(54) Title: LAND VEHICLES AND SYSTEMS WITH CONTROLLABLE SUSPENSION SYSTEMS

FIG. 1A

(57) Abstract: The land vehicle includes a body, a controllable suspension system, the controllable suspension system for controlling suspension movements between the body and land engagers. The land vehicle includes a computer system and suspension sensors located proximate the land engagers for measuring suspension parameters representative of suspension movements between the body and the land engagers and outputting a plurality of suspension sensor measurement output signals. The land vehicle includes controllable force suspension members located proximate the land engagers and the suspension sensors, the controllable force suspension members applying suspension travel forces between the body and the land engagers to control the suspension movements. The land vehicle computer system includes controllable suspension system algorithms for controlling the controllable force suspension members to control vehicle body motion and the suspension movements between the body and the land engagers and inhibit the driver from crossing into an identified impending driver vehicle safety margin.

LAND VEHICLES AND SYSTEMS WITH CONTROLLABLE SUSPENSION SYSTEMS

5 This application claims the benefit of U.S. Provisional Application No. 61/334,649,
filed May 14, 2010, which is herein incorporated by reference.

Field of the Invention

10 The invention relates to the field of land vehicles. The invention relates to land
vehicles with controllable suspension systems. More particularly the invention relates to
controllable suspension systems for large military vehicles that are used in a variety of
conditions, including on road and off road.

Summary of the Invention

15 In an embodiment the invention includes a land vehicle for driving by an occupant
human driver. The land vehicle includes a body, a power plant and a plurality of land
engagers, the land engagers for engaging land and propelling the land vehicle across land.
The land vehicle includes a controllable suspension system for controlling a plurality of
suspension movements between the body and the land engagers. The land vehicle includes a
computer system with computer readable medium. The land vehicle includes a plurality of
20 suspension sensors located proximal to the land engagers for measuring a plurality of
suspension parameters representative of suspension movements between the body and the
land engagers and outputting a plurality of suspension sensor measurement output signals.
The land vehicle includes a plurality of controllable force suspension members located
proximal the land engagers and the suspension sensors, the controllable force suspension
25 members for applying a plurality of controllable suspension travel forces between the body
and the land engagers to control the suspension movements. The land vehicle includes a body
motion sensor, the body motion sensor for outputting a plurality of vehicle body motion
measurement output signals. The land vehicle preferably includes a vehicle databus
interfacing with the computer system, the vehicle databus communicating a plurality of
30 vehicle data communication signals. Preferably the computer system receives the signals and
the computer readable medium includes first program instructions with the computer system
executing a controllable suspension system algorithm for controlling the controllable force
suspension members to control vehicle body motion and the suspension movements between
the body and the land engagers, and the computer readable medium includes second program

instructions with the computer system executing a driver suspension feedback algorithm for monitoring signals, to identify an impending driver land vehicle safety margin and controlling the controllable force suspension members to warn the driver of the impending driver land vehicle safety margin.

5

13. A method of controlling a vehicle driven by a driver, said vehicle having a body, a power plant, and a controllable suspension system, said controllable suspension system for controlling a plurality of suspension movements, said method including:

10 providing at least a first suspension sensor for measuring a plurality of suspension parameters representative of suspension movements of said body and outputting a plurality of suspension sensor measurement output signals;

providing at least a first controllable force suspension member, said at least first controllable force suspension members for applying a plurality of controllable suspension travel forces;

15 providing a body motion sensor, said body motion sensor for outputting a plurality of vehicle body motion measurement output signals;

monitoring a plurality of sensor signals to identify an impending driver vehicle safety margin and controlling said at least first controllable force suspension member to inhibit said driver from crossing into said identified impending driver vehicle safety margin.

20

In an embodiment the invention includes a method of controlling a vehicle driven by an occupant driver. The vehicle includes a body and a power plant. Preferably the vehicle includes a plurality of land engagers, the land engagers for engaging land and propelling the vehicle across land. The vehicle includes a controllable suspension system, the controllable suspension system for controlling a plurality of suspension movements, preferably between
25 the body and the land engagers. The method includes providing at least a first suspension sensor for measuring a plurality of suspension parameters representative of suspension movements of the body and outputting a plurality of suspension sensor measurement output signals. The method includes providing at least a first controllable force suspension member, the at least first controllable force suspension member for applying a plurality of controllable
30 suspension travel forces to control the suspension movements. The method includes providing a body motion sensor, the body motion sensor for outputting a plurality of vehicle body motion measurement output signals. The method includes providing a vehicle databus, the vehicle databus communicating a plurality of vehicle data communication signals. The method includes monitoring signals to identify an impending driver vehicle safety margin and

controlling the at least first controllable force suspension member to inhibit the driver from crossing into said identified impending driver vehicle safety margin. Preferably the method includes altering the control of the controllable force suspension members wherein the driver is warned of the impending driver land vehicle safety margin

5

In an embodiment the invention includes a vehicle driver control system for controlling a vehicle driven by an occupant driver, the vehicle having a body, a power plant, and a controllable suspension sub-system, the controllable suspension sub-system for controlling a plurality of suspension movements. The vehicle driver control system includes a plurality of suspension sensors for measuring a plurality of suspension parameters representative of suspension movements of the body and outputting a plurality of suspension sensor measurement output signals. The vehicle driver control system includes a plurality of controllable force suspension members, the controllable force suspension members for applying a plurality of controllable suspension travel forces. The vehicle driver control system includes a body motion sensor, the body motion sensor for outputting a plurality of vehicle body motion measurement output signals. The vehicle driver control system includes a vehicle databus, the vehicle databus communicating a plurality of vehicle data communication signals. The vehicle driver control system includes a computer sub-system for monitoring vehicle data communication signals to identify an impending driver vehicle safety margin and controlling the controllable force suspension members to inhibit the driver from crossing into said identified impending driver land vehicle safety margin. Preferably the controllable force suspension members are controlled to warn the driver of the driver's approach of the identified impending driver land vehicle safety margin.

25

In an embodiment the invention includes a system for controlling a vehicle driven by a human occupant driver, the vehicle having a body, a power plant, and a controllable suspension, the controllable suspension for controlling a plurality of suspension movements. The system includes a means for outputting a plurality of suspension measurement signals. The system includes at least a first controllable force suspension member, the controllable force suspension member for applying a plurality of controllable suspension travel forces. The system includes a means for outputting a plurality of body motion measurement signals. The system includes a means for communicating a plurality of vehicle data communication signals. The system includes a control means for monitoring the signals to identify an impending driver vehicle safety margin and controlling the controllable force suspension

30

member to inhibit the driver's entry into the impending driver land vehicle safety margin. Preferably the controllable force suspension member is controlled wherein in the driver is compelled to avoid the impending driver land vehicle safety margin, preferably with a controllable force suspension member warning.

5

In an embodiment the invention includes a suspension control system including a computer system; at least one suspension sensor located proximal to at least some of the suspension locations for measuring suspension parameters; at least one controllable force suspension members located proximal to at least one of the suspension locations capable of applying forces across the suspension; a body motion sensor for measuring vehicle body motion; a vehicle databus interfacing with the computer system; wherein the computer system receives the sensors' output signals and implements a suspension control algorithm for controlling the at least one controllable force suspension member; and the computer system includes regime recognition signal monitoring instructions for using inputted signals for determining a vehicle operating parameter and/or a vehicle operating configuration and/or vehicle safety margin to recognize a driving regime, and wherein the suspension control algorithm adjusts to the recognized driving regime, and preferably warns the driver of the vehicle with the control of the controllable force suspension members.

20

In an embodiment the invention includes a suspension control system including computer system; a plurality of suspension sensors located proximal to at least some of the suspension locations for measuring suspension parameters; a plurality of controllable force suspension members located proximal to at least some of the suspension locations capable of applying forces across the suspension; a body motion sensor for measuring vehicle body motion; a vehicle databus interfacing with the computer system; wherein the computer system receives the sensors' output signals and implements a suspension control algorithm for controlling the controllable force suspension members; and the computer system monitors the health of the controllable suspension system with monitoring of the sensors and assessing the health of a plurality of vehicle suspension components; and the computer system includes regime recognition instructions for using the sensors and data on the databus for determining a vehicle operating parameter and/or a vehicle operating configuration to recognize a regime, and wherein the suspension control algorithm adjusts to the recognized regime.

25

30

In an embodiment the invention includes a land vehicle, the land vehicle having a body, a power plant and a plurality of land engagers, the land engagers for engaging land and propelling the land vehicle across land. The land vehicle includes a controllable suspension system, the controllable suspension system for controlling a plurality of suspension movements between the body and the land engagers. The land vehicle includes a computer system with computer readable medium. The land vehicle includes a plurality of suspension sensors located proximal to the land engagers for measuring a plurality of suspension parameters representative of suspension movements between the body and the land engagers and outputting a plurality of suspension sensor measurement output signals. The land vehicle includes a plurality of controllable force suspension members located proximal the land engagers and the suspension sensors, the controllable force suspension members for applying a plurality of controllable suspension travel forces between the body and the land engagers to control the suspension movements. The land vehicle includes a body motion sensor, the body motion sensor for outputting a plurality of vehicle body motion measurement output signals. The land vehicle includes a vehicle databus interfacing with the computer system, the vehicle databus communicating a plurality of vehicle data communication signals. The computer system receives the suspension sensor measurement output signals and the vehicle body motion measurement output signals and the computer readable medium including a first program instruction with the computer system executing a controllable suspension system algorithm for controlling the controllable force suspension members to control vehicle body motion and the suspension movements between the body and the land engagers, and the computer readable medium including a second program instruction with the computer system executing a health usage monitoring algorithm for monitoring the output signals and assessing a health and a usage of a vehicle suspension component.

In an embodiment the invention includes a land vehicle system, for a land vehicle having a body, a power plant and a plurality of land engagers, the land engagers for engaging land and propelling the land vehicle across land. The land vehicle system includes a controllable suspension system, the controllable suspension system for controlling a plurality of suspension movements between the body and the land engagers. The land vehicle system includes a computer system with computer readable medium. The land vehicle system includes a plurality of suspension sensors located proximal to the land engagers and suspension locations for measuring a plurality of suspension parameters representative of suspension movements between the body and the land engagers and outputting a plurality of

suspension sensor measurement output signals. The land vehicle system includes a plurality of controllable force suspension members located proximal the land engagers and the suspension sensors, the controllable force suspension members for applying a plurality of controllable suspension travel forces between the body and the land engagers to control the suspension movements. The land vehicle system includes a body motion sensor, the body motion sensor for outputting a plurality of vehicle body motion measurement output signals, wherein the computer system receives the suspension sensor measurement output signals and the vehicle body motion measurement output signals and executes a controllable suspension system algorithm for controlling the controllable force suspension members to control vehicle body motion and the suspension movements between the body and the land engagers, and the computer system executes a health usage monitoring algorithm for monitoring these output signals and assessing a health usage of a suspension related component.

In an embodiment the invention includes a monitoring apparatus for diagnosing faults in a land vehicle having a body, a power plant and a plurality of land engagers, the land engagers for engaging land and propelling the land vehicle across land. The apparatus includes a controllable suspension system, the controllable suspension system for controlling a plurality of suspension movements between the body and the land engagers, with a plurality of suspension sensors located proximal to the land engagers for measuring a plurality of suspension parameters representative of suspension movements between the body and the land engagers and outputting a plurality of suspension sensor measurement output signals; a plurality of controllable force suspension members located proximal the land engagers and the suspension sensors, the controllable force suspension members for applying a plurality of controllable suspension travel forces between the body and the land engagers to control the suspension movements; and a body motion sensor, the body motion sensor for outputting a plurality of vehicle body motion measurement output signals. The apparatus receives the suspension sensor measurement output signals and the vehicle body motion measurement output signals and executes controllable suspension system instructions for controlling the controllable force suspension members to control vehicle body motion and the suspension movements between the body and the land engagers, and the apparatus includes reference data store containing failure mode identification data and associated system data sampled from behavior of the controllable suspension system in the failure mode; and a similarity engine responsive to monitored system data indicative of monitored behavior of the controllable suspension system, for generating at least one similarity value for a comparison

of the monitored data to the failure mode associated system data, as a diagnostic indication of the failure mode.

In an embodiment the invention includes a method for diagnosing faults in a land vehicle having a body, a power plant and a plurality of land engagers, the land engagers for engaging land and propelling the land vehicle across land. The method includes providing a controllable suspension system, the controllable suspension system disposed between the body and the land engagers to control a plurality of suspension movements between the body and the land engagers, the controllable suspension system including a plurality of suspension sensors located proximal to the land engagers suspension locations for measuring a plurality of suspension parameters representative of suspension movements between the body and the land engagers and outputting a plurality of suspension sensor measurement output signals; a plurality of controllable force suspension members located proximal the land engagers and the suspension sensors, the controllable force suspension members for applying a plurality of controllable suspension travel forces between the body and the land engagers to control the suspension movements; a body motion sensor, the body motion sensor for outputting a plurality of vehicle body motion measurement output signals; with the controllable suspension system receiving the suspension sensor measurement output signals and the vehicle body motion measurement output signals and executing controllable suspension system instructions for controlling the controllable force suspension members to control vehicle body motion and the suspension movements between the body and the land engagers, and the controllable suspension system acquiring monitored controllable suspension system data indicative of monitored controllable suspension behavior of the controllable suspension system; sampling controllable suspension system data from a controllable suspension failure mode to define controllable suspension reference system data associated with the controllable suspension failure mode, and comparing for similarity the monitored system data to the reference system data to generate a similarity value as a diagnostic indication of the controllable suspension failure mode.

In an embodiment the invention includes a monitoring apparatus for diagnosing faults in a land vehicle having a body, a power plant and a plurality of land engagers, the land engagers for engaging land and propelling the land vehicle across land. The apparatus including a controllable suspension system, the controllable suspension system for controlling a plurality of suspension movements between the body and the land engagers, a

plurality of suspension sensors located proximal to the land engagers for sensing a plurality of suspension measurables and outputting a plurality of suspension sensor measurement output signals; a plurality of controllable force suspension members located proximal the land engagers and the suspension sensors, the controllable force suspension members for applying
5 a plurality of controllable suspension travel forces between the body and the land engagers to control the suspension movements; a body motion sensor, the body motion sensor for outputting a plurality of vehicle body motion measurement output signals. The apparatus receives the suspension sensor measurement output signals and the vehicle body motion measurement output signals and executes controllable suspension system instructions for
10 controlling the controllable force suspension members to control vehicle body motion and the suspension movements between the body and the land engagers, and the apparatus including computer readable failure mode reference identification data for detecting a failure mode in the controllable suspension system; and the apparatus compares monitored controllable suspension system data to the failure mode reference identification data to a diagnose an
15 impending failure mode of the controllable suspension system.

In an embodiment the invention includes a monitoring method for diagnosing faults in a plurality of land vehicles. The method includes providing a plurality of land vehicles comprised a body, a power plant and a plurality of land engagers, the land engagers for
20 engaging land and propelling the land vehicles across land, the land vehicles including a controllable suspension system, the controllable suspension system for controlling a plurality of suspension movements between the body and the land engagers, the controllable suspension system including a plurality of suspension sensors located proximal to the land engagers suspension locations for sensing a plurality of suspension measurables and
25 outputting a plurality of suspension sensor measurement output signals; the controllable suspension system including a plurality of controllable force suspension members located proximal the land engagers and the suspension sensors, the controllable force suspension members for applying a plurality of controllable suspension travel forces between the body and the land engagers to control the suspension movements; the controllable suspension
30 system including a body motion sensor, the body motion sensor for outputting a plurality of vehicle body motion measurement output signals. The method includes receiving the suspension sensor measurement output signals and the vehicle body motion measurement output signals and executing controllable suspension system instructions for controlling the controllable force suspension members to control vehicle body motion and the suspension

movements between the vehicle bodies and the land engagers, and providing computer readable failure mode reference identification data for detecting a failure mode in the controllable suspension systems; and comparing monitored controllable suspension system data to the failure mode reference identification data to a diagnose a failure mode of the controllable suspension systems.

In an embodiment the invention includes a vehicle suspension control system including a vehicle computer system; a plurality of suspension sensors disposed proximate to a plurality of suspension locations of a suspension for measuring suspension parameters of a plurality of suspension components; a body motion sensor for measuring body motion; a databus interfacing with the computer system; wherein the computer system receives the sensors' output signals and implements a suspension algorithm for the suspension members; and the computer system monitors the health of the suspension system with monitoring of the sensors and assessing the health of a plurality of suspension components; and the computer system includes regime recognition instructions for using the sensors and data on the databus for determining an operating parameter and an operating configuration to recognize a regime, and wherein the suspension control algorithm adjusts to the recognized regime.

In an embodiment the invention includes a monitoring method for diagnosing faults in a plurality of vehicles. The method includes providing a plurality of vehicles comprised of a body, a power plant and a plurality of engagers, the engagers for propelling the vehicles, the vehicles including a motion control suspension system, the suspension system for controlling a plurality of movements between the body and the engagers, the suspension system including a plurality of suspension sensors located proximal to the engagers for sensing a plurality of suspension measurables and outputting a plurality of suspension sensor measurement output signals; the controllable suspension system including a body motion sensor, the body motion sensor for outputting a plurality of vehicle body motion measurement output signals; receiving the suspension sensor measurement output signals and the vehicle body motion measurement output signals and executing suspension system instructions, and providing computer readable failure mode reference identification data for detecting a failure mode in the suspension systems; and comparing monitored suspension system data to the failure mode reference identification data to a diagnose a failure mode of the suspension systems.

It is to be understood that both the foregoing general description and the following detailed description are exemplary of the invention, and are intended to provide an overview or framework for understanding the nature and character of the invention as it is claimed. The accompanying drawings are included to provide a further understanding of the invention, and are incorporated in and constitute a part of this specification. The drawings illustrate various embodiments of the invention and together with the description serve to explain the principals and operation of the invention.

Brief Description of the Drawings

FIG. 1A-E illustrates a land vehicle with a controllable suspension system.

FIG. 2A-B illustrate a vehicle controllable suspension computer system.

FIG. 3 illustrates a semi-active controllable suspension system.

FIG. 4 illustrates a controllable force suspension member magneto-rheological fluid damper.

FIG. 5 illustrates land vehicles with controllable suspension systems.

FIG. 6A-B illustrate a land vehicle with a vehicle controllable suspension computer system with a controllable suspension system for controlling controllable force suspension.

FIG. 7 illustrates a tracked tank land vehicle with a controllable suspension system, with a computer system, suspension sensors and controllable force suspension members at suspension locations for controlling suspension movements between the vehicle body and tracks.

FIG. 8 illustrates a land vehicle truck with a controllable suspension system, with a computer system, suspension sensors and controllable force suspension members at suspension locations for controlling suspension movements between the truck body and wheels.

FIG. 9 illustrates a land vehicle with a controllable suspension system, with a computer system, suspension sensors and controllable force suspension members at suspension locations for controlling suspension movements between the vehicle body and wheels.

Detailed Description of the Preferred Embodiment

Additional features and advantages of the invention will be set forth in the detailed description which follows, and in part will be readily apparent to those skilled in the art from that description or recognized by practicing the invention as described herein, including the detailed description which follows, the claims, as well as the appended drawings.

25

Reference will now be made in detail to the present preferred embodiments of the invention, examples of which are illustrated in the accompanying drawings.

30

In an embodiment the invention includes a suspension control system 21 including a computer system 23; a plurality of suspension sensors 25 located proximal to at least some of the suspension locations 27 for measuring suspension parameters; a plurality of controllable force suspension members 29 located proximal to at least some of the suspension locations 27

capable of applying forces across the suspension; a body motion sensor 31 for measuring vehicle body motion; a vehicle databus 33 interfacing with the computer system 23; wherein the computer system 23 receives the sensors' output signals and implements a suspension control algorithm for controlling the controllable force suspension members 29; and the
5 computer system 23 monitors the health of the controllable suspension system with monitoring of the sensors and assessing the health of a plurality of vehicle suspension components 35; and the computer system 23 includes regime recognition instructions for using the sensors and data on the databus 33 for determining a vehicle operating parameter and/or a vehicle operating configuration and/or vehicle safety margin to recognize a regime,
10 and wherein the suspension control algorithm adjusts and controls the controllable force suspension members 29 to the recognized regime, preferably with the controllable force suspension members 29 controlled to warn a driver 100 of a land vehicle 37 of an impending driver safety margin wherein the driver is inhibited from crossing the safety margin.

15 In embodiments the invention preferably includes a land vehicle 37, the land vehicle 37 having a body 39, a power plant 41 and a plurality of land engagers 43, the land engagers 43 for engaging land and propelling the land vehicle 37 across land, the land vehicle 37 including a controllable suspension system, the controllable suspension system for controlling a plurality of suspension movements between the body 39 and the land engagers
20 43. In embodiments the land engagers 43 are preferably wheels. In embodiments the land engagers 43 are preferably moving tracks. Preferably the land vehicles 37 are utility vehicles, preferably non-car vehicles, preferably non-light duty utility vehicles with plurality of driven on/off-road engagers, preferably with the land vehicles 37 transporting payloads and cargo in which the mass of the land vehicle and payload/cargo, and the gross vehicle weight and
25 center of gravity have a considerable variation over time, preferably from a first gross vehicle weight/ center of gravity to a later distal mission time second gross vehicle weight/center of gravity. In embodiments the vehicles are off road enabled with more than two driven wheels. Preferably the land vehicles 37 are non-light duty vehicles having gross vehicle weight
30 $>7,700\text{lbs}$, $\geq 8,500\text{lbs}$, $\geq 10,000\text{lbs}$, $\geq 14,000\text{lbs}$, $\geq 20,000\text{lbs}$, $\geq 24,000\text{lbs}$, $\geq 29,000\text{lbs}$, $\geq 29,000\text{lbs}$, $\geq 32,000\text{lbs}$, $\geq 33,000\text{lbs}$. Preferably the land vehicles 27 are off-road/on-road vehicles preferably designed to drive both on and off road, preferably with the land vehicles
27 designed for military missions. Preferably the land vehicles 27 are military land vehicles 27 with payloads/cargos and center of gravities that vary over time. Preferably the military land vehicles 27 safety margins of driving vary with a variation of payloads/cargos and center

of gravities. Preferably with the non-light duty land vehicles 27, light duty vehicles are for example class A thru F2 automobiles; class MPV-B thru MPV-E multi-purpose vehicles; class SUV-A thru SUV-E sport utility vehicles; class PUP-B thru PUP-D pickup trucks; class CDV, MIC, MVAN vans (reference Global Insight World Car Industry Forecast Report, December 2006).

The land vehicle 37 with land engagers 43 and controllable suspension system for controlling suspension movements between the body 39 and the land engagers 43 includes a computer system 23 with computer readable medium; and a plurality of suspension sensors 25 located proximal to at least some of the land engagers 43 suspension locations 27, for measuring a plurality of suspension parameters representative of suspension movements between the body 39 and the land engagers 43 and outputting a plurality of suspension sensor measurement output signals; a plurality of controllable force suspension members 29 located proximal the land engagers 43 and the suspension sensors 25, the controllable force suspension members 29 for applying a plurality of controllable suspension travel forces between the body 39 and the land engagers 43 to control the suspension movements. In a preferred embodiment the controllable force suspension members 29 are dampers, preferably controllable force dampers with suspension displacement sensors.

The controllable suspension system includes a body motion sensor 31, the body motion sensor 31 for outputting a plurality of vehicle body motion measurement output signals. In a preferred embodiment the body motion sensor 31 is an inertial sensor, and is preferably integrated with in the computer system 23 with the suspension controller unit and the usage monitor.

The vehicle includes a vehicle databus 33 interfacing with the computer system 23, the vehicle databus 33 communicating a plurality of vehicle data communication signals with the computer system 23.

Preferably the computer system 23 receives the suspension sensor measurement output signals and the vehicle body motion measurement output signals and the computer readable medium includes first program instructions with the computer system 23 executing a controllable suspension system algorithm for controlling the controllable force suspension members 29 to control vehicle body motion and the suspension movements between the body

39 and the land engagers 43, and the computer readable medium including second program instructions with the computer system 23 executing a health usage monitoring algorithm for monitoring the output signals and assessing a health and a usage of a vehicle suspension component.

5

Preferably the vehicle includes the suspension usage safety margin monitoring functionality with the controllable semi-active suspension. Preferably with the system the usage safety margin monitoring function accesses suspension component data such as suspension displacements, damper dissipated power and temperatures. Preferably with the system different suspension control algorithms or gains are employed based on usage identified mission profiles or usage regimes to provide improved performance, safety and/or improved mission reliability. Preferably with the system the suspension control algorithm and the monitoring utilize the additional data signals from the vehicle data bus (preferably engine rpm, steering angle, tire speeds, brake engagement) and associated regimes to improve performance, safety and failure detection. Preferably with the body motion inertial measurement system and the suspension displacement sensors the system provides a vibration and load dosimeter. Preferably with the body motion inertial measurement system and the suspension displacement sensors the system provides an indication of the health of suspension components 35. Preferably with the body motion inertial measurement system and the suspension displacement sensors the system provides an improved terrain mapping. Preferably with the body motion inertial measurement system and the suspension displacement sensors the system provides an estimation of gross vehicle weight and CG, center of gravity location, with such signals monitored for vehicle safety margins. Preferably with the monitoring system with the inertial measurement system and the suspension displacement sensors the vehicle system provides a vibration and load dosimeter. In particular, the displacement sensors across the suspension system preferably sense and record loads to the vehicle chassis coming through the suspension, and preferably to loads/power absorbed by the driver. This, in combination, with vibration sensing can be used to assess load and vibration history of the vehicle and provide a measured basis for prognostics based on, for example, fatigue accumulation. Preferably with the usage monitoring system with the inertial measurement system and the suspension displacement sensors provide an indication of the health of vehicle suspension components 35, such as vehicle suspension springs, bushings, tie-rods, and associated vehicle components which are associated and connected with the suspension. The vehicle monitoring system detects anomalies in these sensor signals

30

when compared to baseline (healthy suspension) signals. This system also provides faulty component isolation to enable faster “pit-crew style” human maintenance with the human maintainers preferably provided advanced communication of the needed repair and required suspension components 35 for the repair. Furthermore, the suspension control system 21 preferably in addition to safety margin warnings, modifies the suspension control policy in the event of a suspension component failure or impending failure to provide an optimal limp-home mode, preferably by controllably limiting the force through a controllable force suspension member that has a detected failure or impending failure mode.

In an embodiment the vehicle system provides for geographic terrain mapping of the land engaged by the land engagers 43. The body motion sensor 31 inertial measurement system and the suspension displacement sensors preferably provide *improved terrain mapping*. Consider the single vehicle suspension corner illustrated in FIG. 13 where x_i is the terrain profile, x_t is the time displacement, x_r is the suspension displacement which is measured and x_m is the corner body displacement which can be estimated from the inertial measurement system in high-pass-filtered manner. The terrain profile is approximated by

$$x_i = x_m - x_r - x_t$$

where x_m and x_r are known, but x_t must be approximated by one of the following ways.

- a. Assume $k_t \gg k_s$ such that $x_t \ll x_r$, then x_t is assume negligible.
- b. Assume tire damping and m_a are small (i.e., $k_t/m_a \gg k_s/m$). Then,

$$x_t = \frac{1}{k_t} (k_s x_r + b(\dot{x}_r) \dot{x}_r)$$

If no land engaging tire lifting is assumed and masses and spring rates are known, then x_t can be approximated by passing measure signals through 2nd order filters based on system dynamic modeling.

Further accuracy in terrain mapping can be derived from averaging front and rear corner estimations on the vehicle. This may, for example, help remove data anomalies due to land engaging tire lift.

This terrain mapping technique provides the terrain characteristics that have relatively high spatial frequency (bumps, pot holes, ditches, etc.) – the cut-off of which is vehicle speed dependent. Low spatial frequency terrain characteristics, such as hills, can be estimated from an on-board geographic positioning input such as on-board GPS (Global Positioning Satellite) with known accuracy limits.

Preferably with the system the suspension displacement sensors output signals provide the system with inputs for a calculation of an *estimation of gross vehicle weight and CG (center of gravity) location*. This is preferably done by simple statics equations based on suspension displacement measurements. Such information is preferably used to calculate safety margins, monitor safety margins, detect exceedance, or determine excess capacity, or for usage monitoring, or for route planning, or to monitor fuel burn or payload depletion, preferably to monitor the payload depletion of expendable payloads such as vehicle carried ammunition.

Preferably the system monitoring provides access to suspension component data signals from the sensors such as suspension displacements, damper dissipated power and damper temperatures. Preferably different suspension control algorithms or gains are employed based on identified mission profiles or usage regimes to provide improved safety, performance and/or improved mission reliability.

Preferably with the vehicle the computer system 23 computer readable medium includes third program instructions with the computer system 23 executes a regime recognition algorithm for using the output signals and the vehicle data communication signals from the databus 33 to determine a vehicle operating parameter. Preferably with the vehicle the computer system 23 computer readable medium includes third program instructions with the computer system 23 executes a regime recognition algorithm for using the output signals and the vehicle data communication signals from the databus 33 to determine a vehicle operating configuration. Preferably the regime recognition algorithm identifies the type of terrain that the vehicle is engaging, and preferably modifies the controllable suspension system algorithm in accordance with the identified terrain type, preferably with such identified terrain type utilized in the monitoring of impending safety margins.

Preferably the regime safety margin recognition algorithm identifies a vehicle operating configuration, such as a the vehicle weight cargo, fuel, personnel, and/or how the vehicle is functioning and driving and preferably modifies the controllable suspension system algorithm in accordance with the vehicle operating configuration. Preferably with the vehicle

5 the computer system 23 regime recognition algorithm identifies both regimes internal to the vehicle and regimes external to the vehicle, and modifies the controllable suspension system algorithm in accordance with such recognized regimes. The regime recognition includes data signals from the suspension sensors 25 and body motion and the databus 33 with the regime recognizing the internal and external environmental conditions such as payload how the land

10 engagers 43 are engaging the land such as a muddy off road, the body motion such as on a steep slope, with the controllable suspension system algorithm modified in response to the regime recognition algorithm, preferably with different algorithm gains depending upon the external environment regime, such as type of terrain and/or internal environment regime, such as location of vehicle CG and how the driver is driving through such external

15 environment. The controllable suspension system algorithm is preferably modified in response to the regime recognition algorithm. Preferably the regime recognition algorithm utilizes the sensor output signals and the vehicle data communication signals from the databus 33 to determine at least a vehicle operating parameter and a vehicle operating configuration and wherein the controllable suspension system algorithm is modified in

20 response to the regime recognition algorithm. Preferably different controllable suspension system algorithm gains are utilized depending upon the type of terrain or location of vehicle CG, vehicle operating parameters, operator accelerating/braking, internal and external inputs and comparisons with stored data.

25 In an embodiment preferably the at least first controllable force suspension member is comprised of a semi-active damper, preferably with a control signal to the damper varies the damper force produced by damper. In preferred embodiments the semi-active damper is a magnetorheological fluid damper. In preferred embodiments the semi-active damper is controllable valve damper. In preferred embodiments the semi-active damper is a servo valve

30 controlled damper. In preferred embodiments the semi-active damper is a controllable variable orifice damper. In preferred embodiments the semi-active damper is a controllable variable fluid flow damper.

In an embodiment preferably the at least a first controllable force suspension member is comprised of an actuator, preferably with a control signal to the actuator produces an active suspension contraction or extension.

5 In an embodiment preferably the at least a first controllable force suspension member is comprised of a controllable spring. Preferably the controllable spring is comprised of an adjustable air spring member. In preferred embodiments the controllable spring is combined with a semi-active damper, preferably a magnetorheological fluid damper. Preferably the controllable spring adjustable air spring member is controlled to adjust the vehicle height.

10

Preferably the suspension sensors 25 suspension sensor measurement output signals include a plurality of displacements between the body 39 and the land engagers 43.

15 Preferably the body motion sensor 31 vehicle body motion measurement output signals include a plurality of rate sensor output signals, such as degree/sec, angular rate.

20 Preferably the body motion sensor 31 vehicle body motion measurement output signals include a plurality of accelerometer output signals, such as m/sec^2 , linear acceleration. Preferably the body motion sensor 31 vehicle body motion measurement output signals include a plurality of six degrees of freedom of body motion output signals.

25 Preferably the computer system 23 stores a plurality of condition data for a plurality of vehicle suspension components 35 in the computer readable accessible data storage medium.

25

Preferably the computer system 23 provides a perceptible output when a vehicle suspension component is in need of corrective action such as in need of repair or replacement of a component because of a detected failure or a detected impending failure mode.

30 Preferably the controllable suspension system algorithm is modified in response to the monitored health usage of a sensed vehicle suspension component. The controllable suspension system algorithm is preferably modified control the suspension force and/or ride height and to provide optimal limp-home mode, and to preferably limit force through

suspension controllable force members, such as a failing damper, in response to identified suspension component failure/impending failure modes.

Preferably the vehicle computer system 23 outputs a plurality of suspension output data to an external computer, the external computer external to the vehicle, preferably a central depot computer, preferably logistics maintenance computer.

Preferably the suspension control algorithm adapts/adjusts gains and controls the suspension based on the type of terrain, such as paved road, unpaved dirt road, off-highway, no road at all, and uses current sensed terrain engaged land data and also compared with past terrain stored and/or shared data for the geographic location and how the driver is driving the vehicle. Preferably with adjustable height suspension, preferably with controllable springs and adjustable height air springs, the height is lowered for on road travel, and the height is raised for off road travel, especially for terrain with large obstacles, such as rocks and logs.

Preferably the monitoring system anticipates and identifies failures before and after failures, and then adjust the suspension for limp home, preferably limiting suspension force through damaged/failing/failed suspension components 35/systems. Preferably with the land engagers 43 primary controllable suspension system sensor output signals are outputted and the body sensor motion output signals are outputted to the computer system 23 which analyzes suspension system displacement at the land engagers 43 to both monitor and collect data on the land/terrain that is being engaged and on the condition and health of the suspension system between the land engager and the body 39 and the nearness of safety margins on how the driver is driving the vehicle. Preferably the system provides for monitoring of vehicle gross weight and CG, and additionally for backup monitoring of fuel usage, ammunition usage, and other consumable usage during a trip. Preferably the system reduces loading coming through the suspension system, preferably with transmission of forces through the suspension members increased to warn of an impending safety margin hazard. Preferably the system provides for terrain mapping and regime recognition, and collects vehicle data signals, preferably suspension sensor signals and body motion data signals combined with geographic location data signals, such as from GPS, to provide road/terrain condition map from land engagers 43 engagement of the land collecting data on the land engaged. Preferably the system provides improved suspension control, safety and vehicle mobility with regime recognition.

In an embodiment the invention includes a land vehicle 37 system for a land vehicle 37 having a body 39, a power plant 41 and a plurality of land engagers 43 the land engagers 43 for engaging land and propelling the land vehicle 37 across land. Preferably the system is for military land vehicles 37. Preferably the system is for utility vehicles, preferably non-car
5 vehicles, preferably non-light duty utility vehicles with plurality of driven on/off-road engagers, preferably more than two driven wheels.

Preferably the land vehicle system includes a controllable suspension system. Preferably the controllable suspension system controls a plurality of suspension movements,
10 between a first vehicle body and a second vehicle body, preferably between the body 39 and the land engagers 43, and a computer system 23 with computer readable medium. The computer system 23 preferably comprises a central computer with a central processor, preferably for controlling a plurality of controllable force suspension members 29. In alternative embodiments the computer system 23 preferably comprises a distributed computer
15 system 23 with subunits proximate suspension sites/controllable force suspension members 29 located proximal the land engagers 43, with the distributed processing subunits linked together to communicate data. Preferably the land vehicle 37 controllable suspension system includes a plurality of suspension sensors 25 located proximal to, all or some of, the land engagers 43 suspension locations 27 for measuring a plurality of suspension parameters
20 representative of suspension movements between the body 39 and the land engagers 43 and outputting a plurality of suspension sensor measurement output signals; a plurality of controllable force suspension members 29 located proximal the land engagers 43 and the suspension sensors 25, the controllable force suspension members 29 for applying a plurality of controllable suspension travel forces between the body 39 and the land engagers 43 to
25 control the suspension movements; and body motion sensor 31, the body motion sensor 31 for outputting a plurality of vehicle body motion measurement output signals.

Preferably the land vehicle controllable suspension system includes a vehicle databus 33 interfacing with the computer system 23, the vehicle databus 33 communicating a plurality
30 of vehicle data communication signals. Preferably the computer system 23 receives the suspension sensor measurement output signals and the vehicle body motion measurement output signals and executes a controllable suspension system algorithm for controlling the controllable force suspension members 29 to control vehicle body motion and the suspension movements between the body 39 and the land engagers 43.

Preferably the computer system 23 executes a health usage monitoring algorithm for monitoring the output signals and assessing a health usage of a vehicle component, preferably a plurality of vehicle components in the suspension and connected with the suspension.

5 Preferably the system includes a vehicle databus 33 interface interfacing with the computer system 23, the vehicle databus 33 interface communicating a plurality of vehicle data communication signals to the computer system 23.

10 Preferably the computer system 23 executes a regime recognition algorithm for using the output signals and inputted vehicle data communication signals from a vehicle databus 33 output to determine a vehicle operating parameter, such as a terrain type or a vehicle operating configuration such as the current loaded gross vehicle weight. Preferably the computer system 23 executes a regime recognition algorithm for using the output signals and the vehicle data communication signals from the databus 33 to determine a vehicle operating
15 configuration and the controllable suspension system algorithm is modified in response to the regime recognition algorithm. Preferably the computer system 23 executes a regime recognition algorithm for using the output signals to determine at least a vehicle operating parameter and a vehicle operating configuration and wherein the controllable suspension system algorithm is modified in response to the regime recognition algorithm, such as
20 different suspension algorithm gains are utilized depending upon type of terrain or location of vehicle CG, vehicle operating parameters, operator gas/braking, internal and external environmental inputs and comparisons with stored data.

25 Preferably the at least a first controllable force suspension member is comprised of a semi-active damper, with a control signal to the damper varying the damper force produced by damper, preferably a MR damper.

30 Preferably the at least a first controllable force suspension member is comprised of an active suspension actuator.

Preferably the at least a first controllable force suspension member is comprised of a controllable spring, preferably adjustable air spring member.

Preferably the suspension sensors 25 suspension sensor measurement output signals include a plurality of displacements between the body 39 and the land engagers 43.

5 Preferably the body motion sensor 31 vehicle body motion measurement output signals include a plurality of rate sensor output signals (degree/sec, angular rate).

Preferably the body motion sensor 31 vehicle body motion measurement output signals include a plurality of accelerometer output signals (m/sec², linear acceleration). Preferably the body motion sensor 31 vehicle body motion measurement output signals
10 include a plurality of six degrees of freedom of body motion output signals. Preferably the computer system 23 stores a plurality of condition data for a plurality of vehicle suspension components 35 in the medium. Preferably the computer system 23 provides a perceptible output when a vehicle suspension component is in need of corrective action. Preferably the controllable suspension system algorithm is modified in response to a health/usage of a
15 sensed vehicle suspension component. Preferably the computer system 23 output signals a plurality of suspension output data to an external computer, preferably a central depot computer, preferably a logistics maintenance computer.

In an embodiment the invention includes a monitoring apparatus for diagnosing faults
20 in the land vehicle 37 having a body 39, a power plant 41 and a plurality of land engagers 43, the land engagers 43 for engaging land and propelling the land vehicle 37 across land.

The apparatus including the controllable suspension system, the controllable suspension system for controlling a plurality of suspension movements between the body 39
25 and the land engagers 43. The monitoring apparatus includes the plurality of suspension sensors 25 located proximal to the land engagers 43 suspension locations 27 for measuring a plurality of suspension parameters representative of suspension movements between the body 39 and the land engagers 43 and outputting a plurality of suspension sensor measurement output signals. The monitoring apparatus includes the plurality of controllable force
30 suspension members 29 located proximal the land engagers 43 and the suspension sensors 25, the controllable force suspension members 29 for applying a plurality of controllable suspension travel forces between the body 39 and the land engagers 43 to control the suspension movements. The monitoring apparatus includes the body motion sensor 31, the body motion sensor 31 for outputting a plurality of vehicle body motion measurement output

signals. The monitoring apparatus receives the suspension sensor measurement output signals and the vehicle body motion measurement output signals and executes controllable suspension system instructions for controlling the controllable force suspension members 29 to control vehicle body motion and the suspension movements between the body 39 and the land engagers 43, and the apparatus including computer system 23 reference data store containing failure mode identification data and associated system data sampled from behavior of the controllable suspension system in the failure mode; and a similarity engine responsive to monitored system data indicative of monitored behavior of the controllable suspension system, for generating at least one similarity value for a comparison of the monitored data to the failure mode associated system data, as a diagnostic indication of the failure mode. The monitoring apparatus preferably includes the computer system 23, with a central computer and/or distributed computer system 23 with subunits proximate suspension sites/controllable force suspension members 29 located proximal the land engagers 43, linked together to communicate data. The monitoring apparatus preferably includes the vehicle databus 33 interfacing with the computer system 23, the vehicle databus 33 communicating a plurality of vehicle data communication signals. Preferably the system data is residual data. Preferably the monitoring apparatus further includes a model for generating estimates of operational data in response to receiving operational data from the system; and a signal generator for differencing the estimates and the received operational data to generate the residual data. Preferably the model for generating estimates is a non-parametric model. Preferably the monitoring apparatus further includes a failure identification module responsive to similarity values from the similarity engine for determining an indicated failure mode. Preferably the failure identification module compares similarity values for a plurality of failure modes in the data store, and identifies at least the failure mode with the highest similarity as an indicated failure mode of the system. Preferably the failure identification module compares similarity values for a plurality of failure modes in the data store, and identifies at least the failure mode with the highest average similarity as an indicated failure mode of the system. Preferably the failure identification module compares similarity values for a plurality of failure modes in the data store, and identifies as an indicated failure mode of the system at least the failure mode with at least a selected number of highest similarities over a window of successive comparisons.

In an embodiment the invention includes a method for diagnosing faults in a land vehicle 37 having a body 39, a power plant 41 and a plurality of land engagers 43, the land

engagers 43 for engaging land and propelling the land vehicle 37 across land, the method including: providing a controllable suspension system, the controllable suspension system disposed between the body 39 and the land engagers 43 to control a plurality of suspension movements between the body 39 and the land engagers 43, the controllable suspension system including a plurality of suspension sensors 25 located proximal to all or some of the land engagers 43 suspension locations 27 for measuring a plurality of suspension parameters representative of suspension movements between the body 39 and the land engagers 43 and outputting a plurality of suspension sensor measurement output signals; a plurality of controllable force suspension members 29 located proximal the land engagers 43 and the suspension sensors 25, the controllable force suspension members 29 for applying a plurality of controllable suspension travel forces between the body 39 and the land engagers 43 to control the suspension movements; a body motion sensor 31, the body motion sensor 31 for outputting a plurality of vehicle body motion measurement output signals; with the controllable suspension system receiving the suspension sensor measurement output signals and the vehicle body motion measurement output signals and executing controllable suspension system instructions for controlling the controllable force suspension members 29 to control vehicle body motion and the suspension movements between the body 39 and the land engagers 43, and the controllable suspension system acquiring monitored controllable suspension system data indicative of monitored controllable suspension behavior of the controllable suspension system; sampling controllable suspension system data from a controllable suspension failure mode to define controllable suspension reference system data associated with the controllable suspension failure mode, and comparing for similarity the monitored system data to the reference system data to generate a similarity value as a diagnostic indication of the controllable suspension failure mode. Preferably the controllable suspension system data is residual controllable suspension data. Preferably the method further comprises generating estimates of operational data in response to acquiring operational controllable suspension data from the controllable suspension system; and differencing the estimates and the received operational data to generate the residual controllable suspension data. Preferably the method further comprises the step of determining an indicated controllable suspension failure mode based on similarity values resulting from the similarity comparisons. Preferably the determining step comprises comparing the similarity values for a plurality of controllable suspension failure modes, and identifying at least the controllable suspension failure mode with the highest similarity as an indicated controllable suspension failure mode of the system. Preferably the determining step

comprises comparing the similarity values for a plurality of failure modes, and identifying at least the failure mode with the highest average similarity as an indicated failure mode of the system.

5 In an embodiment, the invention provides diagnostic capabilities in a monitoring system for land vehicles 27 and controllable suspension system. Preferably a collection of diagnostic conditions is provided as part of the operation of the computer controlled controllable suspension system on-line monitoring of the vehicle suspension system and vehicle components from physical components and subsystems instrumented with sensors.

10 Output signals created by the on-line monitoring are preferably compared to the diagnostic conditions collection, and if a signature of one or more diagnostic conditions is recognized in such output signals, the system provides a diagnosis of a possible impending suspension system failure mode. Preferably the diagnostics utilize a nonparametric empirical model that generates estimates of sensor values in response to receiving actual sensor values from the

15 controllable suspension system sensors. The estimated sensor values generated by the model are preferably subtracted from the actual sensor values to provide residual signals for the sensors. During normal vehicle use with the controllable suspension and related components functioning properly as modeled by the empirical model the residual signals are essentially zero with some noise from the underlying physical parameters and the sensor noise. Such

20 residuals become move from zero when the controllable suspension and related vehicle components begin to fail. Preferably a sensitive statistical test such as the sequential probability ratio test is applied to the residuals to provide the earliest possible decision whether the residuals are moving off zero, often at such an early stage that the residual trend away from zero is still buried in the noise level. Preferably when a decision is made that the

25 residual is non-zero, an alert is generated for that sensor for the relevant time period. Alternatively an alert may be generated to enforce thresholds on the residual itself for each parameter, alerting on that parameter when the thresholds are exceeded. The collected recorded diagnostic conditions can be referenced using the residual data itself, or alternatively using the sequential probability ratio test alert information or the residual

30 threshold alert information. Failure modes are preferably stored in the computer system 23 computer readable medium recordable diagnostic conditions collection. When the pattern of sequential probability ratio test alerts or residual threshold alerts matches the stored signature the failure mode is recognized, and the diagnosis made. Alternatively, when the residual data pattern is similar to a residual data pattern in the stored collection using a similarity engine,

the corresponding failure mode is recognized and the diagnosis made. Preferably when the failure mode is recognized the controllable suspension system adjusts the control of the suspension system in response to such diagnosis, preferably when force through a diagnosed component is to be limited until appropriate repair is made to correct such failure mode, in addition to providing explanatory descriptions, suggested investigative steps, and suggested repair steps either to a vehicle operator or communicated to an external depot maintenance computer.

In an embodiment, the invention includes a monitoring apparatus for diagnosing faults in a land vehicle 37 having a body 39, a power plant 41 and a plurality of land engagers 43, the land engagers 43 for engaging land and propelling the land vehicle 37 across land. The apparatus including a controllable suspension system, the controllable suspension system for controlling a plurality of suspension movements between the body 39 and the land engagers 43, a plurality of suspension sensors 25 located proximal to all or some of the land engagers 43 suspension locations 27 for sensing a plurality of suspension measurables and outputting a plurality of suspension sensor measurement output signals; a plurality of controllable force suspension members 29 located proximal the land engagers 43 and the suspension sensors 25, the controllable force suspension members 29 for applying a plurality of controllable suspension travel forces between the body 39 and the land engagers 43 to control the suspension movements; a body motion sensor 31, the body motion sensor 31 for outputting a plurality of vehicle body motion measurement output signals; the apparatus receives the suspension sensor measurement output signals and the vehicle body motion measurement output signals and executes controllable suspension system instructions for controlling the controllable force suspension members 29 to control vehicle body motion and the suspension movements between the body 39 and the land engagers 43, and the apparatus including computer readable failure mode reference identification data for detecting a failure mode in the controllable suspension system; and the apparatus compares monitored controllable suspension system data to the failure mode reference identification data to diagnose an impending failure mode of the controllable suspension system. The apparatus including the computer system 23 with the central computer and/or the distributed computer system 23 with subunits proximate suspension sites/controllable force suspension members 29 located proximal the land engagers 43, and linked together to communicate data. The apparatus preferably includes the vehicle databus 33 interfacing with the computer system 23, the vehicle databus 33 communicating a plurality of vehicle data communication signals.

Preferably the apparatus includes a global geographic positioning input, wherein the apparatus collects the suspension sensor measurement output signals and the vehicle body motion measurement output signals with the geographic positioning inputs to provide a computer readable media stored geographic data map indicating land terrain suspension land engagement conditions for geographic positions engaged by the land engagers 43. Preferably the apparatus at a later time, when returning to an already engaged land geographic position, the apparatus modifies the control of the controllable suspension system in response to the computer readable media stored geographic data map, preferably using a stored map to know when to adjust and change the suspension system from past history saved in map data.

10 Preferably the apparatus output signals the computer readable media stored geographic data map indicating land terrain suspension land engagement conditions for geographic positions engaged by the land engagers 43 to an external computer. Preferably the apparatus receives a shared computer readable media stored geographic data map indicating land terrain suspension land engagement conditions for geographic positions engaged by the land engagers 43 of another vehicle from an external computer.

In an embodiment, the invention includes a monitoring method for diagnosing faults in a plurality of land vehicles 37. The method includes providing a plurality of land vehicles 37 comprised a body 39, a power plant 41 and a plurality of land engagers 43, the land engagers 43 for engaging land and propelling the land vehicles 37 across land, the land vehicles 37 including a controllable suspension system, the controllable suspension system for controlling a plurality of suspension movements between the body 39 and the land engagers 43, the controllable suspension system including a plurality of suspension sensors 25 located proximal to all or some of the land engagers 43 suspension locations 27 for sensing a plurality of suspension measurables and outputting a plurality of suspension sensor measurement output signals; the controllable suspension system including a plurality of controllable force suspension members 29 located proximal the land engagers 43 and the suspension sensors 25, the controllable force suspension members 29 for applying a plurality of controllable suspension travel forces between the body 39 and the land engagers 43 to control the suspension movements; the controllable suspension system including a body motion sensor 31, the body motion sensor 31 for outputting a plurality of vehicle body motion measurement output signals. The method includes receiving the suspension sensor measurement output signals and the vehicle body motion measurement output signals and executing controllable suspension system instructions for controlling the controllable force

suspension members 29 to control vehicle body motion and the suspension movements between the vehicle bodies and the land engagers 43. The method includes providing computer readable failure mode reference identification data for detecting a failure mode in the controllable suspension systems and comparing monitored controllable suspension system data to the failure mode reference identification data to diagnose an impending failure mode of the controllable suspension systems. Preferably the method includes providing the vehicles with a global geographic positioning input device for providing each vehicle with its geographic positioning input while engaging land (GPS, global position satellite, inertia guidance tracking positioning) and collecting the suspension sensor measurement output signals and the vehicle body motion measurement output signals with the geographic positioning inputs to provide a computer readable media stored geographic data map indicating land terrain suspension land engagement conditions for geographic positions engaged by the land engagers 43. Preferably the method includes outputting the computer readable media stored geographic data map indicating land terrain suspension land engagement conditions for geographic positions engaged by the land engagers 43 to an external computer. Preferably the method includes sharing the computer readable media stored geographic data map indicating land terrain suspension land engagement conditions for geographic positions engaged by the land engagers 43 with a plurality of the vehicles. Preferably the method includes adjusting the controllable suspension system in response to the computer readable media stored geographic data map indicating land terrain suspension land engagement conditions for geographic positions engaged by the land engagers 43 when returning to the geographic position. Preferably the method includes adjusting the controllable suspension system in response to the shared computer readable media stored geographic data map indicating land terrain suspension land engagement conditions for geographic positions engaged by the land engagers 43 when engaging land at the collected geographic position. Preferably the method includes outputting to an external computer at least one controllable suspension system data output chosen from the controllable suspension system data output group of the suspension sensor measurement output signals, the vehicle body motion measurement output signals, the compared monitored controllable suspension system data, the failure mode reference identification data, and the diagnose of an impending failure mode. Preferably the method includes sharing the controllable suspension system data output with a plurality of the vehicles.

In an embodiment the invention includes a land vehicle 37 for driving by an occupant human driver 100. The land vehicle 37 includes a body 39, a power plant 41 and a plurality of land engagers 43, the land engagers 43 for engaging land and propelling the land vehicle across land. The land vehicle 37 includes a controllable suspension system 21 for controlling a plurality of suspension movements between the body 39 and the land engagers 43. The land vehicle 37 includes a computer system 23 with computer readable medium 24. The land vehicle 37 includes a plurality of suspension sensors 25 located proximal to the land engagers 43 for measuring a plurality of suspension parameters representative of suspension movements between the body 39 and the land engagers 43 and outputting a plurality of suspension sensor measurement output signals. The land vehicle 37 includes a plurality of controllable force suspension members 29 located proximal the land engagers 43 and the suspension sensors 25, the controllable force suspension members 29 for applying a plurality of controllable suspension travel forces between the body 39 and the land engagers 43 to control the suspension movements. The land vehicle 37 includes a body motion sensor 31, the body motion sensor 31 for outputting a plurality of vehicle body motion measurement output signals. The land vehicle 37 includes a vehicle databus 33 interfacing with the computer system 23, the vehicle databus 33 communicating a plurality of vehicle data communication signals. Preferably the computer system 23 receives the suspension sensor measurement output signals and the vehicle body motion measurement output signals and the computer readable medium 24 includes first program instructions with the computer system 23 executing a controllable suspension system control algorithm for controlling the controllable force suspension members 29 to control vehicle body motion and the suspension movements between the body 39 and the land engagers 43, and the computer readable medium 24 includes second program instructions with the computer system 23 executing a driver suspension feedback algorithm for monitoring signals, preferably including vehicle data communication signals, to identify an impending driver land vehicle safety margin and controlling the controllable force suspension members 29 to warn the driver 100 of the impending driver land vehicle safety margin. Preferably the driver suspension feedback algorithm includes a driver vehicle speed regulation override which controls the controllable force suspension members 29 to provide the warning to the driver 100 of the impending driver land vehicle safety margin.

Preferably the controllable force suspension members 29 are controlled to warn the driver 100 of the impending driver land vehicle safety margin. Preferably the controllable

force suspension members 29 are controlled to warn the driver 100 of the impending driver land vehicle safety margin by increasing a level of power absorbed by the driver 100 by increasing the transmission of force through the controllable force suspension members 29, preferably as compared to maximizing isolation of the driver 100 from the terrain and decreasing the level of power absorbed by the driver 100. Preferably instead of controlling the suspension members 29 to limit driver 100 absorbed power, the system increases driver absorbed power as driver 100 increases speed, wherein the drivers speed is reduced/regulated as the driver's speed approaches the safety margin. Preferably the computer system executes a regime recognition algorithm for using the output signals and the vehicle data communication signals from the databus to determine a vehicle operating parameter of the vehicle 37 and how the driver 100 is driving the vehicle 37.

Preferably the driver suspension feedback algorithm monitors the vehicle data communication signals, the suspension sensor measurement output signals, and the vehicle body motion measurement output signals to identify the impending driver land vehicle safety margin and control the controllable force suspension members 29 to warn the driver 100 of the impending driver land vehicle safety margin. Preferably the computer system executes a regime recognition algorithm for using the signals including the vehicle data communication signals from the databus to determine a vehicle operating configuration of the vehicle 37.

Preferably controlling the controllable force suspension members 29 to warn the driver 100 of the impending driver land vehicle safety margin includes increasing a suspension control gain of at least one controllable force suspension member 29. Preferably the system increases the suspension control gain by increasing a suspension control damping gain to at least one controllable force suspension member damper to warn the driver. Preferably the system increases driver absorbed power while enhancing vehicle stability by increasing suspension inertial damping gains. Preferably the controllable suspension system algorithm is modified in response to the regime recognition algorithm. Preferably controlling the controllable force suspension members 29 to warn the driver 100 of the impending driver land vehicle safety margin includes increasing a suspension damping force gain. Preferably the system executes a regime recognition algorithm for using the output signals and the vehicle data communication signals from the databus to determine at least a vehicle operating parameter and a vehicle operating configuration and wherein the controllable suspension

system algorithm is modified in response to the regime recognition algorithm, preferably with an increased suspension control gain warning the driver.

5 Preferably controlling the controllable force suspension members 29 to warn the driver 100 of the impending driver land vehicle safety margin includes repetitively switching between a suspension high damping state and a suspension low damping state. Preferably an overspeed indicator warning is provided to the driver by dithering the vehicle suspension between two different suspension states, preferably switching a semi-active damper quickly between high and low damping state such that driver 100 physically feels the effects of such personally. Preferably the at least first controllable force suspension member 29 is comprised of a semi-active damper.

15 Preferably the driver suspension feedback algorithm monitors a measured calculated vehicle gross weight and a driver driving pattern to identify an unsafe driving speed impending driver land vehicle safety margin and controls the controllable force suspension members 29 to warn the driver 100 of the impending driver land vehicle safety margin. Preferably at least a first controllable force suspension member 29 is comprised of an actuator.

20 Preferably the driver suspension feedback algorithm monitors for an impending vehicle roll-over regime and control the controllable force suspension members 29 to warn the driver 100 of the impending vehicle roll-over regime.

Preferably the driver suspension feedback algorithm monitors at least one roll-over signal selected from the roll-over signal input group including vehicle lateral acceleration input signals, roll-rate input signals, and steering wheel angle input signals.

30 Preferably the driver suspension feedback algorithm monitors the measured vehicle gross weight and a vehicle speed and controls the controllable force suspension members 29 to warn the driver 100 of an impending driver land vehicle safety margin speed for the measured vehicle gross weight, preferably with the speed regulation override algorithm responding to measured vehicle gross weight and vehicle speed and controls the suspension to regulate the vehicle speed.

Preferably the body motion sensor vehicle body motion measurement output signals include a plurality of accelerometer output signals.

5 Preferably the body motion sensor vehicle body motion measurement output signals include a plurality of six degrees of freedom of body motion output signals.

Preferably the computer system stores a plurality of condition data for a plurality of vehicle components in the computer readable medium.

10 In an embodiment the invention includes a method of controlling a land vehicle 37 driven by an occupant driver 100. The vehicle includes a body 39 and a power plant 41. Preferably the vehicle 37 includes a plurality of land engagers 43, the land engagers 43 for engaging land and propelling the land vehicle 37 across land. The vehicle 37 includes a controllable suspension system 21, the controllable suspension system 21 for controlling a
15 plurality of suspension movements, preferably between the body 39 and the land engagers 43. The method includes providing a plurality of suspension sensors 25 for measuring a plurality of suspension parameters representative of suspension movements of the body 39 and outputting a plurality of suspension sensor measurement output signals. The method includes providing a plurality of controllable force suspension members 29, the controllable force
20 suspension members 29 for applying a plurality of controllable suspension travel forces to control the suspension movements. The method includes providing a body motion sensor 31, the body motion sensor 31 for outputting a plurality of vehicle body motion measurement output signals. The method includes monitoring signals, to identify an impending driver land vehicle safety margin and controlling the controllable force suspension members 29 to inhibit
25 the driver from crossing into the identified impending driver land vehicle safety margin. Preferably the computer system 23 receives the suspension sensor measurement output signals and the vehicle body motion measurement output signals and the computer readable medium 24 including a first program instruction with the computer system executing a controllable suspension system algorithm for controlling the controllable force suspension
30 members 29 to control vehicle body motion and the suspension movements between the body 39 and the land engagers 43, and the computer readable medium including a second program instruction with the computer system 23 executing a driver suspension feedback algorithm for monitoring vehicle data communication signals to identify an impending driver land vehicle

safety margin and controlling the controllable force suspension members to warn the driver of the impending driver land vehicle safety margin.

5 Preferably controlling the controllable force suspension members 29 to warn the driver 100 of the impending driver land vehicle safety margin includes increasing a level of power absorbed by the driver 100, preferably with the system instead of controlling the suspension members 29 to limit driver absorbed power, the system increases driver 100 absorbed power as driver 100 increases speed to inhibit crossing the approaching safety margin, preferably with such suspension feedback the driver reduces/regulates the speed
10 when approaching the safety margin.

Preferably the computer system includes instructions with the computer system executing a regime recognition algorithm for using the sensor output signals and the vehicle data communication signals from the databus to determine vehicle operating parameters and
15 vehicle operating configurations.

Preferably the system monitors the vehicle data communication signals, the suspension sensor measurement output signals, and the vehicle body motion measurement output signals to identify the impending driver land vehicle safety margin and controls the
20 controllable force suspension members to warn the driver of the impending driver land vehicle safety margin.

Preferably controlling the controllable force suspension members to warn the driver of the impending driver land vehicle safety margin includes increasing a suspension control
25 gain, preferably with increasing driver absorbed power while enhancing vehicle stability by increasing the suspension control damping gains in suspension members 29. Preferably control of suspension members 29 is modified in response to a regime recognition algorithm, preferably with increased suspension control gains warning the driver. Preferably controlling the controllable force suspension members 29 to warn the driver 100 of the impending driver
30 land vehicle safety margin includes increasing a suspension damping gain for controllable force suspension member damper. Preferably the system executes a regime recognition algorithm for using the sensor output signals and the vehicle data communication signals from the databus to determine at least a vehicle operating parameter and a vehicle operating

configuration and wherein the controllable suspension system algorithm is modified in response to the regime recognition algorithm.

5 Preferably controlling the controllable force suspension members 29 to warn the driver 100 of the impending driver land vehicle safety margin includes repetitively switching between a suspension high damping state and a suspension low damping state. Preferably the driver is warned of an overspeed safety margin by dithering the vehicle suspension between two different suspension states, preferably switching a semi-active damper quickly between high and low damping states such that driver 100 feels the effects of such physically and
10 personally.

Preferably the method includes monitoring a measured vehicle gross weight and a driver driving pattern to identify an unsafe driving speed impending driver land vehicle safety margin and controlling the controllable force suspension members 29 to warn the driver of
15 the impending driver land vehicle safety margin.

Preferably the method includes monitoring for an impending vehicle roll-over regime and controlling the controllable force suspension members 29 to warn the driver of the impending vehicle roll-over regime.
20

Preferably the method includes monitoring at least one roll-over input signal selected from the roll-over signal group including vehicle lateral acceleration signals, roll-rate signals, and steering wheel angle signals.

25 Preferably the method includes monitoring the measured vehicle gross weight and a vehicle speed and controlling the controllable force suspension members to warn the driver of an impending driver land vehicle safety margin speed for the measured vehicle gross weight. Preferably a speed regulation algorithm responds to measured vehicle gross weight and vehicle speed and controls the suspension to regulate the vehicle speed.

30

In an embodiment the invention includes a vehicle driver control system for controlling a vehicle 37 driven by an occupant driver 100, the vehicle 37 having a body 39, a power plant 41, and a controllable suspension sub-system 21, the controllable suspension sub-system 21 for controlling a plurality of suspension movements. The vehicle driver

control system includes a plurality of suspension sensors 25 for measuring a plurality of suspension parameters representative of suspension movements of the body 39 and outputting a plurality of suspension sensor measurement output signals. The vehicle driver control system includes a plurality of controllable force suspension members 29, the controllable force suspension members 29 for applying a plurality of controllable suspension travel forces. The vehicle driver control system includes a body motion sensor 31, the body motion sensor 31 for outputting a plurality of vehicle body motion measurement output signals. The vehicle driver control system includes a vehicle databus 33, the vehicle databus 33 communicating a plurality of vehicle data communication signals. The vehicle driver control system includes a computer sub-system 23 for monitoring vehicle data communication signals to identify an impending driver vehicle safety margin and controlling the controllable force suspension members 29 to inhibit the driver 100 from crossing into the impending driver land vehicle safety margin. Preferably the computer sub-system 23 receives the suspension sensor measurement output signals and the vehicle body motion measurement output signals and the computer readable medium 24 includes a first program instruction with the computer sub-system 23 executing a controllable suspension sub-system algorithm for controlling the controllable force suspension members 29 to control vehicle body motion and the suspension movements between the body 39 and the land engagers 43, and the computer readable medium 24 including a second program instruction with the computer sub-system 23 executing a driver suspension feedback algorithm for monitoring vehicle data communication signals to identify an impending driver land vehicle safety margin and controlling the controllable force suspension members 29 to warn the driver of the impending driver land vehicle safety margin.

Preferably computer sub-system 23 controls the controllable force suspension members 29 to warn the driver 100 of the impending driver land vehicle safety margin with an increasing level of power absorbed by the driver 100. Preferably computer sub-system 23 instead of controlling the suspension members 29 to limit driver absorbed power, the computer sub-system 23 increases driver absorbed power as the driver 100 increases speed, wherein the driver 100 is regulated to reduce the speed when approaching the safety margin. Preferably the computer sub-system computer readable medium 24 includes a program instructions with the computer sub-system 23 executing a regime recognition algorithm for using the sensor output signals and the vehicle data communication signals from the databus to determine a vehicle operating parameter.

Preferably computer sub-system 23 monitors the vehicle data communication signals, the suspension sensor measurement output signals, and the vehicle body motion measurement sensor output signals to identify the impending driver land vehicle safety margin and controls the controllable force suspension members 29 to warn the driver of the impending driver land vehicle safety margin. Preferably the computer sub-system 23 computer readable medium 24 includes a program instruction with the computer sub-system executing a regime recognition algorithm for using the output signals and the vehicle data communication signals from the databus to determine a vehicle operating configuration.

Preferably the computer sub-system 23 controls the controllable force suspension members 29 to warn the driver 100 of the impending driver land vehicle safety margin by increasing a suspension control gain, preferably while increasing driver absorbed power and enhancing vehicle stability by increasing suspension damping gains. Preferably the control of the controllable force suspension members 29 is modified in response to the regime recognition algorithm.

Preferably the computer sub-system 23 includes a regime recognition algorithm for using the output signals and the vehicle data communication signals from the databus to determine at least a vehicle operating parameter and a vehicle operating configuration and wherein the controllable suspension algorithm is modified in response to the regime recognition algorithm.

Preferably the computer sub-system 23 controls the controllable force suspension members 29 to warn the driver 100 of the impending driver land vehicle safety margin by repetitively switching between a suspension high damping state and a suspension low damping state. Preferably an overspeed warning is provided by dithering the vehicle suspension between two different suspension states, preferably switching a semi-active damper member 29 quickly between high and low damping states such that driver 100 feels the effects of such physically and personally. In a preferred embodiment the controllable force suspension members 29 includes an actuator.

Preferably the computer sub-system 23 monitors a measured vehicle gross weight and a driver driving pattern to identify an unsafe driving speed impending driver land vehicle

safety margin and controls the controllable force suspension members 29 to warn the driver 100 of the impending driver land vehicle safety margin.

5 Preferably the computer sub-system 23 monitors for an impending vehicle roll-over regime and controls the controllable force suspension members 29 to warn the driver 100 of the impending vehicle roll-over regime.

10 Preferably the computer sub-system 23 monitors at least one roll-over signal input selected from the roll-over signal input group including vehicle lateral acceleration signals, roll-rate signals, and steering wheel angle signals.

15 Preferably the computer sub-system 23 monitors the measured vehicle gross weight and a vehicle speed and controls the controllable force suspension members 29 to warn the driver 100 of an impending driver land vehicle safety margin speed for the measured vehicle gross weight, preferably with a speed regulation algorithm responding to measured vehicle gross weight and vehicle speed and controlling the suspension to regulate the vehicle speed.

20 In an embodiment the invention includes a system for controlling a vehicle 37 driven by a human occupant driver 100, the vehicle 37 having a body 39, a power plant 41, and a controllable suspension 21, the controllable suspension 21 for controlling a plurality of suspension movements. The system includes a means for outputting a plurality of suspension measurement signals. The system includes at least a first controllable force suspension member 29, the controllable force suspension member 29 for applying a plurality of
25 controllable suspension travel forces. The system includes a means for outputting a plurality of body motion measurement signals. The system includes a means for communicating a plurality of vehicle data communication signals. The system includes a control means for monitoring the signals to identify an impending driver vehicle safety margin and controlling the controllable force suspension member 29 to warn the driver 100 of the impending driver
30 land vehicle safety margin.

Preferably the control means increases a transmission level of environmental inputs through the controllable force suspension member 29 to notify the driver 100 of the impending driver land vehicle safety margin. Preferably the suspension system 21 transmits

increased road terrain inputs to driver 100 proximate the impending driver land vehicle safety margin, such as for the same road terrain but at a first safe speed and/or gross vehicle weight transmission through suspension system 21 is minimized while maintaining vehicle performance and stability, and for the vehicle and same road terrain but at a second unsafe speed and/or gross vehicle weight transmission through suspension system 21 to the driver 100 is not minimized but increased to warn of the driver 100 of the land vehicle safety margin. Preferably the computer sub-system 23 receives the suspension sensor measurement output signals and the vehicle body motion measurement output signals and the computer readable medium 24 includes a first program instructions with the computer sub-system executing a controllable suspension sub-system algorithm for controlling the controllable force suspension members 29 to control vehicle body motion and the suspension movements between the body 39 and the land engagers 43, and the computer readable medium 24 includes second program instructions with the computer sub-system executing a driver suspension feedback algorithm for monitoring vehicle data communication signals to identify an impending driver land vehicle safety margin and controlling the controllable force suspension members 29 to warn the driver of the impending driver land vehicle safety margin.

It will be apparent to those skilled in the art that various modifications and variations can be made to the invention without departing from the spirit and scope of the invention. Thus, it is intended that the invention cover the modifications and variations of this invention provided they come within the scope of the appended claims and their equivalents. It is intended that the scope of differing terms or phrases in the claims may be fulfilled by the same or different structure(s) or step(s).

CLAIMS:

1. A land vehicle for driving by a driver, said land vehicle having a body, a power plant and a plurality of land engagers, said land engagers for engaging land and propelling said land vehicle across land, said land vehicle including a controllable suspension system, said controllable suspension system for controlling a plurality of suspension movements between said body and said land engagers,

a computer system with computer readable medium;

a plurality of suspension sensors located proximal to said land engagers for measuring a plurality of suspension parameters representative of suspension movements between said body and said land engagers and outputting a plurality of suspension sensor measurement output signals;

a plurality of controllable force suspension members located proximal said land engagers and said suspension sensors, said controllable force suspension members for applying a plurality of controllable suspension travel forces between said body and said land engagers to control said suspension movements;

a body motion sensor, said body motion sensor for outputting a plurality of vehicle body motion measurement output signals;

a vehicle databus interfacing with said computer system, said vehicle databus communicating a plurality of vehicle data communication signals;

wherein said computer system receives said suspension sensor measurement output signals and said vehicle body motion measurement output signals and said computer readable medium including a first program instruction with said computer system executing a controllable suspension system algorithm for controlling said controllable force suspension members to control vehicle body motion and said suspension movements between said body and said land engagers, and said computer readable medium including a second program instruction with said computer system executing a driver suspension feedback algorithm for monitoring vehicle data communication signals to identify an impending driver land vehicle safety margin and controlling said controllable force suspension members to warn said driver of said impending driver land vehicle safety margin.

2. A vehicle as claimed in claim 1, wherein controlling said controllable force suspension members to warn said driver of said impending driver land vehicle safety margin includes increasing a level of power absorbed by said driver

3. A vehicle as claimed in claim 1, wherein said driver suspension feedback algorithm monitors said vehicle data communication signals, said suspension sensor measurement output signals, and said vehicle body motion measurement output signals to identify said impending driver land vehicle safety margin and control said controllable force suspension members to warn said driver of said impending driver land vehicle safety margin.
4. A vehicle as claimed in claim 1, wherein controlling said controllable force suspension members to warn said driver of said impending driver land vehicle safety margin includes increasing a suspension control gain.
5. A vehicle as claimed in claim 1 wherein wherein controlling said controllable force suspension members to warn said driver of said impending driver land vehicle safety margin includes repetitively switching between a suspension high damping state and a suspension low damping state.
6. A vehicle as claimed in claim 3 wherein said driver suspension feedback algorithm monitors a measured vehicle gross weight and a driver driving pattern to identify an unsafe driving speed impending driver land vehicle safety margin and controls said controllable force suspension members to warn said driver of said impending driver land vehicle safety margin.
7. A vehicle as claimed in claim 3 wherein said driver suspension feedback algorithm monitors for an impending vehicle roll-over regime and control said controllable force suspension members to warn said driver of said impending vehicle roll-over regime.
8. A vehicle as claimed in claim 7 wherein said driver suspension feedback algorithm monitors at least one roll-over signal input selected from the roll-over signal input group including vehicle lateral acceleration signal inputs, roll-rate signal inputs, and steering wheel angle signal inputs.
9. A vehicle as claimed in claim 6 wherein driver suspension feedback algorithm monitors said measured vehicle gross weight and a vehicle speed and controls said

controllable force suspension members to warn said driver of an impending driver land vehicle safety margin speed for said measured vehicle gross weight.

10. A vehicle as claimed in claim 1 wherein said body motion sensor vehicle body motion measurement output signals include a plurality of accelerometer output signals.

11. A vehicle as claimed in claim 1 wherein said body motion sensor vehicle body motion measurement output signals include a plurality of six degrees of freedom of body motion output signals.

12. A vehicle as claimed in claim 1 wherein said computer system stores a plurality of condition data for a plurality of vehicle components in said medium.

13. A method of controlling a vehicle driven by a driver, said vehicle having a body, a power plant, and a controllable suspension system, said controllable suspension system for controlling a plurality of suspension movements, said method including:

providing at least a first suspension sensor for measuring a plurality of suspension parameters representative of suspension movements of said body and outputting a plurality of suspension sensor measurement output signals;

providing at least a first controllable force suspension member, said at least first controllable force suspension members for applying a plurality of controllable suspension travel forces;

providing a body motion sensor, said body motion sensor for outputting a plurality of vehicle body motion measurement output signals;

monitoring a plurality of sensor signals to identify an impending driver vehicle safety margin and controlling said at least first controllable force suspension member to inhibit said driver from crossing into said identified impending driver vehicle safety margin.

14. A method as claimed in claim 13, wherein controlling said at least first controllable force suspension member to inhibit said driver from crossing into said identified impending driver vehicle safety margin includes increasing a level of power absorbed by said driver

15. A method as claimed in claim 13, including monitoring a plurality of vehicle data communication signals from a vehicle databus, a plurality of suspension sensor measurement

output signals, and a plurality of body motion measurement output signals to identify said impending driver vehicle safety margin and controlling said at least first controllable force suspension member to inhibit said driver from crossing into said identified impending driver land vehicle safety margin.

16. A method as claimed in claim 13, wherein controlling said at least first controllable force suspension member to inhibit said driver of said impending driver vehicle safety margin includes controlling said at least first controllable force suspension member to warn said driver of said impending driver land vehicle safety margin.

17. A method as claimed in claim 16, wherein controlling said at least first controllable force suspension member to warn said driver of said impending driver vehicle safety margin includes increasing a suspension control gain.

18. A method as claimed in claim 16 wherein controlling said at least first controllable force suspension member to warn said driver of said impending driver vehicle safety margin includes repetitively switching between a suspension high damping state and a suspension low damping state.

19. A method as claimed in claim 15 including monitoring a measured vehicle gross weight and a driver driving pattern to identify an unsafe driving speed impending driver vehicle safety margin and controlling said at least first controllable force suspension member to warn said driver of said impending driver vehicle safety margin.

20. A method as claimed in claim 15 including monitoring for an impending vehicle roll-over regime and controlling said at least first controllable force suspension member to warn said driver of said impending vehicle roll-over regime.

21. A method as claimed in claim 20 including monitoring at least one roll-over signal input selected from the roll-over signal input group including vehicle lateral acceleration signal inputs, roll-rate signal inputs, and steering wheel angle signal inputs.

22. A method as claimed in claim 19 including monitoring said measured vehicle gross weight and a vehicle speed and controlling said at least first controllable force suspension

member to warn said driver of an impending driver land vehicle safety margin speed for said measured vehicle gross weight.

23. A vehicle driver control system for controlling a vehicle driven by a driver, said vehicle having a body, a power plant, and a controllable suspension sub-system, said controllable suspension sub-system for controlling a plurality of suspension movements, said vehicle driver control system including:

- a plurality of suspension sensors for measuring a plurality of suspension parameters representative of suspension movements of said body and outputting a plurality of suspension sensor measurement output signals;

- a plurality of controllable force suspension members, said controllable force suspension members for applying a plurality of controllable suspension travel forces;

- a body motion sensor, said body motion sensor for outputting a plurality of vehicle body motion measurement output signals;

- a vehicle databus, said vehicle databus communicating a plurality of vehicle data communication signals;

- a computer sub-system for monitoring a plurality of signals to identify an impending driver vehicle safety margin and controlling said controllable force suspension members to inhibit said driver from crossing into said identified impending driver land vehicle safety margin.

24. A vehicle driver control system as claimed in claim 23, wherein said computer sub-system controls said controllable force suspension members to warn said driver of said impending driver land vehicle safety margin with an increasing level of power absorbed by said driver.

25. A vehicle driver control system as claimed in claim 23, wherein said computer sub-system monitors said vehicle data communication signals, said suspension sensor measurement output signals, and said vehicle body motion measurement output signals to identify said impending driver land vehicle safety margin and controls said controllable force suspension members to warn said driver of said impending driver land vehicle safety margin.

26. A vehicle driver control system as claimed in claim 23, wherein said computer sub-system controls said controllable force suspension members with an increased suspension control gain.
27. A vehicle driver control system as claimed in claim 23, wherein said computer sub-system controls said controllable force suspension members to warn said driver of said impending driver land vehicle safety margin with an increasing suspension damping gain.
28. A vehicle driver control system as claimed in claim 23 wherein said computer sub-system controls said controllable force suspension members to warn said driver of said impending driver land vehicle safety margin includes repetitively switching between a suspension high damping state and a suspension low damping state.
29. A vehicle driver control system as claimed in claim 25 wherein said computer sub-system monitors a measured vehicle gross weight and a driver driving pattern to identify an unsafe driving speed impending driver land vehicle safety margin and controls said controllable force suspension members to warn said driver of said impending driver land vehicle safety margin.
30. A vehicle driver control system as claimed in claim 25 wherein said computer sub-system monitors for an impending vehicle roll-over regime and controls said controllable force suspension members to warn said driver of said impending vehicle roll-over regime.
31. A vehicle driver control system as claimed in claim 30 wherein said computer sub-system monitors at least one roll-over signal input selected from the roll-over signal input group including vehicle lateral acceleration signal inputs, roll-rate signal inputs, and steering wheel angle signal inputs.
32. A vehicle driver control system as claimed in claim 29 wherein said computer sub-system monitors said measured vehicle gross weight and a vehicle speed and controlling said controllable force suspension members to warn said driver of an impending driver land vehicle safety margin speed for said measured vehicle gross weight.

33. A system for controlling a vehicle driven by a human driver, said vehicle having a body, a power plant, and a controllable suspension, said controllable suspension for controlling a plurality of suspension movements, said system including:

a means for outputting a plurality of suspension measurement signals;

at least a first controllable force suspension member, said controllable force suspension member for applying a plurality of controllable suspension travel forces;

a means for outputting a plurality of body motion measurement signals;

a means for communicating a plurality signals;

a control means for monitoring said signals to identify an impending driver vehicle safety margin and controlling said controllable force suspension member to warn said driver of said impending driver land vehicle safety margin.

34. A system as claimed in claim 33, wherein said control means increases a transmission level of environmental inputs through said controllable force suspension member to notify said driver of said impending driver land vehicle safety margin.
