ABSTRACT

A method and apparatus for providing prepaid local telephone services is provided. The method includes determining if a subscriber is making a qualified local telephone call, checking to see if a maximum number of calls have been made by the subscriber and decrementing a call counter if a call in connected. The system includes a switch for receiving telephone calls and identifying subscribers and qualified telephone calls. In addition, the system includes a telephone network element in communication with the switch, the telephone network element having logic for identifying local telephone calls, a notification timer configured to remove the telephone network element from a telephone call after a predetermined period of time, and a call counter for monitoring a number of local calls permitted to a subscriber.

METHOD AND APPARATUS FOR PROVIDING PREPAID LOCAL TELEPHONE SERVICES IN METERED STATES

CROSS REFERENCE TO RELATED APPLICATIONS

[0001] This application is a continuation-in-part of co-pending U.S. application Ser. No. 09/417,266, filed Oct. 12, 1999, the entirety of which is incorporated by reference herein.

BACKGROUND

[0002] Subscribers of local telephone services often sign up for telephone services that are billed out on a monthly basis. Occasionally, some subscribers who are financially capable of paying their bills have difficulty making timely payments for their local telephone services. These late payments result in late payment penalties for the subscriber and added costs to the telephone service provider. In extreme cases, the subscriber's delinquency can adversely affect her credit rating. In an attempt to solve this problem, several types of prepaid telephone services are available that allow for a subscriber to prepay for services.

[0003] One existing type of system treats prepaid local telephone services (hereinafter “prepaid dialtone”) in the same manner as a conventional long distance prepaid card service. The local exchange carrier (LEC) and/or interexchange carrier (IXC) for a particular subscriber will forward all calls to a dedicated prepaid dialtone switch that will determine if the caller has a credit balance in her account. If the prepaid dialtone switch determines that the call can go through, it then routes the call to the local end office and maintains an active connection to the call so that the prepaid dialtone switch may monitor the call and update its database after the call. A disadvantage of this form of prepaid dialtone is that the telephone network needs to maintain a continuous connection to the database monitoring the prepaid subscriber so that the time of the call is monitored and the charges will be debited on, for instance, a per second basis.

[0004] Another version of a prepaid dialtone system utilizes a separate billing service that generates monthly statements and posts deposits received. This system acts to accept prepayment of services but does not adequately address the problem of late payments because there is no mechanism for automatically limiting a subscriber’s usage or automatically shutting off the subscriber’s service at the end of the prepaid service period.

[0005] Accordingly, there is a need for an improved system and method of implementing prepaid dialtone services.

BRIEF DESCRIPTION OF THE DRAWINGS

[0006] FIG. 1 illustrates a prepaid local telephone service application system according to a preferred embodiment;

[0007] FIG. 2 illustrates a prepaid dialtone database for use in the system of FIG. 1;

[0008] FIG. 3 illustrates an advanced intelligent network structure in a local exchange carrier configured to cooperate with the system of FIG. 1;

[0009] FIG. 4 is a flow diagram of a method of implementing prepaid dialtone services with the system of FIG. 1;

[0010] FIG. 5 is a flow diagram of a method of renewing a prepaid dialtone account according to a preferred embodiment;

[0011] FIG. 6 is a call flow diagram according to a presently preferred embodiment; and

[0012] FIGS. 7A-7C are a flow chart illustrating the call processing logic used to provide prepaid dialtone services in metered call states according to a presently preferred embodiment.

DETAILED DESCRIPTION OF THE PRESENTLY PREFERRED EMBODIMENTS

[0013] The present invention provides for an efficient and configurable system and method for implementing and monitoring prepaid dialtone services that avoids the billing difficulties and telephone network resource usage of existing versions of prepaid dialtone services. FIG. 1 illustrates a telecommunications system 10 according to a preferred embodiment. The system preferably includes at least one subscriber at a subscriber telephone 12 in communication with a prepaid local telephone service center 14 via a service provider network, often referred to as a local exchange carrier (LEC) 17, that is part of the public switched telephone network (PSTN) 16. The subscriber telephone 12 may communicate directly with the prepaid local telephone service customer service center 14 directly or via a voice recognition unit (VRU) 18. The subscriber telephone may be a plain old telephone system (POTS) telephone in communication with a standard subscriber line that provides telephone service to the subscriber’s fixed address. As set forth in more detail below, each LEC 17 preferably has advanced intelligent network (AIN) capabilities. The VRU 18 may be any of a number of commonly available VRU’s, such as those available from Dialogic Communications Corporation of Franklin, Tenn., that offer voice and touch tone recognition and response abilities. Preferably, the VRU will be configured to query callers of the service center 14 for information and provide automated account information.

[0014] The service center 14 includes at least one customer service agent 20 for receiving initial prepaid dialtone service requests and general customer service questions. Each customer service agent 20 receives a call from a subscriber after the subscriber has been screened by the VRU 18 to determine the subscriber’s needs. Alternatively, the subscriber may access the customer service center without going through the VRU. The service center is in communication with an application server 22, such as those commonly available from IBM Corporation, containing a prepaid dialtone database 24, a processor 26 and a memory 28. Preferably the processor 26 of the applications server 22 monitors the status of the various subscriber records and manages communications with the telephone network 16 and other resources. In one embodiment, the customer service center 14, VRU 18 and application server 22 may communicate through a hub 29. A provisioning network 31 receives account activation and subsequent account status information generated by the customer service center 14 or applications server 22, via hub 29, when a prepaid dialtone subscriber establishes an account or when the account status changes. The provisioning information generated by the customer service center 14 or application server 22 may reach the LEC 17 for the subscriber through any of a number
of provisioning channels that the particular LEC already uses when provisioning services.

[0015] As shown in FIG. 2, the prepaid dialtone database 24 includes a record 30 for each subscriber to the prepaid dialtone service. Each record 30 preferably contains fields for subscriber identification 32 and history 34, the applicable service plan 36, the rate plan 38 (e.g., the cost for the service period associated with the service plan), the service dates 40, and account status 42. The subscriber identification field 32 may include information such as subscriber name, telephone number, address and a unique subscriber ID. The subscriber history field 34 may include two types of information: customer service notes and transaction records. The customer service notes may contain information entered by customer service agents 20 who have previously spoken with the subscriber. The transaction records are a log of service activations and renewals that are automatically generated when a subscriber initiates or renews the prepaid dialtone service. Transaction records may include previous activation dates, times and dollar amounts, as well as the value identification number (VIN) 13 of the prepaid dialtone service card 11 (see FIG. 1) used and the telephone number from which the activation/renewal call was made.

[0016] The account status field 42 reflects whether a prepaid dialtone subscriber account is active or on hold. The service plan field 36 of the subscriber record 30 contains a product code representative of the specific version of prepaid dialtone service applicable to the subscriber. The service dates field 40 stores the start and end dates of the present period for which the prepaid dialtone service is active.

[0017] As shown in FIG. 3, a suitable LEC 17 may be an advanced intelligent network (AIN) capable network. The network may include one or more service switching points (SSP) 44 in communication with one or more service control points (SCP) 46 via one or more service transfer points (STP) 48. A subscriber telephone 12 preferably is in communication with an SSP 44 over a voice channel.

[0018] The SSP 44 is a programmable switch having the ability to recognize AIN triggers for calls requiring special services. The SSP 44 may be an end office or tandem switch and communicates with a SCP 46. The subscriber telephone 12 communicates with the SSP 44 over a voice/legend channel such as an ordinary telephone line. Multiple connections and combinations of network elements are usable with the present invention. For example, a subscriber on a subscriber telephone 12 may also communicate with a SSP 44 through one or more ordinary switches. In one preferred embodiment, the SSP is configured to receive and store line class codes from the LEC provisioning system 31 (FIG. 1) representative of the version of prepaid dialtone service offered by the particular LEC. The line class code is associated with a particular subscribers telephone number and instructs the SSP to, for example, verify that calls from the subscriber are of the type permitted under the subscribed prepaid dialtone services.

[0019] The service control point (SCP) 46 is a network element containing logic and data necessary to provide functionality required for the operation of a desired communication service. A SCP 46 generally permits separation of service logic from switching functionality such that additional services may be developed without the need to provision significant software in each individual SSP. A suitable SCP 46 is the Advantage SCP manufactured by Lucent Technologies. In a preferred embodiment, the SCP 46 contains service logic for prepaid dialtone services and is also configured to receive a set of records of subscriber names, their telephone numbers and the service time limit at provisioning. This subscriber information originates in the service center 14 and the records are stored in the application server 22 and the memory 50 in the SCP 46. The memory 50 may be integral with the SCP or may be a separate memory device accessible by the SCP 46. In one preferred embodiment, wherein a prepaid dialtone service is implemented in a metered call state (as defined below), the SCPs 46 in metered state LECs 17 also may include a call counter 51 for each prepaid dialtone subscriber in the SCP memory 50 as well as a notification timer 53 useful in the process of counting the number of prepaid calls for prepaid dialtone subscribers in metered states. The notification timer may be implemented using commonly available programming available on the SCP.

[0020] The SCP 46 communicates with SSPS 44 over a data channel via at least one service transfer point (STP) 48. A suitable data signal intended for use with the STPs is the American National Standards Institute (ANSI) signaling system No. 7 (SS7). A suitable SCP/SSP communication protocol is the AIN 0.1 SCP/SSP protocol set forth in Bellcore Technical Reference TR-NWT-001285, entitled AIN Switch-Service Control Point Application Protocol Interface Generic Requirements, Issue 1, Aug. 1992. Other configurations of AIN capable networks may be used to implement a preferred method and system for providing prepaid dialtone services. Additionally, multiple service provider networks, also referred to herein as local exchange carriers (LECs) 17, may access the services of the prepaid dialtone provisioning system 10 so that the prepaid dialtone provisioning system will monitor and maintain all subscriber account records for each of the LECs 17.

[0021] In one embodiment, the SSP 44 may be configured to recognize an off-hook delay trigger from a subscriber line when a subscriber picks up the telephone and dials a number. If the subscriber is a prepaid dialtone subscriber, the SSP preferably contains a line class code associated with the subscriber’s telephone number. The line class code for prepaid dialtone subscribers contains instructions for the SSP to verify that the telephone number dialed by the subscriber is a non-toll intra-LATA (Local Access and Transport Area), toll-free, or 911 call. If the SSP determines that the number does not fall within the allowable category of calls, the call is not connected. Instead, the off-hook delay trigger is escaped and the call is terminated to treatment in the SSP. If the call made by the prepaid dialtone subscriber is an allowable call, the SSP communicates with the SCP and the SCP verifies that the prepaid dialtone account for the subscriber is valid. If the account is still valid, the SCP instructs the SSP to connect the call.

[0022] Referring now to FIG. 4, a method of implementing prepaid dialtone service is described below with relation to the system shown in FIGS. 1-3. When a subscriber 12 desires to participate in the prepaid dialtone service, the subscriber must first purchase a prepaid dialtone card 11. The cards may be purchased from designated retail establishments. The cards will each have a unique value identification number (VIN) that associates a fixed value to a
particular card in a prepaid telephone card database. Once a card 11 has been purchased, the customer service center 14 and the VRU 18 will serve as the primary interface for providing the service to the subscriber 12. Although a card having a unique VIN is described herein, a card is not necessary. The VIN may be printed on other items, or may be verbally provided to a subscriber upon purchase, in other embodiments.

[0023] To initiate service after purchasing a card 11, the subscriber 12 will call into the service center 14 to initiate service. In one embodiment, all calls to the service center first arrive at a VRU that screens the call and offers a menu of touchtone response options to direct the call to an appropriate location. In other embodiments, calls to the service center may arrive directly at the service center 14. The service center 14 may be a live operator who, in real time, assists the caller. In another embodiment, the service center may be an Internet-based service center capable of accepting and processing service requests. The subscriber 12 will provide the customer service agent 20 with information such as the address for the service and the VIN number 13 of the card 11. After verifying the address information and verifying that the VIN number 13 is valid, the customer service agent 20 will provide the subscriber with a telephone number and installation date for the service.

[0024] The customer service agent will communicate with the applications server 22 to initiate a service order that may be processed through a standard automated provisioning system in communication with the LEC 17 for the subscriber 12. Preferably the interface used for provisioning the prepaid dialtone service is an interface such as a standard electronic data interface (EDI) or other type of interface which is capable of connecting to customized interfaces used by the specific LECs of the subscribers to the prepaid dialtone service. After receiving a new prepaid dialtone service request, the service order is entered on the prepaid dialtone database and a provisioning request will be sent to provisioning system 31 and, in a preferred embodiment, results in all the necessary Universal Service Order Codes (USOCs), line class code orders, and field identifiers (FIDs) for the requested version of prepaid dialtone being delivered to the LEC. The USOC is preferably a package USOC that defines a set of individual feature USOCs (e.g., call waiting, voicemail, etc.). Thus, the package USOC represents to the LEC the general type of service order and all the individual features packaged into the service order. In another embodiment, individual feature USOCs may be used in an unbundled form to provide the service order. Line class codes refer to a switch based translator for a particular service that decides which call features are allowed and FIDs refer to codes in a service order that are related to particular services or features.

[0025] In a preferred embodiment, the LEC 17 may implement the prepaid dialtone service in one of two ways depending on the state rules for handling local telephone calls. In states such as Ohio and Indiana where there is no metered service for local calls, the LEC may implement the prepaid dialtone service for a particular subscriber by storing a line class code associated with the subscriber and the prepaid dialtone service in the SCP. In a preferred embodiment, the SCP does not interact with the SSP and the SSP handles all prepaid dialtone calls. In another embodiment, the LEC of states with no metered service for local calls may provide the appropriate SCP with the subscriber's telephone number and an account status indicator (e.g., a variable indicating whether the subscriber account is current or expired) to a memory 50 (see FIG. 3) associated with, or in communication with, an SCP 46 so that the SCP may control whether the SSP may continue connecting local telephone calls for the subscriber. With this network implementation of the prepaid dialtone service, the SSP 44 and SCP 46 cooperate to make sure the subscriber's prepaid dialtone account is current and that the call made by the subscriber is a local call. In either embodiment, the LEC does not continuously meter the call, debit a monetary amount associated with a call, or put a limit on the time of any local calls. Other network implementations, such as an AIN network where the SCP performs both the tasks of identifying local calls and account status, are also contemplated.

[0026] In states where the local telephone services are metered, for example in Illinois, Wisconsin or Michigan, the LEC 17 will again preferably provide the SSP with a line class code associated with the subscriber's telephone number that will cause the SSP to permit local calls. In metered states, however, the prepaid telephone services are implemented in the SCP by providing the SCP 46 with the subscriber's telephone number, a day counter and a call counter to provide a fixed number of local telephone calls to a subscriber for a given service period. The number of calls allowed may be set at a number greater than the average number of calls subscribers make in a given time period to allow for normal calling habits. For example, assuming that 270 calls per month is the average number of calls, the SCP may be programmed to allow 400 calls in a thirty day period for prepaid dialtone subscribers. As with LECs in the non-metered states, the SCP and SSP do not continuously monitor prepaid telephone calls, do not associate a value/ rate with a call or debit a value from an account, and do not limit the length of local telephone calls. In the metered call states, however, the SCP will keep track of a set service period, decrement a call counter every time a local call is completed, and prohibit all calls after a predetermined number of calls have been completed in the service period.

[0027] In either situation, metered state or non-metered state, the SCP preferably does not communicate with the prepaid database. As shown in FIG. 4, the prepaid database 24 keeps track of the service period for each subscriber 12 and operates to automatically remind subscribers of service expiration due dates and automatically communicate service order changes to the LEC if a prepaid dialtone subscriber's account status has changed. As soon as an account is established (at 70), the prepaid subscriber database determines the service period end date for the subscriber (at 72). In one embodiment, a subscriber may renew for a fixed 30 day period. For new subscribers, the application server 22 will determine the date corresponding to 30 days from the service installation date and store that information in the service dates field 40 of the subscriber record 30 in the prepaid dialtone database 24. For renewing subscribers, the applications server will determine the date corresponding to thirty days from the end of the subscriber's current service period. For renewing subscribers who are renewing after the expiration of their previous service period, but before the expiration of the grace period (see below), the service period end date is calculated as 30 days from the date the subscriber's service becomes active. As with new subscribers, the service period dates are stored in the service dates field 40.
of the subscriber record 30. Although a service period of 30
days is specifically addressed her, any service period length
may be implemented as desired.

[0028] After determining the service period, the applica-
tions server 22 monitors the subscriber service periods by
scanning the prepaid dialtone database 24 on a daily basis (at
74). At a desired time before the expiration of a subscriber’s
service period, the applications server will send instructions
to a notification service to automatically notify the sub-
scriber that the service period will expire in a certain number
of days (at 76). In one embodiment, the automatic notifica-
tion may be in the form of a voice mail that supplies termi-
ation date information and is automatically generated and
delivered five days before the service period expires. In
another embodiment, the notification service may be an
automatic calling device that will telephone the subscriber
and play a prerecorded reminder message. In other embodi-
ments, an additional renewal reminder message may be
provided, other reminder periods may be implemented or the
subscriber may be given the option of selecting how far in
advance she wishes to be reminded to renew and/or
informed of a service termination date.

[0029] After notifying the subscriber, the applications
server continues to keep track of subscriber account status
and check on whether the subscriber has renewed (at 78). If
the subscriber has renewed, the process begins again with
the applications server calculating the new service period
and so on. If the service period expires and the subscriber
has not renewed in time, the applications server generates an
instruction directed to the subscriber’s LEC 17 to change the
subscriber account status (at 80). In a preferred embodi-
ment, the applications server allows the subscriber a grace period
in which to renew her account by instructing the LEC to put
the account on hold, such as a vacation-type hold or other
suspended accounts, for example where no dialtone
service is provided but where the telephone line is still
connected. In this manner, the prepaid dialtone subscriber
is given a period of time to renew the account without the
account being terminated and the subscriber having to pay a
fee for reconnecting the telephone service and receiving a
new telephone number in addition to renewing the prepaid
dialtone service. In another embodiment, the prepaid dial-
tone service may allow for emergency calls, such as a 911
call, during the grace period while blocking all other call
attempts.

[0030] The applications server will continue to monitor
the subscriber’s account on a daily basis during a predeter-
mined grace period to see if a renewal has been received (at
82). The grace period may be any desired length of time and
in a preferred embodiment is five days. At the end of the grace
period, the applications server will automatically send
instructions to the LEC to terminate and disconnect the
subscriber’s telephone service (at 84). In other embodi-
ments, the applications server may just automatically send a
termination order to the LEC at the end of the subscriber’s
service period so that the prepaid telephone service and the
telephone line are terminated immediately after the service
period expiration date.

[0031] Referring now to FIG. 5, a process for renewing a
prepaid dialtone service account is shown. While a subscrib-
er’s account is still active, or within a grace period after
expiration of the prepaid dialtone service period, the sub-
scriber may renew her account for another service period.
The subscriber will again obtain a non-reusable prepaid
dialtone card having a fixed monetary value from a retail
location (at 86). The subscriber will dial a service center 14
telephone number and a VRU 18 will receive the telephone
call (at 88, 90). The VRU 18 will prompt the subscriber to
select from a menu of options and the subscriber will select
the account renewal option (at 92, 94).

[0032] When the VRU receives the subscriber’s menu
selection, the VRU will then request information from the
subscriber including the VIN number of the prepaid dialtone
card that the subscriber purchased (at 96). In one embodi-
ment, the VRU 18 will determine if the caller is calling from
her home and match the automatic number identification
(ANI) information of the home number to an established
prepaid dialtone account. The VRU 18, via the applications
server 14, will verify with the prepaid dialtone card database
that the VIN is valid and that the monetary value represented
by the card is sufficient for the services requested. The
applications server will renew the subscriber’s account for
another service period once the VIN and amount are verified
(at 98). The VRU may also inform the subscriber of the new
end date of the prepaid dialtone service she has just pur-
chased.

[0033] In another embodiment, subscribers may pay for
prepaid telephone service using a credit card rather than a
single use prepaid dialtone card purchased at a retailer. In
this embodiment, the VRU would ask the subscriber to
select between a prepaid card or a credit card as a method of
payment, and the applications server would interact with the
appropriate credit agency to determine if the credit card
transaction is valid.

[0034] An advantage of the presently preferred system and
method is that use of LEC resources is minimized. The LEC
is not required to constantly monitor prepaid telephone calls
and does not keep track of monetary values associated with
subscriber accounts. Communication with the service center
14 is minimal and does not tie up LEC resources. In one
embodiment, the LEC will maintain a call counter and a
service period clock for prepaid dialtone subscribers in
metered states. In non-metered states, no call counter or
service period clock is necessary. Preferably, the service
center, via a provisioning network, only communicates with
an LEC to initially establish prepaid dialtone services or to
change the status of an account if a subscriber fails to renew
or renews late.

[0035] Unless the service center communicates informa-
tion to the contrary, the LECs will automatically maintain
active status for currently active prepaid dialtone subscrib-
ers. In metered states, the LEC will automatically reset the
service period and call counter stored in memory 50 in the
SCP 46 at the end of a given subscriber’s service period. In
non-metered states, the LEC will maintain active status for
the prepaid subscribers unless a special instruction (such as
a hold or a disconnect instruction) is received. In this
manner, LEC resources are not burdened by the bulk of the
administrative overhead of managing the prepaid subscrib-
er. Instead, the subscriber accounts and account mainte-
nance are handled by the remotely located service center 14.

[0036] In a preferred embodiment, different types of pre-
paid dialtone services may be offered using the disclosed
system and method. For example, in one embodiment sub-
scribers may be able to select a basic or a premium service for prepaid dialtone. Both basic and premium services could be based on a 30-day service period. The basic service features may include basic dialtone, a state-specific local calling plan, a directory listing, toll call blocking, PUC none (designating a feature that blocks a subscriber from utilizing long distance services), directory assistance (DA) and directory assistance with call completion (DACC) blocking, operator call (0+0-) blocking except in areas without 911, listing services, and no customer billing. The state-specific local calling plans may be as follows based on state/regional call metering regulations: Indiana and Ohio—unlimited local calling; Illinois (bands A & B calling permitted, band C blocked), Michigan, and Wisconsin—a preset limit on the number of local telephone calls allowed per service period. The basic prepaid dialtone service preferably has its own USOC, line class codes and FIDs and these would be invoked by the service instructions sent out to the LEC by the applications server. The premium service may include all the features of the basic service and the following features: voice mail, caller ID with name, call waiting, and non-published listing. As with the basic service, the premium service preferably has its own packaged USOC defining all of the aspects of the service to the LEC supporting the subscriber.

[0037] In addition to the basic sign-up and renewal features described above, the service center, via the VRU may allow subscribers who have existing prepaid dialtone service to retrieve account information on an as-needed basis. Utilizing the same telephone number that allows for the subscriber to sign-up for and renew service, preferably a toll-free number, a subscriber may access information offered by menu driven commands at the VRU. Such information may include the type of prepaid service the subscriber has established, the date the prepaid service will expire, etc. The VRU 18 preferably also allows subscribers to select an option to be connected to a customer service agent 20.

[0038] Referring now to FIGS. 6 and 7, a preferred implementation of prepaid dialtone service in metered call states, such as Illinois, Michigan and Wisconsin, is illustrated. As shown in FIG. 6, the basic call flow for a call initiated by a prepaid dialtone subscriber in a metered state begins with a subscriber dialing a local call 100 that is received at an SSP. If the dialed digits of the call correspond to a permissible telephone call (i.e. intralata local, toll free or 911) the SSP will recognize an off-hook delay trigger assigned to the directory number (DN) of the subscriber and forward an info_collected query 102 to the service control point (SCP). The SCP, upon receiving the query from the SSP, will verify that the subscriber has a prepaid subscription and send an analyze_route response and send_notification message 104 to the SSP. The SSP will then route the call to the dialed number and, when the called party at the dialed number answers the call, establishes communication between the calling party and the called party 106. At the conclusion of the call, the called and/or calling party will go on-hook (i.e., disconnect from the call) 108. The SSP will sense the call termination and forward a termination notification response message to the SCP 110.

[0039] In FIG. 6, a call flow is illustrated assuming that the calling party is a prepaid subscriber, that the prepaid subscriber has not exceeded her call limit for the applicable time period (e.g., 30 day cycle), and that the called party answers the call. FIGS. 7A-7C demonstrate one preferred embodiment for metering the number of calls made by a prepaid dialtone subscriber and handling the various possible call answering scenarios, including busy signals and unanswered calls. Preferably, the metering system implemented on the advanced intelligent network (AIN) system provides prepaid dialtone subscribers a ceiling of 400 calls within a 30-day cycle. The AIN network will deny all local calls from the residential phone of the prepaid dialtone customer, allowing only toll free and 911 calls, after expiration of the 30-day period. After the subscriber reaches a limit of 30 days or 400 calls, the subscriber must use a prepaid long distance telephone card purchased from one of a number of prepaid long distance card vendors, or use some other toll free pre-arranged billing option not associated with the prepaid dialtone for local calls. Although a prepaid dialtone subscriber's telephone calls to that subscriber's own voicemail account may be excepted from the limitation of 400 calls permitted per month, preferably all calls associated with that prepaid dialtone subscriber's residential phone will be counted, including calls to the subscriber's voicemail. This would include the calls a subscriber receives that are forwarded to her voicemail as well as calls from the prepaid dialtone subscriber to pick up the voicemail messages.

[0040] As shown in FIG. 7A, the calling party first picks up the telephone associated with the prepaid dialtone subscriber's account and sends an off-hook signal to the SSP 112. In response, the SSP provides a dialtone 114 to the telephone and the dialed digits from the calling party are received at the SSP 116. If the calling party is a prepaid dialtone subscriber, then the off-hook delay trigger from the subscriber line will be recognized by the SSP and an SSP line class code (LCC) will verify that the dialed digits are intralata local, toll-free, or 911 118. If the SSP sees digits for a call that is not allowable, the SSP will escape the off-hook delay trigger and route the call to vacant treatment 120, consisting of playing a message such as “the call you are making is not allowed” and terminating the call, or simply terminating the call. If the dialed digits detected by the SSP are allowable, the call will encounter an off-hook delay trigger and the SSP will forward an info collected query to the SCP 122.

[0041] Upon receipt of the info_collected query from the SSP, the SCP will determine if the subscriber has a valid prepaid dialtone subscription 124. If a prepaid dialtone subscription is not found associated with the calling party, the SCP will send an analyze route response back to the SSP and the SSP will route the call based on the dialed digits. Even though no prepaid dialtone subscription has been found at the SCP, the SCP will assume that the caller has a valid subscription and note the discrepancy. There may be instances where subscriber information was properly updated at the SSP but not at the SCP, so the caller is given the benefit of the doubt until the SCP operator can verify account status.

[0042] Alternatively, if a prepaid dialtone subscription is identified for the calling party, the SCP service logic will determine if the call is an intralata local call, toll-free call, or 911 call at 138. If the call is toll free or 911, the SCP will send an analyze_route response message back to the SSP and the call will be routed based on the dialed digits. If the
call is a proper intralata local call, the SCP will verify that the subscriber’s call count is greater than 0. If the call count is 0, the SCP will send a send_to_resource response message to the SSP instructing the SSP to terminate the call and play a terminating announcement such as “your call limit has been exceeded.” If the prepaid dialtone subscriber has remaining telephone calls left (i.e. the call count is greater than 0), the SCP sends an analyze route message with send-notification request to the SSP whose combination of analyze route responses and send notification request messages is known as a multiple component message. At the same time that the multiple component message is sent out, the SCP will also start a notification timer associated with the open transaction from the send notification request. As discussed in greater detail below, the notification timer is used to determine when the prepaid dialtone subscriber’s call count should be decremented in to limit the amount of time that an SCP is tied to processing a prepaid dialtone telephone call.

The SSP, upon receipt of the multiple component message from the SCP, routes the call based on the received dialed digits. If the called party is busy, the SSP will send a termination notification response message to the SCP with the termination indicator set to busy (at 150, 152 and 154). Another potential scenario for a call from a prepaid dialtone subscriber is for the prepaid dialtone subscriber to call a party whose telephone continues to ring but who fails to answer and the calling party hangs up before the call is ever answered. In this situation a termination notification response with the termination indicator set to “exception” is sent to the SCP by the SSP. In both the case of a busy signal and the case where there is no answer, the termination notification message preferably stops the notification timer in the SCP so that the SCP will not decrement the call counter. In order to avoid the notification timer expiring prior to receipt of the termination notification, the notification timer is preferably set for a time period sufficient to take into account reasonable delay by the calling party in hanging up the telephone. In the one preferred embodiment, the notification timer is set to a time period of 10 minutes. Finally, assuming that the called party answers the telephone call from the prepaid dialtone subscriber, the call counter at the SCP will preferably be decremented in one of two ways. First, if the calling and called parties go on-hook prior to the expiration of the notification timer, the SCP sends a termination notification response with the termination indicator set to “answer” which will automatically cause the SCP to subtract one from the call count register. Alternatively, the expiration of the notification timer at the SCP (i.e. a telephone conversation lasting longer than the length of the notification timer) will also automatically subtract one from the subscriber’s call count register at the SCP. In addition, the expiration of the notification timer automatically closes the transaction of the call with the SCP such that the SCP is no longer tied up by the telephone call between the called and calling parties.

As has been discussed above, a system and method for providing prepaid local telephone service for subscribers at specific land-line telephone service addresses is provided for metered call states. Qualified local calls are limited by service period and number of calls per service period, and not a per-call time charge. LEC resources are not burdened by the continuous monitoring and administrative tasks of previous systems because the SCP is automatically removed from the telephone call and does not track lengths of calls in order to determine charges. Additionally, the customer service center and application server provide prepaid dialtone plan flexibility and avoids the need to replicate efforts and specially program hardware at each and every LEC interested in offering the prepaid dialtone service described above. The preferred method can permit automated sign-up and renewal of prepaid dialtone services. The prepaid dialtone services provide subscribers with the ability to manage their telephone costs and allow LECs to reduce the billing difficulties associated with subscribers.

It is intended that the foregoing detailed description be regarded as illustrative rather than limiting, and that it be understood that the following claims, including all equivalents, are intended to define the scope of this invention.

We claim:

1. A method for providing prepaid local telephone services to a subscriber having a telecommunications device connected to a subscriber line and in communication with a telephone network via the subscriber line, the method comprising:

   receiving a telephone call from the subscriber at a first network element in the telephone network;

   automatically verifying at the first network element that the telephone call is from a prepaid local telephone service subscriber;

   verifying that the telephone call is a qualified local telephone call;

   exchanging data communications between the first network element and a second network element to determine if a maximum number of local telephone calls has been completed by the subscriber;

   providing instructions from the second network element to the first network element to connect the telephone call if the maximum number of local telephone calls has not been completed; and

   decrementing a call counter at the second network element if the telephone call is completed.

2. The method of claim 1 wherein the first network element comprises a service switching point (SSP).

3. The method of claim 2 wherein the second network element is a service control point (SCP).

4. The method of claim 1 further comprising initiating a notification timer if the predetermined maximum number of local telephone calls has not been reached.

5. The method of claim 4 wherein decrementing the call counter at the second network element further comprises decrementing the call counter upon expiration of a time period monitored by the notification timer.

6. The method of claim 4 wherein decrementing the call counter at the second network element further comprises decrementing the call counter prior to expiration of a predetermined time period monitored by the notification timer upon receipt of a call termination signal from at least one of the subscriber and a party called by the subscriber.

7. The method of claim 4 wherein the call termination signal comprises an on-hook signal.

8. The method of claim 7 wherein the call termination signal further comprises a termination message sent from the first network element to the second network element.
9. A method for providing prepaid local telephone services to a subscriber having a telecommunications device connected to a subscriber line and in communication with a telephone network via the subscriber line, the method comprising:

verifying at a first network element that a telephone call is from a telecommunications device associated with a prepaid local telephone service subscriber based on a telephone number associated with the telecommunications device;

verifying that the telephone call originating from the telecommunications device is a qualified local telephone call;

providing instructions from a second network element to the first network element to connect the telephone call if a maximum number of local telephone calls has not been completed; and

decrementing a call counter at the second network element if the telephone call is connected.

10. The method of claim 9 wherein the first network element comprises a service switching point (SSP).

11. The method of claim 10 wherein the second network element is a service control point (SCP).

12. The method of claim 9 further comprising initiating a notification timer if the maximum number of local telephone calls for the prepaid local telephone service subscriber has not been reached.

13. The method of claim 12 wherein decrementing the call counter at the second network element further comprises decrementing the call counter upon expiration of a time period monitored by the notification timer.

14. The method of claim 12 wherein decrementing the call counter at the second network element further comprises decrementing the call counter prior to expiration of a predetermined time period monitored by the notification timer upon receipt of a call termination signal from at least one of the telecommunications device of the prepaid local telephone service subscriber and a party called from the telecommunications device of the prepaid local telephone service subscriber.

15. The method of claim 12 wherein the call termination signal comprises an on-hook signal.

16. The method of claim 15 wherein the call termination signal further comprises a termination message sent from the first element network to the second network element.

17. A system for monitoring and implementing prepaid dialtone services for local telephone calls in regions having metered calling, the system comprising:

first network means for receiving telephone calls from prepaid local telephone service subscribers, for maintaining information on prepaid local telephone service subscribers and for maintaining information for identifying local telephone calls; and

second network means for determining whether a telephone call received at the first network means is a local telephone call, for removing the second network means from a telephone call transaction after expiration of a predetermined time, and for changing a call counter tracking a number of local telephone calls permitted to a subscriber if the telephone call is a local telephone call from a prepaid local telephone service subscriber and the telephone call has not terminated prior to expiration of the predetermined time.
