DESCRIPTION

[0001] The present invention relates to targeting of sialyl-di-Lewis^a in cancer and isolated antibodies or antibody fragments, such as monoclonal antibodies (mAbs), which bind this glycan as expressed on glycoproteins but not lipids.

[0002] Glycan structures are present on both protein and glycolipid backbones and can be massively over-expressed in cancer due to altered expression of glycosyltransferases. During N-linked glycosylation, proteins in the ER are decorated with a branched 9 mannose sugar $(man)_9$ complex. When the protein exits the ER, mannosidase I removes 4 of the mannose sugars $(man)_5$ and then mannosidases II removes a further 2 $(man)_3$. Glycosyltransferases then build complex glycan structures on this mannose core. These glycans are vital for folding and the function of the proteins. Generating mAbs to glycans expressed on proteins is a problem, as the mAbs rarely see just the small glycan but usually recognise the glycan on the specific protein giving a very restrictive expression.

[0003] During oncogenesis, the glycosylation processes are highly dysregulated leading to altered glycan expression at the surface of cancer cells which results in tumour-associated carbohydrate antigens (TACAs). In tumours, TACAs are not only aberrantly expressed and have a dense distribution compared to normal tissue, but they are also involved in many physiological processes such as protein folding and trafficking, adhesion, and cell proliferation, making them attractive targets for therapeutic mAbs.

[0004] Lewis carbohydrates are ideal candidates for mAb therapy as they have a very limited distribution on normal tissues and are over-expressed in cancers that originated from epithelial cells, particularly in pancreatic and gastrointestinal cancer. They are formed by the sequential addition of fucose onto oligosaccharide precursor chains on glycoproteins and glycolipids, through the action of glycosyltransferases and can be divided in type I chains - which form Le^a and Le^b and type II chains - which form Lewis^x and Lewis^y.

[0005] Sialyl-Lewis^a is a ligand of E-selectin involved in endothelial leukocyte adhesion and is over-expressed in cancers of the hepato-biliary system, pancreas and gastrointestinal tract, while its natural form, di-sialyl-Lewis^a which has an extra sialic acid sugar, is found in non-malignant epithelial cells. Expression of sialyl-Lewis^a was found to increase metastatic potential in pancreatic adenocarcinoma (16, 27) and colon cancer (14, 15). In pancreatic and colon cancer, sialyl-Lewis^a is also used as a tumour marker to monitor responses to therapy (13,17,18). Sialyl-di-Lewis^a (this has the single sialic acid found in cancers but also has the Lewis^a duplicated and is only found on proteins), is expressed by a wide range of pancreatic tumours but has a very restricted normal tissue expression. More recently, human sialyl-Lewis^a mAbs were produced using a patient vaccination strategy that showed specific binding to sialyl-Lewis^a and exhibited ADCC, CDC and anti-tumour activity in a xenograft model (20). One of these mabs, 5B1, is a human IgG1 which predominantly binds Sialyl Lewis^a whether the neuraminic acid is endogenously produced (N-acetyl-neuraminic acid) or exogenously derived (N-glycolyl-neuraminic acid) and whether it is on a long or short spacer. Binding to Sialyl-di-lewis^a or Sialyl lewis^{a-x} is weak and insignificant. The second mab 7E3 is a human IgM which binds equally to Sialyl lewis^a whether the neuraminic acid is endogenously produced (N acetyl neuraminic acid) or exogenously derived (N-glycolyl-neuraminic acid) and whether it is on a long or short spacer, and to Sialyl-di-lewis^a or Sialyl lewis $^{a-x}$. Such anti-Sialyl Lewis^a mabs would have an unacceptable normal distribution, which is supported by the observation that GivaRex (a mouse monoclonal antibody) and its patent (WO0191792) has been abandoned in preclinical studies.

[0006] Noble, Philip W ("Characterisation of anti-glycan monoclonal antibodies", (2011-01-01), pages 1-246, XP055319650, URL: http://eprints.nottingham.ac.uk/12071/1/Final_Thesis_for_Submission_16.6.11.pdf) characterizes an anti-sialyl-di-Lewis^a antibody raised in mice immunized with a range of colorectal cancers.

[0007] Tsuchida et al (Journal of Biological Chemistry; Vol. 278; No. 25; 13 June 20; Pages 22787-22794, 2003) analsysed the biosynthesis of sialyl-diLewis^a using antibodies.

[0008] An aim of the present invention is to provide an improved antibody or antibody fragment for sialyl-di-Lewis^a.

[0009] According to a first aspect of the invention, there is provided an isolated antibody or antibody binding fragment capable of binding sialyl-di-Lewis^a, wherein the antibody or antibody fragment comprises the following six CDRs:

1. a) GFTFNTYA (CDRH1), IRSKSNNYAT (CDRH2) and VGYGSGGNY (CDRH3) of Figure 1a or 2a and
2. b) QSLLNSGNQKNY (CDRL1), WAS (CDRL2) and QNDYSSPFT (CDRL3),

wherein the antibody or antibody fragment is specific for sialyl-di-Lewis^a and sialyl-Lewis^{a-x}.

[0010] Preferred features of the invention are set out in the dependent claims herein. The antibody or antibody fragment is specific for sialyl-di-Lewis^a and sialyl-Lewis^{a-x}. In one embodiment, the antibody or antibody fragment may be specific for sialyl-di-Lewis^a and sialyl-Lewis^{a-x} present in tumour tissue. The antibody or antibody fragment may not bind, or may not significantly bind, mono-sialyl-Lewis^a bound to a glycolipid. Additionally or alternatively, the antibody or antibody fragment may not bind, or may not significantly bind, di-sialyl-Lewis^a. The antibody or antibody fragment may not bind, or may not significantly bind, di-sialyl-Lewis^a present in healthy (non-tumour) tissue.

[0011] Synthetic (i.e. non-natural) molecules may be provided for characterizing the antibody or antibody fragment binding specificity. Such forms may comprise any one of sialyl-di-Lewis^a, sialyl-Lewis^{a-x}, di-sialyl-Lewis^a or mono-sialyl-Lewis^a molecules presented on a protein or lipid (e.g. a glycoprotein or glycolipid). The synthetic molecule may comprise sialyl-Lewis^a with exogenously derived N-glycolyl-neuraminic acid or endogenously derived N-acetyl-neuraminic acid. In one embodiment, the may bind mono-sialyl-Lewis^a, wherein the mono-sialyl-Lewis^a is presented on a glycoprotein. The antibody or antibody fragment may be specific for sialyl-di-Lewis^a, sialyl-Lewis^{a-x} and mono-sialyl-Lewis^a, wherein the mono-sialyl-Lewis^a is presented on a glycoprotein. In an embodiment wherein the antibody or antibody fragment binds to mono-sialyl-Lewis^a presented on a glycoprotein, the mono-sialyl-Lewis^a may be linked to the protein by a spacer, such as a polymer. The polymer may comprise any natural or synthetic molecule that allows sialyl-Lewis^a to bind into a groove of the antibody or antibody fragment. The polymer chain may comprise a glycan chain or amino acid (i.e. a polypeptide). The glycan chain linking the mono-sialyl-Lewis^a to the glycoprotein may comprise at least 4 glycan monomer units. Alternatively, the glycan chain linking the mono-sialyl-Lewis^a to the glycoprotein may comprise at least 5 glycan monomer units. Alternatively, the glycan chain linking the mono-sialyl-Lewis^a to the glycoprotein may comprise at least 6 glycan monomer units. Alternatively, the glycan chain linking the mono-sialyl-Lewis^a to the glycoprotein may comprise at least 7 glycan monomer units. Alternatively, the glycan chain linking the mono-sialyl-Lewis^a to the glycoprotein may comprise at least 8 glycan monomer units. The polypeptide linking the mono-sialyl-Lewis^a to the glycoprotein may comprise at least 4 amino acids. Alternatively, the polypeptide linking the mono-sialyl-Lewis^a to the glycoprotein may comprise at least 5 amino acids. Alternatively, the polypeptide linking the mono-sialyl-Lewis^a to the glycoprotein may comprise at least 6 amino acids. Alternatively, the polypeptide linking the mono-sialyl-Lewis^a to the glycoprotein may comprise at least 7 amino acids. Alternatively, the polypeptide linking the mono-sialyl-Lewis^a to the glycoprotein may comprise at least 8 amino acids.

[0012] The present invention advantageously provides an antibody or antibody fragment, such as a monoclonal antibody, that shows a high specificity for sialyl-di-Lewis^a and sialyl-Lewis^{a-x}. It can also bind to mono-sialyl-Lewis^a when it is linked to a glycoprotein by a glycan chain, suggesting that it requires at least 4 carbohydrates presented in the correct conformation to bind and a spacer (such as a glycan chain) to allow insertion into the antibody groove.

This constraint, in contrast to other mono-sialyl-Lewis^a binding maAbs, gives it the unique ability to bind to glycoproteins but not glycolipids. In contrast to the other mabs, its inability to recognize Sialyl lewis^a alone prevents it from binding to this sugar on glycolipids and gives it a unique and very restrictive normal (i.e. non-cancerous) tissues binding profile. Without being bound by theory, the antibody or antibody fragment may not bind to glycolipid bound Sialyl lewis^a as the lipid is too hyrophobic to allow insertion of the glycan into the deep antibody groove.

[0013] The invention herein has provided, characterised and chimerised an antibody or antibody fragment, such as FG129 mAb. This mAb targets the novel glycan, sialyl-di-Lewis^a (this has the single sialic acid found in cancers but also has the Lewis^a duplicated and is only found on proteins), which is expressed by a wide range of pancreatic tumours but has a very restricted normal tissue expression. Chimeric FG129 (CH129) induces strong ADCC and CDC responses on tumours, suggesting the antigen is a good target for immune mediated killing. This can be further potentiated by redirecting T cell killing by recombination of FG129 with a second mAb recognising and activating T cells. Thus, in addition to the antibody inducing ADCC, a further application of the humanised mAb is in the generation of a bispecific mAb targeting the FG129 and CD3 antigens. The indication for such a bispecific could be but is not restricted to pancreatic cancer. The mAb FG129 also internalised and delivered drugs which efficiently killed tumour cells, demonstrating its ADC potential.

[0014] The isolated antibody or antibody fragment of the invention may be capable of binding sialyl-di-Lewis^a and sialyl-Lewis^{a-x} Neu5Aca2-3Galb1-3(Fuca1-4)GlcNAcb1-3Galb1-4(Fucal-3)GlcNAcb- and mono-sialyl-Lewis^a Neu5Aca2-3Galb1-3(Fucal-4)GlcNAcb-only attached to a glycoprotein. Such antibodies or antibody fragments may be for use in a method for treating cancer. Such a binding partner may be for use in the manufacture of a medicament for the treatment of cancer. Disclosed herein is a method of treating cancer, comprising administering a binding partner of the invention to a subject in need of such treatment.

[0015] The present invention provides the mAb FG129 which binds to sialyl-di-Lewis^a and sialyl-Lewis^{a-x} and mono-sialyl-Lewis^a only attached to a glycoprotein.

[0016] The present invention also provides the chimeric hIgG1 129 which binds to sialyl-di-Lewis^a and sialyl-Lewis^{a-x} and mono-sialyl-Lewis^a only attached to a glycoprotein.

[0017] In this invention we show a murine IgGlk mAb, FG129, which binds to sialyl-di-Lewis^a and was generated by immunising Balb/c mice with tumour plasma membrane lipid extracts. They bind to the cell surface of a range of tumour cell lines but do not bind to any blood or endothelial cells.

[0018] The antibody or antibody fragment may be capable of binding to some pancreatic tumours, for example at least 70% or 74% of pancreatic tumours in a population of patients. The antibody or antibody fragment may be capable of binding to some gastric tumours, for example at least 45% or 50% of gastric tumours in a population of patients. The antibody or antibody fragment may be capable of binding to some colorectal tumours, for example at least 30% or 36% of colorectal tumours in a population of patients. The antibody or antibody fragment may be capable of binding to some ovarian tumours, for example at least 25% or 27% of ovarian tumours in a population of patients. The antibody or antibody fragment may be capable of binding to some non small cell lung cancers, for example at least 5% or 7% of non small cell lung cancers in a population of patients. The tumour tissue binding of the antibody or antibody fragment may be assessed by immunohistochemistry (IHC) on tumour tissue microarrays (TMAs).

[0019] The antibody or antibody fragment may not bind, or may not significantly bind to non-cancerous tissue, such as non-cancerous heart, brain, stomach, or kidney tissue. Additionally or alternatively, the antibody or antibody fragment has low affinity for, or does not significantly bind to non-cancerous tissue of the gallbladder, ileum, liver, lung, oesophagus, pancreas, skin or thymus.

[0020] The antibody or antibody fragment may be capable of binding to glycoprotein-presented sialyl-Lewis^a with an

affinity (KD) of less than about 10^{-6}M. The antibody or antibody fragment may be capable of binding to glycoprotein-presented sialyl-Lewis^a with an affinity (KD) of less than about 10^{-7}M. The antibody or antibody fragment may be capable of binding to glycoprotein-presented sialyl-Lewis^a with an affinity (KD) of less than about 10^{-8}M, 10^{-9}M, 10^{-10}M, 10^{-11}M or 10^{-12}M. The antibody or antibody fragment may be capable of binding to glycoprotein-presented sialyl-Lewis^a with an affinity (KD) of less than about 10^{-13}M. The antibody or antibody fragment may be capable of binding to glycoprotein-presented sialyl-Lewis^a with a dissociation rate (Kd) of 10^{-8} l/s or less. The antibody or antibody fragment may be capable of binding to glycoprotein-presented sialyl-Lewis^a with an association rate (Ka) of at least about 10^4 l/Ms. Binding affinity may be measured by surface plasmon resonance Biacore X.

[0021] The antibody or antibody fragment of the present invention may comprise an amino acid sequence substantially as set out as 1-117 (VH) of Figure 1a or 2a. The member may comprise a binding domain which comprises an amino acid sequence substantially as set out as residues 98 to 106 (CDRH3) of the amino acid sequence of Figure 1a or 2a. The isolated antibody or antibody fragment may additionally comprise one or both, preferably both, of the binding domains substantially as set out as residues 26 to 33 (CDRH1) and residues 50-59 (CDRH2) of the amino acid sequence shown in Figure 1a and 2a.

[0022] The isolated antibody or antibody fragment may comprise one or more binding domains selected from the amino acid sequence of residues 27 to 38 (CDRL1), 56-58 (CDRL2) and 95 to 103 (CDRL3) of Figure 1b or 2b.

[0023] The binding domain may comprise an amino acid sequence substantially as set out as residues 95 to 103 (CDRL3) of the amino acid sequence of Figure 1b and 2b. The isolated antibody or antibody fragment may additionally comprise one or both, preferably both, of the binding domains substantially as set out as residues 27 to 38 and (CDRL1) residues 56 to 58 of (CDRL2) the amino acid sequence shown in Figure 1b and 2b.

[0024] The antibody or antibody fragment of the present invention may comprise a variable heavy and/or light chain sequence comprising CDRH1-3 and CDRL1-3 of antibody FG129. The variable heavy and/or light chain may comprise CDRH1-3 and CDRH1-3 of antibody FG129, and framework regions of FG129.

[0025] Antibodies or antibody fragments which comprise a plurality of binding domains of the same or different sequence, or combinations thereof, are included within the present invention. Each binding domain may be carried by a human antibody framework. For example, one or more framework regions may be substituted for the framework regions of a whole human antibody or of the variable region thereof.

[0026] One isolated antibody or antibody fragment of the invention comprises the sequence substantially as set out as residues 1 to 114 (VL) of the amino acid sequence shown in Figure 1b or 2b.

[0027] Antibodies or antibody fragments having sequences of the CDRs of Figure 1a or 2a may be combined with antibodies or antibody fragments having sequences of the CDRs of Figure 1b or 2b.

[0028] The antibody or antibody fragment of the invention may comprise a light chain variable sequence comprising said CDR1, CDRL2 and CDRL3, anda heavy chain variable sequence comprising said CDRH1, CDRH2 and CDRH3.

[0029] The antibody or antibody fragment of the invention may comprise a VH domain comprising residues 1 to 117 of the amino acid sequence of Figure 1a or 2a, and a VL domain comprising residues 1 to 114 of the amino acid sequence of Figure 1b or 2b.

[0030] The invention also encompasses antibodies or antibody fragments as described above, but in which the sequence of the binding domains are substantially as set out in Figures 1 or 2. Thus, antibodies or antibody fragments as described above are provided, but in which in one or more binding domains differ from those depicted in Figures 1 or 2 by from 1 to 5, from 1 to 4, from 1 to 3, 2 or 1 substitution.

[0031] The invention also encompasses antibodies or antibody fragments having the capability of binding to the same epitopes as the VH and VL sequences depicted in Figures 1 and 2. The epitope of a mAb is the region of its antigen to which the mAb binds. Two antibodies bind to the same or overlapping epitope if each competitively inhibits (blocks) binding of the other to the antigen. That is, a 1x, 5x, 10x, 20x or 100x excess of one antibody inhibits binding of the other by at least 50% but preferably 75%, 90% or even 99% as measured in a competitive binding assay compared to a control lacking the competing antibody (see, e.g., Junghans et al., Cancer Res. 50:1495, 1990).

[0032] Disclosed herein is a binding member which competes for binding to to the same epitope as a antibody or antibody fragment of the first aspect of the invention and optionally wherein the binding member is in the same form as the antibody or antibody fragment of the first aspect of the invention. The binding member may compete for binding to sialyl-di-Lewis^{a} and sialyl-Lewis^{a-x} and mono-sialyl-Lewis^{a} only attached to a glycoprotein with an antibody comprising a VH chain having the amino acid sequence of residues 1 to 117 of Figure 1a or 2a and a VL chain having the amino acid sequence of residues 1 to 114 of Figure 1b or 2b.

[0033] Preferably the competing binding partner competes for binding to to sialyl-di-Lewis^{a} only attached to a glycoprotein with an antibody comprising a VH chain having the amino acid sequence of residues 1 to 117 of Figure 1a or 2a and a VL chain having the amino acid sequence of residues 1 to 114 of Figure 1b or 2b.

[0034] The competing binding partner may compete for binding to sialyl-di-Lewis^{a} and sialyl-Lewis^{a-x} and mono-sialyl-Lewis^{a} only attached to a glycoprotein with an antibody comprising a VH chain having the amino acid sequence of residues 1 to 117 of Figure 1a and a VL chain having the amino acid sequence of residues 1 to 114 of Figure 1b, or with an antibody comprising a VH chain having the amino acid sequence of residues 1 to 117 of Figure 2a and a VL chain having the amino acid sequence of residues 1 to 114 of Figure 2b.

[0035] Preferably, competing binding partners are antibodies, for example monoclonal antibodies, or any of the antibody variants or fragments mentioned throughout this document.

[0036] Once a single, archtypal mAb, for example an FG129 mAb, has been isolated that has the desired properties described herein, it is straightforward to generate other mAbs with similar properties, by using art-known methods. For example, the method of Jespers et al., Biotechnology 12:899, 1994, may be used to guide the selection of mAbs having the same epitope and therefore similar properties to the archtypal mAb. Using phage display, first the heavy chain of the archtypal antibody is paired with a repertoire of (preferably human) light chains to select a glycan-binding mAb, and then the new light chain is paired with a repertoire of (preferably human) heavy chains to select a (preferably human) glycan-binding mAb having the same epitope as the archtypal mAb.

[0037] MAbs that are capable of binding sialyl-di-Lewis^{a} and sialyl-Lewis^{a-x} and mono-sialyl-Lewis^{a} only attached to a glycoprotein and induce ADCC or internalize and are at least 90%, 95% or 99% identical in the VH and/or VL domain to the VH or VL domains of Figures 1 or 2, are included in the invention. Reference to the 90%, 95%, or 99% identity may be to the framework regions of the VH and/or VL domains. In particular, the CDR regions may be identical, but the framework regions may vary by up to 1%, 5%, or 10%. Preferably such antibodies differ from the sequences of Figures 1 or 2 by a small number of functionally inconsequential amino acid substitutions (e.g., conservative substitutions), deletions, or insertions. The antibody fragment may be a Fab, (Fab')2, scFv, Fv, dAb, Fd or a diabody. The antibody may be a polyclonal antibody. The antibody may be a monoclonal antibody. Antibodies of the invention may be humanised, chimeric or veneered antibodies, or may be non-human antibodies of any species. The antibody or antibody fragment of the invention may be a mouse antibody FG129 which comprises a heavy chain as depicted in Figure 1a and a light chain as depicted in Figure 1b.

[0038] The antibody or antibody fragment of the invention may be a chimeric antibody FG129 which comprises a heavy chain as depicted in Figure 2a and a light chain as depicted in Figure 2b.

[0039] Antibodies or antibody fragments of the invention may carry a detectable or functional label.

[0040] One aspect of the invention provides an isolated nucleic acid which comprises a sequence encoding an antibody or antibody fragment of the aspects of the invention. Methods of preparing antibodies or antibody fragments of the invention may comprise expressing said nucleic acids under conditions to bring about expression of said antibody or antibody antibody fragment, and recovering the antibody or antibody fragment.

[0041] Antibodies or antibody fragments according to the invention may be used in a method of treatment or diagnosis of the human or animal body, such as a method of treatment of a tumour in a patient (preferably human) which comprises administering to said patient an effective amount of an antibody or antibody fragment of the invention. The invention also provides an antibody or antibody fragment of the present invention for use as a medicament. An specific antibody or antibody fragment of the present invention may be for use in the manufacture of a medicament for the diagnosis or treatment of a tumour. Another aspect of the invention provides an antibody or antibody fragment of the invention for use in the prevention, treatment or diagnosis of cancer. The cancer may be colorectal cancer, gastric cancer, pancreatic cancer, lung cancer, ovarian cancer or breast cancer. The antibody or antibody fragment may be administered, or arranged to be administered, alone or in combination with other treatments.

[0042] Disclosed herein is the antigen to which the antibodies or antibody fragments of the present invention bind. A sialyl-di-Lewis^{a} which is capable of being bound, preferably specifically, by a antibody or antibody fragment of the present invention is disclosed. The sialyl-di-Lewis^{a} may be provided in isolated form, and may be used in a screen to develop further antibodies or antibody fragments therefor. For example, a library of compounds may be screened for members of the library which bind specifically to the sialyl-di-Lewis^{a}. The sialyl-di-Lewis^{a} may on a protein backbone. When on a protein backbone, it may have a molecular weight of about 50-150kDa, as determined by SDS-PAGE.

[0043] One aspect of the invention provides a method for diagnosis of cancer comprising using an antibody or antibody fragment of the invention to detect sialyl-di-Lewis^{a} and sialyl-Lewis^{a-x} and/or mono-sialyl-Lewis^{a} only attached to a glycoprotein in a sample from an individual. In some embodiments, in the diagnostic method the pattern of glycans detected by the antibody or antibody fragment is used to stratify therapy options for the individual.

[0044] An antibody or antibody fragment of the invention capable of specifically binding sialyl-di-Lewis^{a} and sialyl-Lewis^{a-x} may be for use in the diagnosis or prognosis of colorectal, gastric, pancreatic, lung, ovarian and breast tumours. An isolated specific antibody or antibody fragment of the invention capable of specifically binding sialyl-di-Lewis^{a} and sialyl-Lewis^{a-x} and mono-sialyl-Lewis^{a} only attached to a glycoprotein may be for use in the diagnosis or prognosis of colorectal, gastric, pancreatic, lung, ovarian and breast tumours.

[0045] These and other aspects of the invention are described in further detail below.

[0046] As used herein, a "specific binding member" is a member of a pair of molecules which have binding specificity for one another. The members of a specific binding pair may be naturally derived or wholly or partially synthetically produced. One member of the pair of molecules has an area on its surface, which may be a protrusion or a cavity, which specifically binds to and is therefore complementary to a particular spatial and polar organisation of the other member of the pair of molecules. Thus, the members of the pair have the property of binding specifically to each other. Examples of types of specific binding pairs are antigen-antibody, biotin-avidin, hormone-hormone receptor, receptor-ligand, enzyme-substrate. The present invention is generally concerned with antigen-antibody type reactions, although it also concerns small molecules which bind to the antigen defined herein.

[0047] As used herein, "treatment" includes any regime that can benefit a human or non-human animal, preferably mammal. The treatment may be in respect of an existing condition or may be prophylactic (preventative treatment).

[0048] As used herein, a "tumour" is an abnormal growth of tissue. It may be localised (benign) or invade nearby tissues (malignant) or distant tissues (metastatic). Tumours include neoplastic growths which cause cancer and

include oesophageal, colorectal, gastric, breast and endometrial tumours, as well as cancerous tissues or cell lines including, but not limited to, leukaemic cells. As used herein, "tumour" also includes within its scope endometriosis.

[0049] The term "antibody" as used herein refers to immunoglobulin molecules and immunologically active portions of immunoglobulin molecules, i.e., molecules that contain an antigen binding site that specifically binds an antigen, whether natural or partly or wholly synthetically produced. The term also covers any polypeptide or protein having a binding domain which is, or is homologous to, an antibody binding domain. These can be derived from natural sources, or they may be partly or wholly synthetically produced. Examples of antibodies are the immunoglobulin isotypes (*e.g.,* IgG, IgE, IgM, IgD and IgA) and their isotypic subclasses; fragments which comprise an antigen binding domain such as Fab, scFv, Fv, dAb, Fd; and diabodies. Antibodies may be polyclonal or monoclonal. A monoclonal antibody may be referred to as a "mAb".

[0050] It is possible to take monoclonal and other antibodies and use techniques of recombinant DNA technology to produce other antibodies or chimeric molecules which retain the specificity of the original antibody. Such techniques may involve introducing DNA encoding the immunoglobulin variable region, or the CDRs, of an antibody to the constant regions, or constant regions plus framework regions, of a different immunoglobulin. See, for instance, EP-A-184187, GB 2188638A or EP-A-239400. A hybridoma or other cell producing an antibody may be subject to genetic mutation or other changes, which may or may not alter the binding specificity of antibodies produced.

[0051] As antibodies can be modified in a number of ways, the term "antibody" should be construed as covering any specific antibody or antibody fragment or substance having a binding domain with the required specificity. Thus, this term covers antibody fragments, derivatives, functional equivalents and homologues of antibodies, humanised antibodies, including any polypeptide comprising an immunoglobulin binding domain, whether natural or wholly or partially synthetic. Chimeric molecules comprising an immunoglobulin binding domain, or equivalent, fused to another polypeptide are therefore included. Cloning and expression of chimeric antibodies are described in EP- A-0120694 and EP-A-0125023. A humanised antibody may be a modified antibody having the variable regions of a non-human, *e.g.*, murine, antibody and the constant region of a human antibody. Methods for making humanised antibodies are described in, for example, US Patent No. 5225539.

[0052] It has been shown that fragments of a whole antibody can perform the function of binding antigens. Examples of binding fragments are (i) the Fab fragment consisting of VL, VH, CL and CH1 domains; (ii) the Fd fragment consisting of the VH and CH1 domains; (iii) the Fv fragment consisting of the VL and VH domains of a single antibody; (iv) the dAb fragment [25] which consists of a VH domain; (v) isolated CDR regions; (vi) F(ab')2 fragments, a bivalent fragment comprising two linked Fab fragments; (vii) single chain Fv molecules (scFv), wherein a VH domain and a VL domain are linked by a peptide linker which allows the two domains to associate to form an antigen binding site [26, 27]; (viii) bispecific single chain Fv dimers (WO/1993/011161) and; (ix) "diabodies", multivalent or multispecific fragments constructed by gene fusion (WO94/13804; [28]).

[0053] Diabodies are multimers of polypeptides, each polypeptide comprising a first domain comprising a binding region of an immunoglobulin light chain and a second domain comprising a binding region of an immunoglobulin heavy chain, the two domains being linked (*e.g.,* by a peptide linker) but unable to associated with each other to form an antigen binding site: antigen binding sites are formed by the association of the first domain of one polypeptide within the multimer with the second domain of another polypeptide within the multimer (WO94/13804).

[0054] Where bispecific antibodies are to be used, these may be conventional bispecific antibodies, which can be manufactured in a variety of ways [29], *e.g.,* prepared chemically or from hybrid hybridomas, or may be any of the bispecific antibody fragments mentioned above. It may be preferable to use scFv dimers or diabodies rather than whole antibodies. Diabodies and scFv can be constructed without an Fc region, using only variable domains, potentially reducing the effects of anti-idiotypic reaction.

[0055] Other forms of bispecific antibodies include the single chain "Janusins" described in [30].

[0056] Bispecific diabodies, as opposed to bispecific whole antibodies, may also be useful because they can be readily constructed and expressed in *E. coli.* Diabodies (and many other polypeptides such as antibody fragments)

of appropriate binding specificities can be readily selected using phage display (WO94/13804) from libraries. If one arm of the diabody is to be kept constant, for instance, with a specificity directed against antigen X, then a library can be made where the other arm is varied and an antibody of appropriate specificity selected.

[0057] The term "sialyl-di-Lewis^{a}" refers to the structure:
Neu5Acα2-3Galβ1-3(Fucα1-4)GlcNAcβ1-3Galβ1-3(Fucα1-4)GlcNAcβ.

[0058] The term "mono sialyl-Lewis^{a}" refers to the structure:
Neu5Aca2-3Galb1-3(Fuca1-4)GlcNAcb.

[0059] The term "sialyl-Lewis^{a-x}" refers to the structure:
Neu5Aca2-3Galb1-3(Fuca1-4)GlcNAcb1-3Galb1-4(Fuca1-3)GlcNAcb.

[0060] An "antigen binding domain" is the part of an antibody which comprises the area which specifically binds to and is complementary to part or all of an antigen. Where an antigen is large, an antibody may only bind to a particular part of the antigen, which part is termed an epitope. An antigen binding domain may be provided by one or more antibody variable domains. An antigen binding domain may comprise an antibody light chain variable region (VL) and an antibody heavy chain variable region (VH).

[0061] "Specific" is generally used to refer to the situation in which one member of a specific binding pair will not show any significant binding to molecules other than its specific binding partner(s), and, *e.g.,* has less than about 30% cross reactivity with any other molecule. In other embodiments it has less than 20%, 10%, or 1% cross reactivity with any other molecule. The term is also applicable where *e.g.,* an antigen binding domain is specific for a particular epitope which is carried by a number of antigens, in which case, the specific binding member carrying the antigen binding domain will be able to bind to the various antigens carrying the epitope.

[0062] "Isolated" refers to the state in which specific antibodies or antibody fragments of the invention or nucleic acid encoding such antibodies or antibody fragments will preferably be, in accordance with the present invention. Antibodies and nucleic acid will generally be free or substantially free of material with which they are naturally associated such as other polypeptides or nucleic acids with which they are found in their natural environment, or the environment in which they are prepared (*e.g.*, cell culture) when such preparation is by recombinant DNA technology practised *in vitro* or *in vivo.* Specific antibodies or antibody fragments and nucleic acid may be formulated with diluents or adjuvants and still for practical purposes be isolated - for example, the members will normally be mixed with gelatin or other carriers if used to coat microtitre plates for use in immunoassays, or will be mixed with pharmaceutically acceptable carriers or diluents when used in diagnosis or therapy. Specific binding members may be glycosylated, either naturally or by systems of heterologous eukaryotic cells, or they may be (for example if produced by expression in a prokaryotic cell) unglycosylated.

[0063] By "substantially as set out" it is meant that the CDR regions of the invention will be either identical or highly homologous to the specified regions of Figures 1 or 2. By "highly homologous" it is contemplated that from 1 to 5, from 1 to 4, from 1 to 3, 2 or 1 substitutions maybe made in the CDRs.

[0064] The invention also includes within its scope polypeptides having the amino acid sequence as set out in Figure 1 or 2, polynucleotides having the nucleic acid sequences as set out in Figure A or B and sequences having substantial identity thereto, for example, 70%, 80%, 85%, 90%, 95% or 99% identity thereto. The percent identity of two amino acid sequences or of two nucleic acid sequences is generally determined by aligning the sequences for optimal comparison purposes (*e.g.*, gaps can be introduced in the first sequence for best alignment with the second sequence) and comparing the amino acid residues or nucleotides at corresponding positions. The "best alignment" is an alignment of two sequences that results in the highest percent identity. The percent identity is determined by comparing the number of identical amino acid residues or nucleotides within the sequences (*i.e.,* % identity = number of identical positions/total number of positions x 100).

[0065] The determination of percent identity between two sequences can be accomplished using a mathematical

algorithm known to those of skill in the art. An example of a mathematical algorithm for comparing two sequences is the algorithm of Karlin and Altschul (1990) [31], modified as in Karlin and Altschul (1993) [32]. The NBLAST and XBLAST programs of Altschul *et al.* (1990) [33] have incorporated such an algorithm. BLAST nucleotide searches can be performed with the NBLAST program, score = 100, word length = 12 to obtain nucleotide sequences homologous to a nucleic acid molecules of the invention. BLAST protein searches can be performed with the XBLAST program, score = 50, word length = 3 to obtain amino acid sequences homologous to a protein molecules of the invention. To obtain gapped alignments for comparison purposes, Gapped BLAST can be utilized as described in Altschul *et al.* (1997) [34]. Alternatively, PSI-Blast can be used to perform an iterated search that detects distant relationships between molecules (Id.). When utilizing BLAST, GappedBLAST, and PSI-Blast programs, the default parameters of the respective programs (e.g., XBLAST and NBLAST) can be used. See http://www.ncbi.nlm.nih.gov. Another example of a mathematical algorithm utilized for the comparison of sequences is the algorithm of Myers and Miller, [35]. The ALIGN program (version 2.0) which is part of the GCG sequence alignment software package has incorporated such an algorithm.Other algorithms for sequence analysis known in the art include ADVANCE and ADAM as described in Torellis and Robotti (1994) [36]; and FASTA described in Pearson and Lipman (1988) [37]. Within FASTA, ktup is a control option that sets the sensitivity and speed of the search.

[0066] Antibodies or antibody fragments of the present invention are capable of binding to a sialyl-di-Lewis^a carbohydrate, which may be a sialyl-di-Lewis^a on a protein moiety. In one embodiment, the CDR3 regions, comprising the amino acid sequences substantially as set out as residues 98-106 (CDRH3) of Figure 1a and 2a and 95 to 103 of Figure 1b and 2b, are carried in a structure which allows the binding of these regions to a sialyl-di-Lewis^a carbohydrate.

[0067] The structure for carrying the CDR3s of the invention will generally be of an antibody heavy or light chain sequence or substantial portion thereof in which the CDR3 regions are located at locations corresponding to the CDR3 region of naturally-occurring VH and VL antibody variable domains encoded by rearranged immunoglobulin genes. The structures and locations of immunoglobulin variable domains may be determined by reference to http://www.imgt.org/. The amino acid sequence substantially as set out as residues 98-106 of Figure 1a and 2a may be carried as the CDR3 in a human heavy chain variable domain or a substantial portion thereof, and the amino acid sequence substantially as set out as residues and 95-103 of Figure 1b and 2b may be carried as the CDR3 in a human light chain variable domain or a substantial portion thereof.

[0068] The variable domains may be derived from any germline or rearranged human variable domain, or may be a synthetic variable domain based on consensus sequences of known human variable domains. The CDR3-derived sequences of the invention may be introduced into a repertoire of variable domains lacking CDR3 regions, using recombinant DNA technology.

[0069] For example, Marks *et al.,* (1992) [38] describe methods of producing repertoires of antibody variable domains in which consensus primers directed at or adjacent to the 5' end of the variable domain area are used in conjunction with consensus primers to the third framework region of human VH genes to provide a repertoire of VH variable domains lacking a CDR3. Marks *et al.* (1992) [38] further describe how this repertoire may be combined with a CDR3 of a particular antibody. Using analogous techniques, the CDR3-derived sequences of the present invention may be shuffled with repertoires of VH or VL domains lacking a CDR3, and the shuffled complete VH or VL domains combined with a cognate VL or VH domain to provide antibodies or antibody fragments of the invention. The repertoire may then be displayed in a suitable host system such as the phage display system of WO92/01047 so that suitable antibodies or antibody fragments may be selected. A repertoire may consist of from anything from 10^4 individual members upwards, for example from 10^6 to 10^8 or 10^{10} members.

[0070] Analogous shuffling or combinatorial techniques are also disclosed by Stemmer (1994) [39] who describes the technique in relation to a β-lactamase gene but observes that the approach may be used for the generation of antibodies.A further alternative is to generate novel VH or VL regions carrying the CDR3-derived sequences of the invention using random mutagenesis of, for example, the FG129 VH or VL genes to generate mutations within the entire variable domain. Such a technique is described by Gram *et al.,* (1992) [40], who used error-prone PCR.

[0071] Another method which may be used is to direct mutagenesis to CDR regions of VH or VL genes. Such techniques are disclosed by Barbas *et al.,* (1994) [41] and Schier *et al.,* (1996) [42].

[0072] A substantial portion of an immunoglobulin variable domain will generally comprise at least the three CDR regions, together with their intervening framework regions. The portion may also include at least about 50% of either or both of the first and fourth framework regions, the 50% being the C-terminal 50% of the first framework region and the N-terminal 50% of the fourth framework region. Additional residues at the N- terminal or C-terminal end of the substantial part of the variable domain may be those not normally associated with naturally occurring variable domain regions. For example, construction of antibodies or antibody fragments of the present invention made by recombinant DNA techniques may result in the introduction of N- or C-terminal residues encoded by linkers introduced to facilitate cloning or other manipulation steps, including the introduction of linkers to join variable domains of the invention to further protein sequences including immunoglobulin heavy chains, other variable domains (for example in the production of diabodies) or protein labels as discussed in more detail below.

[0073] One embodiment of the invention provides antibodies or antibody fragments comprising a pair of binding domains based on the amino acid sequences for the VL and VH regions substantially as set out in Figures 1, i.e. amino acids 1 to 117 (VH) of Figure 1a and 2a and amino acids 1 to 114 (VL) of Figure 1b and 2b. Single binding domains based on either of these sequences are within the scope of the invention. In the case of the binding domains based on the amino acid sequence for the VH region substantially set out in Figure 1a and 2a, such binding domains may be used as targeting agents since it is known that immunoglobulin VH domains are capable of binding target antigens in a specific manner.

[0074] In the case of either of the single chain specific binding domains, these domains may be used to screen for complementary domains capable of forming a two-domain antibody or antibody fragment which has *in vivo* properties as good as or equal to the FG88 antibodies disclosed herein.

[0075] This may be achieved by phage display screening methods using the so-called hierarchical dual combinatorial approach as disclosed in WO92/01047 in which an individual colony containing either an H or L chain clone is used to infect a complete library of clones encoding the other chain (L or H) and the resulting two-chain antibody or antibody fragment is selected in accordance with phage display techniques such as those described in that reference. This technique is also disclosed in Marks *et al.,* [38].

[0076] Antibodies or antibody fragments of the present invention may further comprise antibody constant regions or parts thereof. For example, antibodies or antibody fragments based on the VL region shown in Figure 1b and 2b may be attached at their C-terminal end to antibody light chain constant domains including human Cκ or Cλ chains. Similarly, antibody or antibody fragments based on VH region shown in Figure b and 2b may be attached at their C-terminal end to all or part of an immunoglobulin heavy chain derived from any antibody isotype, *e.g.*, IgG, IgA, IgE and IgM and any of the isotype sub- classes, particularly IgG1, IgG2 and IgG4.

[0077] The antibody fragment of the invention may be a scFv comprising, in the following order 1) a leader sequence, 2) a heavy chain variable region, 3) 3x GGGGS spacer, 4) a light chain variable region, and 5) poly-Ala and a 6x His tag for purification. In another embodiment, the antibody fragment is an scFv comprising, in the following order 1) a leader sequence, 2) a light chain variable region, 3) 3x GGGGS spacer, and 4) a heavy chain variable region, optionally further comprising either 5' or 3' purification tags. The antibody or antibody fragment of the invention may be provided in the form of a chimeric antigen receptor (CAR). CARs may also be known as artificial T cell receptors, chimeric T cell receptors, or chimeric immunoreceptors. In an embodiment, where the antibody fragment is an scFv provided in the form of a chimeric antigen receptor (CAR), it may be provided in either the heavy chain-light chain orientation or the light chain-heavy chain orientation.

[0078] Antibodies or antibody fragments of the present invention can be used in methods of diagnosis and treatment of tumours in human or animal subjects. When used in diagnosis, antibodies or antibody fragments of the invention may be labelled with a detectable label, for example a radiolabel such as ^{131}I or ^{99}Tc, which may be attached to antibodies or antibody fragments of the invention using conventional chemistry known in the art of

antibody imaging. Labels also include enzyme labels such as horseradish peroxidase. Labels further include chemical moieties such as biotin which may be detected via binding to a specific cognate detectable moiety, *e.g.*, labelled avidin.

[0079] Although antibodies or antibody fragments of the invention have in themselves been shown to be effective in killing cancer cells, they may additionally be labelled with a functional label. Functional labels include substances which are designed to be targeted to the site of cancer to cause destruction thereof. Such functional labels include toxins such as ricin and enzymes such as bacterial carboxypeptidase or nitroreductase, which are capable of converting prodrugs into active drugs. In addition, the antibodies or antibody fragments may be attached or otherwise associated with chemotherapeutic or cytotoxic agents, such as maytansines (DM1 and DM4), onides, auristatins, calicheamicin, duocamycin, doxorubicin or radiolabels, such as ^{90}Y or ^{131}I.

[0080] Furthermore, the antibodies or antibody fragments of the present invention may be administered alone or in combination with other treatments, either simultaneously or sequentially, dependent upon the condition to be treated. Thus, the present invention further provides products containing an antibody or antibody fragment of the present invention and an active agent as a combined preparation for simultaneous, separate or sequential use in the treatment of a tumour. Active agents may include chemotherapeutic or cytotoxic agents including, 5-Fluorouracil, cisplatin, Mitomycin C, oxaliplatin and tamoxifen, which may operate synergistically with the antibodies or antibody fragments of the present invention. Other active agents may include suitable doses of pain relief drugs such as non-steroidal anti-inflammatory drugs (*e.g.*, aspirin, paracetamol, ibuprofen or ketoprofen) or opitates such as morphine, or anti-emetics.

[0081] Whilst not wishing to be bound by theory, the ability of the antibodies or antibody fragments of the invention to synergise with an active agent to enhance tumour killing may not be due to immune effector mechanisms but rather may be a direct consequence of the antibody or antibody fragment binding to cell surface bound to sialyl-di-Lewis^{a} and sialyl-Lewis$^{a\text{-}x}$ and mono-sialyl-Lewis^{a} only attached to a glycoprotein.

[0082] Antibodies or antibody fragments of the present invention will usually be administered in the form of a pharmaceutical composition, which may comprise at least one component in addition to the antibody or antibody fragment. Thus, the present invention provides a pharmaceutical composition comprising the antibody or antibody fragment of the invention, and a pharmaceutically acceptable carrier, optionally further comprising at least one other pharmaceutical active. Another aspect provides such a pharmaceutical composition for use in the treatment of cancer.

[0083] The pharmaceutical composition may comprise, in addition to active ingredient, a pharmaceutically acceptable excipient, diluent, carrier, buffer, stabiliser or other materials well known to those skilled in the art. Such materials should be non-toxic and should not interfere with the efficacy of the active ingredient. The precise nature of the carrier or other material will depend on the route of administration, which may be oral, or by injection, e.g., intravenous.

[0084] It is envisaged that injections will be the primary route for therapeutic administration of the compositions although delivery through a catheter or other surgical tubing is also used.

[0085] Some suitable routes of administration include intravenous, subcutaneous, intraperitoneal and intramuscular administration. Liquid formulations may be utilised after reconstitution from powder formulations.

[0086] For intravenous injection, or injection at the site of affliction, the active ingredient will be in the form of a parenterally acceptable aqueous solution which is pyrogen-free and has suitable pH, isotonicity and stability. Those of relevant skill in the art are well able to prepare suitable solutions using, for example, isotonic vehicles such as Sodium Chloride Injection, Ringer's Injection, Lactated Ringer's Injection. Preservatives, stabilisers, buffers, antioxidants and/or other additives may be included, as required.

[0087] Pharmaceutical compositions for oral administration may be in tablet, capsule, powder or liquid form. A tablet

may comprise a solid carrier such as gelatin or an adjuvant. Liquid pharmaceutical compositions generally comprise a liquid carrier such as water, petroleum, animal or vegetable oils, mineral oil or synthetic oil. Physiological saline solution, dextrose or other saccharide solution or glycols such as ethylene glycol, propylene glycol or polyethylene glycol may be included. Where the formulation is a liquid it may be, for example, a physiologic salt solution containing non-phosphate buffer at pH 6.8-7.6, or a lyophilised powder.

[0088] The composition may also be administered via microspheres, liposomes, other microparticulate delivery systems or sustained release formulations placed in certain tissues including blood. Suitable examples of sustained release carriers include semipermeable polymer matrices in the form of shared articles, *e.g.*, suppositories or microcapsules. Implantable or microcapsular sustained release matrices include polylactides (US Patent No. 3, 773, 919; EP-A-0058481) copolymers of L-glutamic acid and gamma ethyl-L-glutamate [43], poly (2-hydroxyethyl-methacrylate). Liposomes containing the polypeptides are prepared by well-known methods: DE 3,218, 121A; Epstein et al, PNAS USA, 82: 3688-3692, 1985; Hwang et al, PNAS USA, 77: 4030-4034, 1980; EP-A-0052522; EP-A-0036676; EP-A-0088046; EP-A- 0143949; EP-A-0142541; JP-A-83-11808; US Patent Nos 4,485,045 and 4,544,545.Ordinarily, the liposomes are of the small (about 200-800 Angstroms) unilamellar type in which the lipid content is greater than about 30 mol. % cholesterol, the selected proportion being adjusted for the optimal rate of the polypeptide leakage.

[0089] The composition may be administered in a localised manner to a tumour site or other desired site or may be delivered in a manner in which it targets tumour or other cells.

[0090] The compositions are preferably administered to an individual in a "therapeutically effective amount", this being sufficient to show benefit to the individual. The actual amount administered, and rate and time-course of administration, will depend on the nature and severity of what is being treated. Prescription of treatment, *e.g.*, decisions on dosage etc, is within the responsibility of general practitioners and other medical doctors, and typically takes account of the disorder to be treated, the condition of the individual patient, the site of delivery, the method of administration and other factors known to practitioners. The compositions of the invention are particularly relevant to the treatment of existing tumours, especially cancer, and in the prevention of the recurrence of such conditions after initial treatment or surgery. Examples of the techniques and protocols mentioned above can be found in Remington's Pharmaceutical Sciences, 16th edition, Oslo, A. (ed), 1980 [45].

[0091] The optimal dose can be determined by physicians based on a number of parameters including, for example, age, sex, weight, severity of the condition being treated, the active ingredient being administered and the route of administration. In general, a serum concentration of polypeptides and antibodies that permits saturation of receptors is desirable. A concentration in excess of approximately 0.1nM is normally sufficient. For example, a dose of 100mg/m^2 of antibody provides a serum concentration of approximately 20nM for approximately eight days.

[0092] As a rough guideline, doses of antibodies may be given weekly in amounts of 10-300mg/m^2. Equivalent doses of antibody fragments should be used at more frequent intervals in order to maintain a serum level in excess of the concentration that permits saturation of the $LecLe^X$ carbohydrate.

[0093] The dose of the composition will be dependent upon the properties of the antibody or antibody fragment, *e.g.,* its binding activity and *in vivo* plasma half-life, the concentration of the polypeptide in the formulation, the administration route, the site and rate of dosage, the clinical tolerance of the patient involved, the pathological condition afflicting the patient and the like, as is well within the skill of the physician. For example, doses of 300 µg of antibody per patient per administration are preferred, although dosages may range from about 10 µg to 6 mg per dose. Different dosages are utilised during a series of sequential inoculations; the practitioner may administer an initial inoculation and then boost with relatively smaller doses of antibody.

[0094] This invention may also b e directed to optimise immunisation schedules for enhancing a protective immune response against cancer.

[0095] The antibodies or antibody fragments of the present invention may be generated wholly or partly by

chemical synthesis. The antibodies or antibody fragments can be readily prepared according to well-established, standard liquid or, preferably, solid-phase peptide synthesis methods, general descriptions of which are broadly available (see, for example, in J.M. Stewart and J.D. Young, (1984) [46], in M. Bodanzsky and A. Bodanzsky, (1984) [47]; or they may be prepared in solution, by the liquid phase method or by any combination of solid-phase, liquid phase and solution chemistry, *e.g.*, by first completing the respective peptide portion and then, if desired and appropriate, after removal of any protecting groups being present, by introduction of the residue X by reaction of the respective carbonic or sulfonic acid or a reactive derivative thereof.

[0096] Another convenient way of producing an antibody or antibody fragment according to the present invention is to express the nucleic acid encoding it, by use of nucleic acid in an expression system.

[0097] The present invention further provides an isolated nucleic acid encoding an antibody or antibody fragment of the present invention. Nucleic acid includes DNA and RNA. In a preferred aspect, the present invention provides a nucleic acid which codes for an antibody or antibody fragment of the invention as defined above. Examples of such nucleic acid are shown in Figures 1 and 2. The skilled person will be able to determine substitutions, deletions and/or additions to such nucleic acids which will still provide an antibody or antibody fragment of the present invention.

[0098] The present invention also provides constructs in the form of plasmids, vectors, transcription or expression cassettes which comprise at least one nucleic acid as described above. The present invention also provides a recombinant host cell which comprises a nucleic acid of the invention, optionally in the form of one or more constructs as above. As mentioned, a nucleic acid encoding an antibody or antibody fragment of the invention forms an aspect of the present invention. A method of production of the antibody or antibody fragment of the invention may comprise expression from encoding nucleic acid therefor. Expression may conveniently be achieved by culturing under appropriate conditions recombinant host cells containing the nucleic acid. Following production by expression, an antibody or antibody fragment may be isolated and/or purified using any suitable technique, then used as appropriate.

[0099] Systems for cloning and expression of a polypeptide in a variety of different host cells are well known. Suitable host cells include bacteria, mammalian cells, yeast and baculovirus systems. Mammalian cell lines available in the art for expression of a heterologous polypeptide include Chinese hamster ovary cells, HeLa cells, baby hamster kidney cells, NSO mouse melanoma cells and many others. A common, preferred bacterial host is *E. coli.* The expression of antibodies and antibody fragments in prokaryotic cells such as *E. coli* is well established in the art. For a review, see for example Plückthun (1991) [48]. Expression in eukaryotic cells in culture is alsoavailable to those skilled in the art as an option for production of an antibody or antibody fragment, see for recent review, for example Reff (1993) [49]; Trill *et al.,* (1995) [50].

[0100] Suitable vectors can be chosen or constructed, containing appropriate regulatory sequences, including promoter sequences, terminator sequences, polyadenylation sequences, enhancer sequences, marker genes and other sequences as appropriate.Vectors may be plasmids, viral *e.g.*, 'phage, or phagemid, as appropriate. For further details see, for example, Sambrook *et al.,* (1989) [51]. Many known techniques and protocols for manipulation of nucleic acid, for example in preparation of nucleic acid constructs, mutagenesis, sequencing, introduction of DNA into cells and gene expression, and analysis of proteins, are described in detail in Ausubel *et al.*, (1992)[52].

[0101] Thus, a further aspect of the present invention provides a recombinant host cell comprising nucleic acid as disclosed herein. Disclosed herein is a method comprising introducing such nucleic acid into a host cell. The introduction may employ any available technique. For eukaryotic cells, suitable techniques may include calcium phosphate transfection, DEAE-Dextran, electroporation, liposome-mediated transfection and transduction using retrovirus or other virus, *e.g.*, vaccinia or, for insect cells, baculovirus. For bacterial cells, suitable techniques may include calcium chloride transformation, electroporation and transfection using bacteriophage. The introduction may be followed by causing or allowing expression from the nucleic acid, *e.g.,* by culturing host cells under conditions for expression of the gene.

[0102] The nucleic acid of the invention may be integrated into the genome (*e.g.*, chromosome) of the host cell. Integration may be promoted by inclusion of sequences which promote recombination with the genome, in accordance with standard techniques.

[0103] Disclosed herein is a binding member which competes for binding to the same epitope as an antibody or antibody fragment according to the invention. The competing binding member optionally is in the same format as the antibody or antibody fragment according to the invention described herein, but with different CDR or variable region sequences.

[0104] Disclosed herein is a method which comprises using a construct as stated above in an expression system in order to express an antibody or antibody fragment or polypeptide as above.

[0105] Preferred features of each aspect of the invention are as for each of the other aspects *mutatis mutandis.*

BRIEF DESCRIPTION OF THE DRAWINGS

Figure legends

[0106]

Figure 1a: Amino acid and nucleotide sequence for the mouse IgG1 heavy chain of the FG129 mAb. Numbers refer to the standardised IMGT system for the numbering of antibody sequences [59]. **Figure 1b:** Amino acid and nucleotide sequence for the mouse kappa chain of the FG129 mAb. Numbers refer to the standardised IMGT system for the numbering of antibody sequences [59].

Figure 2: The chimeric version of the FG129 mAb (original murine variable regions linked to human constant region sequence), produced by a transfected cell line, binds the target cell line (HCT-15). **Figure 2a:** Amino acid and nucleotide sequence for the human IgG1 heavy chain of the FG129 mAb. Numbers refer to the standardised IMGT system for the numbering of antibody sequences [59]. **Figure 2b:** Amino acid and nucleotide sequence for the human kappa chain of the FG129 mAb. Numbers refer to the standardised IMGT system for the numbering of antibody sequences [59].

Figure 3a: ELISA screening of FG129 to over 600 glycans arrayed on a glass slide by the CFG. Square represents glucosylamine, circle represents galactose, triangle represents fucose and diamond represents sialic acid.

Figure 3b: Indirect Western blot analysis of the antigens recognised by mAb FG129 and mAb ch 129 (1 µg/ml). Lane M: molecular marker (in red); Lane 1: Colo205 cell lysates ($1x10^5$ cells); Lane 2: Colo205 TGL ($1x10^6$ cells); Lane 3: HCT-15 cell lysates ($1x10^5$ cells); Lane 4: HCT-15 TGL ($1x10^6$ cells); Lane 5: BxPc3 cell lysates ($1x10^5$ cells); Lane 6: BxPc3 TGL ($1x10^6$ cells); Lane 7: LS180 cell lysates ($1x10^5$ cells); Lane 8: LS180 TGL ($1x10^6$ cells). Negative control consisted of omission of primary antibody. CA19.9 was used as positive control recognising sialyl-Lewis^a on glycolipids as well as glycoproteins.

Figure 4: ELISA analysis of FG129 and CH129 binding to sialyl-Lewis^a-HSA. CA19.9 was used as positive control recognising sialyl-Lewis^a on glycolipids as well as glycoproteins. Negative controls consisted of an isotype antibody that does not recognise sialyl-Lewis^a, HSA coated wells, uncoated wells where the antigen was omitted, and wells where FG129 was omitted. Error bars represent the mean ± SD of duplicate wells.

Figure 5a: Binding of FG129 (1µg/ml) by IHC to colorectal, pancreatic, gastric, ovarian and lung TMAs. Representative images of different staining levels are shown i) negative, ii) weak, iii) moderate and iv) strong (magnification x20).

Figure 5b: Kaplan-Meier analysis of disease-free survival of pancreatic patients staining with FG129 mAb. Cut-off

for high versus low was determined by X-tile.

Figure 5c: Normal human tissue (AMSBIO) binding of FG129, showing very limited binding in 1) Gallbladder; 2) Ileum; 3) Liver; 4) Oesophagus; 5) Pancreas; 6)Thyroid (magnification x20).

Figure 6a: Indirect immunofluorescence staining and flow cytometric analysis of FG129 and CH129 (5µg/ml) mAb binding to the cell surface of tumour cell lines.

Figure 6b: Indirect immunofluorescence staining and flow cytometric analysis of FG129 (5µg/ml) mAb binding to the cell surface of HUVEC normal umbilical cells. An anti-CD55 mAb was used as a positive control and an anti-IgG isotype antibody as a negative control.

Figure 6c: Indirect immunofluorescence staining and flow cytometric analysis of FG129 and ch129 (5µg/ml) mAbs binding to whole blood. An anti-HLA mAb w6/32 was used as a positive control and an anti-IgG isotype antibody as a negative control.

Figure 7: Indirect immunofluorescence staining and flow cytometric analysis of titrations of FG129 mAb and CH129 mAb binding to the cell surface of Colo205 (7a), HCT-15 (7b), BxPc3 (7c) and LS180 (7d) cells.

Figure 8: ADCC killing of Colo205 (8a) and HCT-15 (8b) by FG129 and CH129. Erbitux was used as positive control, while PBMCs and cells alone were used as negative controls. Anova test performed using GraphPad Prism6 shows the significant difference between each concentration and the negative control consisting of cells with PBMCs only.

Figure 9: CDC killing of Colo205 by FG129 and CH129. Erbitux was used as positive control, while PBMCs and cells alone were used as negative controls. Anova test performed using GraphPad Prism6 shows the significant difference between each concentration and the negative control consisting of cells with PBMCs only.

Figure 10: Z-stack confocal microscopy of Alexa Fluor® 488 (green) labelled FG129 (panel 10a) and CH129 (panel 10b) internalising in live Colo205, BxPC3 and HCT-15 showing co-localisation with lysosomes. The plasma membrane was labelled with CellMask™ Orange (red/C), the lysosomes with LysoTracker® Deep Red (purple/D) and the nucleus with Hoechst 33258 (blue/A) (magnification x60).

Figure 11a: Cytotoxicity of Fab-ZAP-FG129 in antigen positive (HCT15, Colo205, BxPC3, ASPC1) and negative (LoVo, LS180) cancer cell lines. The cytotoxicity of internalised FG129 pre-incubated with saporin-linked anti-mouse IgG Fab fragment was evaluated using ^{3}H-thymidine incorporation. Results are presented as percentage of proliferation of cells treated with the primary mAb only. Error bars show the mean ± SD from four independent experiments.

Figure 11b: Fab-ZAP-IgG Isotype internalisation assay. Results are presented normalised, as percentage of proliferation of cells treated with the primary mAb only. Error bars show the mean ± SD from three independent experiments.

Figure 11c: Cytotoxicity of Fab-ZAP-CH129 against HCT15, Colo205, BxPC3cancer cell lines. The cytotoxicity of internalised CH129 pre-incubated with saporin-linked anti-human IgG Fab fragment was evaluated using ^{3}H-thymidine incorporation. Results are presented normalised, as percentage of proliferation of cells treated with the primary mAb only. Error bars show the mean ± SD from four independent experiments.

Figure 11d: Fab-ZAP-IgG Isotype internalisation assay. Results are presented normalised, as percentage of proliferation of cells treated with the primary mAb only. Error bars show the mean ± SD from three independent experiments.

Figure 11e: WST8 cytotoxicity assay showing in vitro efficacy of CH129-ADC constructs on Colo205. All three CH129-ADC constructs gave 100% cell killing with the vcE construct giving the highest efficacy (Ec50~10^{-11}M) followed by the DM1 and DM4 constructs showing similar efficacy (Ec50s~10^{-10}M).

Figure 11f: WST8 cytotoxicity assay showing in vitro efficacy of CH129-ADC constructs on HCT-15. CH129

constructs show 50-60% cell killing. Rituximab-ADC constructs were used as controls for specific killing. Ritux-vcE and Ritux-DM1 do not show cell killing. Ritux-DM4 shows similar killing activity to the CH129 constructs, indicating non-specific cell killing.

Figure 11g: WST8 cytotoxicity assay showing bystander killing of the CH129-vcE construct.

Figure 11h: WST8 cytotoxicity assay showing bystander killing of the CH129-DM4 construct.

Figure 11i: WST8 cytotoxicity assay showing bystander killing of the CH129-DM1 construct.

Figure 12a: Sandwich ELISA using FG129 for the detection of secreted sialyl-Lewis^a in sera from pancreatic cancer patients. Negative controls consisted of a normal serum sample from a healthy donor, and 2%BSA-PBS alone. Sialyl-Lewis^a-HSA was used as a positive control.

Figure 12b: Competition FACS assay showing binding to HCT-15 cell line of pre-incubated FG129 with sera from patients from the pancreatic TMA cohort. Positive controls consisted of normal sera samples from five healthy donors (shown as average between the five), and 2%BSA-PBS pre-incubated with FG129. Negative controls consisted of sialyl-Lewis^a-HSA pre-incubated with FG129 and 2%BSA-PBS alone.

Figure 13a: Sequence of FG129-scFv, comprised of 1) leader sequence, 2) heavy chain variable region, 3) 3x GGGGS spacer, 4) light chain variable region, 5) poly-Ala and 6x His tag for purification.

Figure 13b: ELISA analysis of FG129-scFv and CH129 binding to sialyl-Lewis^a-HSA. Error bars represent the mean ± SD of duplicate wells.

Figure 13c: Indirect immunofluorescence staining and flow cytometric analysis of titrations of FG129-scFv binding to the cell surface of Colo205.

DETAILED DESCRIPTION OF THE INVENTION

[0107] The invention will now be described further in the following examples and accompanying drawings.

Methods

[0108]

Binding to tumour cell lines: 1 x 10^5 cancer cells were incubated with 50µl of primary antibodies at 4°C for 1 hr. Cells were washed with 200µl of RPMI 10% new born calf serum (NBCS: Sigma, Poole, UK) and spun at 1,000rpm for 5 min. Supernatant was discarded and 50µl of FITC conjugated anti-mouse IgG Fc specific mab (Sigma; 1/100 in RPMI 10% NBCS) was used as secondary antibody. Cells were incubated at 4°C in dark for 1 hr then washed with 200µl RPMI 10% NBCS and spun at 1,000rpm for 5 min. After discarding supernatant, 0.4% formaldehyde was used to fix the cells. Samples were analysed on a Beckman coulter FC-500 flow cytometer (Beckman Coulter, High Wycombe, UK). To analyse and plot raw data, WinMDI 2.9 software was used. Cellular antibody binding sites for FG129 (used at 30 µg/ml) were calculated using the QIFIKIT® (Dako UK Ltd) according to the manufacturer's recommendations. Specific antibody binding capacity (SABC) was obtained by subtracting the non-specific binding of an isotype control.

Binding to blood: 50µl of healthy donor blood was incubated with 50µl primary antibody at 4°C for 1hr. The blood was washed with 150µl of RPMI 10% NBCS and spun at 1,000rpm for 5min. Supernatant was discarded and 50µl FITC conjugated anti-mouse IgG Fc specific mAb (1/100 in RPMI 10% NBCS) was used as the secondary antibody. Cells were incubated at 4°C in the dark for 1hr then washed with 150µl RPMI 10% NBCS and spun at 1,000rpm for 5min. After discarding the supernatant, 50µl/well Cal-Lyse (Invitrogen, Paisley, UK) was used followed by 500µl/well

distilled water to lyse red blood cells. The blood was subsequently spun at 1,000rpm for 5min. Supernatant was discarded and 0.4% formaldehyde was used to fix the cells. Samples were analysed on a FC-500 flow cytometer (Beckman Coulter). To analyse and plot raw data, WinMDI 2.9 software was used.

Plasma membrane glycolipid extraction: Colo205 cell pellet (5 x 10^7 cells) was resuspended in 500µl of Mannitol/HEPES buffer (50mM Mannitol, 5mM HEPES, pH7.2, both Sigma) and passed through 3 needles (23G, 25G, 27G) each with 30 pulses. 5µl of 1M CaCl2 was added to the cells and passed through 3 needles each with 30 pulses as above. Sheared cells were incubated on ice for 20 min then spun at 3,000g for 15 min at room temperature. Supernatant was collected and spun at 48,000g for 30 min at 4°C and the supernatant was discarded. The pellet was resuspended in 1ml methanol followed by 1ml chloroform and incubated with rolling for 30 min at room temperature. The sample was then spun at 1,200g for 10 min to remove precipitated protein. The supernatant, containing plasma membrane glycolipids, was collected and stored at -20°C.

Glycome analysis: To clarify the fine specificities of the FG129 mAbs further, the antibodies were sent to the Consortium for Functional Glycomics where they were screened against ≥600 natural and synthetic glycans. Briefly, synthetic and mammalian glycans with amino linkers were printed onto N-hydroxysuccinimide (NHS)-activated glass microscope slides, forming amide linkages. Printed slides were incubated with 1µg/ml of antibody for 1hr before the binding was detected with Alexa488-conjugated goat anti-mouse IgG. Slides were then dried, scanned and the screening data compared to the Consortium for Functional Glycomics database.

Affinity analysis

Surface Plasmon Resonance (SPR, Biacore X or 3000, GE Healthcare) analysis was used to investigate real-time binding kinetics of the FG129 mAbs. Polyvalent sialyl Le^a-HSA (Isosep AB, Tullinge, Sweden) was coupled onto a CM5 biosensor chip according to the manufacturer's instructions and a reference cell was treated in a similar manner, but omitting the sialyl Le^a conjugate. FG129, CH129 and scFv129 mAbs diluted in HBS-P buffer (10 mmol/L HEPES, pH 7.4, 150 mmol/L NaCl, 0.005% (v/v) surfactant P20) were run across the chip at a flow rate of 50 µl/min and BIAevaluation software 4.1 was used to determine the kinetic binding parameters from which affinities are calculated.

Lewis antigen and saliva sandwich ELISA

ELISA plates were coated overnight at 4°C with 100 ng/well Lewis-HSA antigens (Isosep), blocked with PBS/BSA and incubated with primary mAbs (direct ELISA). Antibody or Lewis antigen binding was detected using biotinylated secondary mAb (Sigma). Plates were read at 450 nm by Tecan Infinite F50 after incubation with Streptavidin Horseradish Peroxidase (HRPO) conjugate (Invitrogen).

SDS-PAGE and Western blot analysis: Briefly, 1x10^5 or 10^6 cell equivalents of Colo205 cell lysate, plasma membrane, total lipid extract, plasma membrane lipid extract or HCT-15 cell lysates were analysed for FG129 binding. Tumour cell total and plasma membrane lipid extracts and cell lysates were reduced with dithiothreitol (DTT; Pierce Biotechnology, ThermoFisher, Loughborough, UK) and subjected to SDS-PAGE using NOVEX 4% to 12% Bis-Tris gels (Invitrogen), and transferred to Immobilon-FL PVDF membrane (Merck Millipore, Watford, UK) using 1x transfer buffer (20x, Invitrogen) and 20% (v/v) methanol at 30V for 1hr. Membranes were blocked with 5% (w/v) non-fat dry milk in 0.05% (v/v) Tween-PBS for 1hr then probed with primary antibodies diluted in Tween-PBS, 2% BSA for 1hr. Primary antibody binding was detected using biotin-conjugated anti-mouse IgG Fc specific secondary antibody (Sigma; 1/2000 dilution in Tween-PBS, 2% BSA) for 1hr, and visualized using IRDye 800CW streptavidin (LICOR Biosciences, UK; 1/1000 in Tween-PBS 2% BSA).

Identification of FG129 heavy and light chain variable regions.

[0109]

Cell source and total RNA preparation: Approximately 5x10^6 cells from hybridomasFG129 were taken from

tissue culture, washed once in PBS, and the cell pellet treated with 500µl Trizol (Invitrogen). After the cells had been dispersed in the reagent, they were stored at - 80°C until RNA was prepared following manufacturer's protocol. RNA concentration and purity were determined by Nanodrop. Prior to cDNA synthesis, RNA was DNase I treated to remove genomic DNA contamination (DNase I recombinant, RNase-free, Roche Diagnostics, Burgess Hill, UK) following manufacturer's recommendations.

cDNA synthesis: First-strand cDNA was prepared from 3µg of total RNA using a first-strand cDNA synthesis kit and AMV reverse transcriptase following manufacturer's protocol (Roche Diagnostics). After cDNA synthesis, reverse transcriptase activity was destroyed by incubation at 90° C for 10mins and cDNA stored at -20° C.

GAPDH PCR to assess cDNA quality: A PCR was used to assess cDNA quality; primers specific for the mouse GAPDH house-keeping gene (5'-TTAGCACCCCTGGCCAAGG-3' and 5'-CTTACTCCCTTGGAGGCCATG-3') were used with a hot-start Taq polymerase (AmpliTaq Gold 360, Invitrogen) for 35 cycles (95°C, 3mins followed by 35 cycles of 94°C/30secs, 55°C/30secs, 72°C/1min; final polishing step of 10mins at 72°C). Amplified products were assessed by agarose gel electrophoresis.

PCR primer design for cloning FG129 variable regions: Primers were designed to amplify the heavy and light chain variable regions based upon the PCR product sequence data. Primers were designed to allow cloning of the relevant chain into unique restriction enzyme sites in the hIgG1/kappa double expression vector pDCOrig-hIgG1. Each 5' primer was targeted to the starting codon and leader peptide of the defined variable region, with a Kozak consensus immediately 5' of the starting codon. Each 3' primer was designed to be complementary to the joining region of the antibody sequence, to maintain reading frame after cloning of the chain, and to preserve the amino acid sequence usually found at the joining region/constant region junction. All primers were purchased from Eurofins MWG (Ebersberg, Germany).

Heavy chain variable region PCR: Immunoglobulin heavy chain variable region usage was determined using PCR with a previously published set of primers [60]. Previous results using a mouse mAb isotyping test kit (Serotec, Oxford, UK) had indicated that FG129 were both mouse IgG3 antibodies. Appropriate constant region reverse primers were therefore used to amplify from the constant regions. PCR amplification was carried out with 12 mouse VH region-specific 5' primers and 3' primers specific for previously determined antibody subclass with a hot-start Taq polymerase for 35 cycles (94°C, 5min followed by 35 cycles of 94°C/1min, 60°C/1min, 72°C/2min; final polishing step of 20min at 72°C). Amplified products were assessed by agarose gel electrophoresis. Positive amplifications resulted for the VH4 primer.

Light (κ) chain variable region PCRs: Immunoglobulin light chain variable region usage was determined using PCR with a previously published set of primers [60]. Previous results using a mouse mAb isotyping test kit had indicated that FG129 used κ light chains. PCR amplification was carried out with mouse Vκ region-specific 5' and 3' mouse Cκ specific primers with a hot-start Taq polymerase for 35 cycles (94°C, 5mins followed by 35 cycles of 94°C/1min, 60°C/1min, 72°C/2mins; final polishing step of 20mins at 72°C). Amplification products were assessed by agarose gel electrophoresis. Positive amplifications resulted with the Vκ1 and Vκ2 primers for FG129.

PCR product purification and sequencing: PCR products were purified using a Qiaquick PCR purification kit (Qiagen, Crawley, UK). The concentration of the resulting DNA was determined by Nanodrop and the purity assessed by agarose gel electrophoresis. PCR products were sequenced using the originating 5' and 3' PCR primers at the University of Nottingham DNA sequencing facility (http://www.nottingham.ac.uk/life-sciences/facilities/dna-sequencing/index.aspx). Sequences were analysed (V region identification, junction analysis) using the IMGT database search facility (http://www.imgt.org/IMGT_vquest/vquest?livret=0&Option=mouseIg). Sequencing indicated that FG129 had heavy and light chain variable regions from the following families; heavy chain; IGHV6-6*01, IGHJ1*01, light chain; IGKV12-41*01, IGKJ1*01. Sufficient residual constant region was present in the heavy chain sequences to confirm that FG129 was of the mIgG1 subclass.

Cloning strategy: The PCR product for cloning was generated using a proof-reading polymerase (Phusion, New England Biolabs) was cloned into a TA vector (pCR2.1; Invitrogen).

FG129 heavy/light chain PCR for cloning: PCR amplification was carried out using a proof-reading polymerase (Phusion; NEB) and the cloning primers described above using the FG129 cDNA template previously described for

35 cycles (98°C, 3min followed by 35 cycles of 98°C/30sec, 58°C/30sec, 72°C/45sec; final polishing step of 3min at 72°C). Successful amplification was confirmed by agarose gel electrophoresis.

TOPO light chain cloning: Amplified FG129 light chain was treated with Taq polymerase (NEB) for 15min at 72°C to add 'A' overhangs compatible with TA cloning. Treated PCR product was incubated with the TOPO TA vector pCR2.1(Invitrogen) and transformed into chemically competent TOP10F' cells according to manufacturer's instructions. Transformed bacteria were spread on ampicillin (80µg/ml) supplemented LB agar plates, which were then incubated overnight at 37°C. Colonies were grown in liquid culture (LB supplemented with 80µg/ml ampicillin) and plasmid DNA prepared (spin miniprep kit, Qiagen). Presence of an insert was confirmed by sequential digestion with BsiWI and BamHI and agarose gel electrophoresis. Sequencing was carried out on miniprep DNA from colonies using T7 and M13rev primers. The DNA insert from one such colony had the predicted FG129 light chain sequence; a 300ml bacterial LB/ampicillin culture was grown overnight and plasmid DNA prepared by maxiprep (plasmid maxi kit, Qiagen). Maxiprep DNA insert was confirmed by sequencing.

TOPO heavy chain cloning: Amplified FG129 heavy chain was treated with Taq polymerase (NEB) for 15min at 72°C to add 'A' overhangs. Treated PCR product was incubated with the TOPO TA vector pCR2.1 and transformed into chemically competent TOP10F' cells as above. Transformed bacteria were spread on ampicillin supplemented LB agar plates which were then incubated overnight at 37°C. Colonies were grown in liquid culture (LB/ampicillin) and plasmid DNA prepared (spin miniprep kit). Presence of an insert was confirmed by digestion with HindIII and AfeI and agarose gel electrophoresis. Sequencing was carried out on miniprep DNA from a number of colonies using T7 and M13rev primers. The DNA insert from one such colony had the predicted FG129 heavy chain sequence; a 300ml bacterial LB/ampicillin culture was grown overnight and plasmid DNA prepared by maxiprep (plasmid maxi kit, Qiagen). Maxiprep DNA insert was confirmed by sequencing.

pDCOrig-hIgG1 double expression vector light chain cloning: The FG129 light chain was digested from the TOPO vector pCR2.1 by sequential digestion with BsiWI and BamHI and the 400bp insert DNA agarose gel purified using a QIAquick gel extraction kit (Qiagen) following manufacturer's recommendations. This insert was ligated into previously prepared pDCOrig-hIgG1 vector (see above) and transformed into chemically competent TOP10F' cells. Transformations were spread on 35µg/ml Zeocin supplemented LB agar plates which were then incubated overnight at 37°C. Colonies were grown in liquid culture (LB supplemented with 35µg/ml Zeocin) and plasmid DNA prepared (spin miniprep kit, Qiagen). Sequencing was carried out on miniprep DNA from all colonies using a sequencing primer sited in the human kappa constant region. The DNA insert from one of the colonies had the predicted FG129 light chain sequence correctly inserted in pDCOrig-hIgG1; a 300ml bacterial LB/zeocin culture was grown overnight and plasmid DNA prepared by maxiprep (plasmid maxi kit, Qiagen).

pDCOrig-hIgG1 double expression vector heavy chain cloning: The FG129 heavy chain insert was digested from the TOPO vector pCR2.1 by digestion with HindIII and AfeI. Vector (pDCOrig-hIgG1-129k) containing the FG129 kappa light chain (prepared above) was also digested with HindIII and AfeI. The vector DNA was then phosphatase treated according to manufacturer's recommendations (Antarctic Phosphatase, NEB). After agarose gel electrophoresis, the 6.5kb pDCOrig-hIgG1 vector band and 400bp FG129H insert band were isolated using a QIAquick gel extraction kit (Qiagen) following manufacturer's recommendations. The insert was ligated into the pDCOrig-hIgG1 vector and transformed into chemically competentTOP10F' cells. Transformations were spread on 35µg/ml Zeocin supplemented LB agar plates which were then incubated overnight at 37°C. Colonies were grown in liquid culture (LB supplemented with 35µg/ml Zeocin) and plasmid DNA prepared (spin miniprep kit, Qiagen). Presence of an insert was confirmed by digestion with HindIII and AfeI and agarose gel electrophoresis. Sequencing was carried out on miniprep DNA from a number of the colonies using a sequencing primer sited in the human IgG1 constant region. The DNA insert from one of the colonies had the predicted FG129 heavy chain sequence correctly inserted in pDCOrig-hIgG1; a 300ml bacterial LB/zeocin culture was grown overnight and plasmid DNA prepared by maxiprep (plasmid maxi kit, Qiagen). Sequencing was used to confirm that both heavy and light chain loci.

Expression, purification and characterisation of the chimeric antibody constructs. The methodology for the expression and purification of chimeric antibody described in the present invention can be achieved using methods well known in the art. Briefly, antibodies can be purified from supernatant collected from transiently, or subsequently stable, transfected cells by protein A or protein G affinity chromatography based on standard protocols, for example Sambrook *et al.* [61].

Cloning, expression, purification and characterisation of the FG129-scFv The heavy chain and light chain variable region were incorporated *in silico* into a single scFv sequence in the orientation; leader; heavy chain variable domain; spacer (3x GGGGS); light chain variable domain; spacer (6x Ala); purification tag (6x His) and synthesised. After cloning into a eukaryotic expression vector, Expi293 cells were transfected and allowed to produce protein transiently (6 days). His-tagged scFv was purified from Expi-293 supernatant using immobilised cobalt chromatography (HiTrap Talon 1ml columns; GE Healthcare). In the binding assays, a biotinilated anti-His tag antibody was used as a secondary antibody (6x-His Epitope Tag Antibody, Biotin conjugated, clone HIS.H8; Thermo Fisher).

Immunohistochemistry assessment for FG129: To determine the therapeutic value of FG129, it was screened on pancreatic, lung, gastric, ovarian, colorectal cancer tissue microarrays by immunohistochemistry (IHC).

Methodology: Immunohistochemistry was performed using the standard avidin-biotin peroxidase method. Paraffin embedded tissue sections were placed on a 60°C hot block to melt the paraffin. Tissue sections were deparaffinised with xylene and rehydrated through graded alcohol. The sections were then immersed in 500ml of citrate buffer (pH6) and heated for 20min in a microwave (Whirlpool) to retrieve antigens. Endogenous peroxidase activity was blocked by incubating the tissue sections with endogenous peroxidase solution (Dako Ltd, Ely, UK) for 5min. Normal swine serum (NSS; Vector Labs, CA, USA; 1/50 PBS) was added to each section for 20min to block non-specific primary antibody binding. All sections were incubated with Avidin D/Biotin blocking kit (Vector Lab) for 15min each in order to block non-specific binding of avidin and biotin. The sections were re-blocked with NSS (1/50 PBS) for 5mins. Then tissue sections were incubated with primary antibody at room temperature for an hour. Anti-β-2-microglobulin (Dako Ltd; 1/100 in PBS) mAb and PBS alone were used as positive and negative controls respectively. Tissue sections were washed with PBS and incubated with biotinylated goat anti-mouse/rabbit immunoglobulin (Vector Labs; 1/50 in NSS) for 30min at room temperature. Tissue sections were washed with PBS and incubated with preformed 1/50 (PBS) streptavidin- biotin/horseradish peroxidase complex (Dako Ltd) for 30min at room temperature. 3, 3'-Diaminobenzidine tetra hydrochloride (DAB) was used as a substrate. Each section was incubated twice with 100µl of DAB solution for 5min. Finally, sections were lightly counterstained with haematoxylin (Sigma-Aldrich, Poole Dorset, UK) before dehydrating in graded alcohols, cleaning by immersing in xylene and mounting the slides with Distyrene, plasticiser, xylene (DPX) mountant (Sigma).

Patient cohorts: The study populations include cohorts of a consecutive series of 462 archived colorectal cancer (29) specimens (1994 -2000; median follow up 42 months; censored December 2003; patients with lymph node positive disease routinely received adjuvant chemotherapy with 5-flurouracil/folinic acid), 350 ovarian cancer (28) samples (1982-1997; median follow up 192 months: censored November 2005 :patients with stage II to IV disease received standard adjuvant chemotherapy which in later years was platinum based), 142 gastric cancer (26) samples (2001-2006; median follow up 66months; censored Jan 2009; no chemotherapy) 68 pancreatic and 120 biliary/ampullary cancer (27) samples (1993-2010:median 45 months; censored 2012; 25-46% of patients received adjuvant chemotherapy with 5-fluorouracil/folinic acid and gemcitabine) 220 non small cell lung cancers (01/1996-07/2006: median follow up 36 months censored May 2013; none of the patients received chemotherapy prior to surgery but 11 patients received radiotherapy and 9 patients received at least 1 cycle of adjuvant chemotherapy post surgery) obtained from patients undergoing elective surgical resection of a histologically proven cancer at Nottingham or Derby University Hospitals. No cases were excluded unless the relevant clinico-pathological material/data were unavailable.

Confocal microscopy: FG129 and CH129 mAbs were labelled with Alexa-488 fluorophore (A-FG129, A-CH129) according to manufacturer's protocol (Invitrogen). 1.5 x 10^5 HCT-15 cells were grown on sterile circular coverslips (22mm diameter, 0.16-0.19mm thick) in a 6 well plate for 24 hr in 5% CO_2 at 37°C. 24 hours later, cells on coverslips were treated with 5µg/ml of mAbs for 2 hr at 37°C in the dark. 2 hours later, excess/unbound mAbs were washed away using PBS. The cells were then fixed using 0.4% paraformaldehyde for 20 min in the dark. 0.4% paraformaldehyde was washed away using PBS. The coverslips were mounted to slides with PBS:glycerol (1:1). The coverslip edge was sealed with clear nail varnish. Localisation of A-FG129 and A-CH129 mAb was visualised under a confocal microscope (Carl Zeiss, Jena, Germany).

ADCC and CDC: Cells (5×10^3) were co-incubated with 100µl of PBMCs, 10% autologous serum or media alone or with mAbs at a range of concentrations. Spontaneous and maximum releases were evaluated by incubating the

labeled cells with medium alone or with 10% Triton X-100, respectively. After 4hr of incubation, 50µl of supernatant from each well was transferred to 96 well lumaplates. Plates were allow to dry overnight and counted on a Topcount NXT counter (Perkin Elmer, Cambridge, UK). The mean percentage lysis of target cells was calculated according to the following formula:

$$\text{Mean \% lysis} = 100x \frac{\text{mean experimental counts} - \text{mean spontaneous counts}}{\text{mean maximum counts} - \text{mean spontaneous counts}}$$

ADC assay

ADC was evaluated by measuring the cytotoxicity of immune-complexed mAbs with a mouse Fab-ZAP secondary conjugate (Advanced Targeting Systems) (30). Cells were plated in triplicates overnight into 96-well plates (2,000 cells, 90 µl/well). After preincubaton (30 minutes at room temperature) of a concentration range of FG129 or CH129 mAbs with 50 ng of the Fab-ZAP conjugate, 10 µl of conjugate or free mAb was added to the wells and incubated for 72 hours. Control wells, consisted of cells incubated without conjugate, incubated with secondary Fab-ZAP without primary mAb and incubated with a control mAb in the presence of Fab-ZAP. Cell viability was measured by ^{3}H-thymidine incorporation during the final 24 hours. Results are expressed as a percentage of ^{3}H-thymidine incorporation by cells incubated with conjugate compared with primary mAb only.

To further investigate if CH129 would make a promising ADC candidate in a clinical setting, the mab was chemically conjugated to different payload/linker constructs that were pre-clinically and clinically validated. Thus, three CH129 constructs were produced by ADC Biotechnology: one with the auristatin MMAE linked via a cleavable dipeptide valine-citruline linker and a para-aminobenzylalcohol (PABA) self-immolative spacer, one with the DM4 maytansinoid linked via the intermediately cleavable hindered disulphide linker SPDB and one with the DM1 maytansinoid linked through the non-cleavable SMCC linker. A matched set of control ADC constructs was also produced using the non-targeting mab Rituximab, to be used in relevant assay controls.

[0110] The cytotoxic effect of the CH129-ADC constructs was assessed by using the water-soluble tetrazolium salt WST-8 (Sigma) to measure the activity of hydrogenases which is directly proportional with the number of viable cells. Cells were plated in 96-well plates at a density of 2000 cells/90µl/well in 10%FBS-RPMI with Penicillin-Streptomycin (Sigma) and incubated overnight at 37°C, 5%CO2. The ADC constructs were then added to the cells at different concentrations in a final volume of 10µl/well and the plates were incubated at 37°C, 5%CO2 for 72h with the antibody constructs. The WST-8 was then added (10µl/well) and the plates were further incubated 37°C, 5%CO2 for 3h. After the 3h incubation, the plates were read at 450 nm by Tecan Infinite F50. Results are expressed as percentages of control wells, consisting of cells only without any antibody. Cytotoxicity was studied on two colorectal cell lines Colo205 and HCT-15 that express high cell surface densities of the targeted antigen sialyl-lewis-a.

EXAMPLE 1

Generation and initial characterisation of FG129 mAbs

[0111] FG129 was produced by immunising Balb/c mice with plasma membrane lipid extracts from LS180 cells (colorectal cell line) incorporated into liposomes, at two-week intervals over a period of 2 months, alpha-galactosylceramide was used as an adjuvant in the first, third and fourth immunisation and anti-CD40 mAb used during the second immunisation.

[0112] Analysis of antibody response to immunisations: Antibody titres were initially monitored by lipid enzyme-linked immunosorbent assay (ELISA). Flow cytometry analysis (FACS) was also carried out using LS180 tumour cells and Western blot using LS180. The mouse considered to have the best response, compared to the pre-bleed serum control, was boosted intravenously (i.v.) with LS180 plasma membrane lipid extract prior to fusion. 8 days after fusion, supernatants were collected and screened against fresh LS180 tumour cells by flow cytometry.

Hybridomas which demonstrated cell surface binding, using an indirect immunofluorescence assay, were harvested, washed in complete media and spread across 96 well plates at 0.3 cells per well to acquire a clone. The plate was then screened for positive wells and these grown on until a sufficient number of cells was obtained to spread across a 96 well plate at 0.3 cells per well for a second time. If the resulting number of colonies equalled ~30 and all hybridomas were positive, the hybridoma was considered a clone. Methods for clonal expansion, bulk culture and antibody purification of antibodies or antibody fragments are available using conventional techniques known to those skilled in the art.

EXAMPLE 2

Chimerisation of FG129

[0113] The term "chimeric antibody" is intended to refer to antibodies in which the variable region sequences are derived from one species and the constant region sequences are derived from another species, such as an antibody in which the variable region sequences are derived from a mouse antibody and the constant region sequences are derived from a human antibody. Chimeric (or humanised) antibodies of the present invention can be prepared based on the sequence of a murine mAb prepared as described above. The amino acid and nucleotide sequence for the variable and constant regions of the heavy (Figure 1a) and light chains (Figure 1b) of the FG129 mAb are shown in Figures 1. Numbers refer to the standardised IMGT system for the numbering of antibody sequences [49]. The CDR1, CDR 2 and CDR 3 regions are indicated. The FG129 heavy chain belongs to the mouse heavy chain family IGHV10-1*02 (IGHD1-1*01, IGHJ4*01), with three mutations compared to the parental germline gene. The FG129 light chain belongs to the mouse kappa chain family IGKV8-19*01 (IGKJ4*01), with two mutations compared to the parental germline gene.

[0114] FG129 heavy and light chain variable regions were cloned into a human IgG1 expression vector. This was transfected into CHO-S or HEK293 cells and human antibody purified on protein G. The chimeric mAbs CH129 bound to the colorectal cell line, Colo205. The amino acid and nucleotide sequence for the heavy and light chains of the human ch129 mAb are shown in Figures 2a and 2b respectively.

EXAMPLE 3

Defining the epitopes recognised by FG129 and CH129 mAbs

[0115] MAb FG129 is a mouse IgGlk isotype that was generated by immunising Balb/c mice with glycolipid extracts from colorectal cell line LS180. Glycan profiling analysis done by CFG on ≥600 natural and synthetic glycans shows a high specificity of FG129 binding sialyl-di-Lewis^{a} (100%) and sialyl-Lewis$^{a\text{-}x}$ (89%). It can also bind to mono-sialyl-Lewis^{a} (89%), but only if presented on a long carrier (sp8) and not on a short carrier (sp0), suggesting that it requires at least 4 carbohydrates or sufficient space to allow the three carbohydrate residues to insert into the antibody sequence presented in the correct conformation to bind (Figure.3a).

[0116] To analyse if these glycans' were expressed on glycoproteins or glycolipids from tumour cell lines FG129 binding was assessed by Western blotting (figure 3b). Tumour lysates or tumour glycolipid extracts from colorectal (Colo205 HCT-15 and LS180) and pancreatic cells lines (BxPc3), were blotted with FG129, CH129 mAb, secondary antibody alone or CA19.9 (anti-sialyl lewis a Mab). FG129 and CH129 bound to a wide range of glycoproteins in Colo205 and HCT-15 lysate and to a smaller number of glycoproteins in BxPc3 and LS180 lystates. FG129 failed to bind to any of the tumour glycolipid extracts. In contrast, CA19.9 showed binding to a wider range of glycoproteins in BxPc3, Colo205 and LS180 and to glycolipids from BxPc3 and HCT-15 cells. These results suggest that FG129 prefers to bind to six carbohydrate residues and prefers sialyl-di-Lewis^{a} which is predominantly expressed on

proteins. In contrast, CA19.9 which prefers the 3 carbohydrate residue glycan, sialyl-Lewis^a, binds to both lipids and proteins.

[0117] As mAbs require strong affinity to localise within tumours the affinity of FG129 mAb was assessed by Biacore and ELISA. Affinity measurements using SPR (Biacore X or 3000) on a sialyl-Lewis^a (as sialyl-di-Lewis^a is unavailable) coupled chip revealed two possible functional affinities - a dominant one (K_d~10^{-7}M) accounting for 80% of the population and another very high affinity (K_d~10^{-13}M) with fast association (~10^4 1/Ms) and very slow dissociation rate (K_d~10^{-8} l/s) (Table 1a). In particular, the affinity measurements revealed subnanomolar functional affinity for FG129 and nanomolar affinity for CH129 , both showing relatively fast on-rates and slow off-rates for sialyl-Lewis-a binding (Table 1b). The monovalent binding affinity of the scFv129 was lower (10^{-7}M), with a slower on-rate but similar off-rate, suggesting bivalent binding on the chip by FG129 and CH129.

Table 1a. Determination of kinetic sialyl-Lewis^a binding parameters by SPR

Equilibrium dissociation constant K_d (M)	Association rate k_a (1/Ms)	Dissociation rate k_d (1/s)
Major K_{d1} (80%) ~1.3×10^{-7}	k_{a1} ~1.97×10^4	k_{d1} ~2.57×10^{-3}
Minor K_{d2} (20%) ~1.4×10^{-13}	k_{a2} ~8.85×10^4	k_{d2} ~1.35×10^{-8}

Table 1b: Determination of kinetic sialyl-Lewis-a binding parameters by SPR

SPR			
Real-time sialyl Le^a-HSA binding			
mAb	**Association Rate k_{on} (1/Ms)**	**Dissociation Rate k_{off} (1/s)**	**Dissociation Constant Kd (M)**
FG129	6.2×10^5	1.1×10^{-4}	0.2×10^{-9}
CH129	1.3×10^5	2.6×10^{-4}	2.1×10^{-9}
FG129-scFv	3.0×10^3	5.0×10^{-4}	1.7×10^{-7}

[0118] Additionally, antigen binding was assessed by ELISA using sialyl-Lewis^a-HSA which revealed a FG129 and CH129 dose dependent response, confirmed specific sialyl-Lewis^a binding with a subnanomolar Ec_{50} (~10^{-10}M) and also showed no binding to HSA and plastic (Figure 4).

EXAMPLE 4

[0119] *Immunohistochemistry assessment of FG129 and CH129 mAbs.*
To determine the therapeutic value of FG129, it was screened on colorectal, gastric, pancreatic, lung, and ovarian tumour tissue microarrays (TMAs) by immunohistochemistry (IHC).

[0120] The tumour tissue binding of FG129 was assessed by IHC on tumour TMAs. The mAb bound to 74% (135/182) of pancreatic tumours, 50% (46/92) of gastric tumours, 36% (100/281) of colorectal tumours, 27% (89/327) of ovarian and 21% (42/201) of NSCLC tumours (Table 1).

Table 2. Binding of FG129 (1 µg/ml) by IHC to gastric, colorectal, pancreatic, ovarian and lung TMAs by staining intensity

	Gastric		Colorectal		Pancreatic+bilary/ampullary		Ovarian		Lung (adenocarcinoma)	
Staining	**Number**	**%**	**Number**	**%**	**Number**	**%**	**Number**	**%**	**Number**	**%**

Strong	11	12	3	1	37	21	5	2	12	6

[0121] Representatives of different staining levels of tumour tissues with FG129 are shown in Fig. 5a. In pancreatic cancer cohort, Kaplan-Meier analysis of disease-free survival of pancreatic patients revealed a significantly lower mean survival time in the high FG129 binding group (mean survival: 30 months (n=94)) compared to the lower FG129 binding group (mean survival: 90 months (n=82)), p=0.004, Log-Rank test. On multivariate analysis using Cox regression, high FG129 antigen expression in pancreatic cancer was a marker for poor prognosis which was independent of perineural invasion (p=0.003) (Fig. 5b).

[0122] In normal tissue, FG129 had a very restricted binding pattern and did not bind most normal tissues like heart, brain, stomach, and kidney (table 1). Very limited binding was seen in gallbladder (weak), ileum (1%), liver (1%), oesophagus (5%), pancreas (10%), and thyroid (weak: (Fig. 5c). This is in direct contrast to CA19.9 mAb which recognizes sialyl Lewis^a on both lipids and proteins. It binds strongly (3+) to oesophagus, gallbladder and liver, moderately (2+) to breast and weakly (1+) to rectum. FG129 displays strong tumour tissue binding with low normal tissue reactivity, and is associated with poor prognosis in pancreatic cancer patients.

Table 3. Summary of FG129 and CA19.9 binding to a panel of normal tissues using paraffin-fixed sections. Intensity of staining is shown as 0, 1, 2 or 3, relating to negative, weak, moderate or strong binding.

[0123] In normal tissue, CH129 had a very restricted binding pattern and did not bind most normal tissues like heart, brain, stomach, and kidney (table 1). Very limited binding was seen in gallbladder (weak), ileum (1%), liver (1%), oesophagus (5%), pancreas (10%), and thyroid (weak: (Fig. 5a).

EXAMPLE 5

FG129 and CH129 mAbs binding studies

[0124] To determine if any cell line is a good model for tumours expressing sialyl-di-Lewis^a a range of cell lines and normal cells were screened for cell surface binding of FG129. FG129 and CH129 showed strong binding (geometric mean (Gm) ≥1000) to tumour cell lines HCT-15, Colo205, moderate binding (Gm ~100) to BxPc3, ASPC1, LS180, DLD1, and DMS79 and no binding to AGS, SW480, EKVX, MCF-7, LoVo, DU4475, OVCAR3, OVCAR4 and OVCA433. This suggests that HCT-15, Colo205, ASPC1, BxPc3, LS180, DLD1, and DMS79 would be good models for assessing the sensitivity of tumour cells with different cell densities of sialyl-Lewis^a to FG129 therapy (Figure 6a). FG129 failed to bind to normal HUVEC cells (Figure 6b). For comparison, an anti-CD55 mAb was used as a positive control and an anti-IgG isotype antibody as a negative control. Importantly, FG129 and CH129 did not bind to PBMCs from a range of healthy donors (Figure 6c). These results identified several cell lines as models of human tumours for *in vitro* studies and showed that FG129 did not bind to normal blood or endothelial cells suggesting that they would not prevent FG129 localising within tumours.

[0125] The antigen density (SABC) was calculated to be 985,813 and 1,570,563 for HCT-15 and COLO205, respectively. Moderately binding cells included BxPc3 and LS180 (SABC: 300,036 and 469,272 respectively).

[0126] To estimate the affinity of binding to tumour cell lines, varying concentration of FG129 and CH129 mAbs were added to Colo205, HCT-15, BxPC3 and LS180 and binding was detected by indirect immunofluorescence analysis and flow cytometric analysis (figure7). Both FG129 and CH129 bound to the high expressing cell lines with Kd of 6-20nM and to low expressing cell lines with a Kd of 30-50nM. This is higher than binding to sialyl lewis^a -HSA and probably reflects the complexity of glycan exression on the cell surface.

[0127] The antigen density (SABC) was calculated to be 985,813 and 1,570,563 for HCT-15 and COL0205, respectively. Moderately binding cells included BxPc3 and LS180 (SABC: 300,036 and 469,272 respectively).

Example 6

In vitro anti-tumour activity of FG129 and CH129

[0128] The ability of FG129 and CH129 to induce Colo205 and HCT-15 tumor cell death in the presence of human PBMCs through ADCC was investigated. Both the mouse FG129 and chimeric CH129 mAb induced potent cell lysis of both cell lines in a concentration-dependent manner. CH129 had 2-4 increase in killing when compared to the mouse mAb with an EC_{50} value of ~10^{-10}M (Figure 8). The ability of FG129 and CH129 to induce Colo205, tumor cell death in the presence of complement through CDC was investigated. Chimeric but not mouse mabs showed good CDC (figure 9).

EXAMPLE 7

Internalization and ADC (antibody dependent drug cytotoxicity)

[0129] To further determine the therapeutic ability of the FG129 and CH129 the mAbs were screened for their ability to act as a drug carrier by internalising and delivering drug to lysosomes. Cellular internalisation was assessed by confocal microscopy, which showed internalisation of both 129 mAbs over a period of 90 minutes and co-localisation within the lysosomes. The nucleus was stained in blue, plasma membrane in red, lysosomal

compartments in purple and the 129 antibodies in green. Internalisation is seen on high cell surface antigen density colorectal cell lines Colo205 and HCT-15 and on pancreatic cell line BxPC3 (Figure 10a and b).

[0130] Internalisation was confirmed by ADC assays using Fab-ZAP, an anti-mouse IgG or anti-human IgG linked to the ribosome inactivating protein saporin, which killed the cells that internalised the Fab-ZAP-FG129/CH129 immune complex, but left the cells that did not internalise unaffected. Internalisation of Fab-ZAP-FG129 or CH129 led to a dose-dependent decrease in cell viability (Ic50 ~10^{-12}M) on high binding cells Colo205 and HCT-15 but not BxPc3 or ASPC1 (Figure 11a and 11c). No killing of low expressing cell lines LS180 or antigen negative cell line LoVo was observed (Figure 11a). Fab-ZAP alone or Fab-ZAP pre-incubated with an isotype-matched IgG1 antibody against an antigen not expressed by cells, did not kill the cells (Figure 11b and 11d).

[0131] Additionally, to investigate if CH129 would make a promising ADC candidate in a clinical setting, the mab was chemically conjugated to different payload/linker constructs that were pre-clinically and clinically validated. Thus, three CH129 constructs were produced by ADC Biotechnology: one with the auristatin MMAE linked via a cleavable dipeptide valine-citruline linker and a para-aminobenzylalcohol (PABA) self-immolative spacer (CH129-vcE), one with the DM4 maytansinoid linked via the intermediately cleavable hindered disulphide linker SPDB (CH129-DM4) and one with the DM1 maytansinoid linked through the non-cleavable SMCC linker (CH129-DM1). A matched set of control ADC constructs was also produced using the non-targeting mab Rituximab, to be used in relevant assay controls. Cytotoxicity was studied on two colorectal cell lines Colo205 and HCT-15 that express high cell surface densities of the targeted antigen sialyl-lewis-a.

[0132] CH129-ADC constructs give high in vitro target dependant efficacy. Results show a dose dependant decrease in cell death directly related with the decrease in antibody concentration on both cell lines. Cell killing was also target dependent, with higher killing being seen on the higher antigen expressing cell line Colo205, compared to HCT-15. On Colo205 (Figure 11e) all three CH129-ADC constructs gave 100% cell killing with the vcE construct giving the highest efficacy (Ec50~10^{-11M}) followed by the DM1 and DM4 constructs showing similar efficacy (Ec50s~10^{-10}M).

[0133] On HCT-15 (Figure 11f) only 50-60% of the cells were killed at the highest concentrations, with CH129-DM4 giving the best Ec50 of 2x10^{-9}M, while DM1 gave an Ec50 of 6x10^{-9}M and vcE giving an Ec50 of 10^{-8}M. Matched Rituximab-ADC constructs which did not bind the cell line were used as controls to assess the specificity of the killing. The absence of activity of the vcE and DM1 Rituximab constructs, indicates that the activity seen with the targeted constructs is specific, and not due to systemic release of free drug. However, Rituximab-DM4 shows similar activity to the CH129 constructs, suggesting non-specific killing.

[0134] In order to determine if the ADCs with cleavable linkers would kill antigen negative cells from the surroundings of antigen positive cells, the ADC constructs were tested on a mixture of antigen positive and antigen negative cells, and as well on cell lines with heterogeneous tumour antigen expression.

[0135] *ADCs with cleavable linkers give bystander killing compared with uncleavable linkers.* The bystander killing effect of the ADC constructs was evaluated on different cell ratio mixtures of high tumour antigen expressing cells Colo205 with cells that do not express the antigen - AGS. Cells were mixed at ratios of 2:1, 5:1 and 10:1 AGS to Colo205. Colo205 only, and AGS only were used as positive and negative controls respectively. Since AGS is an antigen negative cell line, the killing see on this cell line is non-specific, therefore concentrations at which killing is observed on AGS were not considered when assessing bystander killing. Specific killing is shown in Figures 11g, 11h and 11i highlighted by the rectangle. DM1 was the most stable in this aspect, as it showed killing at concentrations higher than 10nM, while DM4 at 3nM and vcE were less stable showing non-specific killing from 1nM.

[0136] As DM1 is linked with a non-cleavable linker, it consisted the negative control for bystander killing. The difference between the killing given by DM1 and DM4/vcE at the circled concentrations could be due to bystander killing. Thus, DM4 gave a specific killing of ~90%, vcE of ~50-80% while DM1 of ~20% of the cells.

EXAMPLE 8

Expression of sialyl-Lewis A on secreted antigens within sera from cancer patients

[0137] The presence of secreted FG129 antigen in pancreatic patients sera was investigated by sandwich ELISA, which showed that FG129 bound to 33% (7/21) of sera (Figure 12a). When tumours from these patients were analysed by IHC for binding of sialyl-di-Lewis^a on the tumour cells or within the stroma, all but one tumour was positive but only 6 tumours displayed stromal staining. The presence of secreted antigen was significantly associated with stromal tissue staining from tumours resected from these patients (p=0.023, correlation coefficient=0.621) suggesting that staining of resected tumours could predict patients in whom antigen may be present in the serum (Table 4).

Table 4. Tumour and stromal H score by IHC and pancreatic serum binding by sandwich ELISA of FG129

	Tumour H score	Stromal H score	Sandwich ELISA Pane serum binding to FG129 OD
P4	200	100	0.2
P5	180	0	0.05
P9	285	150	0.11
P10	120	0	0.07
P11	60	0	0.05
P12	150	100	006
P18	250	40	0.13
P20	0	0	0.05
P23	260	0	0.06
P32	110	0	0.05
P36	120	0	0.06
P40	280	25	0.06
P41	130	70	0.13

[0138] In order to mimic the *in vivo* setting, it was investigated if at 37°C FG129 would bind preferentially to secreted antigen or to tumour cell surface. Binding of FG129 to secreted antigen or tumour cells was analysed in a competition FACS assay on HCT-15 cells at 37°C. All serum reduced binding to HCT-15 cells but there was no association with secreted sialyl-Lewis^a antigen suggesting the viscosity of the serum reduced the kinetics of mAb binding. Serum from a normal donor which did not have secreted sialyl-Lewis^a antigen also showed a reduction in binding to HCT-15 cells (Gm x to 1200). Antigen positive patient sera also reduced binding (Gm 600-1000) as did antigen negative patent sera (Gm 650-1500). Even though FG129 was pre-incubated with the pancreatic sera, the mAb showed a strong preference for binding to the cells and not to the secreted antigen from the sera (Figure 12b). This suggests that secreted antigen should not prevent FG129 from localising within tumours.

EXAMPLE 9

Cloning, expression, purification and characterization of the FG129-scFv

[0139] With its limited normal tissue binding and the very high tumour tissue binding, the FG129 antibody makes an

attractive candidate to be used in the context of a chimeric antigen receptor (CAR) as a scFv in order to induce anti-tumour T cell responses.

[0140] To determine if the scFv would maintain the binding characteristics of the FG129 full antibody, the heavy chain and light chain variable region were incorporated in silico into a single scFv sequence in the orientation: leader, heavy chain variable domain, spacer (3x GGGGS), light chain variable domain, spacer (6x Ala); purification tag (6x His) and synthesized (Figure 13a). After cloning into a eukaryotic expression vector, Expi293 cells were transfected and allowed to produce protein transiently (6 days). His-tagged scFv was purified from Expi-293 supernatant using immobilised cobalt chromatography. The scFv was then characterised in terms of its binding properties to the sialyl-Lewis-a antigen or to cells expressing the antigen.

[0141] The antigen binding affinity of the FG129-scFv was measured by SPR and by ELISA on sialyl-Lewis-a. In antigen binding assay by ELISA, the FG129-scFv showed specific sialyl-Lewis-a binding that titrated down with decrease in scFv concentration ($Ec50=10^{-6}M$) (Figure 13b). Antigen binding affinity was also measured by SPR which gave a Kd of $10^{-7}M$ (Table 1). In cell binding assays, on Colo205, the FG129-scFv showed a high binding (Gm ~400) and gave a dose dependent response with a submicromolar Kd ($10^{-7}M$) (Figure 13c). Therefore the FG129-scFv maintains a high specific binding comparable to the binding of the full antibody and also displays a high binding affinity ($Kd\sim10^{-7}M$) despite having only one binding instead of the two binding arms of the full FG129 mab.

PATENTKRAV

1. Et isoleret antistof eller antistoffragment, der er i stand til at binde sialyl-di-Lewis^{a}, hvor antistoffet eller antistoffragmentet omfatter de følgende seks CDR'er:

a) GFTFNTYA (CDRH1), IRSKSNNYAT (CDRH2) og VGYGSGGNY (CDRH3), og
b) QSLLNSGNQKNY (CDRL1), WAS (CDRL2) og QNDYSSPFT (CDRL3),

hvor antistoffet eller antistoffragmentet er specifikt for sialyl-di-Lewis^{a} og sialyl-Lewis^{a-x}.

2. Antistof eller antistoffragment ifølge krav 1, hvor antistoffet eller antistoffragmentet er specifikt for sialyl-di-Lewis^{a}, sialyl-Lewis^{a-x} og mono-sialyl-Lewis^{a}, hvor mono-sialyl-Lewis^{a} er bundet til en glycoprotein.

3. Antistof eller antistoffragment ifølge et hvilket som helst af de foregående krav, hvor antistoffet eller antistoffragmentet er bispecifikt, eventuelt hvor det bispecifikke antistof eller antistoffragment er yderligere specifikt for CD3.

4. Antistof eller antistoffragment ifølge et hvilket som helst af de foregående krav, hvor antistoffet eller antistoffragmentet omfatter en let kæde-variabel sekvens, der omfatter nævnte CDRL1, CDRL2 og CDLR3, og en tung kæde-variabel sekvens, der omfatter nævnte CDRH1, CDRH2 og CDRH3.

5. Antistof eller antistoffragment ifølge et hvilket som helst af de foregående krav, hvor CDR'erne bæres af en human antistoframme.

6. Antistof eller antistoffragment ifølge et hvilket som helst af kravene 1 til 4, hvor antistoffet eller antistoffragmentet omfatter et VH-domæne omfattende rester 1 til 117 af aminosyresekvensen i Figur 1a eller 2a, og/eller et VL-domæne omfattende rester 1 til 114 af aminosyresekvensen i Figur 1b eller 2b.

7. Antistof eller antistoffragment ifølge et hvilket som helst af de foregående krav, hvor antistof eller antistoffragment omfatter et humant antistof konstant region, eller hvor antistoffragmentet er en Fab, (Fab ') 2, scFv, Fv, dAb, Fd eller en diabody.

8. Antistof eller antistoffragment ifølge et hvilket som helst af de foregående krav, hvor antistoffragmentet er en scFv omfattende i følgende rækkefølge

a) 1) ledersekvens, 2) variabel region i tung kæde, 3) 3x GGGGS spacer, 4) let kæde variabel region og 5) poly-Ala og en 6x His-tag til oprensning, eller
b) 1) ledersekvens, 2) variabel region med let kæde, 3) 3x GGGGS spacer og 4) tung kæde variabel region, eventuelt yderligere omfattende enten 5'- eller 3'-oprensningstag.

9. Antistof eller antistoffragment ifølge et hvilket som helst af de foregående krav, hvor antistoffet eller antistoffragmentet er tilvejebragt i form af en kimær antigenreceptor (CAR), eventuelt hvor antistoffragmentet er en scFv tilvejebragt i form af en kimær antigenreceptor (CAR) enten i den tunge kæde lette kæde orientering eller den lette kæde tunge kæde orientering.

10. Antistof eller antistoffragment ifølge et hvilket som helst af de foregående krav, hvor antistoffet er

a) et monoklonalt antistof; og/eller
b) et humaniseret, kimært eller fineret antistof; og/eller
c) et lægemiddelkonjugat, såsom et antistof-lægemiddelkonjugat (ADC).

11. Antistof eller antistoffragment ifølge et hvilket som helst af de foregående krav, hvor antistoffet har (i) en tung kæde aminosyresekvens af:

12. Antistof eller antistoffragment ifølge et hvilket som helst af de foregående krav, til anvendelse som et medikament.

13. Antistof eller antistoffragment ifølge et hvilket som helst af kravene 1 til 11, til anvendelse til forebyggelse, behandling eller diagnosticering af cancer.

14. Antistof eller antistoffragment til anvendelse ifølge krav 13, hvor canceren er kolorektal cancer, gastrisk cancer, bugspytkirtelcancer, lungecancer, cancer i æggestokkene eller brystcancer.

15. Antistof eller antistoffragment til anvendelse ifølge krav 12, 13 eller 14, hvor antistoffet eller antistoffragmentet administreres eller arrangeres til administration, alene eller i kombination med andre behandlinger.

16. Nukleinsyre omfattende en sekvens kodende for et antistof eller antistoffragment ifølge et hvilket som helst af kravene 1-11, eventuelt hvor nukleinsyren er en konstruktion i form af et plasmid, vektor, transkription eller ekspressionskassette.

17. Rekombinant værtscelle, der omfatter nukleinsyren ifølge krav 16.

18. Fremgangsmåde til diagnosticering af cancer omfattende anvendelse af et antistof eller antistoffragment ifølge et hvilket som helst af kravene 1 til 11 til kun at påvise glycanerne sialyl-di-Lewis^{a} og sialyl-Lewis^{a-x} og/eller monosialyl-Lewis^{a} bundet til et glycoprotein i en prøve fra et individ, eventuelt hvor mønsteret af glycaner detekteret af antistoffet eller antistoffragmentet bruges til at stratificere terapimuligheder for individet.

19. Farmaceutisk sammensætning omfattende antistoffet eller antistoffragmentet ifølge et hvilket som helst af kravene 1 til 11, og en farmaceutisk acceptabel bærer, eventuelt yderligere omfattende mindst et andet farmaceutisk aktivt.

20. Farmaceutisk sammensætning ifølge krav 19, til anvendelse i behandlingen af cancer.
