A module is provided for attachment to the roof of a bus and includes all of the necessary components for conditioning the return air from the passenger compartment and delivering conditioned air thereto. A plurality of modules can be mounted in various relationships to collectively provide the total capacity required by the bus. Each module includes an evaporator section, a...
condenser section and a power section including a compressor and an inverter. The evaporator sections have a return air compartment that extends a substantial distance across the roof of the bus such that a single design can meet the needs of various return air duct installations of various types of buses. Provision is made for the selective mixing of return air with fresh air, with the mixture then being passed by the evaporator blower through the evaporator coils and into the supply air ducts. The frames of the modules are attached to the roof of the bus by rails which are properly spaced to accommodate the module frames and allow their selective longitudinal placement.
Title: MODULAR AIR CONDITIONER FOR A BUS

Abstract: A module is provided for attachment to the roof of a bus and includes all of the necessary components for conditioning the return air from the passenger compartment and delivering conditioned air thereto. A plurality of modules can be mounted in various relationships to collectively provide the total capacity required by the bus. Each module includes an evaporator section, a condenser section and a power section including a compressor and an inverter. The evaporator sections have a return air compartment that extends a substantial distance across the roof of the bus such that a single design can meet the needs of various return air duct installations of various types of buses. Provision is made for the selective mixing of return air with fresh air, with the mixture then being passed by the evaporator blower through the evaporator coils and into the supply air ducts. The frames of the modules are attached to the roof of the bus by rails which are properly spaced to accommodate the module frames and allow their selective longitudinal placement.

Background of the Invention

[0002] This invention relates generally to air conditioning systems and, more particularly, to an air conditioning system for the rooftop of a bus.

[0003] The most common approach for air conditioning a bus is to locate the air conditioning components on the rooftop thereof. Inasmuch as power is available from the engine that drives the bus, it has become common practice to locate the air conditioning compressor near the drive engine such that the drive engine is drivingly connected to the compressor, with the compressor then being fluidly interconnected to the air conditioning system on a rooftop of a bus. This, of course, requires rather
extensive piping between the engine compartment and the air conditioning unit, thereby increasing installation and maintenance costs.

[0004] Another problem with such existing systems is that the speed that the compressor is driven is dependent on the speed in which the drive engine is running. Thus, when the drive engine is idling in a parking lot, for example, the compressor is running at a relatively slow speed which may not be sufficient to provide the desired degree of air conditioning. It is therefore generally necessary to oversize the compressor in order to obtain the performance needed under these conditions.

[0005] Others problems associated with such a motor driven compressor system is that the open drive compressor needs a shaft seal and a mechanical clutch, both of which are subject to maintenance problems. Further, since DC power is available on a bus, DC motors have been used for the air conditioning system. In general, DC motors are not as reliable as AC motors since they have brushes that wear out, and brushless motors are relatively expensive.

[0006] In addition to the problems discussed hereinabove, it is recognized, that because the wide variety of bus types and application requirements, it has been necessary to provide many different types and variations of air conditioning systems in order to meet these different requirements and vehicle interfaces. As a result, the manufacturing and installation costs, and sustaining engineering resources that are necessary in order to properly maintain and service these units, are relatively high.

[0007] It is therefore an object of the present invention to provide an improved bus top air conditioning system.

[0008] Another object of the present invention is the provision for a bus air conditioning system which is effective at all operating engine speeds of the bus, while at the same time does not require an oversized compressor.

[0009] Yet another object of the present invention is the provision for reducing the manufacturing, installation, and maintenance costs of a bus air conditioning system.

[0010] Yet another object of the present invention is the provision for a bus rooftop air conditioning system which is economical to manufacture and effective in use.
These objects and other features and advantages become more readily apparent upon reference to the following descriptions when taken in conjunction with the appended drawings.

Summary of the Invention

Briefly, in accordance with one aspect of the invention, an air conditioning module is assembled with its condenser coil, evaporator coil and respective blowers located within the module and so situated that a standard module can accommodate various installation interfaces with different types and locations of return air and supply air ducts on a bus.

In accordance with another aspect of the invention, each of a plurality of modules are installed in a centered relationship with respect to a longitudinal centerline of the bus and extend transversely across the width of the bus. The number and length of modules is dependent on the total air conditioning capacity requirement of the bus.

By yet another aspect of the invention, each of the identical modules include all the necessary components with electrical power being provided to the electrical components by an inverter/controller that is powered by an engine motor driven generator.

By another aspect of the invention provision is made for mounting the frames of multiple modules in adjacent or longitudinally spaced positions on the bus rooftop by way of a pair of longitudinally extending rails.

By still another aspect of the invention the evaporator section of the modules has a return air compartment that spans a substantial width of the bus to thereby accommodate various sizes and types of return air interface requirements.

By yet another aspect of the invention the evaporator section of each module has three different vertical levels to accommodate the respective incoming flows of return air and replenishing fresh air, and includes a mixer for selectively varying the amount of each which passes to the fan and then to the evaporator coil.
In the drawings as hereinafter described, a preferred embodiment is depicted; however various other modifications and alternate constructions can be made thereto without departing from the true spirit and scope of the invention.

**Brief Description of the Drawings**

[0019] FIG. 1 is a perspective view of a module as installed on the rooftop of a bus in accordance with a preferred embodiment of the invention.

[0020] FIG. 2 is a perspective view of a module with the top cover removed.

[0021] FIG. 3 is a schematic illustration of the electrical and refrigerant circuits within the module in accordance with the preferred embodiment of the invention.

[0022] FIG. 4 is a front elevational view of the condenser section of the module.

[0023] FIG. 5 is a front elevational view of the evaporator section of the module.

[0024] FIGS. 6–8 are front elevational views of the evaporator section as applied to different types of bus rooftops.

[0025] FIG. 9 is a perspective view of the evaporator section with its fan and mixer.

[0026] FIG. 10 is a bottom perspective view thereof.

[0027] FIG. 11 is a perspective view of the evaporator section showing the fresh air flap in the fully opened position.

[0028] FIG. 12 is a perspective view thereof with the flap in an intermediate position.

[0029] FIG. 13 is a perspective view thereof with the fresh air flap in the closed position.

[0030] FIG. 14 is a perspective view of a pair of modules in adjacent relationship.

[0031] FIG. 15 is a perspective view of three modules in adjacent relationship.
FIG. 16 is a perspective view of four modules in adjacent relationship.

FIG. 17 is a perspective view of the modules frames and related mounting rails.

Description of the Preferred Embodiment

The inventive module is shown generally at 10 in Fig. 1 as applied to the rooftop 11 of a bus in accordance with the present invention. Electrical power is provided to the module 10 by way of line 12, which in turn receives its power from a generator 13 driven by the bus engine 14 as shown.

The module 10 interfaces with openings in the bus top so that fans within the module 10 cause the return air from the passenger compartment to flow upward into the module 10 where it is conditioned, and the conditioned air to then flow downwardly into supply air ducts that carry the conditioned air to the passenger compartment. The various structures and the manner in which they interface with the bus rooftop 11 will more fully described hereinafter.

In Fig. 2, the module 10 is shown with its cover removed to include a frame 16 with an evaporator section 17 attached to one end thereof and a condenser section 18 attached to the other end thereof. Adjacent the condenser section 18 is a power section 19 which includes a compressor 21 and an inverter/controller 22. The manner in which they provided motive power to the refrigerant circuit and electrical power to the electrical components of the module 10 will be more fully described hereinafter.

The evaporator section 17 comprises a pair of identical units in abutting end-to-end relationship with each unit including an evaporator blower 23 with its evaporator blower motor 24, and an evaporator coil 26. Briefly, the evaporator blower 23 draws in return air from the passenger compartment of the bus, and fresh air from outside and passes a mixture of the two through the evaporator coil 26 to be conditioned, after which it flows back to the passenger compartment by way of the supply air ducts. This will be more fully described hereinafter.
[0038] Within the condenser section 18, there is provided a condenser fan 27 driven by an electric motor, and a pair of condenser coils 28 and 29. Briefly, the condenser fan draws air upwardly to create a vacuum below, which in turn causes fresh air to be drawn through the condenser coils 28 and 29 to condense the refrigerant flowing through the coils 28 and 29. The resulting warm air is then discharged upwardly to the atmosphere by the fan 27.

[0039] Referring now to Fig. 3, the module 10 is shown with its electrical connection by way of line 12 to the generator 13 and driving motor 14. The inverter/controller 22 receives AC power from the generator, or alternator, and, in turn provides discretely controlled AC power to the evaporator blower motor 24, the drive motor 31 of the condenser fan 27 and the drive motor 32 of the compressor 21. A plurality of control sensors, shown generally at 33 provide feedback to the inverter/controller 22 as necessary for it to control the AC power being delivered to the various drive motors.

[0040] As will be seen, the refrigeration circuit is a closed circuit through which the refrigerant flows from the compressor 21 to the condenser 29, an expansion valve 34, the evaporator 26 and finally back to the compressor 21. This is accomplished in a conventional manner.

[0041] It will be seen that the module 10 is self-contained with all of the necessary components, with the only input thereto being the electrical power by way of the electrical line 12. Other modules, indicated as numbers 2-6 are identically configured and are powered and controlled in the same manner.

[0042] Returning now to the condenser section 18 as shown in Fig. 4, the flow of air as caused by the condenser fan 27 is shown by the arrows. Fresh air is drawn in through the fresh air intake openings 36 and 37, passes through the respective condenser coils 28 and 29 and then flows upwardly through the condenser fan 27 and the condenser outlet air opening 38 as shown.

[0043] Within the evaporator section 17 as shown in Fig. 5, the relatively warm return air flows upwardly from a return air duct communicating with the passenger compartment and enters a return air compartment 39 of the evaporator
section 17 as shown by the arrows. The evaporator blower 23 causes the return air to flow upwardly to its inlet at the top, and at the same time, fresh air may be brought in by way of a fresh air flap in a manner to be described hereinafter. A mixture of the two airflow streams is thus admitted at the intake of the evaporator blower 23 and caused to flow downwardly and outwardly as indicated by the arrows to the evaporator coils 26. After passing through the evaporator coil 26 it is then caused by a curved cowling 41 to flow downwardly to a supply air duct leading to the passenger compartment. Thus, while the module is operating, there is a constant circuitous flow of return air out of the passenger compartment and of conditioned air back into the passenger compartment. The amount of return air that is discharged to the outside, and also the amount of fresh air that is brought into the circuit from the outside is controlled by the selective movement of the fresh air flaps as will be described hereinafter. There are shown in Figs. 6-8 installations of the module 10 with various types of buses and associated return air and supply air ducts. In Fig. 6, for example, a wide bus installation is shown wherein the existing duct work within the bus includes supply air ducts 43 and 44 near the lateral sides of the bus, and return air ducts 46 and 47 that are closer to the center line of the bus, but are substantially spaced apart. Here it will be seen that the return air ducts 46 and 47 communicate directly with the return air compartment 39 of the module 10, but at a position at near the outer end thereof.

[0044] In Fig. 7, which shows a narrow bus installation, again the supply air ducts 48 and 49 are near the transverse sides of the bus. But the return air ducts 51 and 52 are abutting each other at the center line of the bus. Again, the return air ducts 51 and 52 fluidly communicate with the return air compartment 39, but at the other end thereof.

[0045] Finally, in Fig. 8 there is shown a curved top bus wherein the supply air ducts 53 and 54 are again near the transverse sides of the bus, but the return air ducts 56 and 57 are in intermediate positions, relatively close to the center line but substantially spaced apart. Again, the return air ducts 56 and 57 fluidly
communicate with the return air compartment 39, but at a position intermediate the two ends thereof.

[0046] It will thus be seen that the same identical module is so constructed and designed that it can accommodate any of these various installation requirements without modification of the module itself. That is, the conditioned air discharge opening 40 is sufficiently large and the transverse direction to accommodate the various supply air duct orientations, and, more importantly, the return air compartment 39 is relatively large in the transverse direction so as to accommodate each of the various types of return air duct configuration as shown.

[0047] In order to describe the evaporator section 17, and the manner in which the flow of return air is mixed with the flow of fresh air, reference is made to Figs. 9-13. In Fig. 9, the evaporator blower 23 is shown with its blower inlet 58 receiving the air to be cooled, which flows downwardly and then outwardly toward and through the evaporator coil 26 as shown by the arrows. The cold air then flows further outwardly and downwardly to the supply air duct as shown by the arrow at the left. The air passing into the blower inlet 58 is a mixture of return air that flows upwardly through the channel 59 and the fresh air that flows in through the fresh intake window 41 as shown by the arrows. That is, referring to Fig. 10, the return air which has come into the return air compartment 39 below the evaporator blower 23 flows into an opening 61 and upwardly through the channel 59 as shown by the arrows. When the return air flow reaches the top of the channel 59 the amount of return air, and also the amount of fresh air passing through the fresh air intake window 41 will depend on the position of the fresh air flap 42.

[0048] In Fig. 11, the fresh air flap 42 is shown as attached to a rod 62, which in turn is attached to a rotatable lever 63 for selectively rotating the fresh air flap on its axis to thereby vary the size of the opening at the fresh air intake window 41. The position of the fresh air flap 42 is the fully opened position wherein there is no restriction of the flow of fresh air that is coming into the fresh air intake window 41. When in this position, the fresh air flap also closes off the exit side of the flow channel 59 in which the return air is flowing upwardly. Thus, when the fresh air flap
42 is in the fully opened position, none of the return air passes upwardly into the evaporator blower 23 and the only, and the only air passing into the evaporator blower 23 and on to the evaporator coil 26 is the fresh air coming in through the fresh air intake window 41. The return air in the channel 59 is thus caused to flow out into the atmosphere by way of an opening to be described hereinafter.

[0049] In Fig. 12, the lever 63 and attached rod 62 are selectively moved to adjust the fresh air flow 32 to an intermediate position wherein the exit opening at the top of the channel 59 is uncovered, while at the same time the fresh air flap 42 tends to offer some restriction to the flow of fresh air coming into the fresh air intake window 41. The air being taken into the blower inlet 58 is thus a mixture of return air and fresh air, with only a portion of the return air being discharged to the outside.

[0050] Fig. 13 shows the fresh air flap in the closed position wherein it completely blocks off the fresh air intake window 41 and completely uncovers the channel 59. Thus, when in this position, all of the return air, and no fresh air, passes into the blower inlet 58, through the evaporator coil 26 and to the supply air ducts of the bus. It should, of course, be understood that the fresh air flap 42 maybe placed in any intermediate position not shown in order to obtain the desired mix as appropriate to meet the cooling needs as determined by the load in the passenger compartment of the bus, as well as the environmental conditions outside.

[0051] Of a structure of the evaporator section 17 as described hereinabove will be recognized as providing three levels within the evaporator section in which the flow of air occurs. At a lower level, the return air compartment 39 provides for a flow of return air from the return air duct to the evaporator section 17. At an intermediate level, there is a channel to guide the flow of return air upwardly, and in a parallel route, to provide the flow of mixed air downwardly through the evaporator blower 23. At a third, upper, level, there is a space provided for the flow of fresh air through the fresh air intake window 41, for the mixture of that fresh air with the return air blowing upwardly, and for the mixture to flow into the intake 58 of the blower 58.
While a single unit is shown in its installed position on the bus in Fig. 1, the present module is designed to be "ganged" with one or more other modules to provide a collective air conditioning capacity as necessary to meet the needs of the bus. In Fig. 14, a pair of modules are stacked together, with one being turned, end to end, as shown. In this configuration, the two condensing sections are at the forward and rear ends of the combination, and the two evaporator sections are abutted up against one another. The grill openings are shown at 64 in one unit and at 66 in the other unit, to conduct the flow of fresh air to the evaporator section when the fresh air flap is opened, and for the outflow of returned air when the fresh air flap 42 is fully opened or partially opened. An opening 67 can be provided to augment the flow of fresh air to the evaporator.

In Fig. 15, a pair of modules 68 and 69 are placed in ganged relationship in the manner as described hereinabove. A third module 71 is placed at the other end of module 69, so that it is parallel to the module 69, and not turned end for end as described hereinabove. Thus, the evaporator section of module 71 is adjacent the condenser section of module 69, and in particular, the grill opening 72 are disposed adjacent to the condenser fan of module 69.

In Fig. 16, there are shown four modules 72, 73, 74 and 76, with modules 72 and 73 being parallel with each other and with modules 74 and 76 being parallel with respect to each other but being rotated end for end with respect to the modules 72 and 73.

It should be recognized that the individual modules can be ganged in any combination in order to meet the required capacity for the bus, while also being positioned so that the return air openings in the bus are registrable with the respective inlet and outlet openings in the evaporator sections. While not shown, it should be understood that the modules can also be installed in positions so that they are longitudinally spaced and not necessarily abutted up against each other as shown.

In order to mount the modules, either as a single unit or in combinations as shown, it is desirable to have a method and apparatus for easily attaching the modules to the rooftop of the bus. A preferred approach is to have a
pair of transversely spaced, longitudinally extending rails 77 and 78 which are
attached to a bus by appropriate fasteners or the like. The framework of the
individual modules can then, in turn, be attached to the rails 77 and 79 by
appropriate fasteners such as screws or the like. In Fig. 17, a pair of module frames
78 and 81 are shown, with the frame 81 being turned end for end in a manner as
described hereinabove. This arrangement allows for the modules to be easily
attached to the rails such that they are all centered with respect to the center line of
the bus, and can be attached to the rails 77 and 78 at any longitudinal position that is
desired.

While this invention has been described with reference to a particular
structure disclosed herein, it should be understood that it is not confined to the
details set forth in this application, but is rather intended to cover any modifications
and changes as may come within the scope of the following claims:
We Claim:

1. An air conditioning module (10) for a bus rooftop (11) of the type having at least one return air opening (47) for conducting the flow of return air from the passenger compartment, and at least one supply air opening (44) for conducting the flow of conditioned air to the passenger compartment, comprising:

   a condenser section (18) having at least one condenser coil (28, 29) and a condenser fan (27) for causing ambient air to flow therethrough; and

   an evaporator section (17) having at least one evaporator coil (26) and at least one evaporator fan (23) for causing return air to flow from said return air opening through said evaporator section (17) and to the at least one supply air opening (44); wherein said evaporator section (12) further comprises:

   a return air compartment (39) disposed in a lower portion of said evaporator section (17) and adapted to receive a flow of return air from the return air opening (49);

   a vertical compartment (59) disposed in an internal area and having on one side a channel (59) for the upward flow of return air from the return air compartment and on another side a fan (23) for drawing air downwardly and then outwardly to an evaporator coil (26);

   a mixing compartment disposed in an upper area and fluidly communicating with both said channel (59) and said fan (26) as well as the ambient air by way of a fresh air opening (41), such that within said mixing compartment, fresh air is selectively mixed with return air and with the mixture passing into said fan (23).

2. An air conditioning module as set forth in claim 1 wherein said at least one supply air opening (43) comprises two supply air openings (43, 44), with one on each side of the bus.

3. An air conditioning module as set forth in claim 1 wherein said condenser coil (28, 29) and condenser fan (27) are so situated that the condenser fan (27) draws air through said condenser coil (28, 29).
4. An air conditioning module as set forth in claim 1 wherein said at least one evaporator coil (26) comprises two evaporator coils, with one on either side of the bus.

5. An air conditioning module as set forth in claim 4 wherein said at least one evaporator fan (23) comprises two evaporator fans, with each fan operating to blow air through its respective evaporator coil.

6. An air conditioning module as set forth in claim 5 wherein said evaporator fans (23) are of the centrifugal type.

7. An air conditioning module as set forth in claim 5 wherein said fans (23) are orientated with their axes being vertical.

8. An air conditioning module as set forth in claim 1 wherein there is included in association with said fresh air opening (44), a flap (42) for selectively varying the size of the fresh air opening.

9. An air conditioning module as set forth in claim 1 wherein there is associated with said channel (59) a flap (42) for selectively varying the size of an opening therein.

10. An air conditioning module as set forth in claim 8 wherein said flap (42) simultaneously varies the size of said fresh air opening (41) and said channel (59).

11. An air conditioning module as set forth in claim 10 wherein said flap inversely varies the flow of air in said fresh air opening (41) and said channel (50).

12. An air conditioning module (10) for installation on the rooftop (11) of a bus having at least two supply air openings (43, 44) in the rooftop (11) for fluid communication with

REPLACEMENT SHEET
supply air ducts leading to a passenger compartment and at least one return air opening (46, 47) in the rooftop to fluidly communicate with the return air duct leading from the passenger compartment comprising:

- a housing (16);
- at least one refrigeration circuit (21, 29, 34, 26) disposed in said housing and including at least one evaporator coil (26) and at least one condenser coil (29);
- a condenser section contained in said housing and having a pair of condenser coils (28, 29) and a condenser fan (27) for causing outdoor air to flow through said coils (28, 29);
- an evaporator section (17) contained in said housing and having a pair of evaporator coils (26) and associated fans (23) for causing the flow of air from the return air duct, through said evaporator coils (26) and through a supply air discharge opening in said housing to the rooftop supply air openings;
- a return air compartment (39) disposed in a lower portion of said evaporator section (17) and adapted to receive a flow of return air from the return air opening (49);
- a vertical compartment (59) disposed in an internal area and having on one side a channel (59) for the upward flow of return air from the return air compartment and on another side a fan (23) for drawing air downwardly and then outwardly to an evaporator coil (26);
- a mixing compartment disposed in an upper area and fluidly communicating with both said channel (59) and said fan (26) as well as the ambient air by way of a fresh air opening (41), such that within said mixing compartment, fresh air is selectively mixed with return air and with the mixture passing into said fan (23).

13. An air conditioning module as set forth in claim 12 and including a third section (19) in said housing (16) which includes a compressor (21) and an inverter/controller (22), said compressor (21) being operatively connected in said refrigeration circuit and said inverter/controller (22) being operative to provide electrical power to said compressor (21) and to drive motors of said condenser and evaporator fans.

14. An air conditioning module as set forth in claim 12 wherein said condenser fan (27) is so situated as to draw air through said condenser coils (28, 29).

15. An air conditioning module as set forth in claim 12 wherein said evaporator fans (23) are operative to blow air through their respective evaporator coils (26).

16. An air conditioning module as set forth in claim 12 wherein said rooftop supply air opening (43, 44) is located near an outer side of the bus.

17. An air conditioning module as set forth in claim 12 wherein said rooftop return air opening (46, 47) is located near an longitudinal center line of the bus.

REPLACEMENT SHEET
18. A bus air conditioning system with at least one air conditioning module (10) installed on a bus roof (11) having a pair of supply air openings (44) for conducting the flow of conditioned air downwardly near the outer side of the roof and a return air opening (41) near a longitudinal central axis of the bus comprising:

- a refrigeration circuit (21, 29, 34, 26) for circulating refrigerant serially through a compressor (21), a condenser coil (29), an expansion valve (34) and an evaporator coil (26);

- an evaporator section including an evaporator blower (23) for causing return air to flow from said return air opening (47), into a return air compartment (39) of said evaporator section (17), through said blower (23), through said evaporator coil (26) and then to said supply air opening (44); and

- a condenser fan (27) for causing outside air to flow over said condenser coil (48, 29) and then to be discharged outside;

wherein said evaporator return air compartment (39) is so sized and situated in said module that when said module is in its installed position on the roof, said evaporator return air compartment (39) is disposed directly above and fluidly communicates with the return air opening (47) of the bus;

- a vertical compartment (59) disposed in an internal area and having on one side a channel (59) for the upward flow of return air from the return air compartment and on another side a fan (23) for drawing air downwardly and then outwardly to an evaporator coil (26);

- a mixing compartment disposed in an upper area and fluidly communicating with both said channel (59) and said fan (26) as well as the ambient air by way of a fresh air opening (41), such that within said mixing compartment, fresh air is selectively mixed with return air and with the mixture passing into said fan (23).

19. A bus air conditioner as set forth in claim 18 wherein said rooftop supply air opening (44) is located near the side edges of the bus.

20. An air conditioning module as set forth in claim 18 wherein said rooftop return air opening (47) is located near a longitudinal center line of the bus.

21. An air conditioning module as set forth in claim 18 wherein said return air compartment (39) extends over at least 30% of the length of said module.
