználói végberendezéshez, a felfelé irányú kapcsolati titkosítási sorozat második különböző típusa pedig felhasználói végberendezésekhez kifejezetten hozzárendelhető felfelé irányú kapcsolati titkosítási sorozatok készletéből van kiválasztva.

8. A 6. igénypont szerinti felhasználói végberendezés, ahol az elektronikus feldolgozó áramkör arra van kialakítva, hogy titkosítsa a véletlen elérési üzenetben lévő információt a felfelé irányú kapcsolati titkosítási sorozatok meghatározott első típusa segítségével.
9. A 8. igénypont szerinti felhasználói végberendezés, ahol az adó arra van kialakítva, hogy modulálja a titkosított véletlen hozzáférési üzenetet és leképezze a modulált üzenetet egy rádiócsatornás erőforrásra.
10. Rádiós bázisállomás (18) olyan felhasználói végberendezéseknek (20) való válaszolásra, amelyek szolgáltatást kérnek rádiós csatornán keresztül, amely a következőkre kialakított áramkört (40) tartalmaz:
 - olyan felfelé irányú kapcsolati titkosítási sorozat első típusának adatszórása, amely kifejezetten társítva van egy rádiós bázisállomás cellaterületével vagy véletlen hozzáférési csatornájával, de nincs kifejezetten hozzárendelve felhasználói végberendezéshez;
 - véletlen hozzáférési üzenet vétele az egyik felhasználói végberendezéstől a felfelé irányú kapcsolati titkosítási sorozatok egyik első típusa segítségével;
 - felhasználói végberendezésre jellemző olyan felfelé irányú kapcsolati titkosítási sorozat hozzárendelése az egyik felhasználói végberendezéshez, amely felhasználói végberendezésekhez kifejezetten hozzárendelhető felfelé irányú kapcsolati titkosítási sorozatok második típusából van kiválasztva; és
 - további kommunikáció vétele a kiválasztott felhasználói végberendezésre jellemző felfelé irányú kapcsolati titkosítási sorozattal titkosított felhasználói végberendezéstől a rádiós bázisállomással való további kommunikációhoz.
