BACKGROUND OF THE INVENTION

The disclosure generally relates to the novel compounds of formula I, including their salts, which inhibit HIV integrase and prevent viral integration into human DNA. This action makes the compounds useful for treating HIV infection and AIDS. The invention also encompasses pharmaceutical compositions and methods for treating those infected with HIV.

Human immunodeficiency virus (HIV) has been identified as the etiological agent responsible for acquired immune deficiency syndrome (AIDS), a fatal disease characterized by destruction of the immune system and the inability to fight off life threatening opportunistic infections. Recent statistics (UNAIDS: Report on the Global HIV/AIDS Epidemic, December 1998), indicate that as many as 33 million people worldwide are infected with the virus. In addition to the large number of individuals already infected, the virus continues to spread. Estimates from 1998 point to close to 6 million new infections in that year alone. In the same year there were approximately 2.5 million deaths associated with HIV and AIDS.

There are currently a number of antiviral drugs available to combat the infection. These drugs can be divided into four classes based on the viral protein they target and their mode of action. In particular, saquinavir, indinavir, ritonavir, nelfinavir atazanavir darunavir, amprenavir, fosamprenavir, lopinavir and tipranavir are competitive inhibitors of the aspartyl protease expressed by HIV. Zidovudine, didanosine, stavudine, lamivudine, zalcitabine, emtricitibine, tenofovir and abacavir are nucleoside reverse transcriptase inhibitors that behave as substrate mimics to halt viral cDNA synthesis. The non-nucleoside reverse transcriptase inhibitors,

nevirapine, delavirdine, efavirenz and etravirine inhibit the synthesis of viral cDNA via a non-competitive (or uncompetitive) mechanism. Enfuvirtide and maraviroc inhibit the entry of the virus into the host cell. Used alone these drugs are effective in reducing viral replication. The effect is only temporary as the virus readily develops resistance to all known agents. However, combination therapy has proven very effective at both reducing virus and suppressing the emergence of resistance in a number of patients. In the US, where combination therapy is widely available, the number of HIV-related deaths has declined (Palella, F. J.; Delany, K. M.; Moorman, A. C.; Loveless, M. O.; Furher, J.; Satten, G. A.; Aschman, D. J.; Holmberg, S. D. *N. Engl. J. Med.* 1998, *338*, 853-860).

Unfortunately, not all patients are responsive and a large number fail this therapy. In fact, approximately 30-50% of patients ultimately fail combination therapy. Treatment failure in most cases is caused by the emergence of viral resistance. Viral resistance in turn is caused by the rapid turnover of HIV-1 during the course of infection combined with a high viral mutation rate. Under these circumstances incomplete viral suppression caused by insufficient drug potency, poor compliance to the complicated drug regiment as well as intrinsic pharmacological barriers to exposure provides fertile ground for resistance to emerge. More disturbing are recent findings which suggest that low-level replication continues even when viral plasma levels have dropped below detectable levels (< 50 copies/ml) (Carpenter, C. C.; Cooper, D. A.; Fischl, M. A.; Gatell, J. M.; Gazzard, B. G.; Hammer, S. M.; Hirsch, M. S.; Jacobsen, D. M.; Katzenstein, D. A.; Montaner, J. S.; Richman, D. D.; Saag, M. S.; Schechter, M.; Schooley, R. T.; Thompson, M. A.; Vella, S.; Yeni, P. G.; Volberding, P. A. *JAMA* 2000, *283*, 381-390). Clearly, there is a need for new antiviral agents, preferably targeting other viral enzymes to reduce the rate of resistance and suppress viral replication even further.

HIV expresses three enzymes, reverse transcriptase, an aspartyl protease, and integrase. All three are targets for treating AIDS and HIV infection. HIV integrase is a component of the pre-integration complex of the virus that is assembled in the cell shortly after infection (Chiu, T.K.; Davies, D.R. *Curr. Top. Med. Chem.* 2004, *4*, 965-

977). This enzyme catalyzes the integration of proviral DNA into the host genome and is absolutely required for viral infectivity. Early experiments showed that mutating the active site of integrase within a proviral clone produces virus unable to replicate due to its inability to insert into the host chromosome (Englund, G.; Theodore, T.S.; Freed, E.O.; Engleman, A.; Martin, M.A. *J. Virol.* 1995, *69*, 3216-3219). Selective HIV integrase inhibitors have been shown to possess effective anti-HIV activity in cell culture (Hazuda, D.J.; Felock, P.; Witmer, M.; Wolfe, A; Stillmock, K.; Grobler, J.A.; Espeseth, A.; Gabryelski, L.; Schleif, W.; Blau, C.; Miller, M.D. *Science*, 2000, *287*, 646-650), and it is clear that this class of inhibitors is very effective as part of a combination regimen containing HIV inhibitors of different classes. An HIV integrase inhibitor, raltegravir (ISENTRESS®), has been approved for use in treatment experienced patients based upon 48 week trial results (Cooper, D.A.; Gatell, J.; Rockstroh, J.; Katlama, C.; Yeni, P.; Lazzarin, A.;, Xu, X.;, Isaacs, R.; Teppler, H.; Nguyen, B.Y. *15th Conference on Retroviruses and Opportunistic Infections*, Boston, MA., Feb 3-6, 2008 Abst. 105LB: Evering, T.H.; Markowitz, M. *Drugs Today*, 2007, *43*, 865-877). In addition, a second integrase inhibitor, elvitegravir (GS-9137), completed a successful Phase II trial in combination with ritonavir boosting in naive and treatment experienced patients (Zolopa, A. *14th Conference on Retroviruses and Opportunistic Infections*, Los Angeles, CA. Feb 25-28, 2007 Abst. 143LB). Thus, HIV-1 integrase is a promising target for novel anti-HIV-1 therapeutics.

The invention provides technical advantages, for example, the compounds are novel and inhibit HIV integrase. Additionally, the compounds provide advantages for pharmaceutical uses, for example, with regard to one or more of their mechanism of action, binding, inhibition efficacy, target selectivity, solubility, safety profiles, or bioavailability.

HIV integrase inhibitors have been disclosed in U.S. patents 7,176,196 and 7,173,022 and PCT publications WO 2004/58756 and WO 2004/58757.

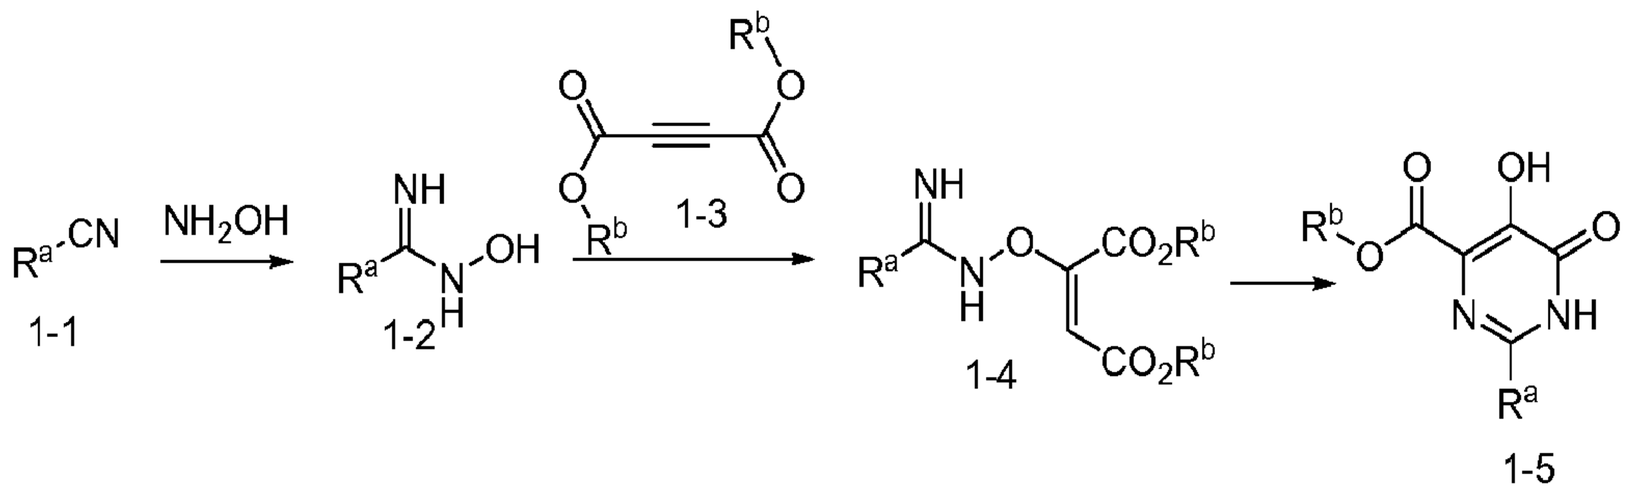
Synthetic Methods

The compounds may be made by methods known in the art including those described below and including variations within the skill of the art. Some reagents and intermediates are known in the art. Other reagents and intermediates can be made by methods known in the art using readily available materials. The following methods are for illustrative purposes and are not intended to limit the scope of the invention. It will be appreciated by those skilled in the art that there are a number of methods available for the synthesis of an appropriately substituted pyrimidinone heterocycles useful for making the compounds of the current invention and that their synthesis is not limited to the methods provided in the following examples. For example, one such method is shown in Scheme I and is similar to that reported in Journal of Heterocyclic Chemistry (1979), 16(7), 1423-4. In this scheme an alkyl- or arylnitrile 1-1 is combined with hydroxylamine to form intermediate 1-2 which in turn is reacted with dialkyl-butynoate 1-3 to form intermediate 1-4. At high temperatures, such as that of refluxing xylenes, intermediate 1-4 undergoes a rearrangement reaction to yield the 5-hydroxy-6-oxo-1,6-dihydropyrimidine-4-carboxylate heterocycle 1-5 which can serve as an advanced intermediate for synthesizing some of the compounds of this invention. The variables (e.g. numbered

"R" substituents) used to describe the synthesis of the compounds are intended only to illustrate how to make the compounds and are not to be confused with variables used in the claims or in other sections of the specification.

Abbreviations used in the schemes generally follow conventions used in the art. Chemical abbreviations used in the specification and examples are defined as follows: "NaHMDS" for sodium bis(trimethylsilyl)amide; "DMF" for N,N-dimethylformamide; "MeOH" for methanol; "NBS" for N-bromosuccinimide; "Ar" for aryl; "TFA" for trifluoroacetic acid; "LAH" for lithium aluminum hydride; "BOC", "DMSO" for dimethylsulfoxide; "h" for hours; "rt" for room temperature or retention time (context will dictate); "min" for minutes; "EtOAc" for ethyl acetate; "THF" for tetrahydrofuran; "EDTA" for ethylenediaminetetraacetic acid; "Et_2O" for diethyl ether; "DMAP" for 4-dimethylaminopyridine; "DCE" for 1,2-dichloroethane; "ACN" for acetonitrile; "DME" for 1,2-dimethoxyethane; "HOBt" for 1-hydroxybenzotriazole hydrate; "DIEA" for diisopropylethylamine, "Nf" for $CF_3(CF_2)_3SO_2$-; and "TMOF" for trimethylorthoformate.

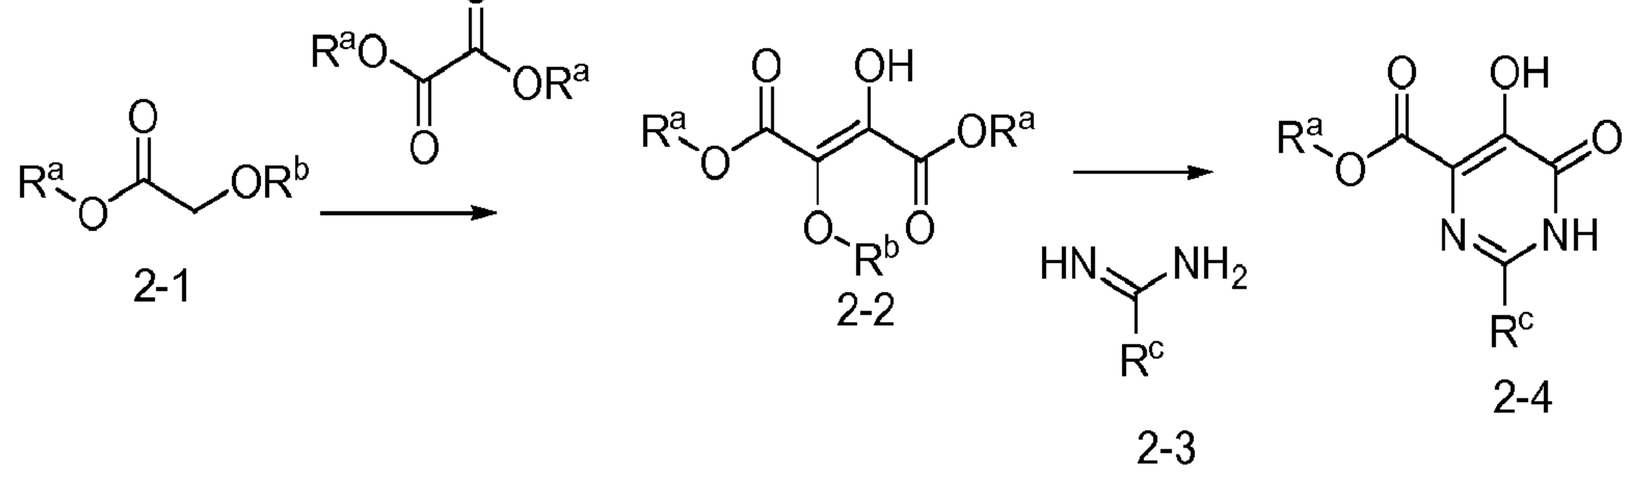
Scheme I



Scheme II demonstrates an alternative method for providing the 5-hydroxy-6-oxo-1,6-dihydropyrimidine-4-carboxylate heterocyclic system which is adapted from the procedure in Inorganic Chemistry (2001), 40(26), 6746-6756. In this scheme, a substituted derivative of glycolic acid, 2-1 is reacted with a diester of oxalic acid under Claisen condensation conditions (Org. React. 1, 266-322 (1942); Modern Synthetic Reactions (W. A. Benjamin, Menlo Park, California, 2nd ed., 1972) pp 734-746, J. Chem. Educ. 56, 721 (1979); J. Am. Chem. Soc. 103, 1338 (1981); Comp. Org. Syn. 2, 795-805 (1991)) to provide intermediate 2-2. This intermediate

can be combined with an amidine, 2-3, under heating to yield the 5-hydroxy-6-oxo-1,6-dihydropyrimidine-4-carboxylate heterocycle, 2-4.

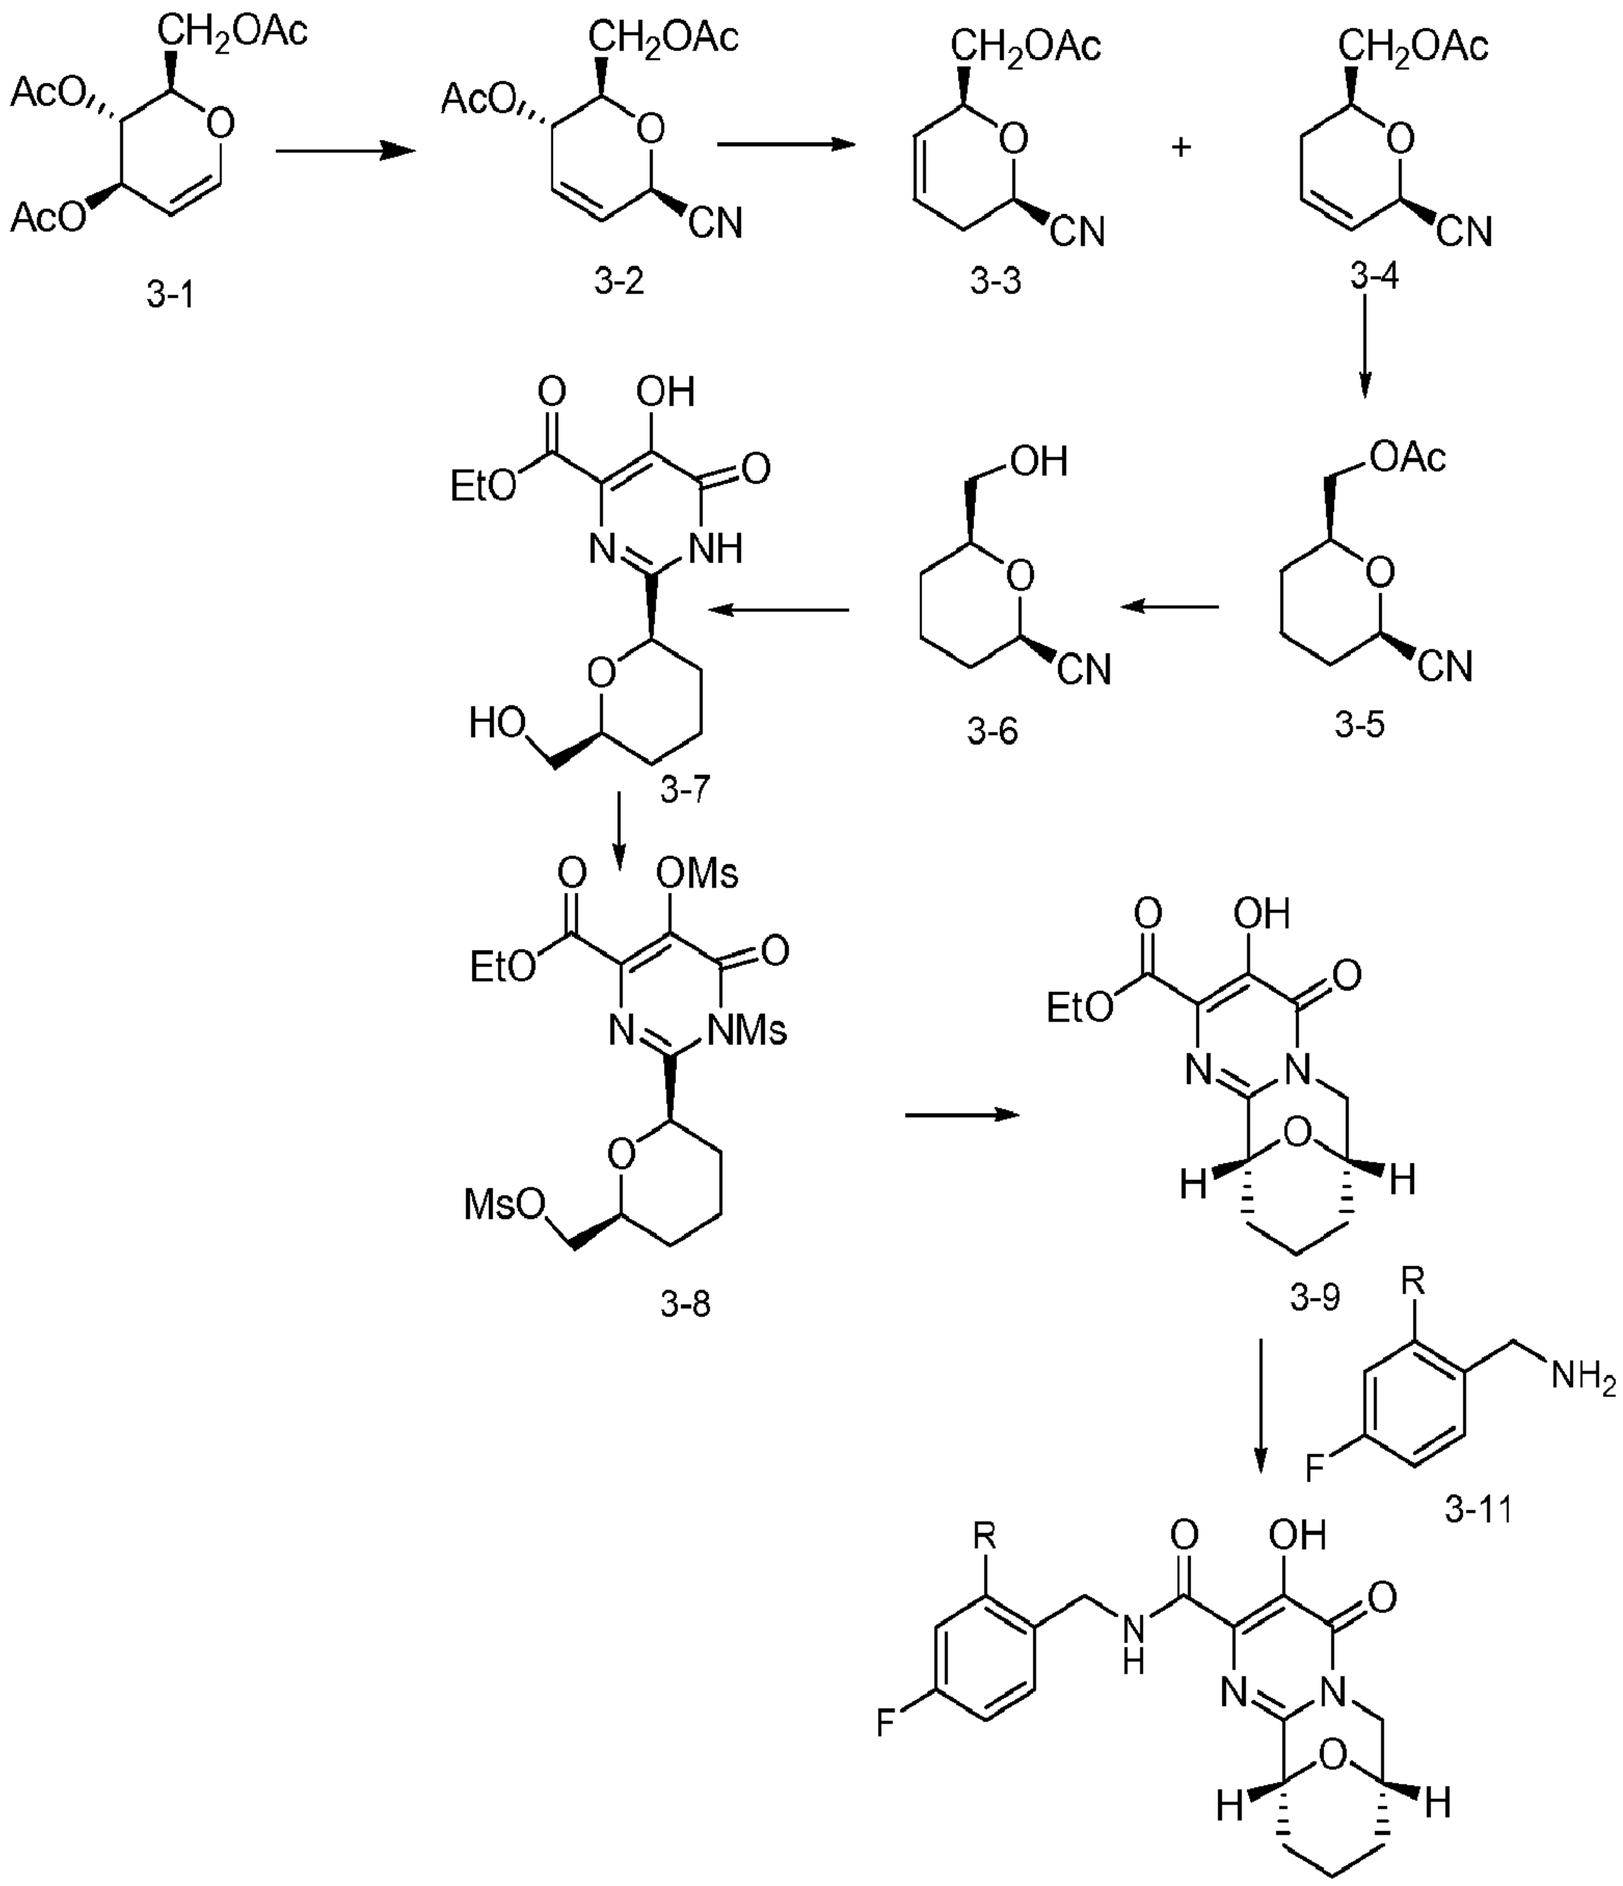
Scheme II



In Scheme III, peracylated glycoside 3-1 can be converted to intermediate 3-2 using synthetic procedures known to those skilled in the art, for example the method described in Carbohydrate Research (1982), 108(2), 229-35. Following this, a method similar to that described in Journal of Organic Chemistry (1988), 53(16), 3723-31 can be used to eliminate the acetoxy group at C-4 yielding a mixture of compounds, 3-3 and 3-4, which upon hydrogenation produce intermediate 3-5. The acetyl group of 3-5 can be removed using common conditions familiar to those skilled in the art. The synthesis of the 5-hydroxy-6-oxo-1,6-dihydropyrimidine-4-carboxylate ring of 3-7 can be assembled as described in Scheme I. Intermediate 3-7 is then treated with ≥ 3 equivalents of methanesulfonyl chloride and diisopropyl-ethylamine to yield 3-8 which when treated with a base such as K_2CO_3 produces the bridged tricyclic-fused, 5-hydroxy-6-oxo-1,6-dihydropyrimidine-4-carboxylate template, 3-8. This intermediate can be converted to the corresponding amide, 3-10, using standard amide bond forming procedures familiar to those skilled in the art. For example, in one method intermediate 3-9 can be combined with the amine, 3-11 and a base such as triethylamine and the mixture heated to effect aminolysis of the ester bond. In another method the hydroxyl group of 3-9 is modified with a protecting group such as benzyl, or a group such as those mentioned in Greene's Protective Groups in Organic Synthesis, 4th Edition, Peter G. M. Wuts, Theodora W. Greene, John Wiley & Sons, Inc. 2007, Hoboken New Jersey. Following this the ester is hydrolyzed to the corresponding carboxylic acid and this is coupled with the amine 3-

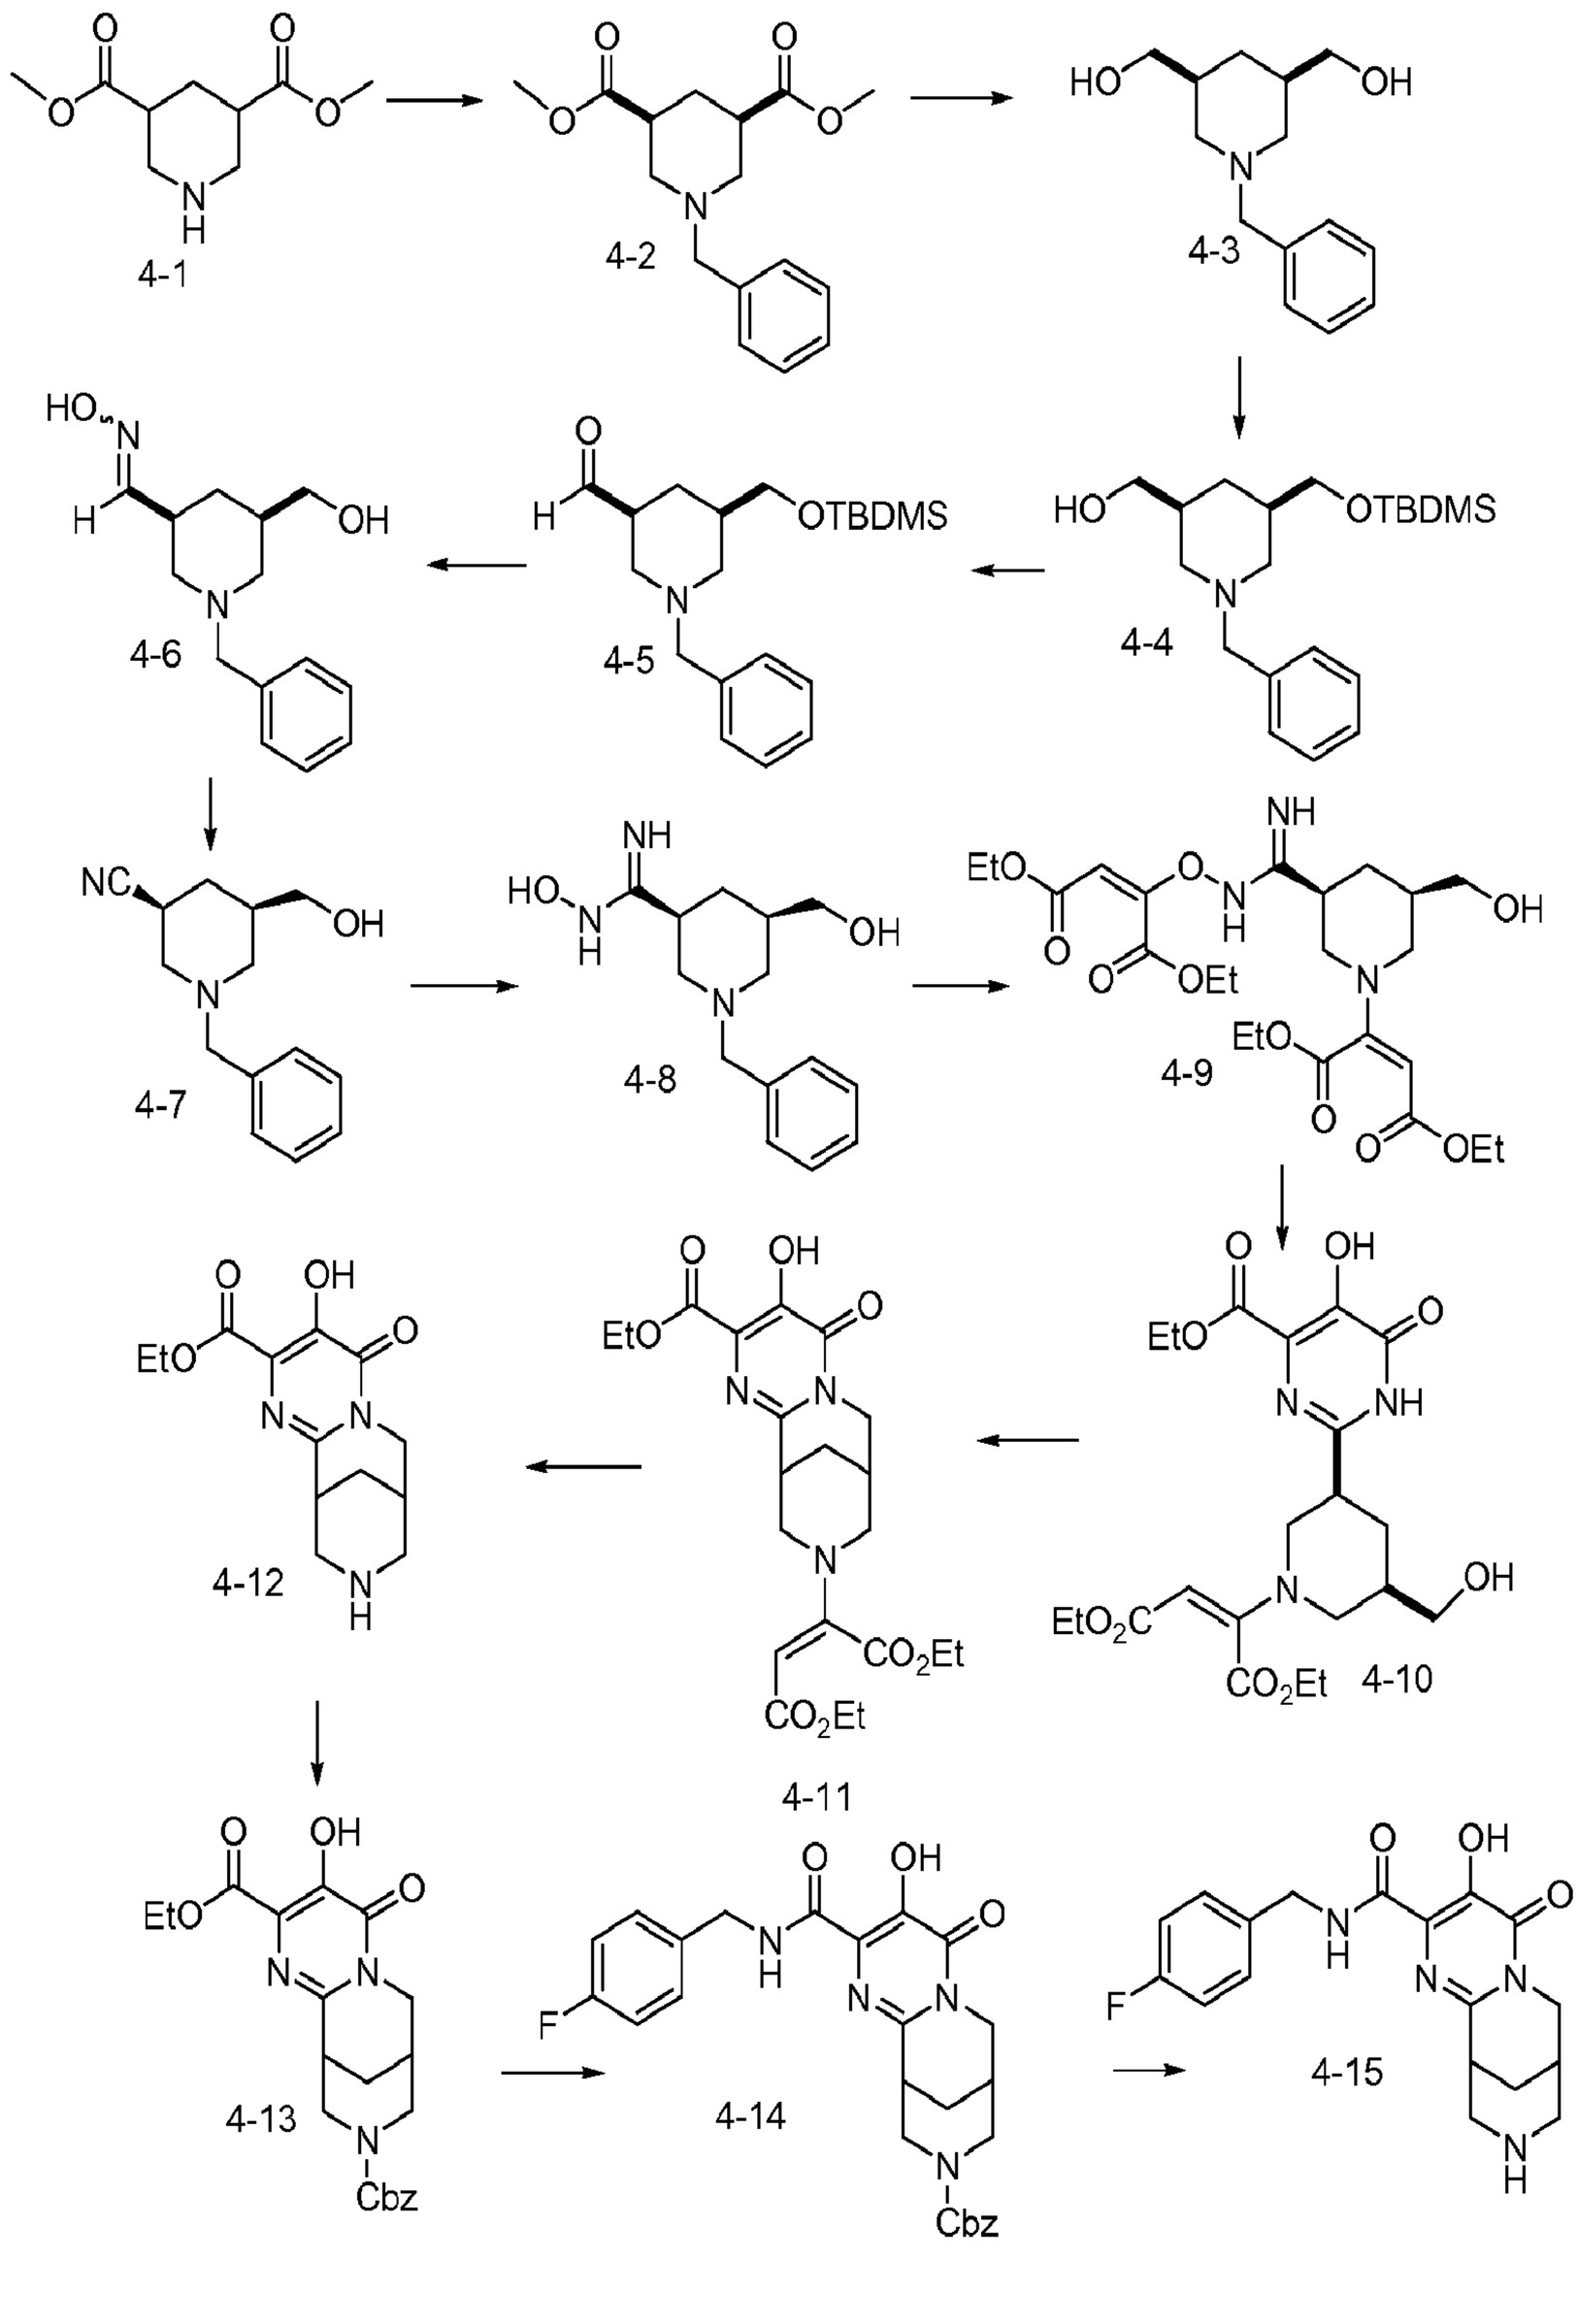
11 using an amide bond forming reagent such as N,N′-dicyclohexylcarbodiimide, O-benzotriazol-1-yl-N,N,N′,N′-bis(pentamethylene)uronium hexafluorophosphate, 1-[3-(dimethylamino)propyl]-3-ethylcarbodiimide methiodide, bromotripyrrolidinophosphonium hexafluorophosphate or other amide bond forming reagents familiar to those skilled in the art. Following this the protecting is removed to produce 3-10.

Scheme III



In Scheme IV, intermediate 4-1 (Tetrahedron Letters (1994), 35(26), 4515-18 and references cited therein) is reacted with benzyl bromide, in the presence of a base such as K_2CO_3, to form the N-benzyl derivative 4-2 (Synth. Commun. 1997, 27 (1), 69-71). It will be appreciated by those skilled in the art that the benzyl group attached to 4-2 serves as a protecting group and that other nitrogen protecting groups could be used in its place. The diester, 4-2 can be treated with lithium aluminum hydride to form the bis-alcohol 4-3. Upon treatment of this intermediate with 1 molar equivalent of tert-butyldiphenylsilyl chloride and sodium hydride the protected intermediate 4-3 is formed. Treatment of this intermediate using Swern reaction conditions (Tetrahedron 34, 1651 (1978)), affords intermediate 4-5. It will be appreciated by those skilled in the art that a number of procedures are available for the conversion of an alcohol to an aldehyde, such as those described in Comprehensive Organic Transformations: A Guide to Functional Group Preparations, Second Edition, Richard C. Larock, John Wiley and Sons, 1999, New York, NY. The aldehyde 4-5 can be is condensed with hydroxylamide to form intermediate 4-6, which is then transformed to the nitrile 4-7. One skilled in the art will appreciate that there are a number of methods available for transforming intermediates such as 4-6 into 4-7. For example Comprehensive Organic Functional Group Transformations II, Alan R. Katritzky, Otho Meth-Cohn, and Charles W. Rees, Elsevier, 1995. Upon treatment of this intermediate with hydroxylamine followed by dialkyl-butynoate, intermediate 4-9 is produced. Formation of the 5-hydroxy-6-oxo-1,6-dihydropyrimidine-4-carboxylate heterocycle and cyclization to form the bridged tricyclic fused ring system can be carried out as described in the previous schemes to afford intermediate 4-11. The ethylene-dicarboxylate group attached to the nitrogen atom of 4-11 can be removed under acidic conditions. The nitrogen is next protected as the corresponding benzylcarbamate (Cbz) using benzylchloroformate and diisopropyldiethylamine to yield 4-13. Amidation to form 4-14 can be accomplished as described previously and following this, removal of the Cbz-protecting group produces 4-15.

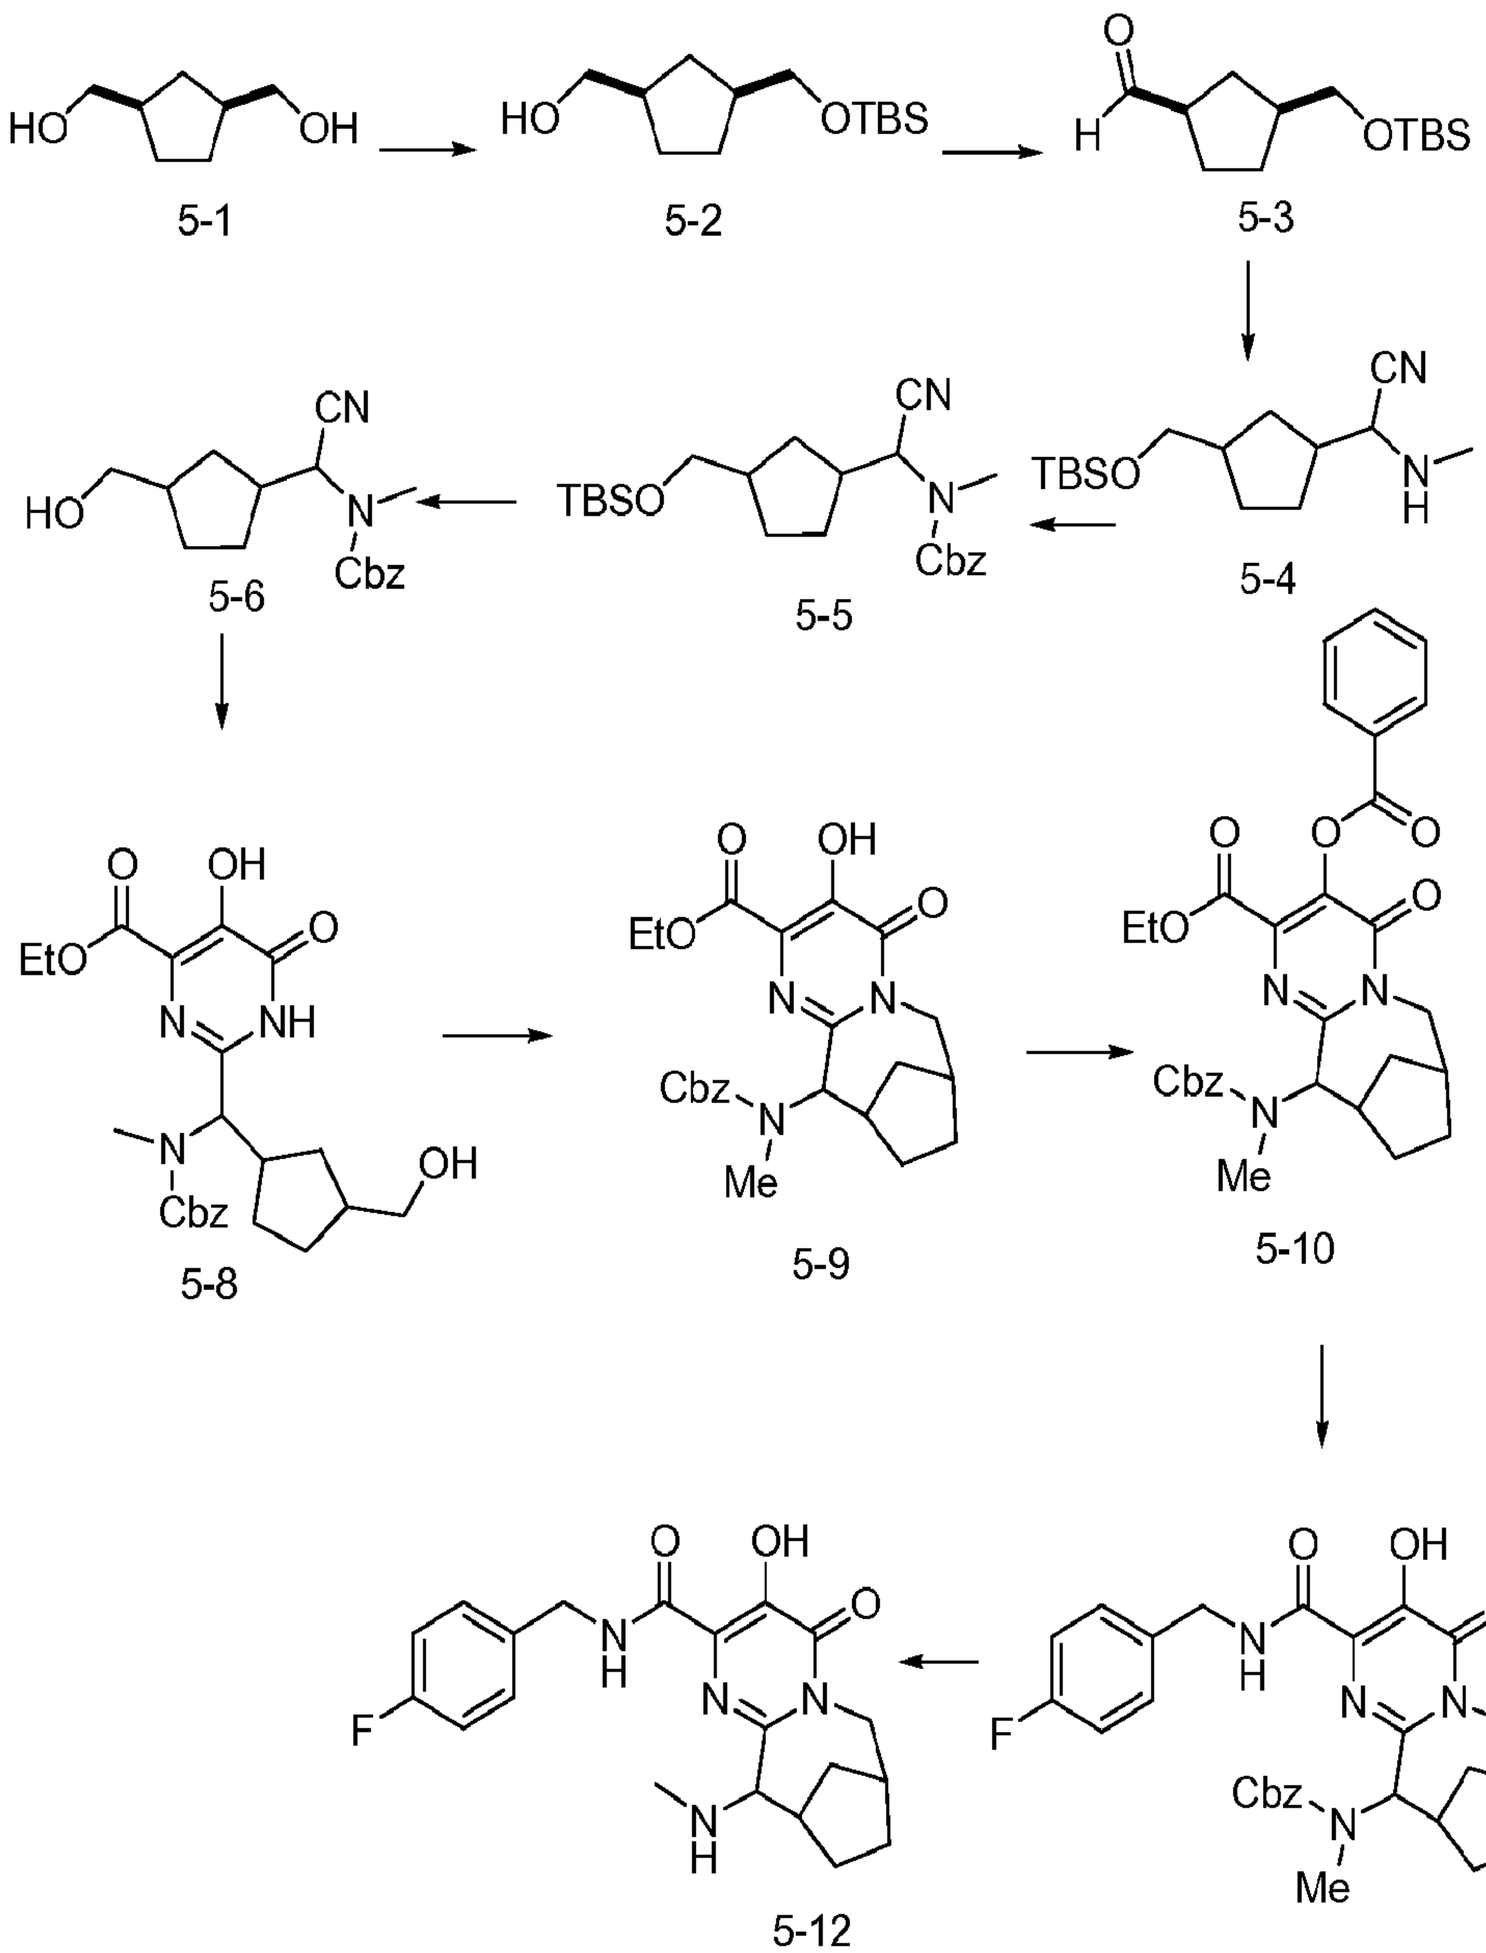
Scheme IV



In Scheme V, diol 5-1 (Tetrahedron Letters (1971), (39), 3587-9; Journal of Organic Chemistry (1975), 40(17), 2488-95) is treated with tert-butyl dimethylsilylchloride in the presence of sodium hydride to deliver intermediate 5-2. Oxidation of this compound under Swern conditions, similar to that described above, yields aldehyde 5-3. Intermediate 5-4 can be synthesized by reacting 5-3 with

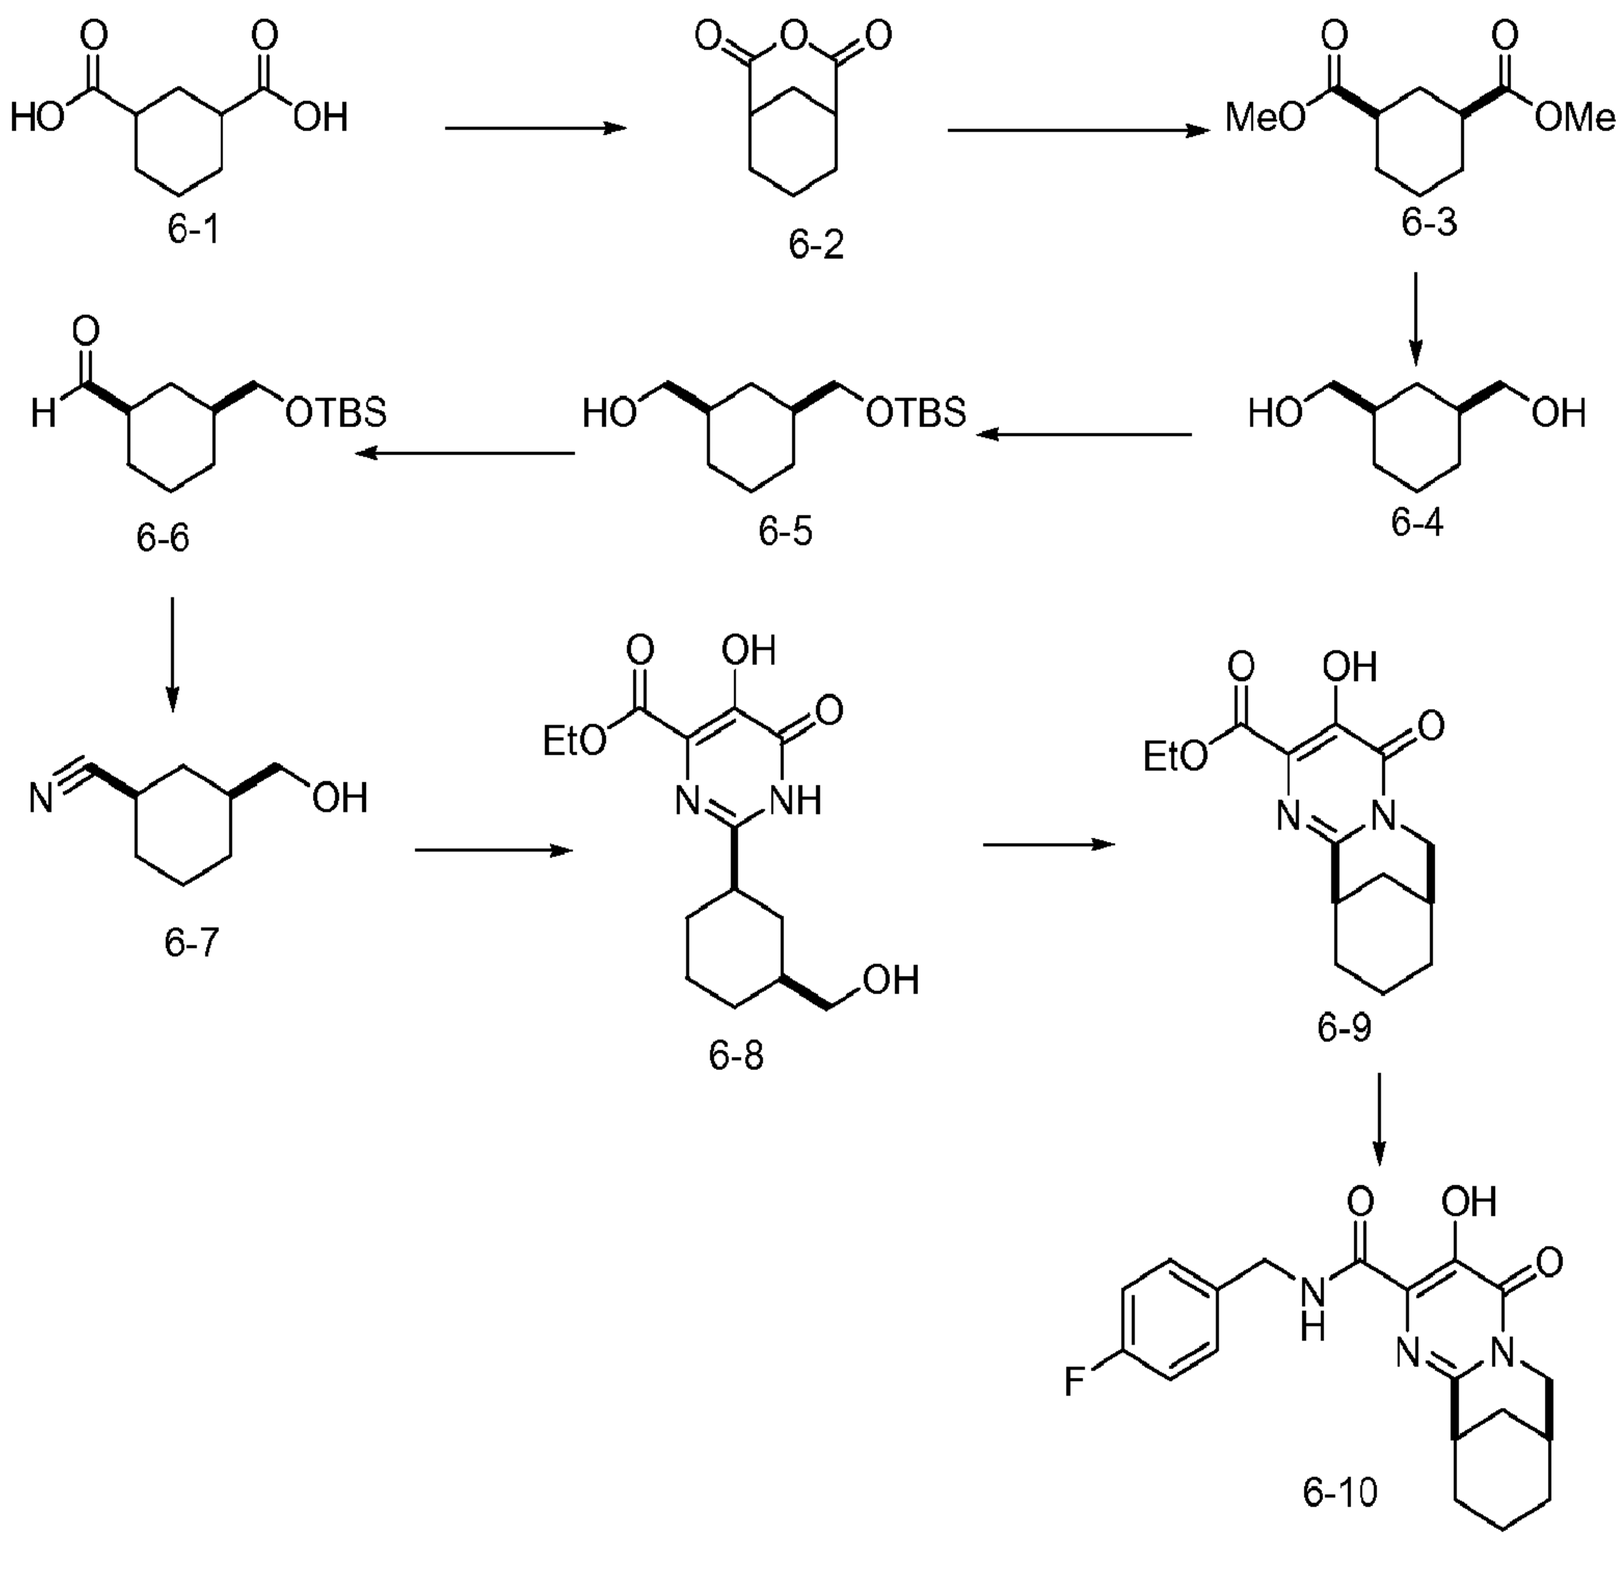
methylamine and potassium cyanide in methanol. Following protection of the nitrogen group as the corresponding Cbz-derivative, the tert-butylsilyl protecting group can be removed to provide intermediate 5-6. Formation of the 5-hydroxy-6-oxo-1,6-dihydropyrimidine-4-carboxylate heterocycle and cyclization to form the bridged tricyclic fused ring system, as described in the previous schemes, affords intermediate 5-9.

Scheme V



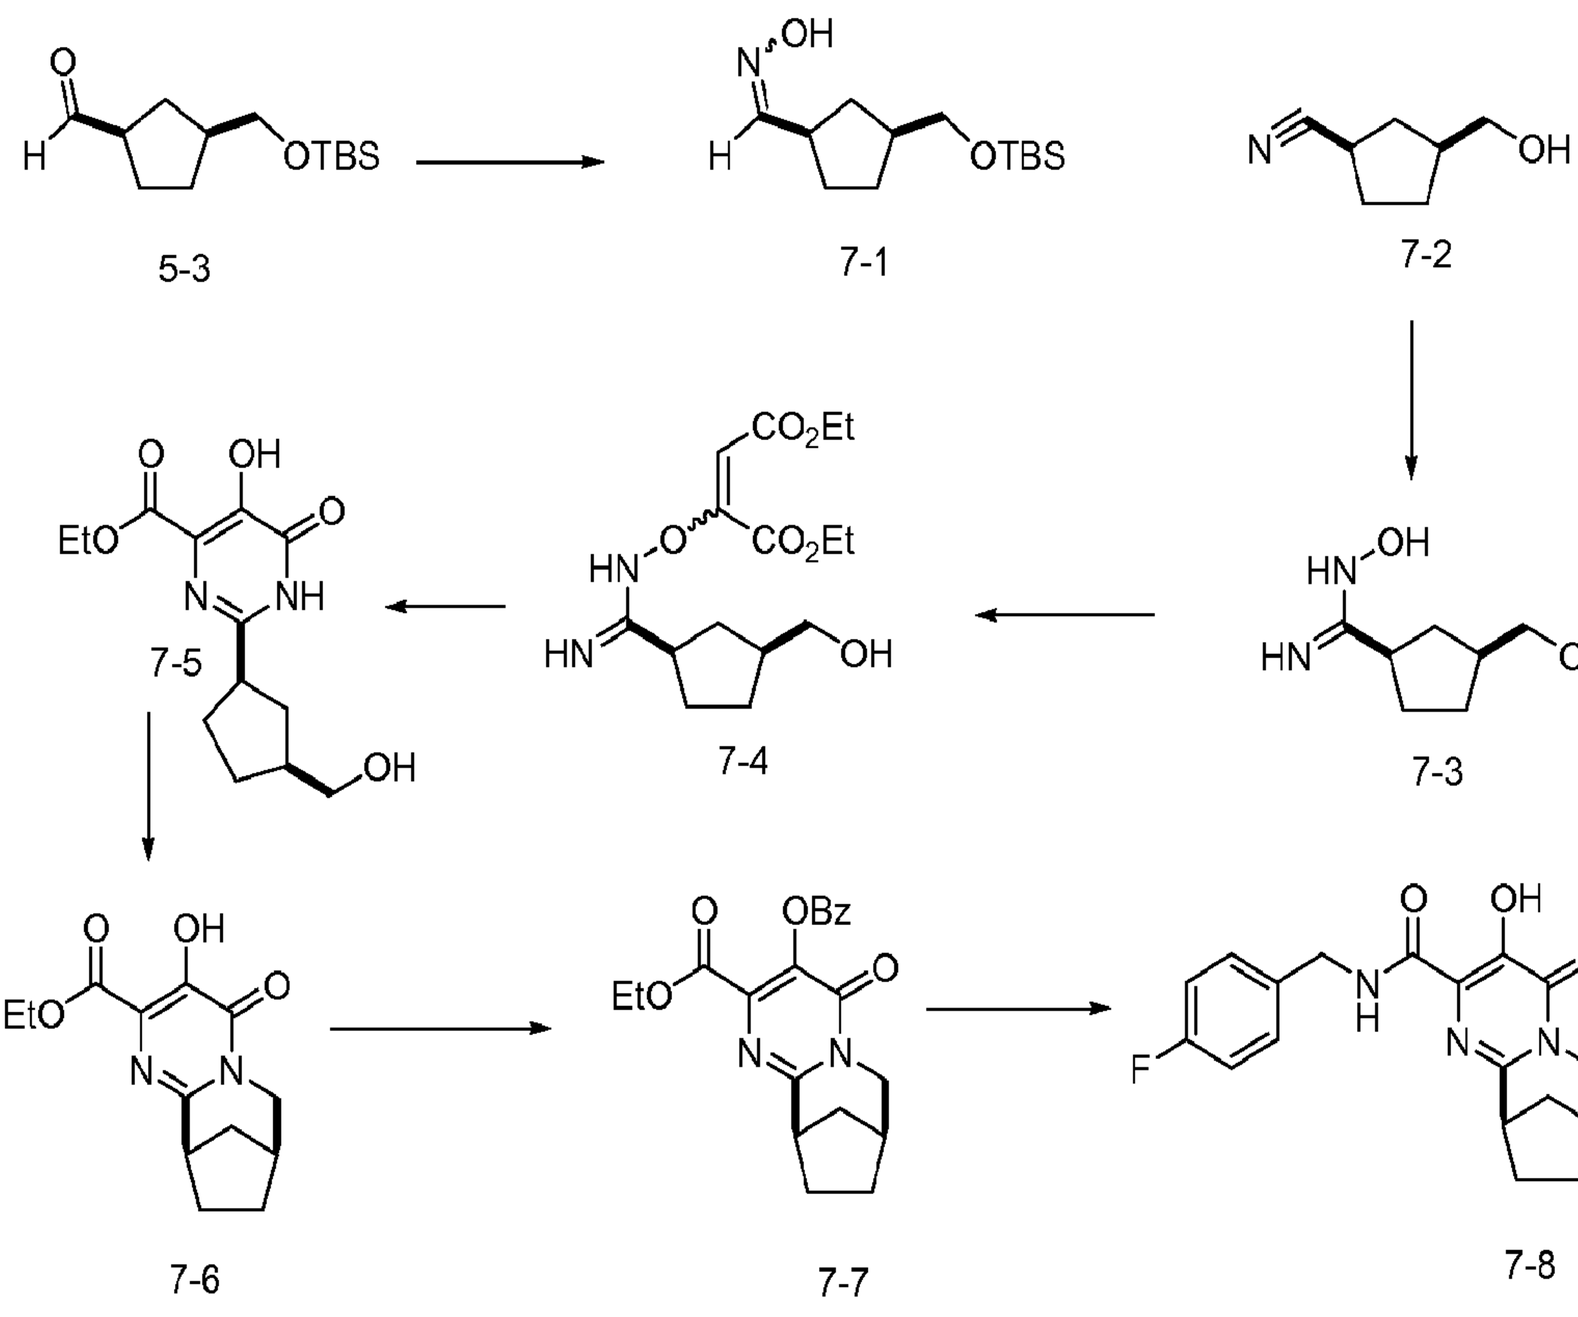
Scheme VI describes yet another method for the synthesis of compounds of this invention. In this method, intermediate 6-1 is converted to the corresponding diester, 6-3, via the anhydride 6-2. Reduction of the ester groups to provide intermediate 6-4, can be accomplished using procedures familiar to those skilled in the art. The subsequent synthetic steps from intermediate 6-4 to the final compound 6-10 can be accomplished using methods similar to those described in the schemes above.

Scheme VI



In Scheme VII, intermediate 5-3 is reacted with hydroxylamine to form, 7-1 and converted into the corresponding nitrile 7-2, as described above in Scheme IV for the synthesis of intermediate 4-7. The synthesis of compound 7-8 can be accomplished using methods similar to hose described in the schemes above.

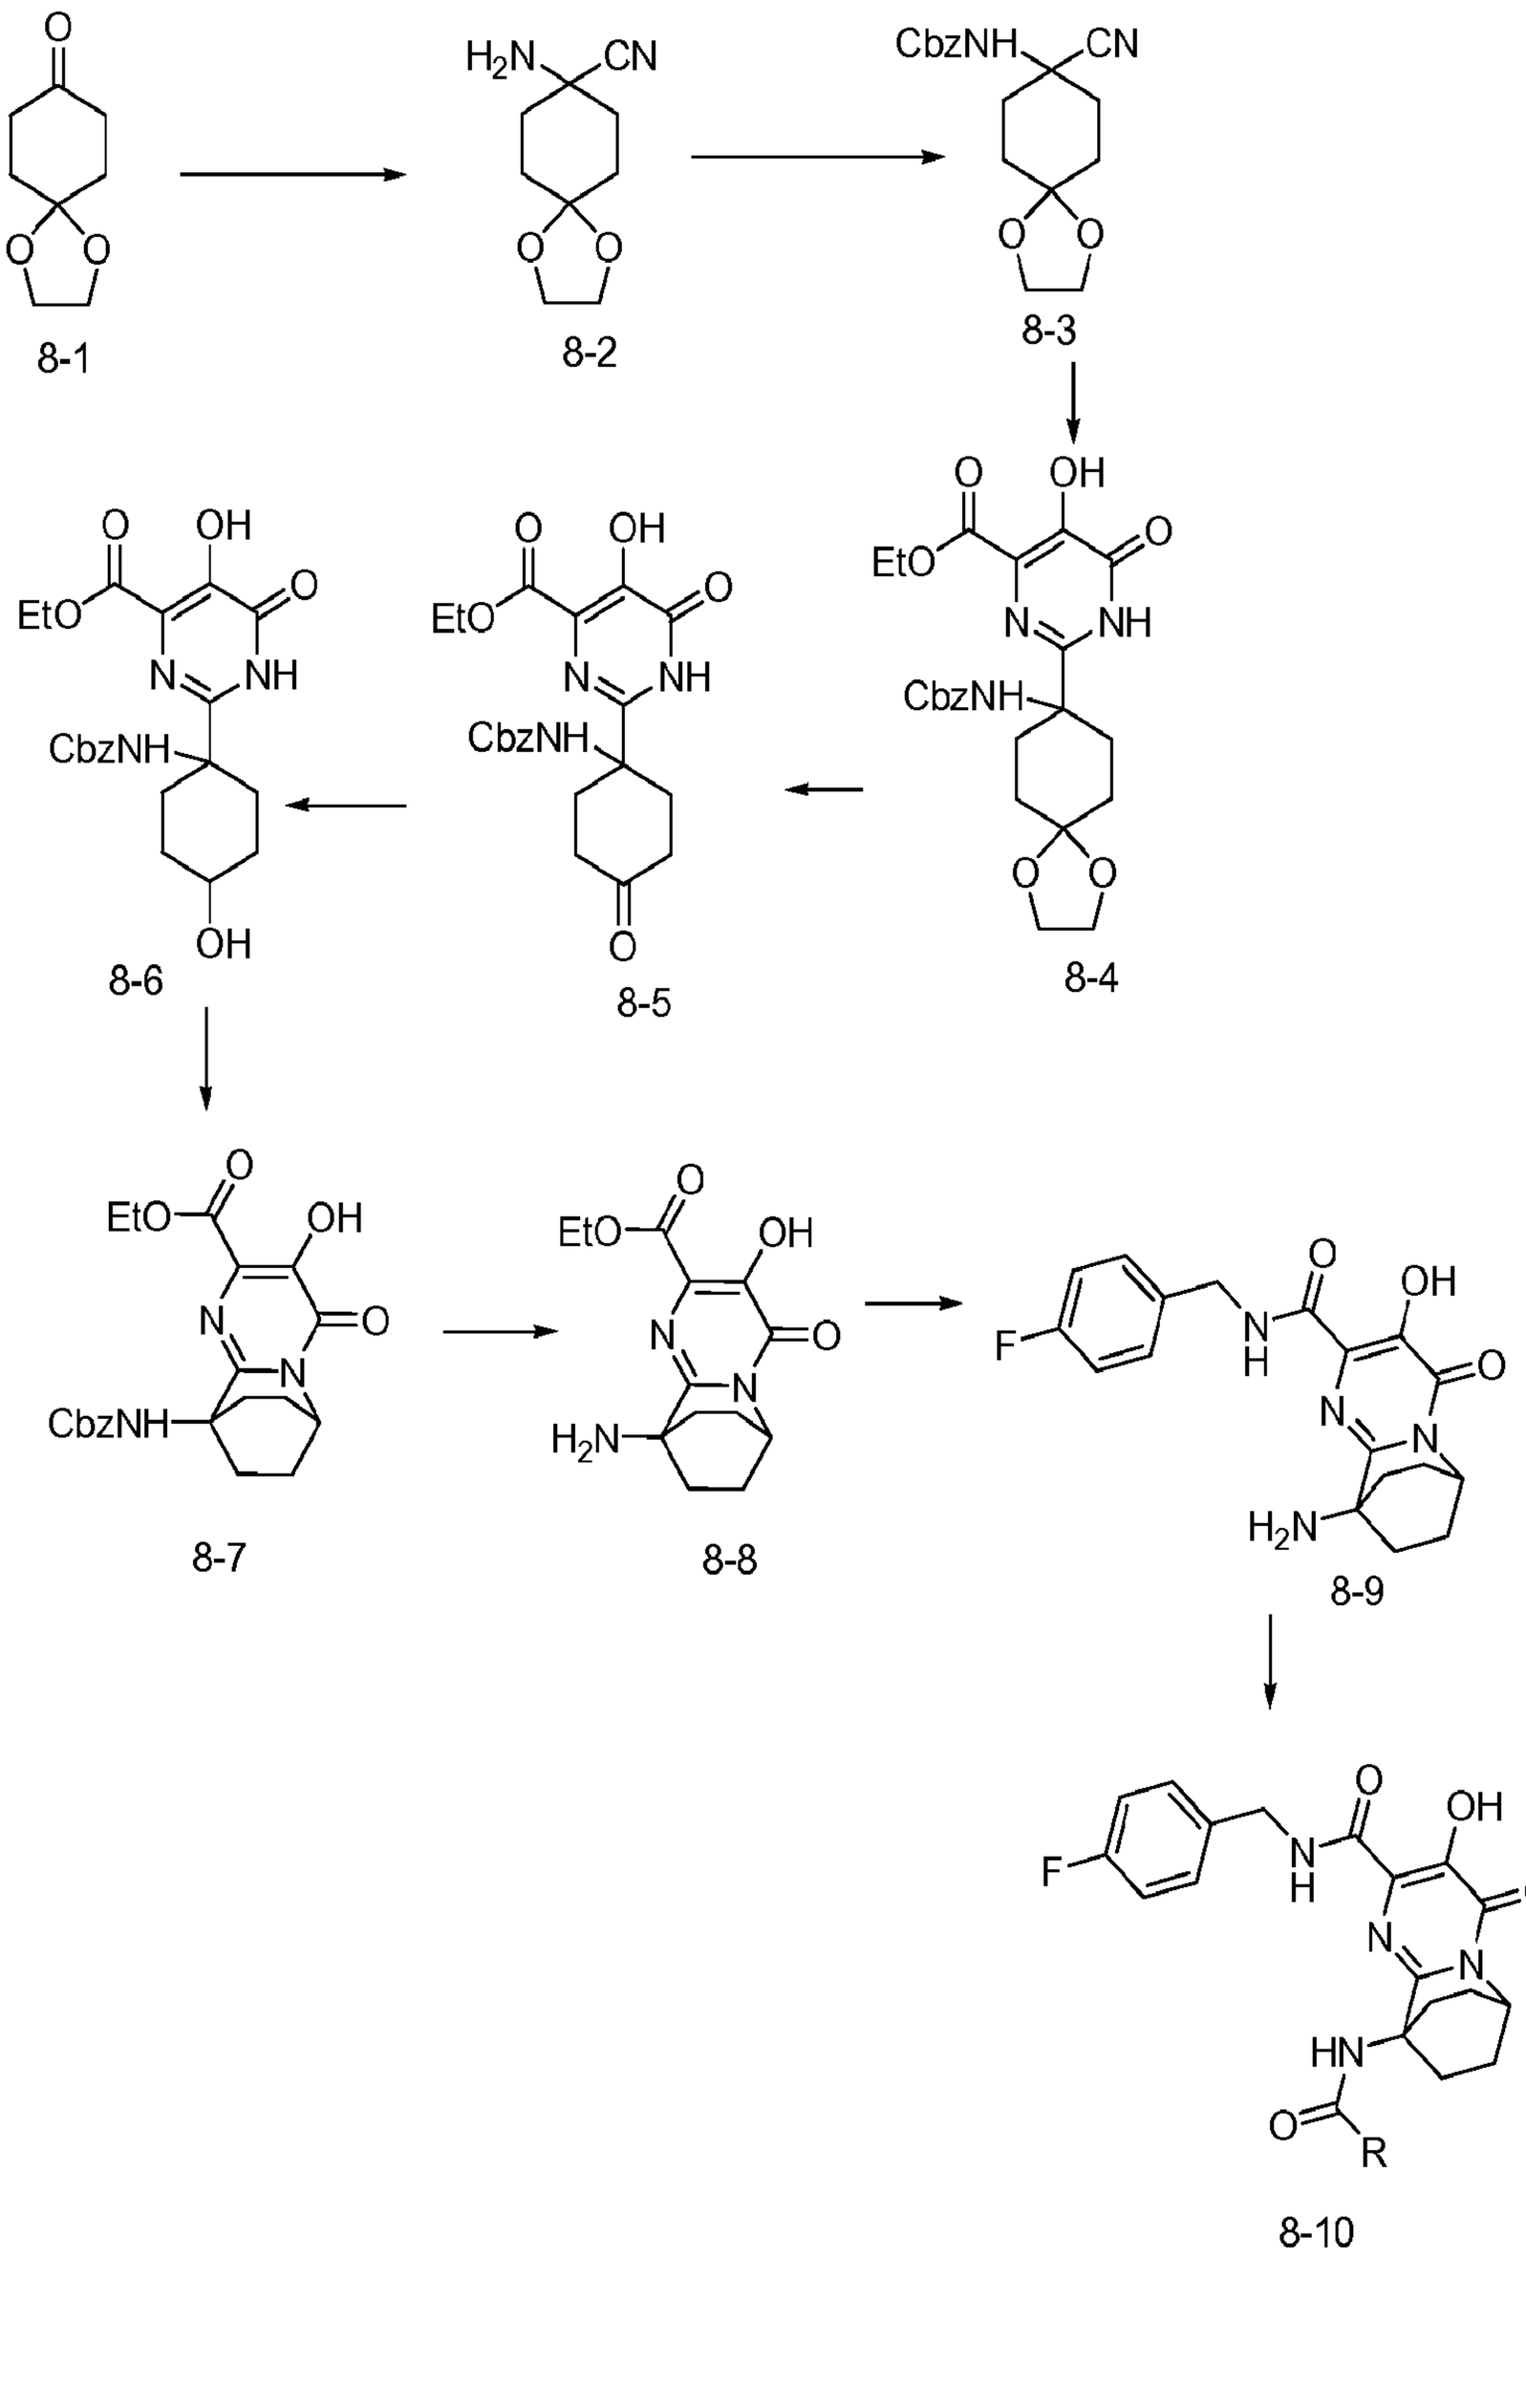
Scheme VII



Treatment of intermediate 8-1, in Scheme VIII, under Strecker reaction conditions (Greenstein, M. Winitz, Chemistry of the Amino Acids vol. 3 (New York, 1961) pp 698-700, G. C. Barrett, Chemistry and Biochemistry of the Amino Acids (Chapman and Hall, New York, 1985) pp 251, 261) provides the amino nitrile 8-2. After protection of the amino-group as the corresponding Cbz-derivative, the 5-hydroxy-6-oxo-1,6-dihydropyrimidine-4-carboxylate heterocycle is formed by sequentially treating the nitrile with, hydroxylamine and diethyl but-2-ynedioate, then heating in xylenes. The cyclic ketal protecting group can be hydrolyzed under acidic conditions to furnish the ketone 8-5 which is then reduced with $NaBH_4$ to provide intermediate 8-6. Cyclization to form intermediate 8-7, can be achieved by first treating this intermediate with methane sulfonyl chloride/triethylamine, to effect mesylation of the hydroxyl group followed by treatment with cesium carbonate. The Cbz-group is hydrolytically removed under standard conditions resulting in intermediate 8-8. Formation of the corresponding 4-fluorobenzylamide can be accomplished using the methods described above. Intermediate 8-9 is then treated

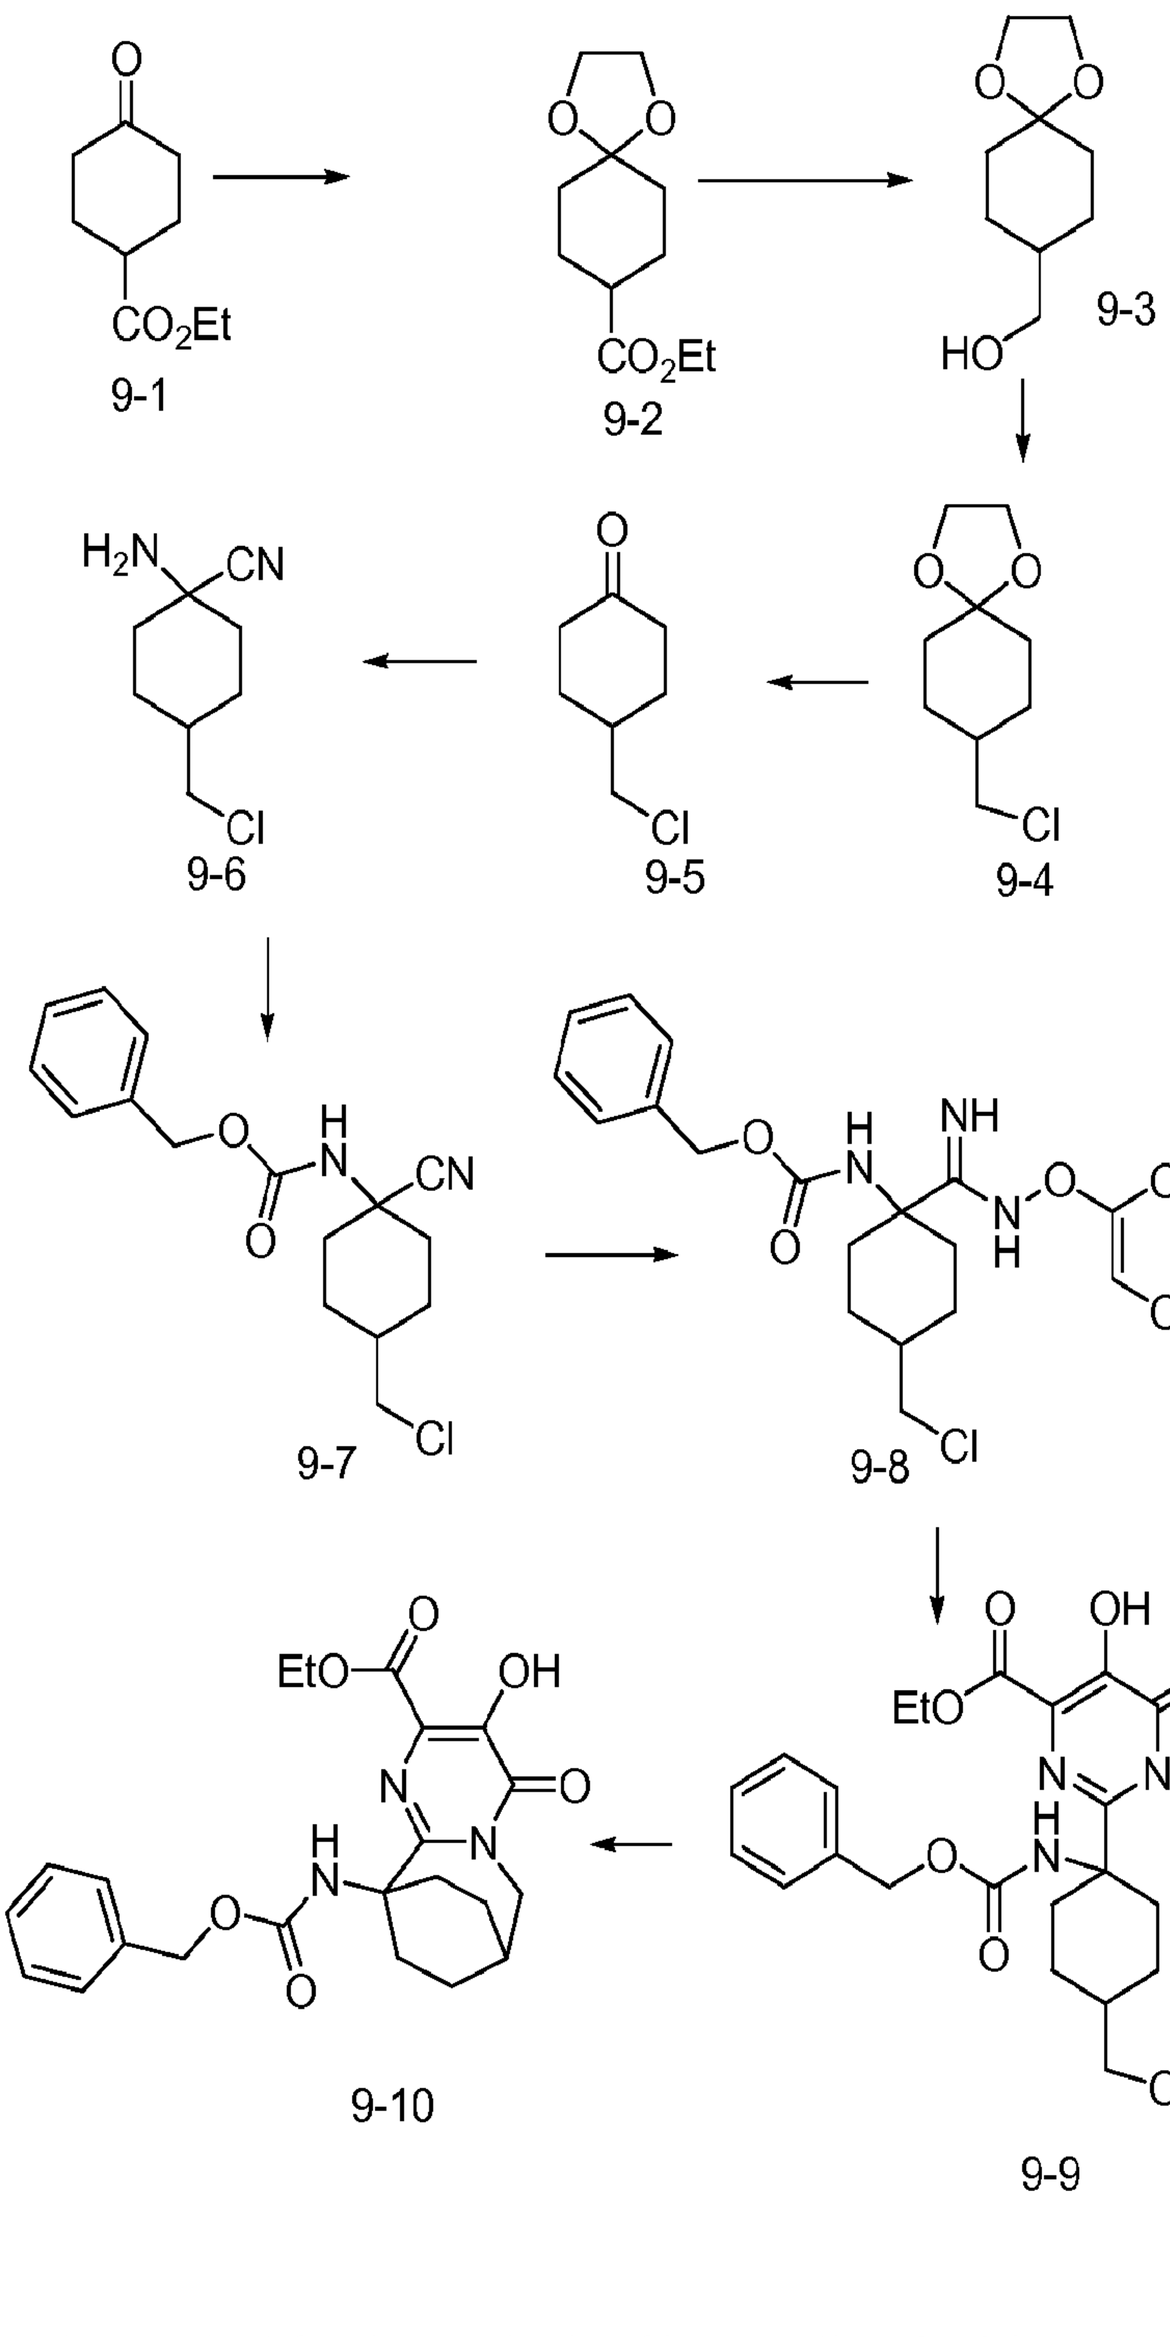
with an activated carboxylic acid, for example and acid chloride, or a carboxylic acid in the presence of an amide bond forming reagent to yield compound 8-10.

Scheme VIII



Scheme IX illustrates a method for the synthesis of intermediate 9-10. In the first step of the sequence compound 9-1 is treated with ethane 1,2-diol and toluene sulfonic acid which yields intermediate 9-2. The carboxylic ester group of 9-2 is reduced using lithium aluminum hydride affording 9-3. Treatment of this intermediate with $SOCl_2$ produces the chloride derivative 9-4. It will be appreciated by those skilled in the art that numerous methods exist for the substitution of an alcohol group with chloride some of which can be found in Comprehensive Organic Transformations: A Guide to Functional Group Preparations, Second Edition, Richard C. Larock, John Wiley and Sons, 1999, New York, NY. Hydrolysis of the cyclic ketal group of intermediate 9-4 provides a ketone, 9-5, which can be taken on as described in the previous schemes, to the 5-hydroxy-6-oxo-1,6-dihydropyrimidine-4-carboxylate derivative 9-9. Under basic conditions the tricyclic ring system is formed via nucleophilic displacement of the chloride group. Compound 9-10 can serve as an advanced intermediate in the synthesis of compounds of this invention.

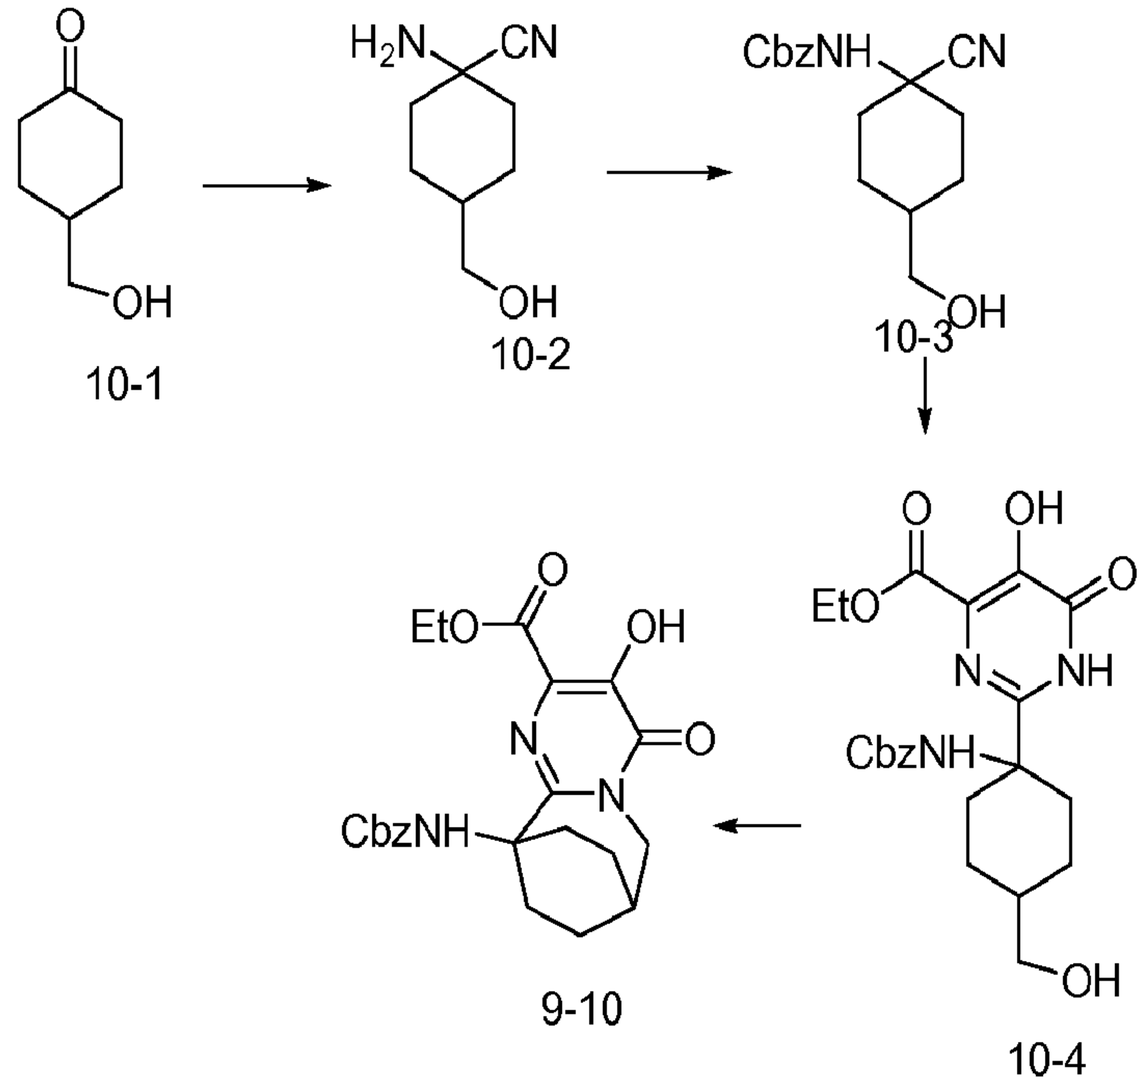
Scheme IX



Another method for the synthesis of intermediate 9-10 is shown in Scheme X. In Scheme X, compound 10-1 can be prepared according to general procedure described in Journal of Organic Chemistry 1997, 62, 5284-5292 from commercially available ethyl 4-oxocyclohexanecarboxylate. A Strecker reaction, like that described in the schemes above produces the amino-nitrile intermediate 10-2 which is carried on to the N-protected intermediate 10-3. Treatment of this compound with

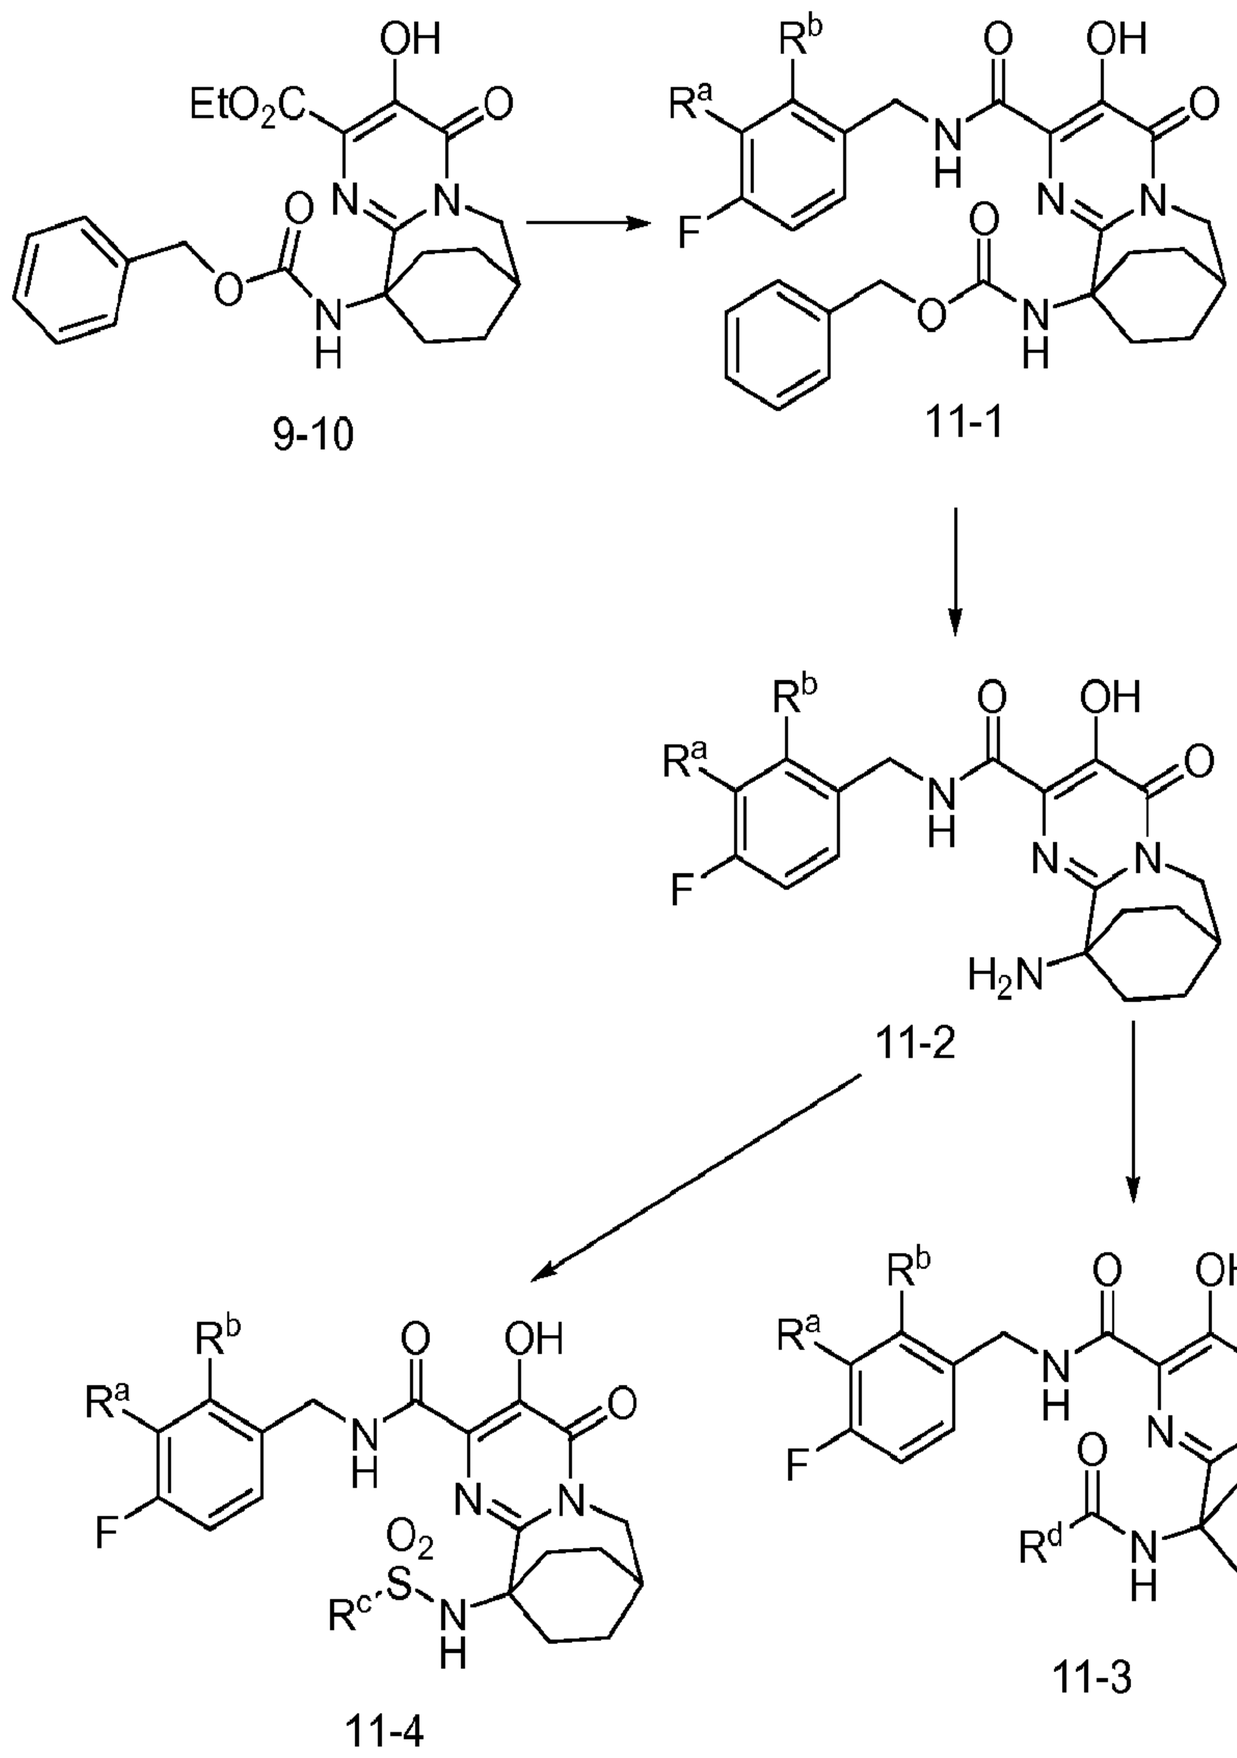
hydroxylamine, followed by diethyl but-2-ynedioate and heating in xylenes affords 10-4. The final cyclization reaction can be carried out as before, via activation of the alcohol with methane sulfonyl chloride followed by ring closing nucleophilic attack by the pyrimidinone nitrogen-group.

Scheme X



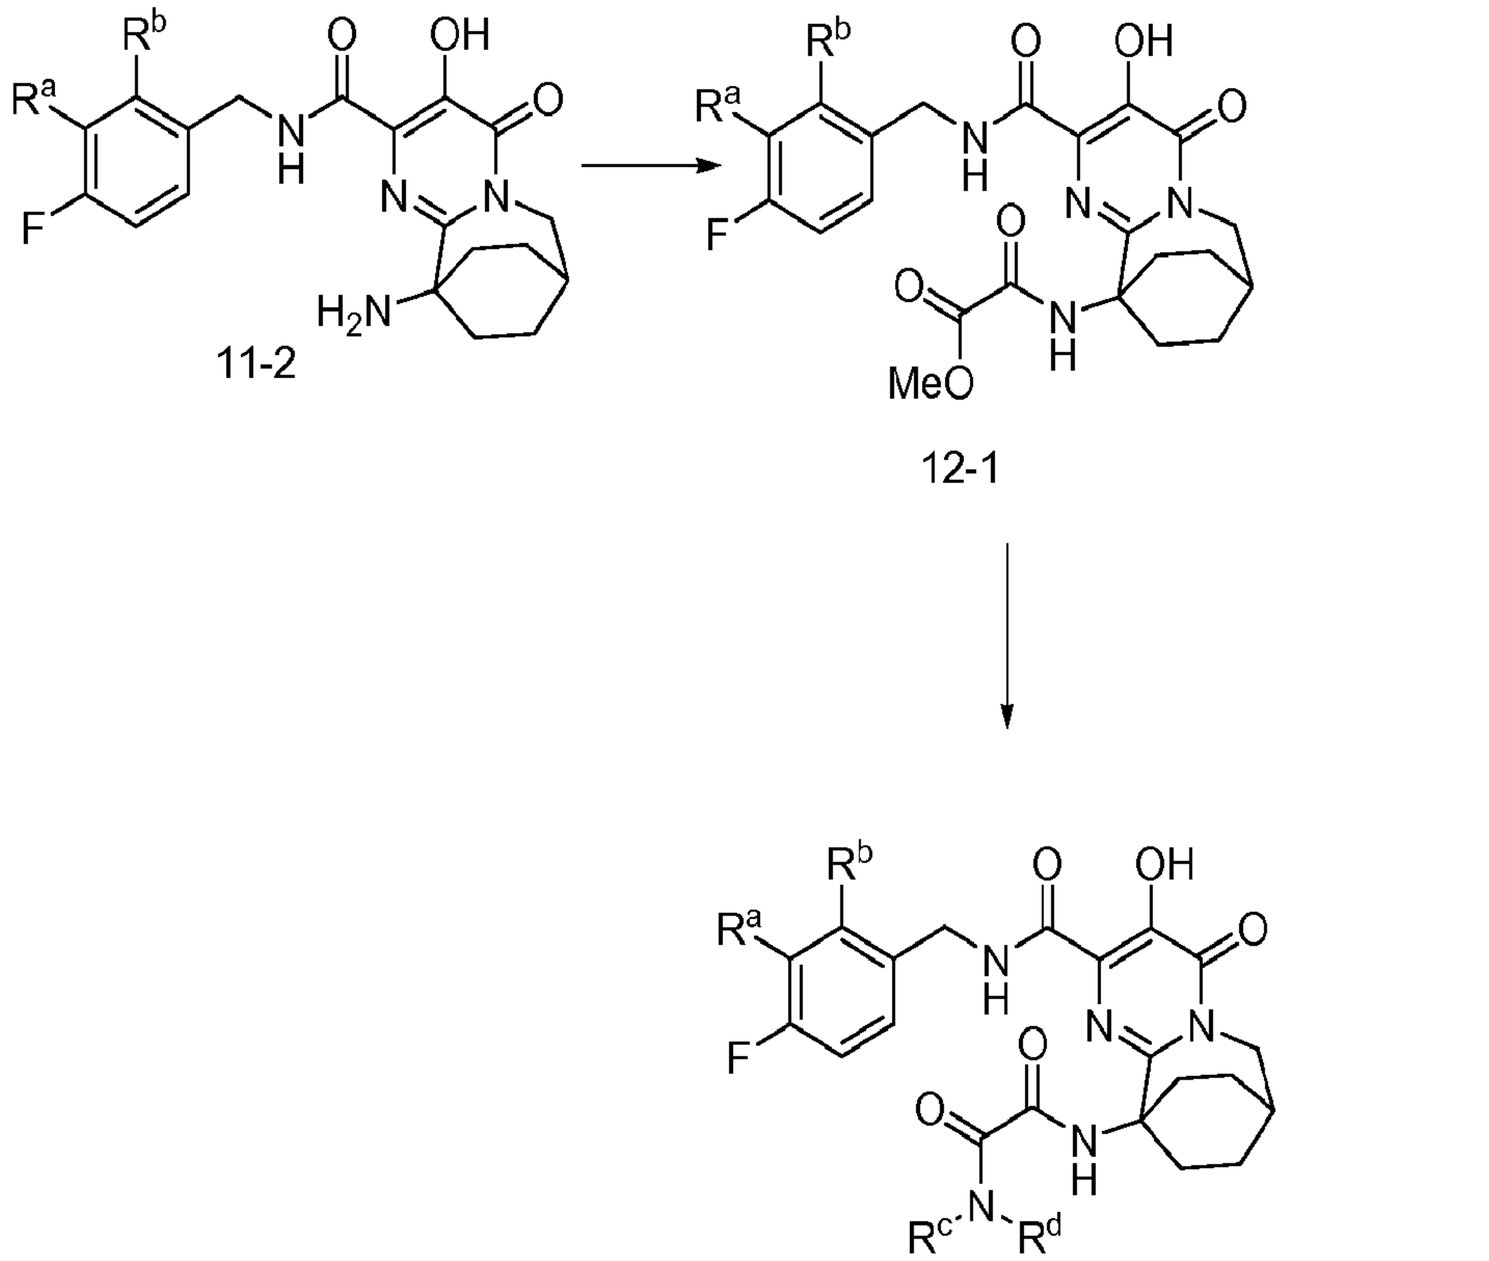
In Scheme XI intermediate 9-10 is treated with a substituted benzylic amine in the presence of triethylamine, with heating, to form the corresponding benzylamide 11-1. The Cbz protecting of 11-1 can be removed using standard hydrogenation conditions (e.g. H_2 and Pd/C) or other methods commonly known to one skilled in the art. In the final step amide, urea, carbamate, sulfonamide and related analogues can be synthesized directly form 11-3 under appropriate conditions. For example amides can be synthesized by treating 11-3 with a carboxylic acid chloride or by reacting it with a carboxylic acid in the presence of an amide bond forming reagent such as HATU. Other analogues are available by treating 11-3 with isocyantes, chlorosulfonates or chloroformates, to name a few. The analogues are treated with $MeNH_2$ in the event that the C3-hydroxyl group of the pyrimidinone ring has been modified.

Scheme XI



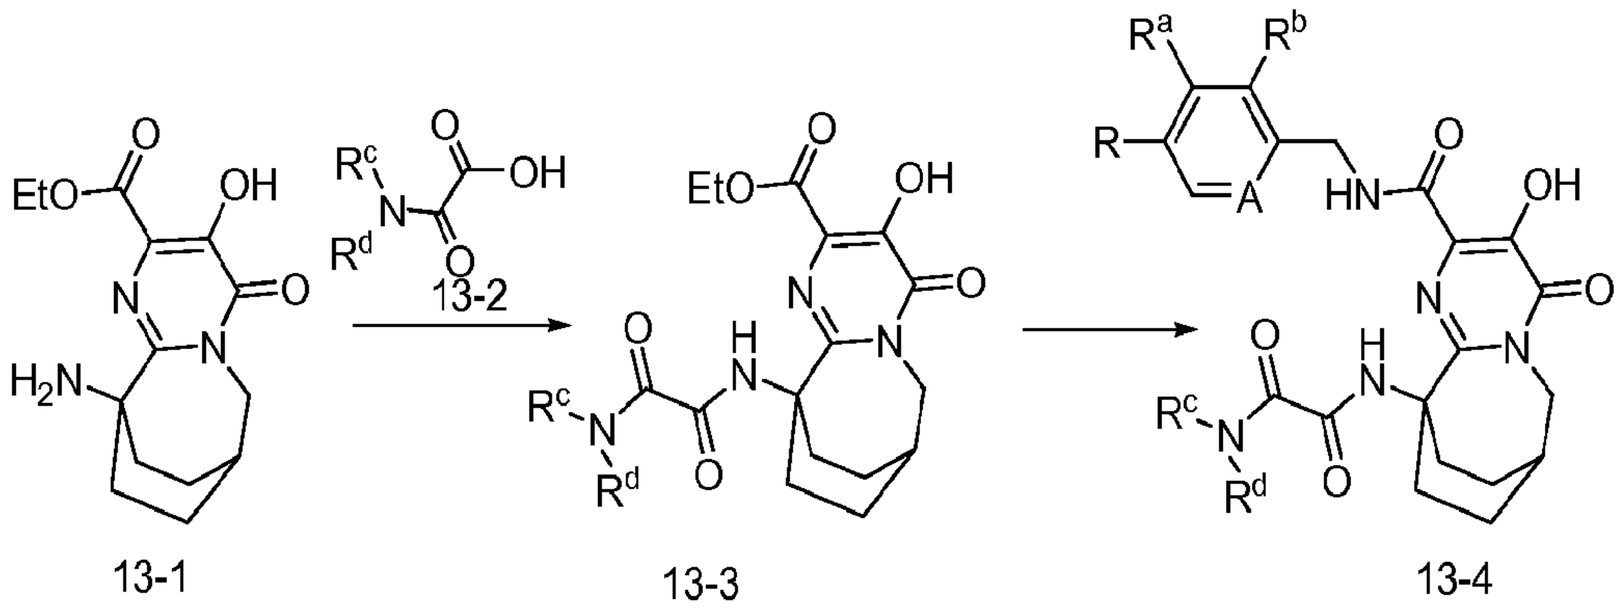
Compounds of this invention can also be synthesized according to the method illustrated in Scheme XII. In this Scheme 11-2 can be synthesized as before. This intermediate is then reacted with 2-chloro-2-oxoacetate in the presence of triethylamine to deliver 12-1. Following this 12-1 is heated with an amine to affect the formation of 12-2. In certain cases intermediate 12-1 need not be isolated but can be carried on to the 12-2 forming step immediately after work-up.

Scheme XII



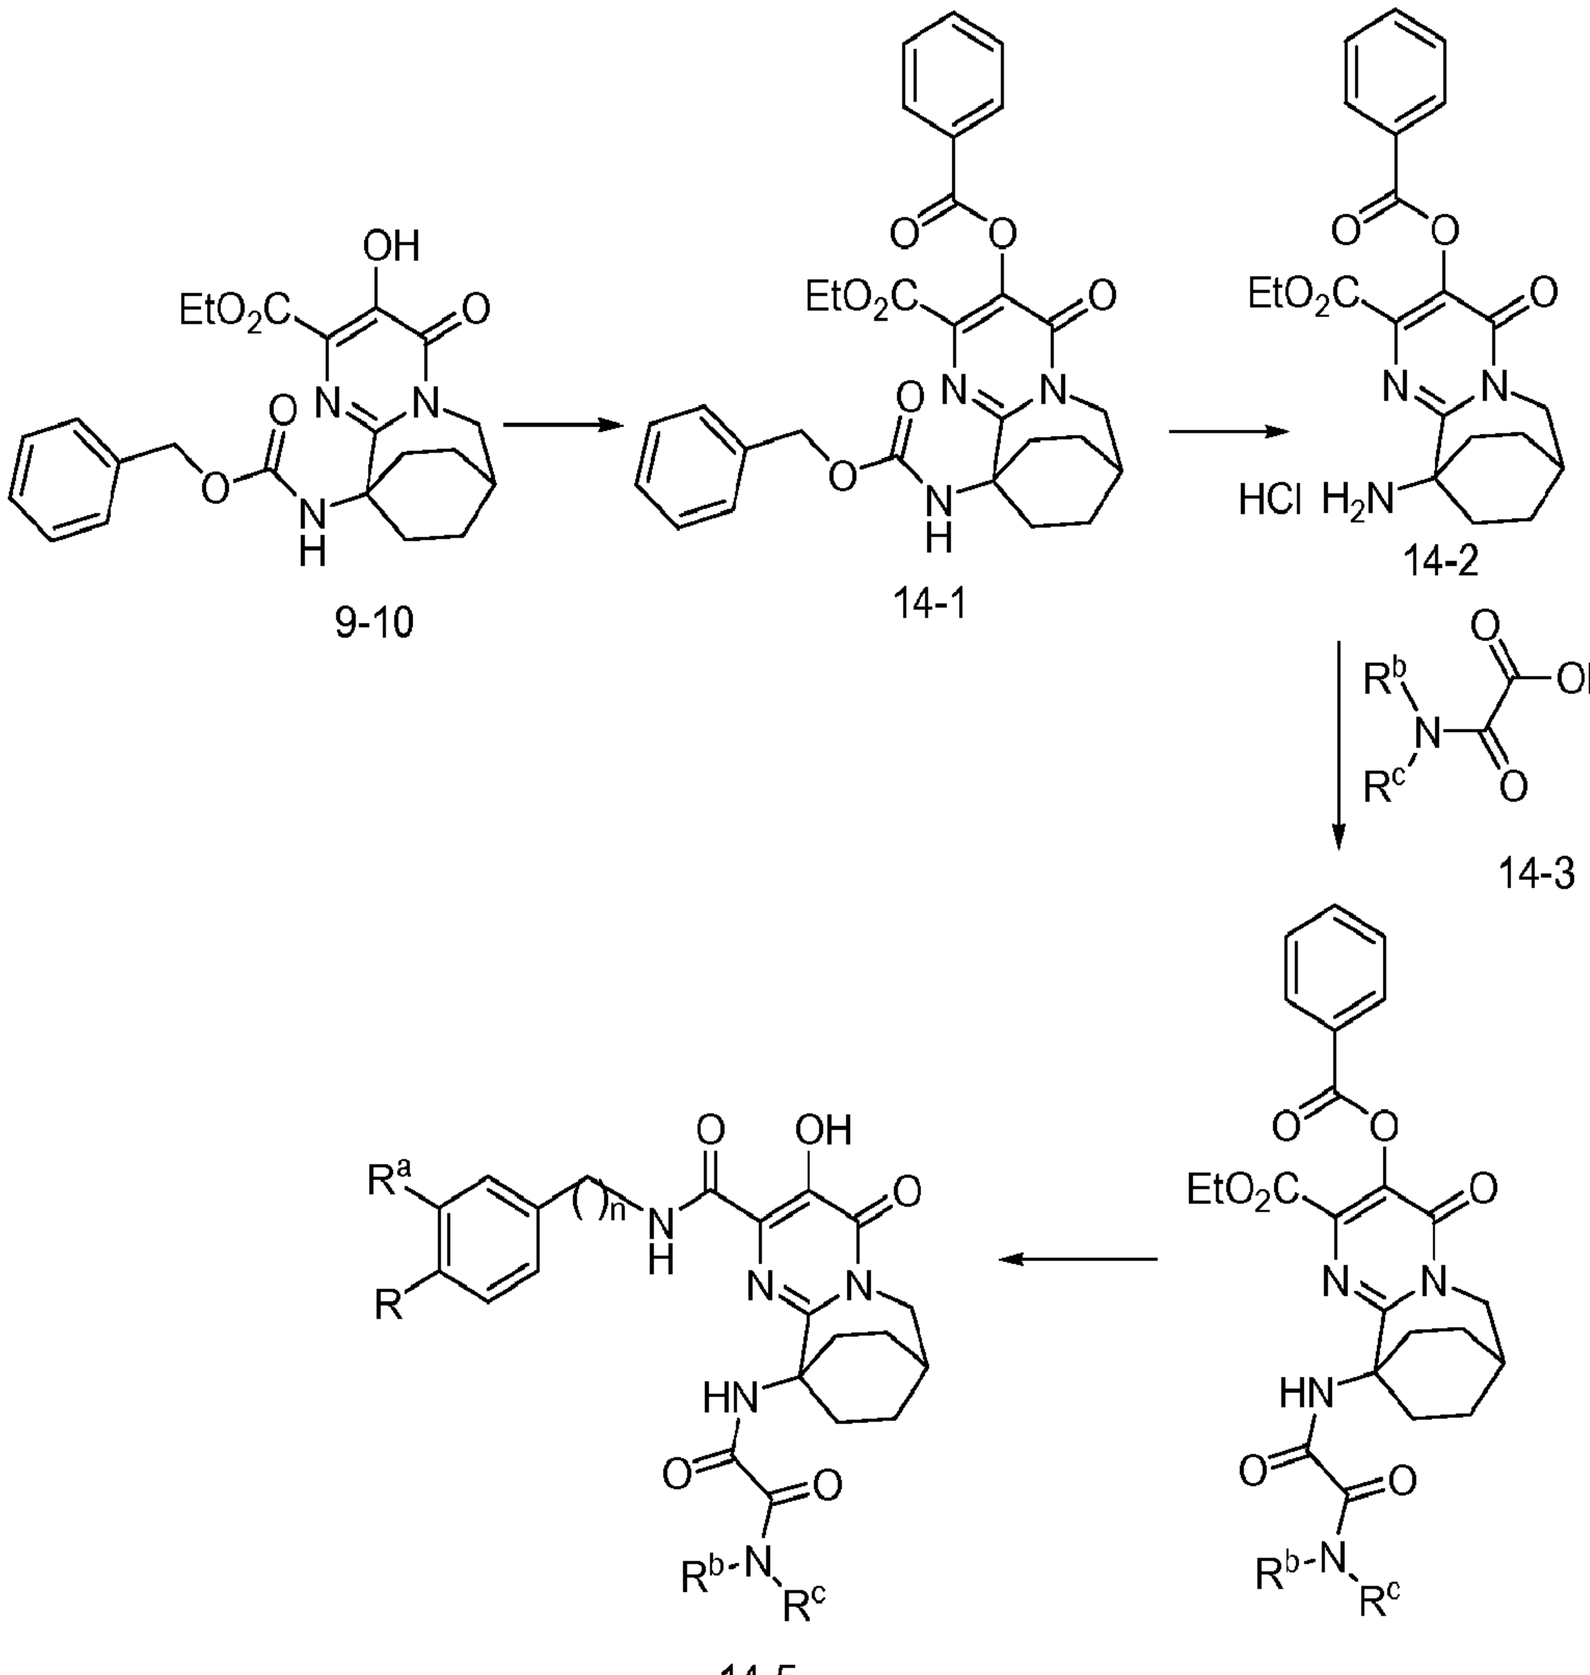
In Scheme XIII, intermediate 13-1 can be coupled with intermediate 13-2 under standard amide-bond forming conditions, for example using the HATU as the coupling reagent in the presence of diisopropyl ethylamine and DMAP. Intermediate 13-3 is then treated with a benzylamine, with heating, as described in the above schemes to produce 13-4.

Scheme XIII



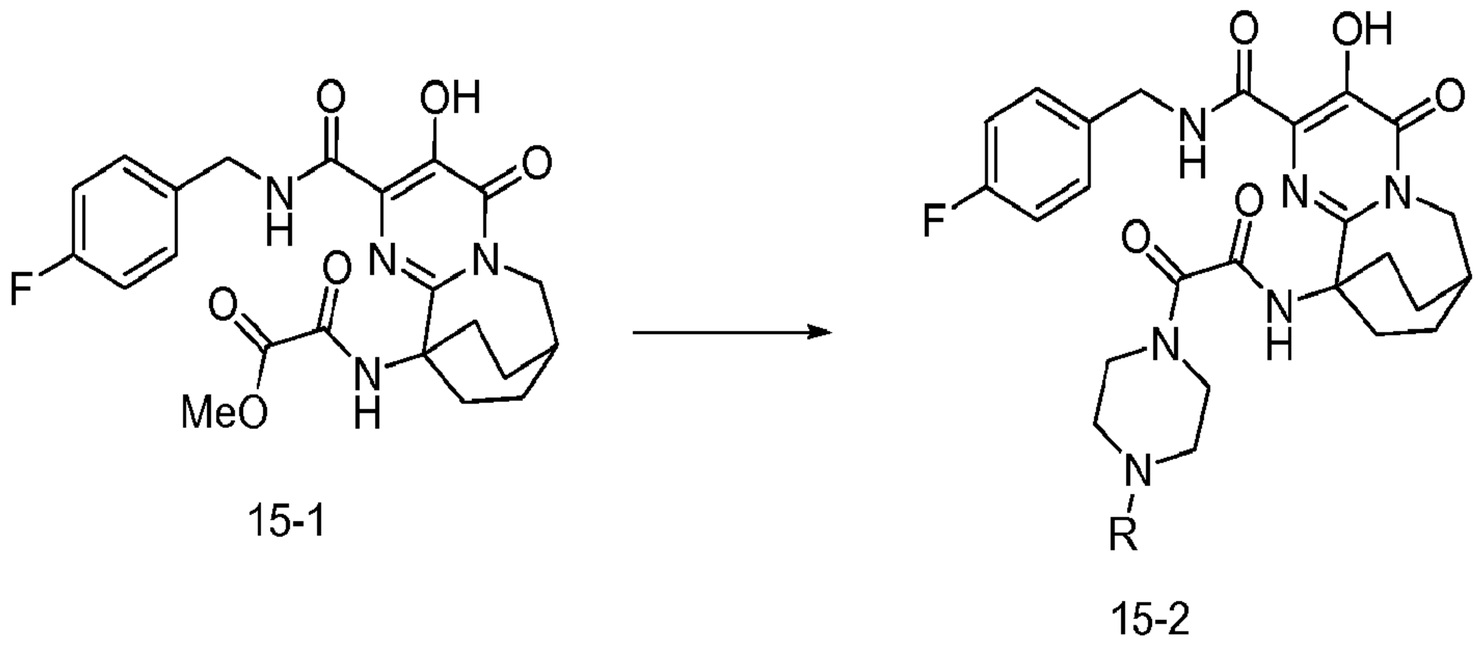
In the method shown in Scheme XIV, intermediate 9-10 is benzoylated by treating it with benzoic acid anhydride and pyridine to form intermediate 14-1. The Cbz protecting group can then be removed by hydrogenolysis to yield intermediate 14-2. Intermediate 14-2 can be coupled with acid 14-3 and the resulting product, 14-4 reacted with a substituted benzyl or substituted phenylpropylamine to provide 14-5.

Scheme XIV



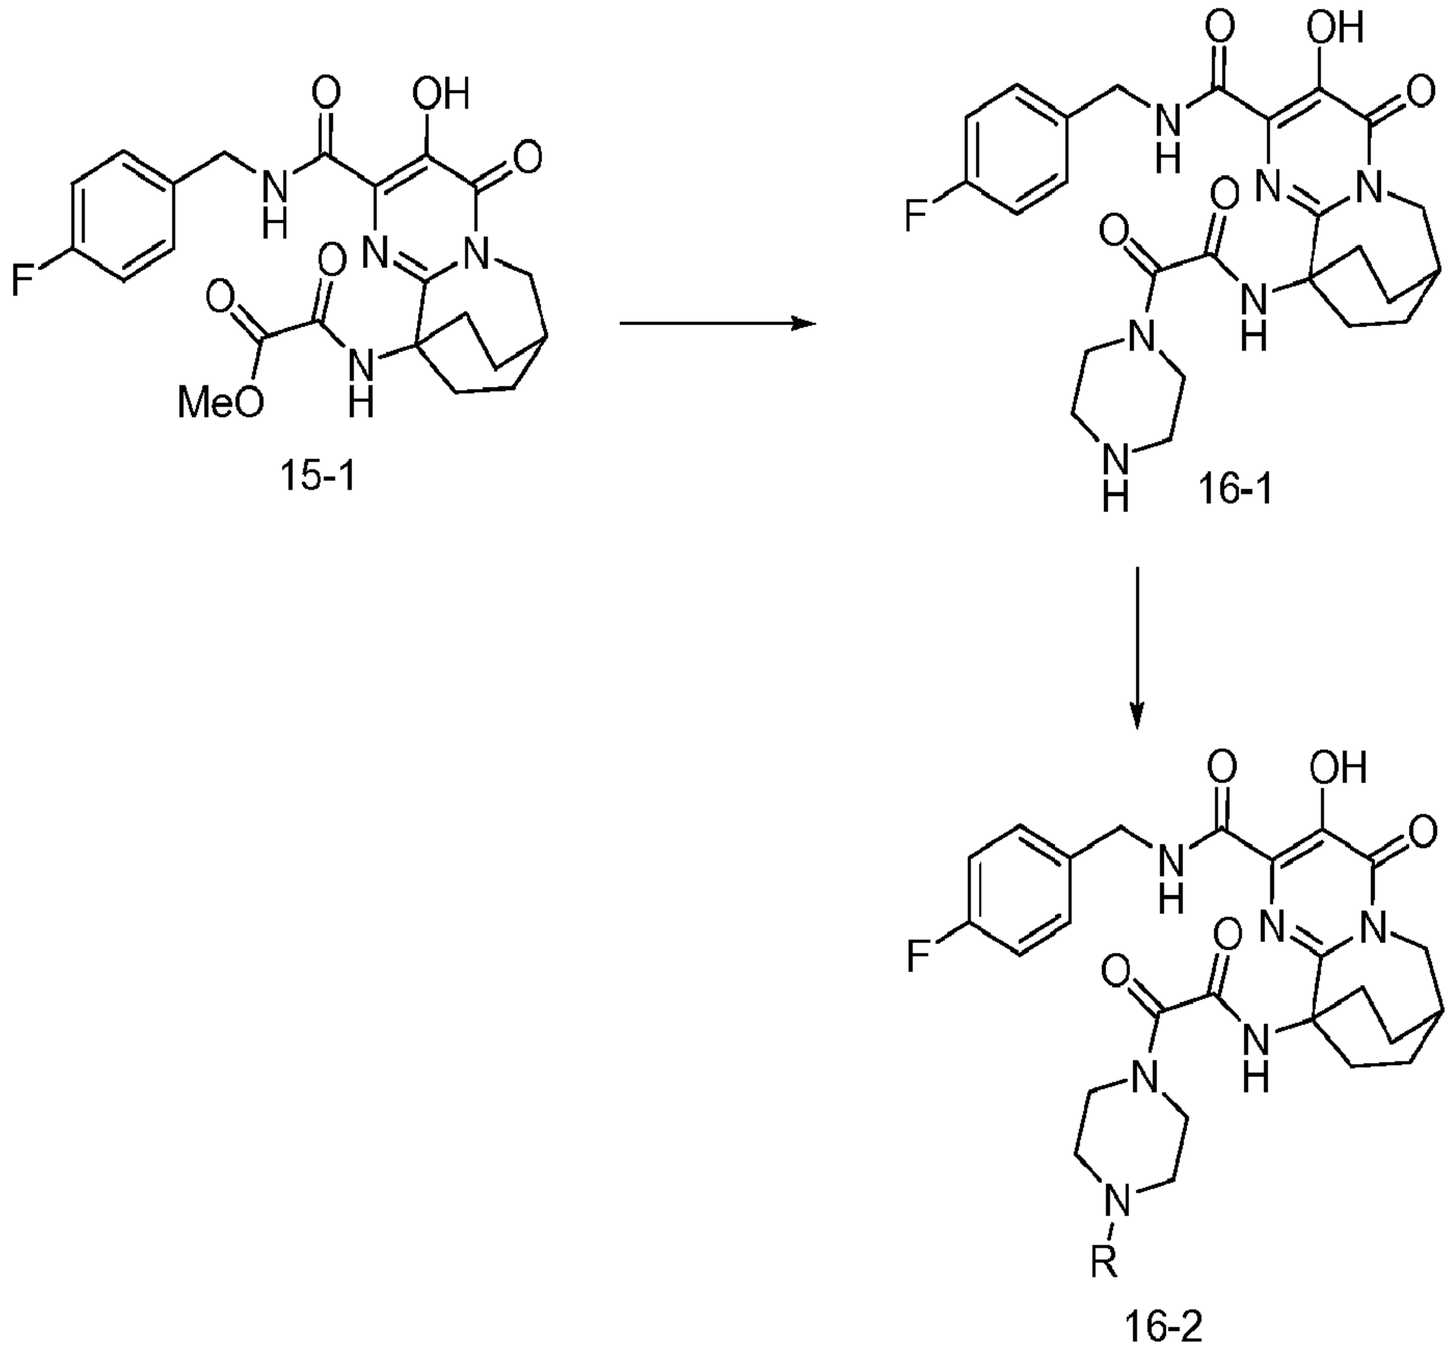
Scheme XV illustrates another method for the synthesis of compounds of this invention. Intermediate 15-1, prepared using methods similar to those described previously, is heated with a substituted piperazine to provide 15-2.

Scheme XV



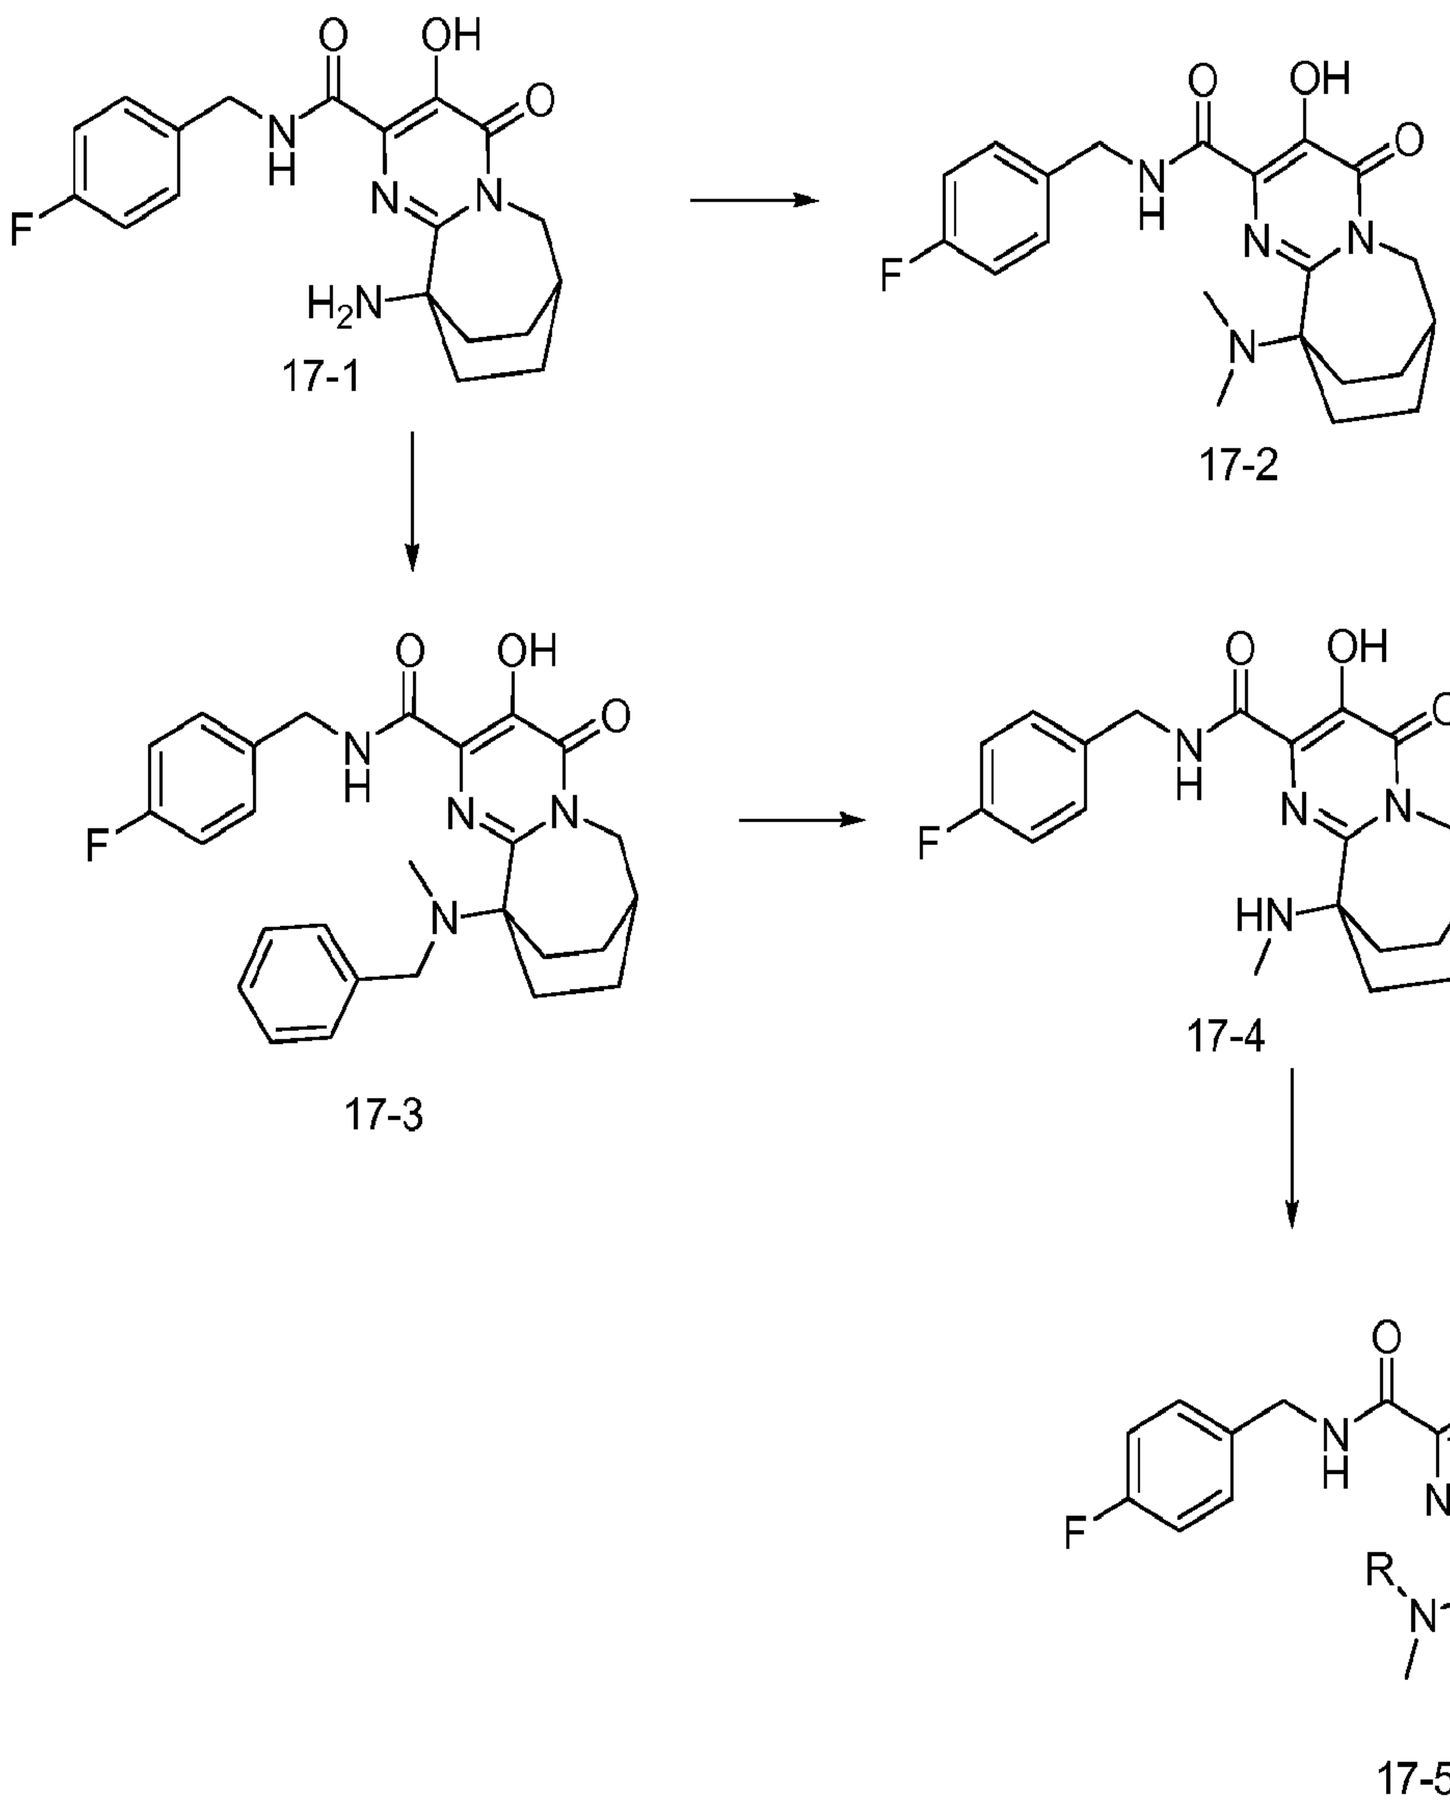
As shown in Scheme XVI, when 15-1 is reacted with piperazine as described in the previous scheme, intermediate 16-1 is produced. The unsubstituted nitrogen of the piperazine ring can be modified by the addition of R to form 16-2. R can be a substituted alkyl group, an acyl group, a sulfonyl group, a urea or related functionality.

Scheme XVI



As shown in Scheme XVII, the bridgehead nitrogen of intermediate 17-1 can be transformed into the corresponding dimethylated analogue, 17-2 via reductive amination, using for example formaldehyde and sodium triacetoxy borohydride. In a similar fashion intermediate 17-3 can be synthesized by sequential introduction of the benzyl group via reductive amination (benzaldehyde, $NaCNBH_3$) followed by introducing of the methyl group in the same way. The benzyl group is then cleaved under reductive conditions, H_2 and Pd/C, to provide 17-4. The nitrogen atom 17-4 can be modified using methods similar to those described above.

Scheme XVII



Additional methods for the synthesis of compounds of this invention are illustrated in Schemes XVIII and XIX.

Scheme XVIII

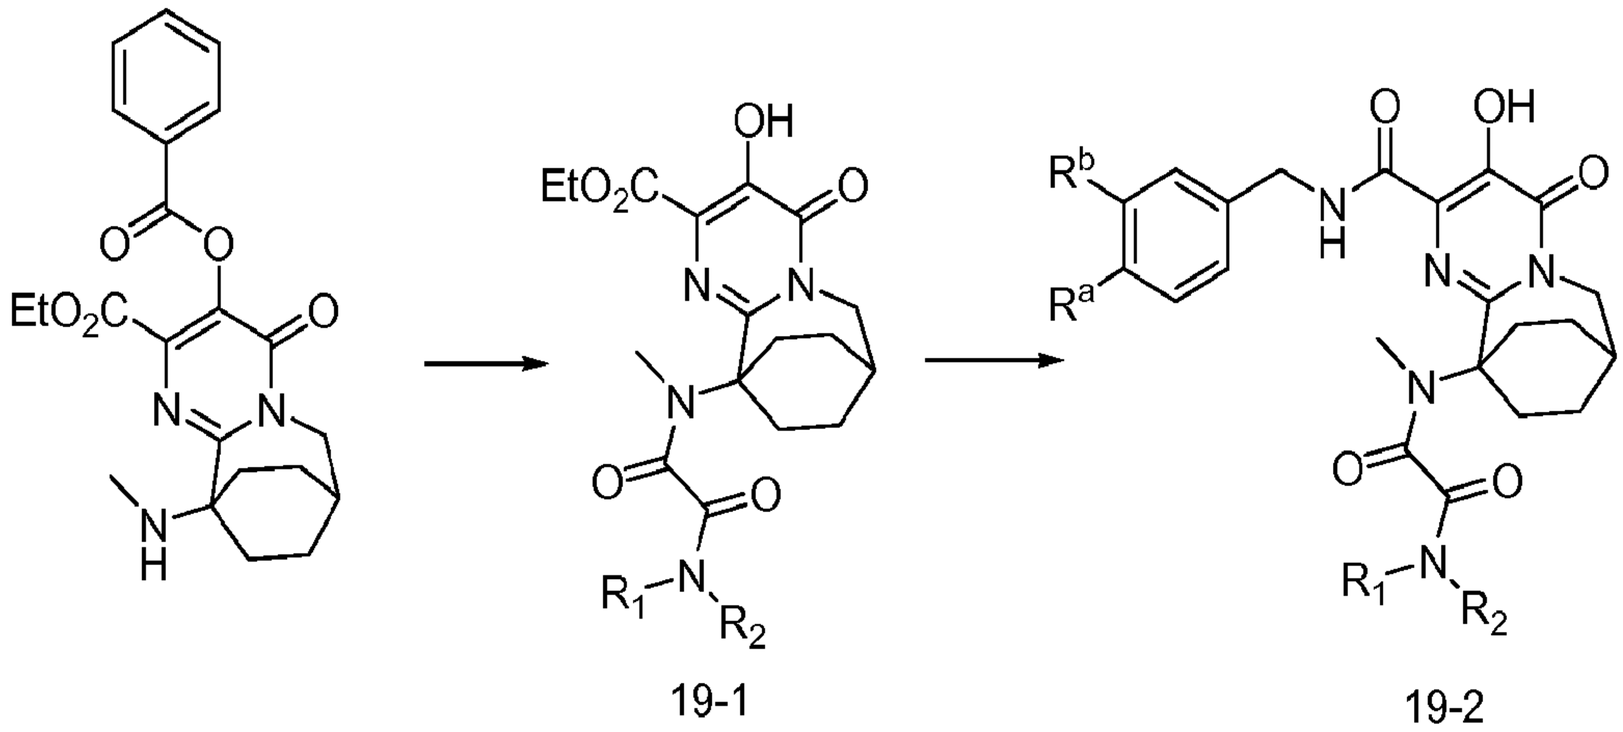
Scheme XIX



The method described in Scheme XX for the synthesis of intermediate 20-2 is similar to that described for intermediate 18-1 in Scheme XVIII except acetaldehyde is used in place of formaldehyde. The subsequent transformations rely on methods described above.

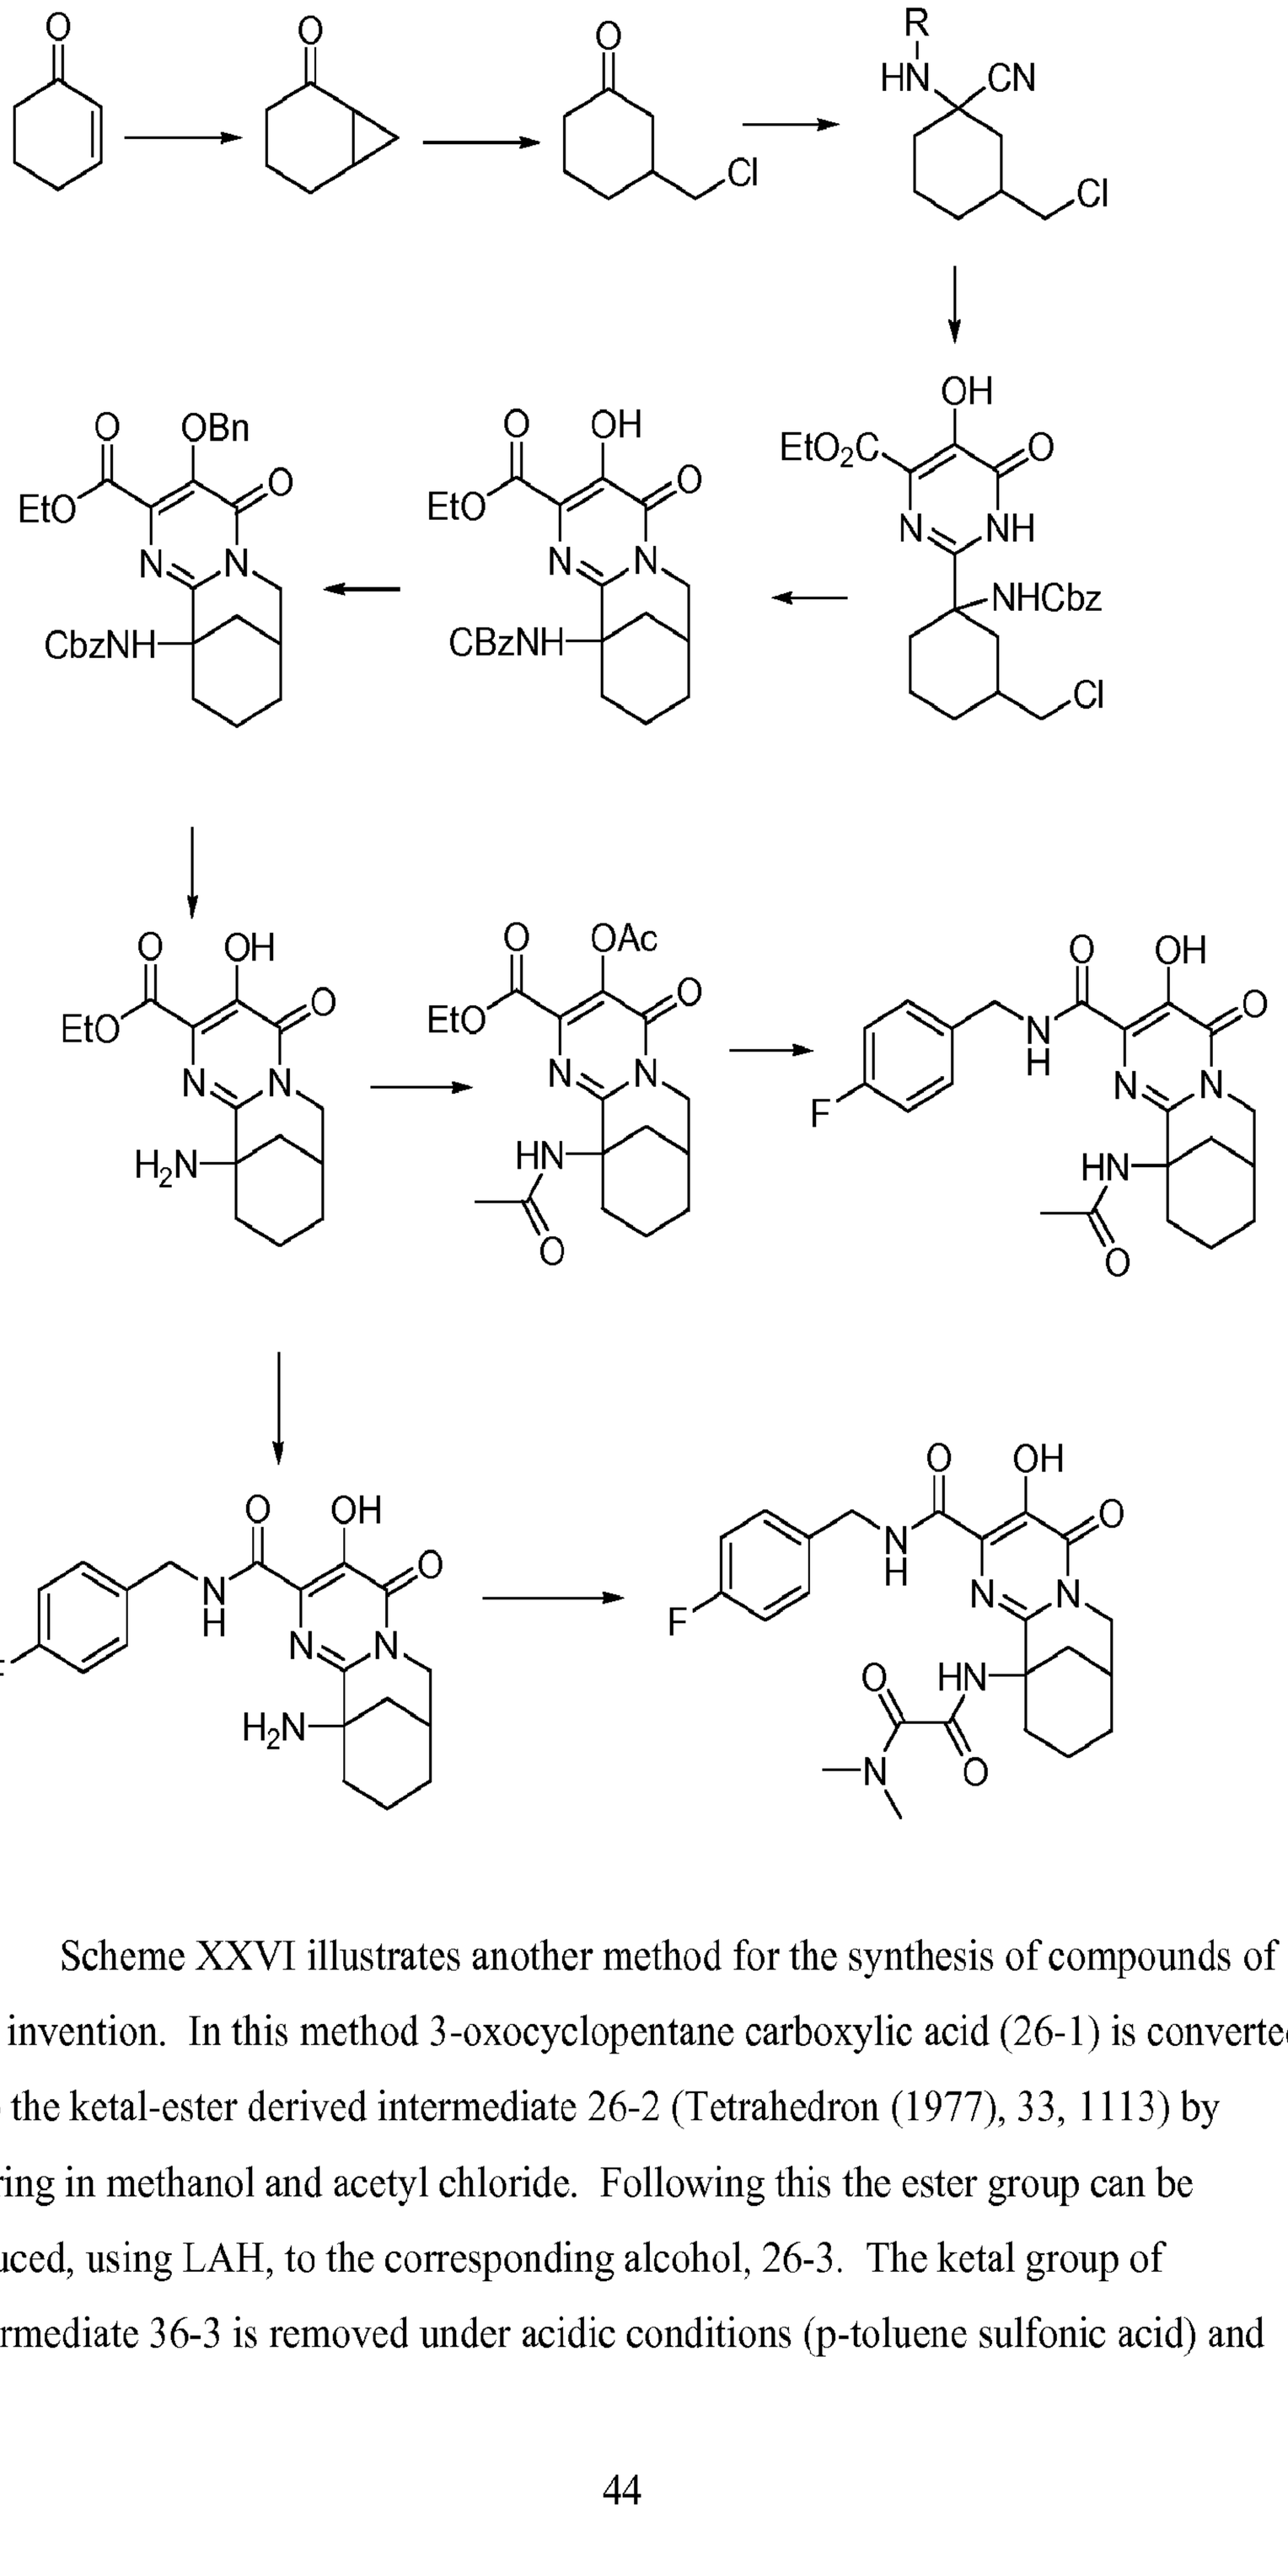
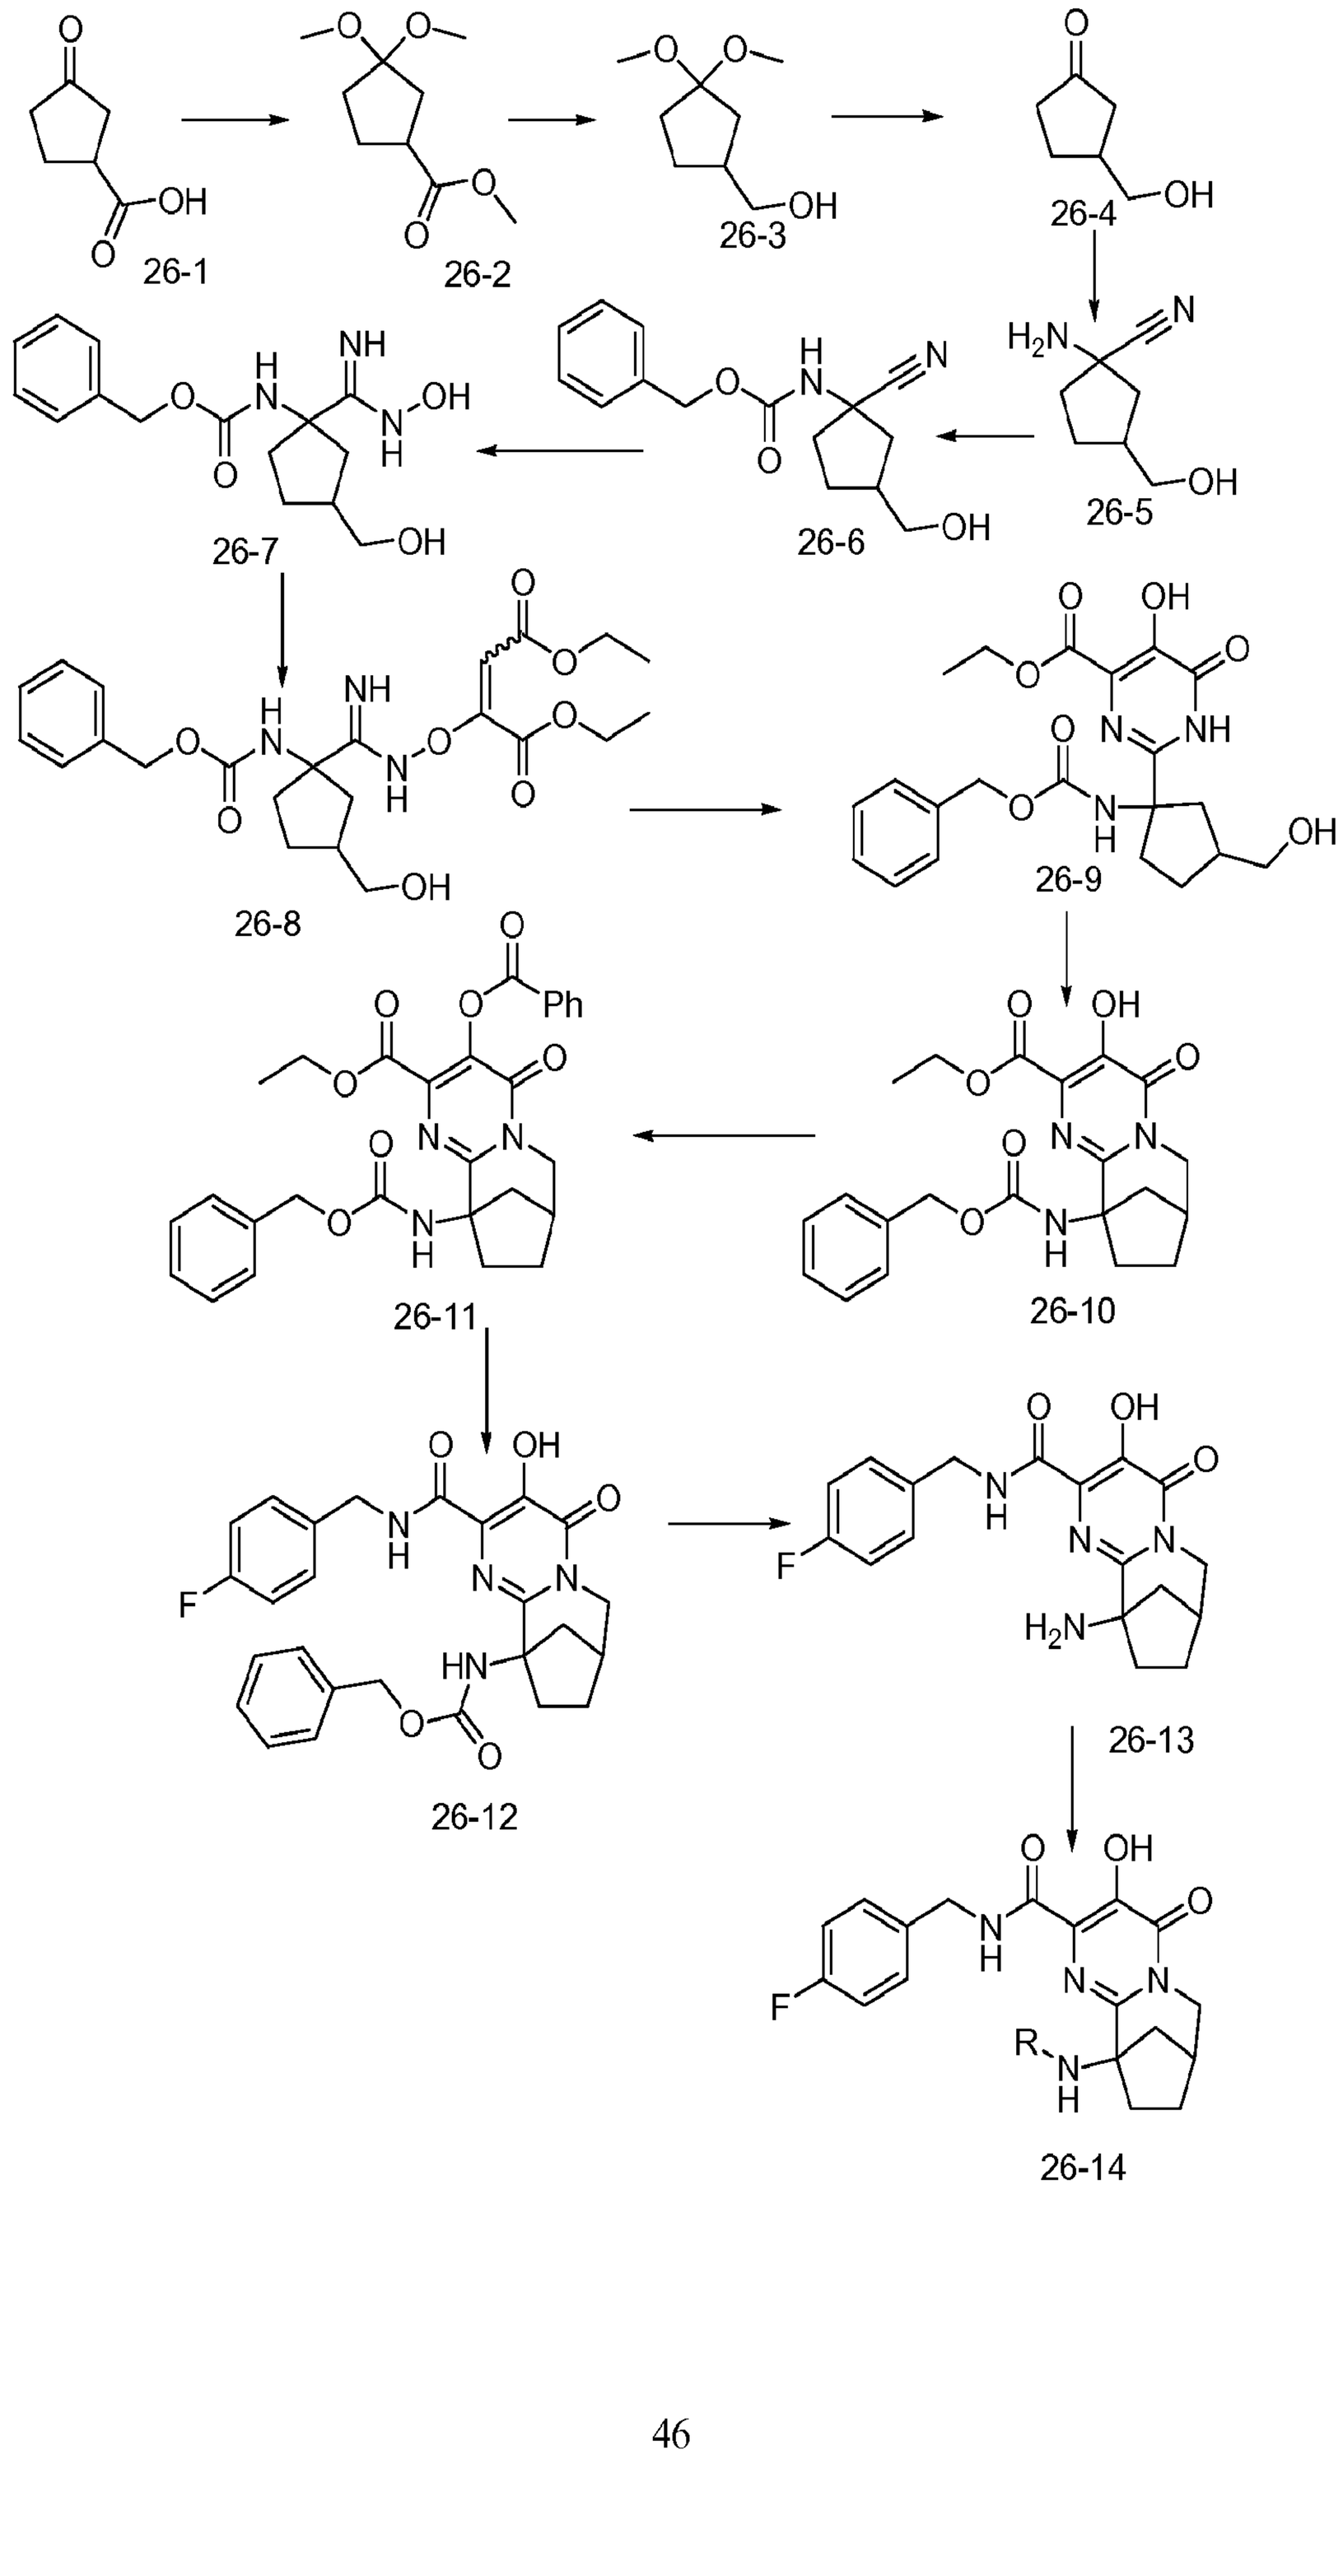
Scheme XXV



Scheme XXVI illustrates another method for the synthesis of compounds of this invention. In this method 3-oxocyclopentane carboxylic acid (26-1) is converted into the ketal-ester derived intermediate 26-2 (Tetrahedron (1977), 33, 1113) by stirring in methanol and acetyl chloride. Following this the ester group can be reduced, using LAH, to the corresponding alcohol, 26-3. The ketal group of intermediate 36-3 is removed under acidic conditions (p-toluene sulfonic acid) and

the 5-hydroxy-6-oxo-1,6-dihydropyrimidine-4-carboxylate derivative 26-9 synthesized using the same reaction sequence used in the previous schemes. Formation of the final ring can be carried out by first treating 26-9 with methane sulfonyl chloride and triethylamine followed by a second step involving treatment with potassium carbonate. The product of this sequence, 26-10 can be esterified to form 26-11 using benzoic acid anhydride. Further transformation of this intermediate using the methods described previously provides, 26-12, 26-13 and 26-14.

Scheme XXVI



A method for the synthesis of advanced intermediate 27-11 is shown in Scheme XXVII. Cyclopentenone, 27-1 can be converted to 27-2 (Tetrahedron Lett. 2005, 46, 6875-6878) by the nucleophilic addition of dimethylmalonate using 2,3,4,6,7,8-hexahydro-1H-pyrimido[1,2-a]pyrimidine as a base. Those skilled in the art will recognize this synthetic transformation as a Michael reaction which can be carried out under a number of different conditions in addition to those shown here as illustrated in; E. D. Bergmann et al., Org. React. 10, 179-555 (1959); H. O. House, Modern Synthetic Reactions (W. A. Benjamin, Menlo Park, California, 2nd ed., 1972) pp 595-623; M. E. Jung, Comp. Org. Syn. 4, 1-67 (1991). In the next step, a methylcarboxylate group of 27-2 is removed at elevated temperature in the presence of dimethyl 2-(3-oxocyclopentyl)malonate to yield intermediate 27-3. This intermediate is then converted to the corresponding dimethyl ketal and the methylcarboxylate group reduced to the corresponding alcohol using $LiBH_4$ to provide 27-5 (J. Org. Chem., 1986, 51 (21), 4000-4005). The ketal group is then hydrolyzed, yielding 27-6, then the pyrimidinone derivative, 27-10, synthesized in the same manner as that described in the above schemes wherein after formation of the amino nitrile, under Strecker reaction conditions, the amino group is protected with Cbz and the nitrile treated with hydroxylamine then diethyl but-2-ynedioate. The bridged bicyclic portion of 27-11 can be formed by treating intermediate 27-10 with methane sulfonyl chloride/triethylamine followed by treatment with a base such as K_2CO_3. Compound 27-11 can serve as an advanced intermediate for the synthesis of compounds of this invention as illustrated in Scheme XVIII.

Biological Methods

HIV-Integrase Inhibition Activity. To evaluate *in-vitro* activity against HIV-integrase, 5 pmole of biotin labeled substrate DNA was bound to 100 μg of Streptavidin coated PVT SPA beads (Amersham Pharmacia Biotech). Recombinant integrase (0.26 ng) was incubated with the beads for 90 min at 37 °C. Unbound enzyme was removed by washing the complex followed by addition of inhibitors and 0.1 fmol of P33 labeled target DNA. The reaction was stopped by adding EDTA to a

final concentration of 10 mM. Samples were counted in TopCountNXT (Packard) and the CPM was used as a measure of integration. The reaction condition was as described in A. Engelman and R. Craigie , *J. Virol.* 69, 5908-5911 (1995). The sequences of substrate and target DNA were described in *Nucleic Acid Research* 22,1121-1122 (1994). Results are shown in the Table 1. Activity equal to A refers to a compound having IC_{50} = < 10 nM while B and C denote compounds having IC_{50} = < 10 nM and IC_{50} < 100 nM and IC_{50} >100nM respectively.

Inhibition of HIV replication. A recombinant NL-Rluc virus was constructed in which a section of the nef gene from NL4-3 was replaced with the *Renilla* Luciferase gene. The NL-RLuc virus was prepared by co-transfection of two plasmids, pNLRLuc and pVSVenv. The pNLRLuc contains the NL-Rluc DNA cloned into pUC18 at the *Pvu*II site, while the pVSVenv contains the gene for VSV G protein linked to an LTR promoter. Transfections were performed at a 1:3 ratio of pNLRLuc to pVSVenv on 293T cells using the LipofectAMINE PLUS kit from Invitrogen (Carlsbad, CA) according to manufactures instruction, and the pseudotype virus generated was titered in MT-2 cells.

Susceptibility of viruses to compounds was determined by incubation in the presence of serial dilutions of the compound. The 50% effective concentration (EC_{50}) was calculated by using the exponential form of the median effect equation where (Fa) = $1/[1+ (ED_{50}/\text{drug conc.})^m]$ (Johnson VA, Byington RT. Infectivity Assay. In *Techniques in HIV Research*. ed. Aldovini A, Walker BD. 71-76. New York: Stockton Press.1990). The anti-viral activity of compounds was evaluated under three serum conditions, 10% FBS, 15mg/ml human serum albumin/10% FBS or 40% human serum/5% FBS, and the results from at least 2 experiments were used to calculate the EC_{50} values. Results are shown in the Table 2. Activity equal to A refers to a compound having $IC_{50} = < 10$ nM while B and C denote compounds having $IC_{50} = < 10$ nM and $IC_{50} < 100$ nM and $IC_{50} > 100$nM respectively.

"Combination," "coadministration," "concurrent," and similar terms referring to the administration of a compound of Formula I with at least one anti-HIV agent mean that the components are part of a combination antiretroviral therapy or highly

active antiretroviral therapy (HAART) as understood by practitioners in the field of AIDS and HIV infection.

"Therapeutically effective" means the amount of agent required to provide a meaningful patient benefit as understood by practitioners in the field of AIDS and HIV infection. In general, the goals of treatment are suppression of viral load, restoration and preservation of immunologic function, improved quality of life, and reduction of HIV-related morbidity and mortality.

"Patient" means a person infected with the HIV virus and suitable for therapy as understood by practitioners in the field of AIDS and HIV infection.

"Treatment," "therapy," "regimen," "HIV infection," "ARC," "AIDS" and related terms are used as understood by practitioners in the field of AIDS and HIV infection.

The compounds of this invention are generally given as pharmaceutical compositions comprised of a therapeutically effective amount of a compound of Formula I or its pharmaceutically acceptable salt and a pharmaceutically acceptable carrier and may contain conventional excipients. A therapeutically effective amount is that which is needed to provide a meaningful patient benefit. Pharmaceutically acceptable carriers are those conventionally known carriers having acceptable safety profiles. Compositions encompass all common solid and liquid forms including capsules, tablets, losenges, and powders as well as liquid suspensions, syrups, elixers, and solutions. Compositions are made using common formulation techniques, and conventional excipients (such as binding and wetting agents) and vehicles (such as water and alcohols) are generally used for compositions.

Solid compositions are normally formulated in dosage units and compositions providing from about 1 to 1000 mg of the active ingredient per dose are preferred. Some examples of dosages are 1 mg, 10 mg, 100 mg, 250 mg, 500 mg, and 1000 mg. Generally, other antiretroviral agents will be present in a unit range similar to agents of that class used clinically. Typically, this is 0.25-1000 mg/unit.

Liquid compositions are usually in dosage unit ranges. Generally, the liquid composition will be in a unit dosage range of 1-100 mg/mL. Some examples of dosages are 1 mg/mL, 10 mg/mL, 25 mg/mL, 50 mg/mL, and 100 mg/mL. Generally, other antiretroviral agents will be present in a unit range similar to agents of that class used clinically. Typically, this is 1-100 mg/mL.

The invention encompasses all conventional modes of administration; oral and parenteral methods are preferred. Generally, the dosing regimen will be similar to other antiretroviral agents used clinically. Typically, the daily dose will be 1-100 mg/kg body weight daily. Generally, more compound is required orally and less parenterally. The specific dosing regime, however, will be determined by a physician using sound medical judgement.

The invention also encompasses methods where the compound is given in combination therapy. That is, the compound can be used in conjunction with, but separately from, other agents useful in treating AIDS and HIV infection. Some of these agents include HIV attachment inhibitors, CCR5 inhibitors, CXCR4 inhibitors, HIV cell fusion inhibitors, HIV integrase inhibitors, HIV nucleoside reverse transcriptase inhibitors, HIV non-nucleoside reverse transcriptase inhibitors, HIV protease inhibitors, budding and maturation inhibitors, immunomodulators, and anti-infectives. In these combination methods, the compound of Formula I will generally be given in a daily dose of 1-100 mg/kg body weight daily in conjunction with other agents. The other agents generally will be given in the amounts used therapeutically. The specific dosing regime, however, will be determined by a physician using sound medical judgement.

Table 4 lists some agents useful in treating AIDS and HIV infection which are suitable for this invention.

Bicycle[4.1.0]heptan-2-one. The title compound was prepared by following the procedure described in O.O. Grygorenko et al., *Tetrahedron: Asymmetry*, **2006**,

17, 252. In a dry round bottom flask, 60% (in mineral oil) NaH (4.49 g, 112 mmol) was triturated with hexanes three times, and placed under high vacuum to further dry. To DMSO (100 mL) in an oven-dried three neck flask under nitrogen was added the concentrated NaH in small portions. The temperature was kept between 15-25°C. Once gas evolution had subsided, trimethylsulfoxonium iodide (24.73 g, 112 mmol) was added via a powder addition funnel in small portions keeping the temperature between 15-25°C. The suspension was allowed to stir for 2 h during which time it became a milky solution. Cyclohex-2-enone (10 g, 104 mmol) in DMSO (25 mL) was then slowly added drop-wise. The solution became red and was stirred for 0.5 h at room temperature and 2 h at 50°C. It was then poured into 100 mL of ice water. The water was extracted with Et_2O (4 x 100 mL). The ether extracts were combined, dried ($MgSO_4$) and concentrated under reduced pressure. The resulting red oil was purified by distillation. Fractions distilling ate 65 and 70°C were collected. Ethanediamide, N'-[2-[[[(4-fluorophenyl)methyl]amino]carbonyl]-6,7,8,9-tetrahydro-4-oxo-3-(phenylmethoxy)-7,10-methanopyrimido[1,2-a]azepin-10(4H)-yl]-N,N-dimethyl-. A solution of ethanediamide, N'-[2-[[[(4-fluorophenyl)methyl]amino]carbonyl]-6,7,8,9-tetrahydro-3-hydroxy-4-oxo-7,10-methanopyrimido[1,2-a]azepin-10(4H)-yl]-N,N-dimethyl (0.160 g, 0.350 mmol) in dry DMF (5 mL) was treated with benzyl bromide (0.050 mL, 0.420 mmol) and potassium carbonate (0.276 g, 2 mmol) and stirred with heating (60°C oil bath) overnight. The solvent was removed under reduced pressure and the residue was dissolved in EtOAc (20 mL) and washed with 1.0 N HCl (2 x 20 mL). The organic layer was dried ($MgSO_4$), filtered, and concentrated under reduced pressure to give the crude product as a light brown oil, which partially solidified upon standing. The solid was triturated with Et_2O several times then loaded onto a Biotage 25+M samplet and purified with Biotage flash chromatography system, eluting with a solvent gradient of 40% to 100% hexanes in EtOAc. The individual diastereomers of this compound were separated by chiral SFC chromatography (5 micron 30 x 250 mm Chiralcel OD-H column eluting with 70% CO_2 30% MeOH and 0.1% diethylamine at 35 °C and 150 Bar). Two separately eluting compounds were isolated, a faster eluting compound (isomer A) and a slower eluting compound (isomer B).
