TREATMENT OF PRDC IN PIGS

SEQUENCE LISTING

This application contains a sequence listing in paper format and in computer readable format, the teachings and content of which are hereby incorporated by reference. The sequence listing is identical with that incorporated in WO06/072065.

BACKGROUND OF THE INVENTION

Field of the Invention

The present invention relates to the use of an immunogenic composition comprising a porcine circovirus type 2 (PCV2) antigen for the prevention and treatment of porcine respiratory disease complex (PRDC) in animals, preferably in pigs.

Description of the Prior Art

Porcine circovirus type 2 (PCV2) is a small (17 - 22 nm in diameter), icosahedral, non-enveloped DNA virus, which contains a single-stranded circular genome. PCV2 shares approximately 80% sequence identity with porcine circovirus type 1 (PCV1). However, in contrast with PCV1, which is generally non-virulent, infection of swine with PCV2 has recently associated with a number of diseases syndromes which have been collectively named Porcine Circovirus Diseases (PCVD) (also known as Porcine Circovirus associated Diseases (PCVAD)) (Allan et al, 2006, IPVS Congress). Postweaning Multisystemic Wasting Syndrome (PMWS) is generally regarded to be the major clinical manifestation of PCVD. (Harding et al., 1997, Swine Health Prod; 5: 201-203; Kennedy et al., 2000, J Comp Pathol; 122: 9-24). PMWS affects pigs between 5-18 weeks of age. PMWS is clinically characterized by wasting, paleness of the skin, unthriftiness, respiratory distress, diarrhea, icterus, and
jaundice. In some affected swine, a combination of all symptoms will be apparent while other affected swine will only have one or two of these symptoms. (Muirhead, 2002, Vet. Rec; 150: 456) During necropsy, microscopic and macroscopic lesions also appear on multiple tissues and organs, with lymphoid organs being the most common site for lesions. Allan and Ellis, 2000; J Vet. Diagn. Invest., 12: 3-14). A strong correlation has been observed between the amount of PCV2 nucleic acid or antigen and the severity of microscopic lymphoid lesions. Mortality rates for swine infected with PCV2 can approach 80%.

The extent of the involvement of PCV2 in swine diseases other than PMWS is currently poorly understood (Chae, Veterinary J., 2005; 169: 326-336). There are several potentially related conditions reported in the literature including porcine respiratory disease complex (PRDC), porcine dermatopathy and nephropathy syndrome (PDNS), reproductive failure, granulomatous enteritis and potentially, congenital tremors (CT-AII) and perinatal myocarditis (Chae, Veterinary J., 2005; 169: 326-336). Among these, PRDC is considered to have the greatest economical impact in Europe due to its general high prevalence, high morbidity rate (30-70% on affected farms) and mortality rate (4-6% on affected farms) (Kim et al., Veterinary J., 2003; 166: 251-256).

Pneumonia in pigs suffering from PRDC is due to a combination of both viral and bacterial agents such as PRRSV, Swine influenza virus (SIV), Mycoplasma hyopneumoniae, Actinobacillus pleuropneumoniae and Pasteurella multocida. Although the aetiology involves multiple pathogens and varies from farm to farm PRRSV and Mycoplasma hyopneumoniae are the two most common pathogens isolated from PCV2 positive pigs exhibiting PRDC (Kim et al., Veterinary J., 2003; 166: 251-256). Whether PCV2 plays any
role in cause of PRDC or in manifestation, severity, or prolongation of clinical signs of PRDC is yet not known.

Compared with other viral pathogens PCV2 was consistently diagnosed in lung lesions of pigs suffering from PRDC. Prospective studies have documented that pneumonia and often systemic illness, resulting from co-infection with PCV2 and PRRSV is more severe than that associated with infection by either agent alone. It can therefore be assumed that there is an apparent synergy between PCV2 and other pathogens that has been observed in respiratory disease cases in the field (Ellis et al., Veterinary Microbiol., 2004; 98: 159-163). However, it is yet not known whether PCV2, if present in pigs suffering from PRDC, has any influence on the clinical signs of PRDC in pigs. Due to the ubiquity of PCV2 with up to 100% seropositive animals at the end of fattening it may similarly be possible that PCV2 has no influence at all on the disease expression of PRDC but is just an unrelated co-infecting agent.

Whereas PMWS mostly affects young pigs, typically between 5 and 12 weeks of age, PRDC is predominantly seen in growing to finishing pigs, typically around 16 to 22 weeks of age. The morbidity ranges from 30-70% with an average mortality of 4-6% (Kim et al., Veterinary J., 2003; 166: 251-256). Clinically signs of PRDC are prolonged and unusually severe cough and dyspnea that is refractory to antibiotic therapy, slow growth, decreased feed efficiency, lethargy, anorexia, and a marked increase in mortality in the middle to late phase of fattening.

A hallmark of microscopic lesions PRDC is bronchointerstitial pneumonia with peribronchial and peribronchiolar fibrosis. Alveolar septa are markedly thickened by infiltrates of macrophages (Chae, Veterinary J., 2005; 169: 326-336).
Approaches to treat PCV2 infections based on a DNA vaccine are described in U.S. Patent No. 6,703,023. In WO 03/049703 production of a live chimeric vaccine is described, comprising a PCV-I backbone in which an immunogenic gene of a pathogenic PCV2 strains replaces a gene of the PCV-I backbone. WO99/18214 has provided several PCV2 strains and procedures for the preparation of a killed PVC2 vaccine. However, no efficacy data have been reported. An effective ORF-2 based subunit vaccine has been reported in WO06/072065. Any of such vaccines are intended to be used for the vaccination/treatment of swine or pigs older than 3 weeks of age. None of these vaccines have been described for the prophylaxis or treatment of pigs suffering from PRDC, in particular in PCV2 positive pigs, suffering from PRDC.

Moreover, such vaccines have not been described to confer protective immunity against PCV2 infection or reducing, lessening the severity of, or curing any clinical symptoms associated therewith in pigs already having anti-PCV2 antibodies, preferably having maternal anti-PC2 antibodies.

BRIEF DESCRIPTION OF THE DRAWINGS

**Figure 2:** Development of the difference in body weight (IVP-CP) and mean virus load (log10) over the course of the study.
DISCLOSURE OF THE INVENTION

PRDC is characterized by a multiple clinical signs, including prolonged and unusually severe cough and dyspnea that is refractory to antibiotic therapy, slow growth, decreased feed efficiency, lethargy, anorexia, and a marked increase in mortality in the middle to late phase of fattening. Those clinical signs are associated with large number of various pathogens. Involvement and, if any, the extent of involvement of PCV2 in PRDC was not known so far. It has been surprisingly found that among various pathogens, PCV2 also plays an important role in manifestation, severity and prolongation of clinical signs of PRDC. Thus among others, PCV2 is one of causative agents of PRDC in pigs.

In general, the impact of one causative agent on a multiple caused disease (= multi-factorial disease) like PRDC is not predictable. A causative agent may have no effect but also displace, repress, supersede, overlay or strengthen the effect of the others on the manifestation, severity and prolongation of clinical signs of a multi-factorial disease like PRDC. For example, reduction or elimination of one causative agent of a multi-factorial disease like PRDC may have no effect on the clinical appearance of that disease if at least one further causative agent is present, but also can significantly reduce the clinical symptoms of that disease, even in the presence of any other causative agent. The higher the number of causative agents that are involved, the lower the expectation that a reduction or elimination of only one causative agent has an positive influence on the duration of the manifestation, severity or prolongation of the disease. It has been surprisingly found now that manifestation, severity and prolongation of clinical signs of PRDC in pigs can be lessened or reduced by the prophylaxis or treatment of threatened or affected animals with PCV2 antigen. In particular, severity and prolongation of clinical signs of or associated with PRDC can
strongly be lessened and reduced in pigs infected with PCV2 in combination with pathogens known to cause or be associated with PRDC in pigs, such as PRRSV, *Mycoplasma hyopneumoniae*, *Bordetella bronchiseptica*, Swine influenza virus, *Mycoplasma hyorhinis* and/or *Pasteurella multocida*. In other words, prophylaxis and treatment of pigs suffering from PRDC with PCV2 antigen have a positive impact on the overall health of the pigs, weight gain during fattening, and mortality in the middle to late phase of fattening of pigs, in particular as these factors - overall health, weight gain, mortality - are known to be negatively affected by PRRSV, *Mycoplasma hyopneumoniae*, *Bordetella bronchiseptica*, Swine influenza virus, *Mycoplasma hyorhinis* and/or *Pasteurella multocida*.

Therefore, according to one aspect, the present invention provides a method for the prophylaxis and treatment of porcine respiratory disease complex (PRDC) and/or any clinical signs associated with PRDC in an animal, comprising the step of administering a therapeutically effective amount of PCV2 antigen or an immunogenic composition comprising an PCV2 antigen to an animal in need of such treatment.

The clinical signs associated with PRDC are selected from the group consisting of cough and dyspnea, slow growth, decreased feed efficiency, lethargy, anorexia, and/or a marked increase in mortality in the middle to late phase of fattening. Thus according to an other aspect, the present invention relates to a method for the prophylaxis and treatment of cough and dyspnea, slow growth, decreased feed efficiency, lethargy, anorexia, and/or a marked increase in mortality associated with PRDC in an animal, comprising the step of administering a therapeutically effective amount of PCV2 antigen or an immunogenic composition comprising an PCV2 antigen to an animal in need of such treatment.
composition comprising an PCV2 antigen to an animal in need of such treatment. Preferably, the cough and dyspnea, are refractory to antibiotic therapy.

The terms "antigen" as used herein refer to an amino acid sequence which elicits an immune response in a host. An antigen, as used herein, includes the full-length sequence of any PCV2 proteins, analogs thereof, or immunogenic fragments thereof. The term "immunogenic fragment" refers to a fragment of a protein which includes one or more epitopes and thus elicits the immune response in a host. Such fragments can be identified using any number of epitope mapping techniques, well known in the art. See, e.g., Epitope Mapping Protocols in Methods in Molecular Biology, Vol. 66 (Glenn E. Morris, Ed., 1996) Humana Press, Totowa, New Jersey. For example, linear epitopes may be determined by e.g., concurrently synthesizing large numbers of peptides on solid supports, the peptides corresponding to portions of the protein molecule, and reacting the peptides with antibodies while the peptides are still attached to the supports. Such techniques are known in the art and described in, e.g., U.S. Patent No. 4,708,871; Geysen et al. (1984) Proc. Natl. Acad. Sci. USA 81:3998-4002; Geysen et al. (1986) Molec. Immunol. 23:709-715. Similarly, conformational epitopes are readily identified by determining spatial conformation of amino acids such as by, e.g., x-ray crystallography and 2-dimensional nuclear magnetic resonance. See, e.g., Epitope Mapping Protocols, supra.

Synthetic antigens are also included within the definition, for example, polyepitopes, flanking epitopes, and other recombinant or synthetically derived antigens. See, e.g., Bergmann et al. (1993) Eur. J. Immunol. 23:2777-2781; Bergmann et al. (1996), J. Immunol. 157:3242-
An "immune response" means but is not limited to the development in a host of a cellular and/or antibody-mediated immune response to an antigen, a immunogenic composition or vaccine of interest. Usually, an "immune response" includes but is not limited to one or more of the following effects: the production or activation of antibodies, B cells, helper T cells, suppressor T cells, and/or cytotoxic T cells, directed specifically to an antigen or antigens included in the composition or vaccine of interest. Preferably, the host will display either a therapeutic or a protective immunological (memory) response such that resistance to new infection will be enhanced and/or the clinical severity of the disease reduced. Such protection will be demonstrated by either a reduction in number or severity of, or lack of one or more of the symptoms associated with PCV2 infections, in delay of onset of viremia, in a reduced viral persistence, in a reduction of the overall viral load and/or a reduction of viral excretion.

The terms "immunogenic composition" or "vaccine" (both terms are used synonymously) as used herein refers to any pharmaceutical composition containing a PCV2 antigen, which composition can be used to prevent or treat a PCV2 infection-associated disease or condition in a subject. A preferred immunogenic composition can induce, stimulate or enhance the immune response against PCV2. The term thus encompasses both subunit immunogenic compositions, as described below, as well as compositions containing whole killed, or attenuated and/or inactivated PCV2.
Thus according to another aspect, the present invention relates to a method for the prophylaxis and treatment of porcine respiratory disease complex (PRDC) and/or any clinical signs associated with PRDC in an animal, comprising the step of administering an effective amount of PCV2 antigen or an immunogenic composition comprising an PCV2 antigen to that animal in need of such treatment, wherein the immunogenic composition is subunit immunogenic composition, a compositions containing whole killed, or attenuated and/or inactivated PCV2.

The term "subunit immunogenic composition" as used herein refers to a composition containing at least one immunogenic polypeptide or antigen, but not all antigens, derived from or homologous to an antigen from PCV2. Such a composition is substantially free of intact PCV2. Thus, a "subunit immunogenic composition" is prepared from at least partially purified or fractionated (preferably substantially purified) immunogenic polypeptides from PCV2, or recombinant analogs thereof. A subunit immunogenic composition can comprise the subunit antigen or antigens of interest substantially free of other antigens or polypeptides from PCV2, or in fractionated from. A preferred immunogenic subunit composition comprises the PCV2 ORF-2 protein as described below. Most preferred are immunogenic subunit compositions, which comprise any of the PCV2 antigens provided in WO06/072065, which are all incorporated herein by reference in their entirety.

According to further aspect, the immunogenic composition as used herein most preferably comprises the polypeptide, or a fragment thereof, expressed by ORF-2 of PCV2. PCV2 ORF-2DNA and protein, used herein for the preparation of the compositions and within the processes provided herein is a highly conserved domain within PCV2 isolates and thereby,
any PCV2 ORF-2 would be effective as the source of the PCV ORF-2 DNA and/or polypeptide as used herein. A preferred PCV2 ORF-2 protein is that of SEQ ID NO: 11 of WO06/072065. A further preferred PCV ORF-2 polypeptide is provided as SEQ ID NO: 5 of WO06/072065. However, it is understood by those of skill in the art that this sequence could vary by as much as 6-10% in sequence homology and still retain the antigenic characteristics that render it useful in immunogenic compositions. The antigenic characteristics of an immunological composition can be, for example, estimated by the challenge experiment as provided by Example 4 of WO06/072065. Moreover, the antigenic characteristic of a modified antigen is still retained, when the modified antigen confers at least 70%, preferably 80%, more preferably 90% of the protective immunity as compared to the PCV2 ORF-2 protein, encoded by the polynucleotide sequence of SEQ ID NO:3 or SEQ ID NO:4 as provided in WO06/072065.

Thus according to a further aspect, the present invention provides a method for the prophylaxis and treatment of porcine respiratory disease complex (PRDC) and/or any clinical signs associated with PRDC in an animal, comprising the step of administering an effective amount of PCV2 antigen or an immunogenic composition comprising an PCV2 antigen to that animal in need of such treatment, wherein the PCV2 antigen is an antigen PCV2 ORF-2 protein that has at least 70%, preferably, 80% even more preferably 90% of the protective immunity as compared to compared to the PCV2 ORF-2 protein, encoded by the polynucleotide sequence of SEQ ID NO:3 or SEQ ID NO:4 as provided in WO06/072065. Preferably said PCV2 ORF-2 have the sequence of SEQ ID NO: 11 or SEQ ID NO: 5 of WO06/072065.
In some forms, immunogenic portions of PCV2 ORF-2 protein are used as the antigenic component in the immunogenic composition, comprising PCV2 antigen. The term "immunogenic portion" as used herein refers to truncated and/or substituted forms, or fragments of PCV2 ORF-2 protein and/or polynucleotide, respectively. Preferably, such truncated and/or substituted forms, or fragments will comprise at least 6 contiguous amino acids from the full-length ORF-2 polypeptide. More preferably, the truncated or substituted forms, or fragments will have at least 10, more preferably at least 15, and still more preferably at least 19 contiguous amino acids from the full-length PCV ORF-2 polypeptide. Two preferred sequences in this respect are provided as SEQ ID NO: 9 and SEQ ID NO: 10 of WO06/072065. It is further understood that such sequences may be a part of larger fragments or truncated forms.

As mentioned above, a further preferred PCV2 ORF-2 polypeptide is any one encoded by the nucleotide sequences of SEQ ID NO: 3 or SEQ ID NO: 4. However, it is understood by those of skill in the art that this sequence could vary by as much as 6-20% in sequence homology and still retain the antigenic characteristics that render it useful in immunogenic compositions. In some forms, a truncated or substituted form, or fragment of this PVC2 ORF-2 polypeptide is used as the antigenic component in the composition. Preferably, such truncated or substituted forms, or fragments will comprise at least 18 contiguous nucleotides from the full-length PCV2 ORF-2 nucleotide sequence, e.g. of SEQ ID NO: 3 or SEQ ID NO: 4. More preferably, the truncated or substituted forms, or fragments, will have at least 30, more preferably at least 45, and still more preferably at least 57 contiguous nucleotides of the full-length PCV2 ORF-2 nucleotide sequence, e.g. SEQ ID NO: 3 or SEQ ID NO: 4.
"Sequence Identity" as it is known in the art refers to a relationship between two or more polypeptide sequences or two or more polynucleotide sequences, namely a reference sequence and a given sequence to be compared with the reference sequence. Sequence identity is determined by comparing the given sequence to the reference sequence after the sequences have been optimally aligned to produce the highest degree of sequence similarity, as determined by the match between strings of such sequences. Upon such alignment, sequence identity is ascertained on a position-by-position basis, e.g., the sequences are "identical" at a particular position if at that position, the nucleotides or amino acid residues are identical. The total number of such position identities is then divided by the total number of nucleotides or residues in the reference sequence to give \% sequence identity. Sequence identity can be readily calculated by known methods, including but not limited to, those described in Computational Molecular Biology, Lesk, A. N., ed., Oxford University Press, New York (1988), Biocomputing: Informatics and Genome Projects, Smith, D.W., ed., Academic Press, New York (1993); Computer Analysis of Sequence Data, Part I, Griffin, A.M., and Griffin, H. G., eds., Humana Press, New Jersey (1994); Sequence Analysis in Molecular Biology, von Heinge, G., Academic Press (1987); Sequence Analysis Primer, Gribskov, M. and Devereux, J., eds., M. Stockton Press, New York (1991); and Carillo, H., and Lipman, D., SIAM J. Applied Math., 48: 1073 (1988), the teachings of which are incorporated herein by reference. Preferred methods to determine the sequence identity are designed to give the largest match between the sequences tested. Methods to determine sequence identity are codified in publicly available computer programs which determine sequence identity between given sequences. Examples of such programs include, but are not limited to, the GCG program package (Devereux, J., et al., Nucleic Acids Research, 12(1):387 (1984)), BLASTP, BLASTN and FASTA (Altschul, S. F. et al., J. Molec. Biol,
215:403-410 (1990). The BLASTX program is publicly available from NCBI and other sources (BLAST Manual, Altschul, S. et al, NCVI NLM NIH Bethesda, MD 20894, Altschul, S. F. et al., J. Molec. Biol, 215:403-410 (1990), the teachings of which are incorporated herein by reference). These programs optimally align sequences using default gap weights in order to produce the highest level of sequence identity between the given and reference sequences. As an illustration, by a polynucleotide having a nucleotide sequence having at least, for example, 85%, preferably 90%, even more preferably 95% "sequence identity" to a reference nucleotide sequence, it is intended that the nucleotide sequence of the given polynucleotide is identical to the reference sequence except that the given polynucleotide sequence may include up to 15, preferably up to 10, even more preferably up to 5 point mutations per each 100 nucleotides of the reference nucleotide sequence. In other words, in a polynucleotide having a nucleotide sequence having at least 85%, preferably 90%, even more preferably 95% identity relative to the reference nucleotide sequence, up to 15%, preferably 10%, even more preferably 5% of the nucleotides in the reference sequence may be deleted or substituted with another nucleotide, or a number of nucleotides up to 15%, preferably 10%, even more preferably 5% of the total nucleotides in the reference sequence may be inserted into the reference sequence. These mutations of the reference sequence may occur at the 5' or 3' terminal positions of the reference nucleotide sequence or anywhere between those terminal positions, interspersed either individually among nucleotides in the reference sequence or in one or more contiguous groups within the reference sequence.

Analogously, by a polypeptide having a given amino acid sequence having at least, for example, 85%, preferably 90%, even more preferably 95% sequence identity to a reference amino acid sequence, it is intended that the given amino acid sequence of the polypeptide is identical to the reference sequence except that the given polypeptide sequence may include...
up to 15, preferably up to 10, even more preferably up to 5 amino acid alterations per each
100 amino acids of the reference amino acid sequence. In other words, to obtain a given
polypeptide sequence having at least 85%, preferably 90%, even more preferably 95%
sequence identity with a reference amino acid sequence, up to 15%, preferably up to 10%,
even more preferably up to 5% of the amino acid residues in the reference sequence may be
deleted or substituted with another amino acid, or a number of amino acids up to 15%,
preferably up to 10%, even more preferably up to 5% of the total number of amino acid
residues in the reference sequence may be inserted into the reference sequence. These
alterations of the reference sequence may occur at the amino or the carboxy terminal
positions of the reference amino acid sequence or anywhere between those terminal positions,
interspersed either individually among residues in the reference sequence or in the one or
more contiguous groups within the reference sequence. Preferably, residue positions which
are not identical differ by conservative amino acid substitutions. However, conservative
substitutions are not included as a match when determining sequence identity.

"Sequence homology", as used herein, refers to a method of determining the relatedness of
two sequences. To determine sequence homology, two or more sequences are optimally
aligned, and gaps are introduced if necessary. However, in contrast to "sequence identity",
conservative amino acid substitutions are counted as a match when determining sequence
homology. In other words, to obtain a polypeptide or polynucleotide having 95% sequence
homology with a reference sequence, 85%, preferably 90%, even more preferably 95% of the
amino acid residues or nucleotides in the reference sequence must match or comprise a
conservative substitution with another amino acid or nucleotide, or a number of amino acids
or nucleotides up to 15%, preferably up to 10%, even more preferably up to 5% of the total
amino acid residues or nucleotides, not including conservative substitutions, in the reference sequence may be inserted into the reference sequence. Preferably the homolog sequence comprises at least a stretch of 50, even more preferably at least 100, even more preferably at least 250, and even more preferably at least 500 nucleotides.

A "conservative substitution" refers to the substitution of an amino acid residue or nucleotide with another amino acid residue or nucleotide having similar characteristics or properties including size, hydrophobicity, etc., such that the overall functionality does not change significantly.

"Isolated" means altered "by the hand of man" from its natural state, i.e., if it occurs in nature, it has been changed or removed from its original environment, or both. For example, a polynucleotide or polypeptide naturally present in a living organism is not "isolated," but the same polynucleotide or polypeptide separated from the coexisting materials of its natural state is "isolated", as the term is employed herein.

Thus, according to a further aspect, the present invention provides a method for the prophylaxis and treatment of porcine respiratory disease complex (PRDC) and/or any clinical signs associated with PRDC in an animal, comprising the step of administering an effective amount of PCV2 antigen or an immunogenic composition comprising an PCV2 antigen to that animal in need of such treatment, wherein said PCV2 ORF-2 protein is anyone of those, described above. Preferably, said PCV2 ORF-2 protein is

i) a polypeptide comprising the sequence of SEQ ID NO: 5, SEQ ID NO: 6, SEQ ID NO: 9, SEQ ID NO: 10 or SEQ ID NO: 11 of WO06/07065;
ii) any polypeptide that is at least 80% homologous to the polypeptide of i),

iii) any immunogenic portion of the polypeptides of i) and/or ii)

iv) the immunogenic portion of iii), comprising at least 10 contiguous amino acids included in the sequences of SEQ ID NO: 5, SEQ ID NO: 6, SEQ ID NO: 9, SEQ ID NO: 10 or SEQ ID NO: 11 of WO06/072065,

v) a polypeptide that is encoded by a DNA comprising the sequence of SEQ ID NO: 3 or SEQ ID NO: 4 of WO06/072065.

vi) any polypeptide that is encoded by a polynucleotide that is at least 80% homologous to the polynucleotide of v),

vii) any immunogenic portion of the polypeptides encoded by the polynucleotide of v) and/or vi)

viii) the immunogenic portion of vii), wherein polynucleotide coding for said immunogenic portion comprises at least 30 contiguous nucleotides included in the sequences of SEQ ID NO: 3, or SEQ ID NO: 4 of WO06/072065.

Preferably any of those immunogenic portions have the immunogenic characteristics of PCV2 ORF-2 protein that is encoded by the sequence of SEQ ID NO: 3 or SEQ ID NO: 4 of WO06/07065.

According to a further aspect, PCV2 ORF-2 protein is provided in the immunogenic composition at an antigen inclusion level effective for inducing the desired immune response, namely reducing the incidence of, lessening the severity of, or preventing or reducing PRDC and/or any clinical symptoms associated PRDC. Preferably, the PCV2 ORF-2 protein inclusion level is at least 0.2 µg antigen / ml of the final immunogenic composition (µg/ml),
more preferably from about 0.2 to about 400 µg/ml, still more preferably from about 0.3 to about 200 µg/ml, even more preferably from about 0.35 to about 100 µg/ml, still more preferably from about 0.4 to about 50 µg/ml, still more preferably from about 0.45 to about 30 µg/ml, still more preferably from about 0.6 to about 15 µg/ml, even more preferably from about 0.75 to about 8 µg/ml, even more preferably from about 1.0 to about 6 µg/ml, still more preferably from about 1.3 to about 3.0 µg/ml, even more preferably from about 1.4 to about 2.5 µg/ml, even more preferably from about 1.5 to about 2.0 µg/ml, and most preferably about 1.6 µg/ml.

According to a further aspect, the PCV ORF-2 antigen inclusion level is at least 0.2 µg/PCV2 ORF-2 protein as described above per dose of the final antigenic composition (µg/dose), more preferably from about 0.2 to about 400 µg/dose, still more preferably from about 0.3 to about 200 µg/dose, even more preferably from about 0.35 to about 100 µg/dose, still more preferably from about 0.4 to about 50 µg/dose, still more preferably from about 0.45 to about 30 µg/dose, still more preferably from about 0.6 to about 15 µg/dose, even more preferably from about 0.75 to about 8 µg/dose, even more preferably from about 1.0 to about 6 µg/dose, still more preferably from about 1.3 to about 3.0 µg/dose, even more preferably from about 1.4 to about 2.5 µg/dose, even more preferably from about 1.5 to about 2.0 µg/dose, and most preferably about 1.6 µg/dose.

The PCV2 ORF-2 polypeptide used in the immunogenic composition in accordance with the present invention can be derived in any fashion including isolation and purification of PCV2 ORF2, standard protein synthesis, and recombinant methodology. Preferred methods for obtaining PCV2 ORF-2 polypeptide are provided in WO06/072065, the teachings and
content of which are hereby incorporated by reference in its entirety. Briefly, susceptible cells are infected with a recombinant viral vector containing PCV2 ORF-2 DNA coding sequences, PCV2 ORF-2 polypeptide is expressed by the recombinant virus, and the expressed PCV2 ORF-2 polypeptide is recovered from the supernatant by filtration and inactivated by any conventional method, preferably using binary ethylenimine, which is then neutralized to stop the inactivation process.

The immunogenic composition as used herein also refers to a composition that comprises i) any of the PCV2 ORF-2 protein described above, preferably in concentrations described above, and ii) at least a portion of the viral vector expressing said PCV2 ORF-2 protein, preferably of a recombinant baculovirus. Moreover, the immunogenic composition can comprise i) any of the PCV2 ORF-2 proteins described above, preferably in concentrations described above, ii) at least a portion of the viral vector expressing said PCV2 ORF-2 protein, preferably of a recombinant baculovirus, and iii) a portion of the cell culture supernatant.

Thus, according to a further aspect, the present invention provides a method for the prophylaxis and treatment of porcine respiratory disease complex (PRDC) and/or any clinical signs associated with PRDC in an animal, comprising the step of administering an effective amount of PCV2 antigen or an immunogenic composition comprising an PCV2 antigen to that animal in need of such treatment, wherein the PCV2 antigen is recombinant PCV2 ORF-2, preferably a baculovirus expressed PCV2 ORF-2. Preferably those recombinant or baculovirus expressed PCV2 ORF-2 having the sequence as described above.
The immunogenic composition as used herein also refers to a composition that comprises i) any of the PCV2 ORF-2 proteins described above, preferably in concentrations described above, ii) at least a portion of the viral vector expressing said PCV2 ORF-2 protein, preferably of a recombinant baculovirus, and iii) a portion of the cell culture; wherein about 90% of the components have a size smaller than 1 µm.

The immunogenic composition as used herein also refers to a composition that comprises i) any of the PCV2 ORF-2 proteins described above, preferably in concentrations described above, ii) at least a portion of the viral vector expressing said PCV2 ORF-2 protein, iii) a portion of the cell culture, iv) and inactivating agent to inactivate the recombinant viral vector preferably BEI, wherein about 90% of the components i) to iii) have a size smaller than 1 µm. Preferably, BEI is present in concentrations effective to inactivate the baculovirus, preferably in an amount of 2 to about 8 mM BEI, preferably of about 5 mM BEI.

The immunogenic composition as used herein also refers to a composition that comprises i) any of the PCV2 ORF-2 proteins described above, preferably in concentrations described above, ii) at least a portion of the viral vector expressing said PCV2 ORF-2 protein, iii) a portion of the cell culture, iv) an inactivating agent to inactivate the recombinant viral vector preferably BEI, and v) a neutralization agent to stop the inactivation mediated by the inactivating agent, wherein about 90% of the components i) to iii) have a size smaller than 1 µm. Preferably, if the inactivating agent is BEI, said composition comprises sodium thiosulfate in equivalent amounts to BEI.
The polypeptide is incorporated into a composition that can be administered to an animal susceptible to PCV2 infection. In preferred forms, the composition may also include additional components known to those of skill in the art (see also Remington's Pharmaceutical Sciences. (1990). 18th ed. Mack Publ., Easton). Additionally, the composition may include one or more veterinary-acceptable carriers. As used herein, "a veterinary-acceptable carrier" includes any and all solvents, dispersion media, coatings, adjuvants, stabilizing agents, diluents, preservatives, antibacterial and antifungal agents, isotonic agents, adsorption delaying agents, and the like. In a preferred embodiment, the immunogenic composition comprises PCV2 ORF-2 protein as provided herewith, preferably in concentrations described above, which is mixed with an adjuvant, preferably Carbopol, and physiological saline.

Those of skill in the art will understand that the composition used herein may incorporate known injectable, physiologically acceptable sterile solutions. For preparing a ready-to-use solution for parenteral injection or infusion, aqueous isotonic solutions, such as e.g. saline or corresponding plasma protein solutions, are readily available. In addition, the immunogenic and vaccine compositions of the present invention can include diluents, isotonic agents, stabilizers, or adjuvants. Diluents can include water, saline, dextrose, ethanol, glycerol, and the like. Isotonic agents can include sodium chloride, dextrose, mannitol, sorbitol, and lactose, among others. Stabilizers include albumin and alkali salts of ethylenediaminetetraacetic acid, among others.

"Adjuvants" as used herein, can include aluminium hydroxide and aluminium phosphate, saponins e.g., Quil A, QS-21 (Cambridge Biotech Inc., Cambridge MA), GPI-0100 (Galenica

20
Pharmaceuticals, Inc., Birmingham, AL), water-in-oil emulsion, oil-in-water emulsion, water-in-oil-in-water emulsion. The emulsion can be based in particular on light liquid paraffin oil (European Pharmacopeia type); isoprenoid oil such as squalane or squalene oil resulting from the oligomerization of alkenes, in particular of isobutene or decene; esters of acids or of alcohols containing a linear alkyl group, more particularly plant oils, ethyl oleate, propylene glycol di-(caprylate/caprate), glyceryl tri-(caprylate/caprate) or propylene glycol dioleate; esters of branched fatty acids or alcohols, in particular isostearic acid esters. The oil is used in combination with emulsifiers to form the emulsion. The emulsifiers are preferably nonionic surfactants, in particular esters of sorbitan, of mannide (e.g. anhydromannitol oleate), of glycol, of polyglycerol, of propylene glycol and of oleic, isostearic, ricinoleic or hydroxystearic acid, which are optionally ethoxylated, and polyoxypropylene-polyoxyethylene copolymer blocks, in particular the Pluronic products, especially L121. See Hunter et al., The Theory and Practical Application of Adjuvants (Ed.Stewart-Tull, D. E. S.). John Wiley and Sons, NY, pp51-94 (1995) and Todd et al., Vaccine 15:564-570 (1997).

For example, it is possible to use the SPT emulsion described on page 147 of "Vaccine Design, The Subunit and Adjuvant Approach" edited by M. Powell and M. Newman, Plenum Press, 1995, and the emulsion MF59 described on page 183 of this same book.

A further instance of an adjuvant is a compound chosen from the polymers of acrylic or methacrylic acid and the copolymers of maleic anhydride and alkenyl derivative. Advantageous adjuvant compounds are the polymers of acrylic or methacrylic acid which are cross-linked, especially with polyalkenyl ethers of sugars or polyalcohols. These compounds are known by the term carbomer (Pham.europa Vol. 8, No. 2, June 1996). Persons skilled in
the art can also refer to U. S. Patent No. 2,909,462 which describes such acrylic polymers cross-linked with a polyhydroxylated compound having at least 3 hydroxyl groups, preferably not more than 8, the hydrogen atoms of at least three hydroxyls being replaced by unsaturated aliphatic radicals having at least 2 carbon atoms. The preferred radicals are those containing from 2 to 4 carbon atoms, e.g. vinyls, allyls and other ethylenically unsaturated groups. The unsaturated radicals may themselves contain other substituents, such as methyl. The products sold under the name Carbopol; (BF Goodrich, Ohio, USA) are particularly appropriate. They are cross-linked with an allyl sucrose or with allyl pentaerythritol. Among them, there may be mentioned Carbopol 974P, 934P and 971P. Most preferred is the use of Carbopol, in particular the use of Carbopol 971P, preferably in amounts of about 500 µg to about 5 mg per dose, even more preferred in an amount of about 750 µg to about 2.5 mg per dose and most preferred in an amount of about 1 mg per dose.

Further suitable adjuvants include, but are not limited to, the RIBI adjuvant system (Ribi Inc.), Block co-polymer (CytRx, Atlanta GA), SAF-M (Chiron, Emeryville CA), monophosphoryl lipid A, Avridine lipid-amine adjuvant, heat-labile enterotoxin from E. coli (recombinant or otherwise), cholera toxin, IMS 1314, or muramyl dipeptide among many others.

Preferably, the adjuvant is added in an amount of about 100 µg to about 10 mg per dose. Even more preferably, the adjuvant is added in an amount of about 100 µg to about 10 mg per dose. Even more preferably, the adjuvant is added in an amount of about 500 µg to about 5 mg per dose. Even more preferably, the adjuvant is added in an amount of about 750 µg to
about 2.5 mg per dose. Most preferably, the adjuvant is added in an amount of about 1 mg per dose.

Additionally, the composition can include one or more pharmaceutical-acceptable carriers.

As used herein, "a pharmaceutical-acceptable carrier" includes any and all solvents, dispersion media, coatings, stabilizing agents, diluents, preservatives, antibacterial and antifungal agents, isotonic agents, adsorption delaying agents, and the like. Most preferably, the composition provided herewith, contains PCV2 ORF-2 protein recovered from the supernatant of in vitro cultured cells, wherein said cells were infected with a recombinant viral vector containing PCV2 ORF-2DNA and expressing PCV2 ORF-2 protein, and wherein said cell culture was treated with about 2 to about 8 mM BEI, preferably with about 5 mM BEI to inactivate the viral vector, and an equivalent concentration of a neutralization agent, preferably sodium thiosulfate solution to a final concentration of about 2 to about 8 mM, preferably of about 5 mM.

The present invention also relates to the use of an immunogenic composition for the prophylaxis or treatment of PRDC or the reduction of any clinical signs associated with PRDC that comprises i) any of the PCV2 ORF-2 proteins described above, preferably in concentrations described above, ii) at least a portion of the viral vector expressing said PCV2 ORF-2 protein, iii) a portion of the cell culture, iv) an inactivating agent to inactivate the recombinant viral vector preferably BEI, and v) an neutralization agent to stop the inactivation mediated by the inactivating agent, preferably sodium thiosulfate in equivalent amounts to BEI; and vi) a suitable adjuvant, preferably Carbopol 971 in amounts described above; wherein about 90% of the components i) to iii) have a size smaller than 1 µm.
According to a further aspect, this immunogenic composition further comprises a pharmaceutical acceptable salt, preferably a phosphate salt in physiologically acceptable concentrations. Preferably, the pH of said immunogenic composition is adjusted to a physiological pH, meaning between about 6.5 and 7.5.

The immunogenic composition as used herein also refers to a composition that comprises per one ml i) at least 1.6 µg of PCV2 ORF-2 protein described above, ii) at least a portion of baculovirus expressing said PCV2 ORF-2 protein iii) a portion of the cell culture, iv) about 2 to 8 mM BEI, v) sodium thiosulfate in equivalent amounts to BEI; and vi) about 1 mg Carbopol 971, and vii) phosphate salt in a physiologically acceptable concentration; wherein about 90% of the components i) to iii) have a size smaller than 1 µm and the pH of said immunogenic composition is adjusted to about 6.5 to 7.5.

The immunogenic compositions can further include one or more other immuno-modulatory agents such as, e.g., interleukins, interferons, or other cytokines. The immunogenic compositions can also include Gentamicin and Merthiolate. While the amounts and concentrations of adjuvants and additives useful in the context of the present invention can readily be determined by the skilled artisan, the present invention contemplates compositions comprising from about 50 µg to about 2000 µg of adjuvant and preferably about 250 µg/ ml dose of the vaccine composition. Thus, the immunogenic composition as used herein also refers to a composition that comprises from about lug/ml to about 60 µg/ml of antibiotics, and more preferably less than about 30 µg/ml of antibiotics.
The immunogenic composition as used herein also refers to a composition that comprises i) any of the PCV2 ORF-2 proteins described above, preferably in concentrations described above, ii) at least a portion of the viral vector expressing said PCV2 ORF-2 protein, iii) a portion of the cell culture, iv) an inactivating agent to inactivate the recombinant viral vector preferably BEI, and v) an neutralization agent to stop the inactivation mediated by the inactivating agent, preferably sodium thiosulfate in equivalent amounts to BEI; vi) a suitable adjuvant, preferably Carbopol 971 in amounts described above; vii) a pharmaceutical acceptable concentration of a saline buffer, preferably of a phosphate salt, and viii) an anti-microbiological active agent; wherein about 90% of the components i) to iii) have a size smaller than 1 µm.

The immunogenic composition as used herein also refers to Ingelvac® CircoFLEX™, (Boehringer Ingelheim Vetmedica Inc, St Joseph, MO, USA), CircoVac® (Merial SAS, Lyon, France), Porcilis PCV (Intervet Inc., Millsboro, DE, USA), or Suvaxyn PCV-2 One Dose® (Fort Dodge Animal Health, Kansas City, KA, USA). Thus, the present invention also provides a method for the prophylaxis and treatment of porcine respiratory disease complex (PRDC) and/or any clinical signs associated with PRDC in an animal, comprising the step of administering a therapeutically effective amount of PCV2 antigen or an immunogenic composition comprising an PCV2 antigen to an animal in need of such treatment, wherein wherein said immunogenic composition comprising an PCV2 antigen is Ingelvac® CircoFLEX™, CircoVac®, Porcilis PCV and/or Suvaxyn PCV-2 One Dose®, preferably it is Ingelvac® CircoFLEX™.
As described above, PCV2 has been identified to be one relevant causative agent of PRDC. Most of the pigs suffering from PRDC are positive for PCV2 (e.g. Kim et al., Veterinary Journal (2003) 166: 251-256). The treatment of pigs with PCV2 antigen results in reduction of the respiratory symptoms of PRDC (see Example 3). Thus according to a further aspect, the present invention provides a method for the prophylaxis and treatment of porcine respiratory disease complex (PRDC) and/or any clinical signs associated with PRDC in an animal, comprising the step of administering a therapeutically effective amount of PCV2 antigen or an immunogenic composition comprising an PCV2 antigen to an animal in need of such treatment, wherein the PRDC or the clinical signs associated with PRDC is/are associated with or caused by PCV2. Moreover, the present invention also provides a method for the prophylaxis and treatment of porcine respiratory disease complex (PRDC) and/or any clinical signs associated with PRDC in an animal, comprising the step of administering a therapeutically effective amount of PCV2 antigen or an immunogenic composition comprising an PCV2 antigen to an animal in need of such treatment, wherein the PRDC or the clinical signs associated with PRDC is/are associated with or caused by PCV2 and PRRSV, *Actinobacillus pleuropneumoniae*, *Mycoplasma hyopneumoniae*, *Bordetella bronchiseptica*, Swine influenza virus, *Mycoplasma hyorhinis*, *Streptococcus suis* and/or *Pasteurella multocida*.

As PCV2 is one of the causative agents of PRDC, herds which are positive for PCV2 bear a higher risk to develop PRDC or to develop a more serious duration of PRDC with serious clinical symptoms then PCV2 free herds. The term "herd that is positive for PCV2" as used herein means that at least 1% preferably 10%, more preferably 30%, even more preferably 50%, most preferably 70% of the animals of a herd are infected or become infected to any
time with PCV2. This does not necessarily mean, that any animal of the herd develops clinical symptoms known to be caused by PCV2, such as PMWS or PRDC. Thus according to a further aspect, the present invention also provides a method for the prophylaxis and treatment of porcine respiratory disease complex (PRDC) and/or any clinical signs associated with PRDC in an animal, comprising the step of administering a therapeutically effective amount of PCV2 antigen or an immunogenic composition comprising an PCV2 antigen to an animal in need of such treatment, wherein the animal belonging to a herd that is positive for PCV2. Preferably, the PRDC and/or any clinical signs associated with PRDC are caused by PCV2.

As PRDC and the clinical symptoms of PRDC can also be lessened or reduced in the in animals that are co-infected with other causative pathogens of PRDC, the present invention also provides a method for the prophylaxis and treatment of porcine respiratory disease complex (PRDC) and/or any clinical signs associated with PRDC in an animal, comprising the step of administering a therapeutically effective amount of PCV2 antigen or an immunogenic composition comprising an PCV2 antigen to an animal in need of such treatment, wherein the animal belonging to a herd that is positive for PCV2 and one or more further pathogen(s) selected from the group consisting of PRRSV, *Mycoplasma hyopneumoniae*, *Actinobacillus pleuropneumoniae*, *Bordetella bronchiseptica*, Swine influenza virus, *Mycoplasma hyorhinis*, *Streptococcus suis* and/or *Pasteurella multocida*. Preferably, the PRDC and/or any clinical signs associated with PRDC are caused by PCV2 and at least one other PRDC causing pathogen. The term "a herd that is positive for PCV2 and one or more further pathogen(s) selected from the group consisting of PRRSV, *Mycoplasma hyopneumoniae*, *Actinobacillus pleuropneumoniae*, *Bordetella bronchiseptica*, Swine influenza virus, *Mycoplasma hyorhinis*, *Streptococcus suis* and/or *Pasteurella multocida*"
"multocida", as used herein means, that at least 10%, preferably 30%, more preferably 50%, even more preferably 70% of the animals of a herd are infected or become infected to any time with PCV2 and at least one of the further pathogens list below. This does not necessarily mean, that any animal of the herd develops clinical symptoms known to be caused by PCV2 and at least one of the pathogen listed above, e.g. PRDC. Preferably, the PRDC and/or any clinical signs associated with PRDC are caused at least by PCV2.

PRDC does not only affect a defined number of animals, it normally affects all animals of herd (the whole herd). In other words, if at least one animal of a farm develops PRDC, the causative agents of PRDC are presistently presence within the live stock of that farm. Thus according to a further aspect, the present invention also provides a method for the prophylaxis and treatment of porcine respiratory disease complex (PRDC) and/or any clinical signs associated with PRDC in an animal, comprising the step of administering a therapeutically effective amount of PCV2 antigen or an immunogenic composition comprising an PCV2 antigen to an animal in need of such treatment, wherein the animal belonging to a herd that is positive for PCV2. Preferably, the PRDC and/or any clinical signs associated with PRDC are caused by PCV2. The term "a herd that is positive for PCV2" as used herein means that at least 1% preferably 10%, more preferably 30%, even more preferably 50%, most preferably 70% of the animals of a herd are infected or become infected to any time with PCV2. This does not necessarily mean, that any animal of the farm develops clinical signs known to be caused by PCV2, such as PMWS or PRDC. Preferably, the PRDC and/or any clinical signs associated with PRDC are caused by PCV2.
As PRDC and the clinical symptoms of PRDC can also be lessened or reduced in the in animals that are co-infected with other causative pathogens of PRDC, the present invention also provides a method for the prophylaxis and treatment of porcine respiratory disease complex (PRDC) and/or any clinical signs associated with PRDC in an animal, comprising the step of administering a therapeutically effective amount of PCV2 antigen or an immunogenic composition comprising an PCV2 antigen to an animal in need of such treatment, wherein the animal belonging to a farm that is positive for PCV2 and one or more further pathogen(s) selected from the group consisting of PRRSV, Mycoplasma hyopneumoniae, Actinobacillus pleuropneumoniae, Bordetella bronchiseptica, Simian influenza virus, Mycoplasma hyorhinis, Streptococcus suis and/or Pasteurella multocida. Preferably, the PRDC and/or any clinical signs associated with PRDC are caused by PCV2 and at least one other PRDC causing pathogen. The term "a herd that is positive for PCV2 and one or more further pathogen(s) selected from the group consisting of PRRSV, Mycoplasma hyopneumoniae, Actinobacillus pleuropneumoniae, Bordetella bronchiseptica, Swine influenza virus, Mycoplasma hyorhinis and/or Pasteurella multocida", as used herein means, that at least 10%, preferably 30%, more preferably 50%, even more preferably 70% of the animals of a herd are infected or become infected to any time with PCV2 and at least one of the further pathogens listed below. This does not necessarily mean, that any animal of the herd develops clinical symptoms known to be caused by PCV2 and at least one of the pathogen listed above, e.g. PRDC.

Maternally derived immunity has been shown to confer a certain degree of protection against PCV2 infection and clinical diseases associated with PCV2 infections. This protection has been shown to be titer dependent: higher titers are generally protective whereas lower titers.
are not (McKeown et al., 2005; Clin. Diagn. Lab. Immunol.; 12: 1347-1351). The mean antibody half-life in weanlings has been estimated to be 19.0 days and the window for PCV2-passive antibody decay within a population is relatively wide (Opriessnig et al. 2004, J. Swine Health Prod. 12:186-191). The presence of maternal derived antibodies not only may confer a certain degree of protection against viral infections, which however is not predictable, but may also be known to impair the efficacy of immunization. It has surprisingly be found, that the presence of anti-PCV2 antibodies, in particular of anti-PCV2 antibody titers of up to 1:20480, does not affect the efficacy of the PCV2 treatment. Thus according to a further aspect, the present invention provides a method for the prophylaxis and treatment of porcine respiratory disease complex (PRDC) and/or any clinical signs associated with PRDC in an animal, comprising the step of administering a therapeutically effective amount of PCV2 antigen or an immunogenic composition comprising an PCV2 antigen to an animal in need of such treatment having anti-PCV2 antibodies, preferably wherein said animal has a detectable anti-PCV2 antibody titer of up to 1:100, preferably of more than 1:100, even more preferably of more than 1:250, even more preferably of more than 1:500, even more preferably of 1:640; even more preferably of more than 1:750, most preferably of more than 1:1000. Preferably, those anti-PCV2 antibody titer is detectable and quantifiable in a specific anti-PCV2 immune assay, preferably in the assay as described in Example 2.

Methods for detection and quantification of anti-PCV2 antibodies are well known in the art. For example detection and quantification of PCV2 antibodies can be performed by indirect immunofluorescence as described in Magar et al., 2000, Can. J. Vet Res.; 64: 184-186 or Magar et al., 2000, J. Comp. Pathol; 123: 258-269. Further assays for quantification of anti-PCV2 antibodies are described in Opriessnig et al., 2006, 37th Annual Meeting of the
American Association of Swine Veterinarians. Moreover, example 2 also describes an indirect immunofluorescence assay, that can be used by a person skilled in the art. In cases of controversial results and in any question of doubt, anti-PCV2 titers as mentioned herein, refer to those which are can be estimated by the assay as described in Example 2.

According to a further, more general aspect, the present invention provides a method for the prophylaxis of PRDC, preferably associated with or caused by PCV2, or for reduction of clinical symptoms caused by or associated with PRDC in young animals, comprising the step of administering an effective amount of a PCV2 antigen to that young animal in need of such treatment.

The term "young animal" as used herein refers to an animal of 1 to 22 days of age. Preferably, by the term young animal, an animal of 1 to 20 days of age is meant. More preferably, the term young animal refers to an animal of 1 to 15 days of age, even more preferably of 1 day of age to 14 days of age, even more preferably of 1 to 12 days of age, even more preferably of 1 to 10 days of age, even more preferably of 1 to 8 days of age, even more preferably of 1 to 7 days of age, even more preferably of 1 to 6 days of age, even more preferably of 1 to 5 days of age, even more preferably of 1 to 4 days of age, even more preferably of 1 to 3 days of age, even more preferably of 1 or 2 day(s) of age, most preferably to an animal of 1 day of age. Thus according to a further aspect, the present invention provides a method for the prophylaxis of PRDC, preferably associated with or caused by PCV2, or for reduction of clinical symptoms caused by or associated with PRDC in young animals, comprising the step of administering an effective amount of a PCV2 antigen to an animal of 1 to 22 days of age, preferably of 1 to 20 days of age, more preferably of 1 to 15
days of age, even more preferably of 1 to 14 days of age, even more preferably of 1 to 12
days of age, even more preferably of 1 to 10 days of age, even more preferably of 1 to 8 days
of age, even more preferably of 1 to 7 days of age, even more preferably of 1 to 6 days of
age, even more preferably of 1 to 5 days of age, even more preferably of 1 to 4 days of age,
even more preferably of 1 to 3 days of age, even more preferably of 1 or 2 day(s) of age, most
preferably at 1 day of age in need of such treatment. For example evidence is given that
vaccination/treatment on 19 to 22 days of age show high efficacy of vaccination. Moreover,
vaccination/treatment at days 12 to 18 of age has also be shown to be very effective in
reduction of clinical symptoms associated with or caused by PRDC, reduction of overall viral
load, reduction of duration of viremia, delay in onset of viremia, weight gain.

Due to the ubiquity of PCV2 in the field most of the young piglets are seropositive in respect
to PCV2. Thus according to a further aspect, the present invention provides a method for the
prophylaxis of PRDC, preferably associated with or caused by PCV2, or for reduction of
clinical symptoms caused by or associated with PRDC in young animals having anti-PCV2
antibodies, preferably at the day of vaccination, comprising the step of administering an
effective amount of a PCV2 antigen to an animal of 1 to 22 days of age, preferably of 1 to 20
days of age, more preferably of 1 to 15 days of age, even more preferably of 1 to 14 days of
age, even more preferably of 1 to 12 days of age, even more preferably of 1 to 10 days of age,
even more preferably of 1 to 8 days of age, even more preferably of 1 to 7 days of age, even
more preferably of 1 to 6 days of age, even more preferably of 1 to 5 days of age, even more
preferably of 1 to 4 days of age, even more preferably of 1 to 3 days of age, even more
preferably at 1 or 2 day(s) of age, most preferably at 1 day of age in need of such treatment.
Preferably, said young animals, at the day of vaccination/treatment, have a detectable anti-
PCV2 antibody titer of up to 1:100, preferably of more than 1:100, even more preferably of more than 1:250, even more preferably of more than 1:500, even more preferably of 1:640, even more preferably of more than 1:750, most preferably of more than 1:1000 at the day of vaccination/treatment.

As described above, vaccination/treatment of animals suffering from PRDC with PCV2 antigen resulted in shortening of viremic phase as compared to non vaccinated control animals. The average shortening time was 15.4 days as compared to non vaccinated control animals of the same species. Therefore, according to a further aspect, the present invention also provides a method for the treatment or prophylaxis of PRDC, preferably associated with or caused by PCV2, or for reduction of clinical symptoms caused by or associated with a PRDC in animals, comprising the step of administering an effective amount of a PCV2 antigen to that animal in need of such treatment, wherein the treatment or prophylaxis results in shortening of the viremia phase of 5 or more days, preferably 6 or more day, even more preferably of 7 or more days, even more preferably of 8 or more days, even more preferably of 9, even more preferably of 10, even more preferably of 12, even more preferably of 14, most preferably of more than 15 days as compared to animals of a non-treated control group of the same species.

In general, the vaccination of pigs suffering from PRDC resulted in a reduction in the loss of weight gain, reduction in clinical respiratory signs such as cough and dyspnea, a shorter duration of viremia, an earlier end to viremia, and a lower virus load. Therefore, according to a further aspect, the present invention provides a method for the treatment or prophylaxis of PRDC, preferably associated with or caused by PCV2, or for reduction of clinical symptoms
associated with or caused by PRDC in animals, comprising the step of administering an effective amount of PCV2 antigen to an animal in need of such treatment, wherein said treatment or prophylaxis results in an improvement in comparison to animals of a non-treated control group of the same species in a vaccine efficacy parameter selected from the group consisting of a reduction in the loss of weight gain, reduction in clinical respiratory signs such as cough and dyspnea, a shorter duration of viremia, an earlier end to viremia, a lower virus load, or combinations thereof.

The term "an effective amount" as used herein means but is not limited to an amount of antigen, that elicits or is able to elicit an immune response in an animal, to which said effective dose of PCV2 antigen is administered.

The amount that is effective depends on the ingredients of the vaccine and the schedule of administration. Typically, when an inactivated virus or a modified live virus preparation is used in the combination vaccine, an amount of the vaccine containing about $10^{20}$ to about $10^{90}$ TCID$_{50}$/dose, preferably about $10^{30}$ to about $10^{80}$ TCID$_{50}$/dose, more preferably, about $10^{40}$ to about $10^{80}$ TCID$_{50}$/dose. In particular, when modified live PCV2 is used in the vaccines, the recommended dose to be administered to the susceptible animal is preferably about $10^{30}$ TCID$_{50}$ (tissue culture infective dose 50% end point)/dose to about $10^{60}$ TCID$_{50}$/dose and more preferably about $10^{40}$ TCID$_{50}$/dose to about $10^{50}$ TCID$_{50}$/dose. In general, the quantity of antigen will be between 0.2 and 5000 micrograms, and between $10^{20}$ and $10^{90}$ TCID$_{50}$, preferably between $10^{30}$ and $10^{60}$ TCID$_{50}$, more preferably between $10^{40}$ and $10^{50}$ TCID$_{50}$, when purified antigen is used.
Sub-unit vaccines are normally administered with an antigen inclusion level of at least 0.2 µg antigen per dose, preferably with about 0.2 to about 400 µg/dose, still more preferably with about 0.3 to about 200 µg/dose, even more preferably with about 0.35 to about 100 µg/dose, still more preferably with about 0.4 to about 50 µg/dose, still more preferably with about 0.45 to about 30 µg/dose, still more preferably with about 0.6 to about 16 µg/dose, even more preferably with about 0.75 to about 8 µg/dose, even more preferably with about 1.0 to about 6 µg/dose, still more preferably with about 1.3 to about 3.0 µg/dose.

Unexpectedly, it was found that the prophylactic use of the immunogenic compositions described supra, is effective for reduction of clinical symptoms caused by or associated with PRDC, preferably caused at least by PCV2 in animals. Moreover, the antigenic composition described herein reduces the overall circovirus load including a later onset, a shorter duration, an earlier end of viremia, and a reduced viral load and its immunosuppressive impact in animals suffering from PRDC, and thereby resulting in a higher level of general disease resistance and a reduced incidence of PRDC.

The composition according to the invention may be applied intradermally, intratracheally, or intravaginally. The composition preferably may be applied intramuscularly or intranasally, most preferably intramuscularly. In an animal body, it can prove advantageous to apply the pharmaceutical compositions as described above via an intravenous or by direct injection into target tissues. For systemic application, the intravenous, intravascular, intramuscular, intranasal, intraarterial, intraperitoneal, oral, or intrathecal routes are preferred. A more local application can be effected subcutaneously, intradermally, intracutaneously, intracardially, intralobally, intramedullarly, intrapulmonarily or directly in or near the tissue to be treated.
(connective-, bone-, muscle-, nerve-, epithelial tissue). Depending on the desired duration and effectiveness of the treatment, the compositions according to the invention may be administered once or several times, also intermittently, for instance on a daily basis for several days, weeks or months and in different dosages.

Preferably, at least one dose of the immunogenic composition as described above is intramuscularly administered to the subject in need thereof. According to a further aspect, the PCV2 antigen or the immunogenic composition comprising any such PCV2 antigen as described herein is bottled in and administered at one (1) mL per dose. Thus, according to a further aspect, the present invention also provides a 1 mL immunogenic composition, comprising PCV-2 antigen as described herein, for the treatment or prophylaxis of porcine respiratory disease complex (PRDC) and/or any clinical signs associated with PRDC, preferably caused by PCV2, in animals, comprising the step of administering an effective amount of a PCV2 antigen to that animal in need of such treatment.

According to a further aspect, at least one further administration of at least one dose of the immunogenic composition as described above is given to a subject in need thereof, wherein the second or any further administration is given at least 14 days beyond the initial or any former administrations. Preferably, the immunogenic composition is administered with an immune stimulant. Preferably, said immune stimulant is given at least twice. Preferably, at least 3 days, more preferably at least 5 days, even more preferably at least 7 days are in between the first and the second or any further administration of the immune stimulant. Preferably, the immune stimulant is given at least 10 days, preferably 15 days, even more preferably 20, even more preferably at least 22 days beyond the initial administration of the
immunogenic composition provided herein. A preferred immune stimulant is, for example, keyhole limpet hemocyanin (KLH), preferably emulsified with incomplete Freund's adjuvant (KLH/ICFA). However, it is herewith understood, that any other immune stimulant known to a person skilled in the art can also be used. The term "immune stimulant" as used herein, means any agent or composition that can trigger the immune response, preferably without initiating or increasing a specific immune response, for example the immune response against a specific pathogen. It is further instructed to administer the immune stimulant in a suitable dose.

The present invention also relates to the use of a PCV2 antigen or an immunogenic composition comprising PCV2 antigen for the preparation of a medicine for the prophylaxis and treatment of porcine respiratory disease complex (PRDC) and/or any clinical sign associated with PRDC in an animal. Preferably, the PRDC or the clinical signs associated with PRDC are caused at least PCV2, more preferably in combination with one or more further pathogens selected from the group consisting of PRRSV, Mycoplasma hyopneumoniae, Actinobacillus pleuropneumoniae, Bordetella bronchiseptica, Simian influenza virus, Mycoplasma hyorhinis, Streptococcus suis and/or Pasteurella multocida. More preferably, the PCV2 antigen is a recombinant antigen, preferably PCV2 ORF-2, even more preferably Ingelvac® CircoFLEX™.

The "animal" as used herein means swine, pig or piglet. Thus, according to a further aspect the present invention provides a method for the prophylaxis and treatment of porcine respiratory disease complex (PRDC) and/or any clinical signs associated with PRDC in a pig, comprising the step of administering a therapeutically effective amount of PCV2 antigen or
an immunogenic composition comprising an PCV2 antigen to a pig in need of such treatment. Preferably, the PRDC is caused at least by PCV2, preferably in combination with at least one further aetiologic agent known to cause PRDC, e.g. PRRSV, *Mycoplasma hyopneumoniae, Actinobacillus pleuropneumoniae, Bordetella bronchiseptica, Swine influenza virus, Mycoplasma hyorhinis, Streptococcus suis* and/or *Pasteurella multocida*. Preferably, the PCV2 antigen or immunogenic composition comprising PCV2 antigen is anyone of those described *supra*, most preferably the PCV2 antigen is Ingelvac® CircoFLEX™.

**DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS**

The following examples set forth preferred materials and procedures in accordance with the present invention. Although any methods and materials similar or equivalent to those described herein can be used in the practice or testing of the present invention, the preferred methods, devices, and materials are now described. It is to be understood, however, that these examples are provided by way of illustration only, and nothing therein should be deemed a limitation upon the overall scope of the invention.

**EXAMPLE 1**

**Preparation of PCV2 ORF-2 antigen**

Initial SF+ cell cultures from liquid nitrogen storage were grown in Excell 420 media (JRH Biosciences, Inc., Lenexa, KS) in suspension in sterile spinner flasks with constant agitation. The cultures were grown in 100 mL to 250mL spinner flasks with 25 to 150 mL of Excell
420 serum-free media. When the cells had multiplied to a cell density of 1.0 - 8.0 x 10^6 cells/mL, they were split to new vessels with a planting density of 0.5 - 1.5 x 10^6 cells/mL. Subsequent expansion cultures were grown in spinner flasks up to 36 liters in size or in stainless steel bioreactors of up to 300 liters for a period of 2-7 days at 25 - 29°C.

After seeding, the flasks were incubated at 27°C for four hours. Subsequently, each flask was seeded with a recombinant baculovirus containing the PCV2 ORF-2 gene (SEQ ID NO: 4). The recombinant baculovirus containing the PCV2 ORF-2 gene was generated as described in WO06/072065. After being seeded with the baculovirus, the flasks were then incubated at 27 ± 2°C for 7 days and were also agitated at 100 rpm during that time. The flasks used ventilated caps to allow for air flow.

After incubation, the resulting supernatant were harvested, filtered in order to remove cell debris and inactivated. The supernatant was inactivated by bringing its temperature to 37 ± 2°C and binary ethylenimine (BEI) is added to the supernatant to a final concentration of 5mM. The samples were then stirred continuously for 72 to 96 hrs. A 1.0 M sodium thiosulfate solution to give a final minimum concentration of 5 mM was added to neutralize any residual BEI. After inactivation, PCV2 ORF-2 buffered with phosphate buffer and Carpol was added to about 0.5 to 2.5 mg/dose. The final dose comprises about 16 µg PCV2 ORF-2 antigen.
EXAMPLE 2

Anti PCV-2 Immuno assay

PKI 5 (e.g. ATCC CCL-33) or VIDO R1 cells described in WO 02/07721, are seeded onto a 96 well plate (about 20,000 to 60,000 cells per wells). Cells are infected with a PCV2 isolate, when monolayers are approximately 65 to 85% confluent. Infected cells are incubated for 48 hours. Medium is removed and wells are washed 2 times with PBS. The wash buffer is discarded and cells are treated with cold 50/50 methanol/acetone fixative (-100 µl/well) for about 15 min at about -20°C. The fixative is discarded and the plates are air dried. Serial dilutions of porcine serum samples are prepared in PBS, added to the plates and incubated to allow antibodies to bind if present in the serum samples for about 1 hr at 36,5±1°C. In addition, serial dilutions of an anti-PCV2 positive and negative control sample (Positive Control and Negative Control Samples) are run in parallel. The plates are then washed three times with PBS. The PBS is discarded. Plates are then stained with a commercial Goat anti-Swine FITC conjugate diluted 1:100 in PBS and incubated for about 1 hr at 36.5+PC, which allows detection of antibodies bound to infected cells. After incubation is complete, the microplates are removed from incubator, the conjugate is discarded and the plates are washed 2 times with PBS. The plates were read using UV microscopy and individual wells reported as positive or negative. The Postive Control and Negative Control samples are used to monitor the test system. If the controls are within expected ranges the test results are acceptable in regard to test method parameters. The serum antibody titers were calculated using the highest dilution showing specific IFA reactivity and the number of wells positive per dilution, or a 50% endpoint is calculated using the appropriate Reed-Muench formula.
EXAMPLE 3

Efficacy of PCV2 ORF-2 (Ingelvac® CircoFLEX™) in treatment of PRDC

OBJECTIVE

The purpose of this study was the demonstration of the efficacy of Ingelvac® CircoFLEX in the control of PCV2 associated PRDC.

STUDY PERFORMANCE

1542 conventional pigs belonging to three consecutive week groups, each comprising approximately 500 animals, were included into the study. The study animals were blocked by weight and litter assignment and randomly assigned to one group of vaccinates (n=769) and one control group (n=773).

- **Group 1**: At study day 0 the pigs were vaccinated intramuscularly at the age of approximately 20 days by a single dose of Ingelvac® CircoFLEX containing PCV2 ORF-2 protein as active substance with an RP of 1 (per dose of 1 ml) and Carbopol® as adjuvant.

- **Group 2**: The control group received 1 ml of control article which contained PCV2 ORF-2 protein free cell culture supernatant and Carbopol® as adjuvant.

- **Group 3**: Untreated pigs.

20 The study was terminated at the end of fattening (study week 22).

Parameters recorded

Parameters recorded were as follows:

- Individual body weight (all animals)
- Frequency of 'runts' (all animals)
- Clinical signs (all animals)
- Mortality (all animals)
- PCV2 viremia in serum: onset, end, duration of viremia, virus load
  (17% of study animals)
- Necropsy (every dead or euthanized animal, if possible)

**Disease Situation at the Farm**

According to the disease history of the rearing and fattening farm, animals experienced respiratory symptoms related to the Porcine Respiratory Disease Complex (PRDC) from the middle of fattening onwards. These symptoms were accompanied by a reduced weight gain (ADWG 750-780g) and an increased mortality rate (5.5-6.6%) during the fattening period. Pathogens that were considered to be involved in PRDC at that time were PCV2, PRRSV, *Pasteurella multocida*, *Bordetella bronchiseptica* and occasionally SIV. For the course of this study *Mycoplasma hyopneumoniae* and *Mycoplasma hyorhinis* were additionally found to be involved in this disease complex. Interestingly, results from this study give evidence for the fact that both the PRRSV and the *Mycoplasma hyopneumoniae* infection occurred approximately 4-6 weeks before onset of PCV2 viremia. However, as the number of dead animals over the course of the study and the frequency of respiratory symptoms before and after the onset of PCV2 viremia reveal, animals remained rather unaffected from these two infectious pathogens.

**RESULTS**

*Body weight, Weight gain, Average Daily Weight Gain*
Body weight of the two treatment groups was comparable at the time of study initiation. At study weeks 17 and 22 the body weight of the vaccinated group was significantly higher than the body weight of the placebo-treated group ($p = 0.0007$ and $p < 0.0001$, respectively).

From study initiation until study week 22 vaccinated animals had gained 2.8 kg more weight than placebo-treated animals. This corresponds to a 13 g/d higher ADWG in vaccinated animals from study initiation until study week 17 and a 18 g/d higher ADWG in vaccinated animals until study week 22. For the entire fattening period (study week 7-22), the ADWG could thus be increased from 777 g/d in placebo-treated animals (comparable to historical 750-780 g/d ADWG) to 803 g/d in vaccinated animals (Table 1 and Figure 1).

Viremia in Blood

Vaccinated animals showed a slightly later onset of viremia (1.5 days later), a significant earlier end of viremia ($p < 0.0001$), a significant shorter duration of viremia ($p < 0.0001$), a significant lower number of positive sampling days per animal ($p < 0.0001$) and a significant
general reduction in the virus load (p < 0.0001). The highest proportion of viremic animals was observed at study week 17 with 75% viremic animals in the placebo group and 28% viremic animals in the vaccinated group.

Correlation of Viremia in Blood with Body Weight

Figure 2 illustrates the virus load in sample animals of both treatment groups over the course of the study compared to the difference in live body weight (CP-IVP) of all animals from both treatment groups on the respective weighing time points. When comparing the curves for body weight difference with the bars representing the virus load, it becomes obvious that the observed differences in body weight between both treatment groups (study weeks 17 and 22) occur after the onset of viremia (study week 14-16). While the virus load is decreasing after a peak at study week 17 the difference in body weight between groups is further increasing until the end of fattening. Together these data give evidence for a correlation between the observed higher body weight gain development at study weeks 17 and 22 in the vaccinated group and the onset, duration and level of viremia.
Calculation of the Spearman rank coefficient confirmed the existence of a statistical significant correlation between viremia and the difference in weight gain development in placebo-treated animals at study weeks 17 and 22. A low body weight in placebo-treated animals was correlated with an early onset, a long duration of viremia and a high virus load. For vaccinated animals no such correlation could be found indicating that the higher body weight in the vaccinated animals is the result of a delayed onset and shorter duration of viremia as well as of a lower virus load in blood.

**Frequency of Runts**

No significant differences in the frequency of 'runts' could be observed between the vaccinated and the placebo-treated group on any of the respective weighing time points. After the onset of PCV2 viremia (study week 14-16), the frequency of 'runts' was generally low in both treatment groups (2.2-3.9%).

**Clinical Signs**

Before onset of viremia predominant clinical signs were lamenesses, cough and diarrhea (in 8-12% of animals). They occurred with equal frequency in both treatment groups. Upon necropsy of dead animals and subsequent microbiological examination *Streptococcus suis* was identified as possible infectious pathogen for lamenesses, *Haemophilus parasuis* and *Bordetella bronchiseptica* were identified as possible infectious pathogens for cough and
haemolytic *E. coli* was identified as possible reason for diarrhea.

After the onset of viremia the predominant clinical symptoms observed in animals of both treatment groups were cough and lamenesses. Serological periodic analyses for other infectious pathogens and microbiological findings upon necropsy revealed that PCV2 viremia was accompanied by a (preceding) PRRSV and *Mycoplasma hyopneumoniae* infection. Together with PCV2 these infectious pathogens form part of PRDC which is considered to be the cause for the increased frequency of coughing animals after the onset of viremia. Compared to the placebo-treated animals, the frequency of cough and dyspnea in vaccinated animals was reduced by 12.2% and 17.5%, respectively. These findings are however without any statistical significance. The increased frequency of lamenesses after the onset of viremia compared to the time before onset of viremia is most likely been caused by chronic forms of *Streptococcus suis* arthritis or by weaknesses of the joint apparatus and affected both treatment groups in the same way (*p* = 0.8321). Similarly, the frequency of other clinical findings (diarrhea, skin abnormalities, behaviour) after the onset of viremia was almost equal between the two treatment groups.

**Mortality**

Before onset of viremia the mortality rate was comparable in both treatment groups (vaccinated animals: 5.20%, placebo-treated animals: 5.17%). After the onset of viremia placebo-treated animals had a significant higher mortality rate than vaccinated animals (vaccinated animals: 1.51%, placebo-treated animals: 3.68%, *p* = 0.0127). Compared to placebo-treated animals, the mortality rate in vaccinated animals was reduced by 59%.
CONCLUSION

The study has been conducted on a farm that showed typical symptoms of PRDC at the late phase of fattening. At the age of 17 to 19 weeks pigs developed respiratory symptoms, an increased mortality rate and a loss of weight gain. Upon serological and microbiological screening PCV2, PRRSV, *Mycoplasma hyopneumoniae*, *Mycoplasma hyorhinis* and *Pasteurella multocida* were identified as possible pathogens being involved in this disease complex.

Compared to the placebo-treated control group the following statistical significant findings were noted for the vaccinated group:

- reduction of loss of weight gain
- reduction of mortality
- reduction of the duration of viremia and earlier end of viremia
- reduction of the virus load
- reduction of cough and dyspnea

As expected, no statistical significant differences could be observed with regard to the frequency of 'runts' since the occurrence of 'runts' is not a typical finding for PRDC.

Together these findings allow the following conclusions:

1. The study has been conducted in a herd that got affected with PRDC at the middle to late phase of fattening. PCV2 was clearly involved in this disease complex since respiratory symptoms, loss of weight gain and an increase in mortality was only observed after the onset of viremia.
2. Vaccination of animals with Ingelvac® CircoFLEX™ could reduce or even prevent clinically relevant parameters that are related to PCV2 associated PRDC
CLAIMS

1. Use of PCV2 antigen or an immunogenic composition comprising PCV2 antigen for the preparation of a medicine for the prophylaxis and treatment of porcine respiratory disease complex (PRDC) and/or any clinical sign associated with PRDC in an animal.

2. The use according to claim 1, wherein the medicine is administered to an animal in need of such treatment in a therapeutically effective amount.

3. The use according to claim 1 or 2, wherein the clinical sign associated with PRDC is selected from the group consisting of cough and dyspnea, slow growth, decreased feed efficiency, lethargy, anorexia, and/or a marked increase in mortality in the middle to late phase of fattening.

4. The use according to claim 3, wherein the cough and dyspnea, are refractory to antibiotic therapy.

5. The use according to any one of claims 1 to 4, wherein the PRDC is associated with a PCV2 infection.

6. The use according to claim 5, wherein the PRDC is caused by PCV2.

7. The use according to claim 6, wherein the PRDC is further associated with and/or caused by an infection with PRRSV, *Mycoplasma hyopneumoniae, Bordetella bronchiseptica,*
Swine influenza virus, *Actinobacillus pleuropneumoniae*, *Mycoplasma hyorhinis*, *Streptococcus suis* and/or *Pasteurella multocida*.

8. The use according to any one of claims 1 to 7, wherein the animal belonging to a herd that is positive for PCV2.

9. The use according to any one of claims 1 to 8, wherein the animal belonging to a herd that is positive for PCV2 and one or more further pathogen(s) selected from the group consisting of PRRSV, *Mycoplasma hyopneumoniae*, *Bordetella bronchiseptica*, Swine influenza virus, *Mycoplasma hyorhinis*, *Streptococcus suis* and/or *Pasteurella multocida*.

10. The use according to any one of claims 1 to 9, wherein the animal belonging to a farm that is positive for PCV2.

11. The use according to any one of claims 1 to 10, wherein the animal belonging to a farm that is positive for PCV2 and one or more further pathogen(s) selected from the group consisting of PRRSV, *Mycoplasma hyopneumoniae*, *Bordetella bronchiseptica*, Swine influenza virus, *Mycoplasma hyorhinis*, *Streptococcus suis* and/or *Pasteurella multocida*.

12. The use according to any one of claims 1 to 11, wherein the PCV2 antigen is a polypeptide having at least 80% homology with ORF-2 of PCV2.

13. The use according to any one of claims 1 to 12, wherein said PCV-2 antigen is a recombinant baculovirus expressed ORF-2 of PCV2.
14. The use according to any one of claims 1 to 13, wherein the PCV2 antigen is Ingelvac® CircoFLEX™.

15. The use according to any one of claims 1 to 14, wherein the animal is swine.

16. A method for the prophylaxis and treatment of porcine respiratory disease complex (PRDC) and/or any clinical sign associated with PRDC in an animal, comprising the step of administering a therapeutically effective amount of PCV2 antigen or an immunogenic composition comprising an PCV2 antigen to an animal in need of such treatment.

17. The method according to claim 16, wherein the clinical sign associated with PRDC is selected from the group consisting of cough and dyspnea, slow growth, decreased feed efficiency, lethargy, anorexia, and/or a marked increase in mortality in the middle to late phase of fattening.

18. The method according to claim 17, wherein the cough and dyspnea, are refractory to antibiotic therapy.

19. The method according to any one of claims 16 to 18, wherein the PRDC is associated with a PCV2 infection.

20. The method according to claim 19, wherein the PRDC is caused by PCV2.
21. The method according to claim 20, wherein the PRDC is further associated with and/or caused by an infection with PRRSV, *Mycoplasma hyopneumoniae*, *Bordetella bronchiseptica*, Swine influenza virus, *Actinobacillus pleuropneumoniae*, *Mycoplasma hyorhinis*, *Streptococcus suis* and/or *Pasteurella multocida*.

22. The method according to any one of claims 16 to 21, wherein the animal belonging to a herd that is positive for PCV2.

23. The method according to any one of claims 16 to 22, wherein the animal belonging to a herd that is positive for PCV2 and one or more further pathogen(s) selected from the group consisting of PRRSV, *Mycoplasma hyopneumoniae*, *Bordetella bronchiseptica*, Swine influenza virus, *Mycoplasma hyorhinis*, *Streptococcus suis* and/or *Pasteurella multocida*.

24. The method according to any one of claims 16 to 23, wherein the animal belonging to a farm that is positive for PCV2.

25. The method according to any one of claims 16 to 24, wherein the animal belonging to a farm that is positive for PCV2 and one or more further pathogen(s) selected from the group consisting of PRRSV, *Mycoplasma hyopneumoniae*, *Bordetella bronchiseptica*, Swine influenza virus, *Mycoplasma hyorhinis*, *Streptococcus suis* and/or *Pasteurella multocida*.
26. The method according to any one of claims 16 to 25, wherein the PCV2 antigen is a polypeptide having at least 80% homology with ORF-2 of PCV2.

27. The method according to any one of claims 16 to 26, wherein said PCV-2 antigen is a recombinant baculovirus expressed ORF-2 of PCV2.

28. The method according to any one of claims 16 to 27, wherein the PCV2 antigen is Ingelvac® CircoFLEX™.

29. The method according to any one of claims 16 to 28, wherein the animal is swine.

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1 [X] Claims Nos because they relate to subject matter not required to be searched by this Authority, namely

Although claims 16-29 are directed to a method of treatment of the human/animal body, the search has been carried out and based on the alleged effects of the compound/composition.

2 [ ] Claims Nos because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically

3 [ ] Claims Nos because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 64(a)

This International Searching Authority found multiple inventions in this international application, as follows:

1 [ ] As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.

2 [ ] As all searchable claims could be searched without effort justifying an additional fees, this Authority did not invite payment of additional fees.

3 [ ] As only some of the required additional search fees were timely paid by the applicant, this International search report covers only those claims for which fees were paid, specifically claims Nos.

4 [ ] No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims, It is covered by claims Nos.

Remark on Protest

- [ ] The additional search fees were accompanied by the applicant's protest and, where applicable, the payment of a protest fee.
- [ ] The additional search fees were accompanied by the applicant's protest but the applicable protest fee was not paid within the time limit specified in the invitation.
- [ ] No protest accompanied the payment of additional search fees.
