### Background of the Invention

Many elderly humans (greater than 65 years of age) have been immunized or exposed to many diseases, such as influenza, yet many may still require immunization in order to remain healthy. The immune response to active immunization tends to decrease with age.

10 Improving the response to influenza vaccines has been a major initiative since the 1970s (Mostow SR, et al. (1973) Inactivate vaccines in Volunteer studies with very high doses of influenza vaccine purified by zonal centrifugation Postgrad Med. J. 49: 152-158). Numerous investigators have explored the effect of doses of hemagglutinin (HA) greater than the standard 15 µg dose. The most thorough and well documented effort to provide an efficacious flu vaccine for the elderly has involved  
15 FluZone®. Three successive trials (Keitel et al. (2006) Safety of high doses of influenza vaccine and effect on antibody responses in elderly persons. Arch. Intern. Med. 166: 1121-1127 (Table 1); Couch et al. (2007) Safety and immunogenicity of a high dose trivalent influenza vaccine among elderly subjects Vaccine 25: 7656-7663 (Table 2) and Falsey et al., (2009) Randomized, double-blind controlled phase 3 trial comparing the immunogenicity of high-dose and standard-dose influenza vaccine in adults 65 years  
20 and older. J. Infect Dis. 200: 172-180 (Table 3)) have shown that increasing the dose of HA from 15 µg to 60 µg, focusing on the HA component, yields an improvement in HA1 titers of about 1.6 to 1.7 fold.

In general, the elderly are a difficult population for influenza vaccination. While increasing the amount of vaccine administered provides some benefit, it is not a proportional increase. Adjuvants may also help increase immunogenicity but they also increase the possibility of adverse reactions. Thus, there has been limited improvement in boosting the immune response in elderly to influenza by increasing the amount of HA administered. There is still a need for improved vaccine formulations for the elderly which provide increased immunity for the elderly.

#### Summary of the Invention

The invention is generally directed to methods of stimulating immune responses in older and elderly humans. The present invention includes compositions and methods of stimulating an immune response in a human, comprising the step of administering to the human a composition comprising at least a portion of at least one flagellin and at least a portion of at least one antigen, wherein the composition is administered to the human in a dose sufficient to provoke an immune response where the human is an elderly human, that is a human who is older than 49 years of age. In certain embodiments the compositions are administered to humans who are older than 55 years of age, or older than 60 years of age or older than 65 years of age or older than 70 years of age or older than 75 years of age or older than 80 years of age.

The compositions of the present invention comprise at least a portion of at least one flagellin and at least a portion of at least one antigen. The flagellin and the antigen may be associated in different ways. For example, the flagellin and the antigen may be part of a fusion protein in which the flagellin portion is associated with the antigen by constructing a DNA or RNA sequence that when expressed produces a protein containing both flagellin and antigen portions as part of a protein. The flagellin portion and antigen portion can be associated in other ways, for example each of these portions may be associated with a particle or some type of carrier where both the flagellin portion and the antigen portion may be attached to the carrier or particle.

The present invention also relates to compositions and methods of stimulating an immune response in an elderly human population, comprising the step of administering to the human population a composition that includes a fusion protein comprising at least a portion of at least one flagellin and at least a portion of at least one antigen, wherein seroconversion rate is at least 50% or at least 60% or at least 70% or at least 80% or at least 90% or at least 95% or at least 99%

The present invention also relates to compositions and methods of stimulating an immune response in an elderly human population, comprising the step of administering to the human population a composition that includes a fusion protein comprising at least a portion of at least one flagellin and at least a portion of at least one antigen, wherein the seroresponse rate is at least 50% or at least 60% or at least 70% or at least 80% or at least 90% or at least 95% or at least 99%

The present invention also relates to compositions and methods of stimulating an immune response in an elderly human population, comprising the step of administering to the human population a composition that includes a fusion protein comprising at least a portion of at least one flagellin and at least a portion of at least one antigen, wherein the seroprotection rate is at least 50% or at least 60% or at least 70% or at least 80% or at least 90% or at least 95% or at least 99%.

#### Detailed Description of the Invention

The features and other details of the invention, either as steps of the invention or as combinations of the parts of the invention will now be more particularly described, and pointed out in the claims. It will be understood that the particular embodiments of the invention are shown by way of  
10 illustration and not as limitations to the invention. The principle features of this invention can be employed in various embodiments without departing from the scope of the invention.

In an embodiment, the invention is a method of stimulating an immune response in a human, comprising the step of administering to the human a composition comprising at least one portion of at least one antigen and at least one portion of at least one flagellin, wherein the composition is  
15 administered to a human that is at least 49 years old. Administration of the composition to the human can provide protective immunity against an infection consequent to exposure of the human to a source of the antigen.

The compositions of the present invention comprise at least a portion of at least one flagellin and at least a portion of at least one antigen. The flagellin and the antigen may be associated in  
20 different ways. For example, the flagellin and the antigen may be part of a fusion protein in which the flagellin portion is associated with the antigen by constructing a DNA or RNA sequence that when expressed produces a protein containing both flagellin and antigen portions as part of a protein. The flagellin portion and antigen portion can be associated in other ways, for example each of these portions may be associated with a particle or a carrier where both the flagellin portion and the antigen portion,  
25 including but not limited to proteins, lipoproteins, carbohydrates, polysaccharides and/or lipids, may be attached to the carrier or particle. The particle or carrier can be any vehicle by which the flagellin portion and the antigen portion can be associated such that when introduced to a human an immune response is generated. Particle formulations may be made of a variety of materials, including but not limited to lipids, proteins, waxes or amino acids, polysaccharides, polyacrylic substances or organic  
30 acids. In one embodiment, the flagellin portion and antigen portion may be associated with virosomes as, for example, described in US Patent Publication No. 20100136053 which is herein incorporated by

reference. Other potential particles to which the antigen(s) and flagellin(s) may be attached may include but are not limited to virus-like particles, biodegradable microspheres, liposomes, peptide nanoparticles, nanoparticles and self-assembling virus like particles as described in WO2010/002818 herein incorporated by reference. In one embodiment flagellin and antigen are associated with self-assembling peptide nanoparticles (SAPN). SAPN are described in PCT patent application WO 2009/109428 herein incorporated by reference. These nanoparticles are comprised of aggregates of a continuous peptidic chain comprising two oligomerization domains connected by a linker segment wherein one or both oligomerization domains incorporate T-cell epitopes and/or B-cell epitopes within their peptide sequence.

Antigens that can be used in combination with flagellin in the compositions and methods of the present invention are any antigen that will provoke an immune response in a human. Antigens used in the compositions of the present invention include viral antigens such as influenza viral antigens (e.g. hemagglutinin (HA) protein, matrix 2 (M2) protein, neuraminidase), respiratory syncytial virus (RSV) antigens (e.g. fusion protein, attachment glycoprotein), papillomaviral (e.g. human papilloma virus (HPV), such as an E6 protein, E7 protein, L1 protein and L2 protein), Herpes Simplex, rabies virus and flavivirus viral antigens (e.g. Dengue viral antigens, West Nile viral antigens), hepatitis viral antigens including antigens from HBV and HC. Antigens used in the compositions of the present invention include bacterial antigens including those from *Streptococcus pneumonia*, *Haemophilus influenza*, *Staphylococcus aureus*, *Clostridium difficile* and enteric gram-negative pathogens including *Escherichia*, *Salmonella*, *Shigella*, *Yersinia*, *Klebsiella*, *Pseudomonas*, *Enterobacter*, *Serratia*, *Proteus*. Antigens used in the compositions of the present invention include fungal antigens including those from *Candida spp.*, *Aspergillus spp.*, *Cryptococcus neoformans*, *Coccidioides spp.*, *Histoplasma capsulatum*, *Pneumocystis carinii*, *Paracoccidioides brasiliensis*, *Plasmodium falciparum*, *Plasmodium vivax*, *Plasmodium ovale*, and *Plasmodium malariae*.

The ratio of flagellin to antigen in the compositions of the present invention may be from about 100:1 to about 1:100. In other embodiments the ratio of flagellin to antigen may be from about 1:20 to about 20:1. In a preferred embodiment of flagellin and influenza antigen the ratio of flagellin to influenza antigen is from about 1:20 to about 1:5. In some embodiments, especially those where flagellin and influenza antigen are linked in a fusion protein the ratio of flagellin to influenza antigen may be from 5:1 to 1:5.

The compositions of the present invention may include one or more types of flagellin associated with one or more type of antigens. With respect to particle carriers several different flagellin may be associated with one or more antigens which may be on the same or different particles.

In preferred embodiments the antigen contained within the compositions of the present invention is an antigen from influenza virus. A preferred antigen is hemagglutinin (HA). In preferred embodiments the HA sequences are conjugated to flagellin or to engineered flagellins as described in WO 2009/128950 herein incorporated by reference. Preferred embodiments of the present invention that utilize HA as an antigen are VAX 125, VAX 128A, VAX 128B and VAX 128C. VAX125, also known as STF2.HA1(SI), is a recombinant fusion protein that consists of Salmonella typhimurium flagellin type 2 (STF2), a TLR5 ligand, fused at its C-terminus to the globular head (amino acids 62-284) of the HA1 domain of the HA of influenza A/Solomon Islands/3/2006 (H1N1) and has a molecular mass of 77,539 kDa. By molecular weight approximately two-thirds of the vaccine composition is flagellin and one-third is influenza HA globular head. Thus, a 3 ug dose consists of 2 ug of flagellin and 1 ug of influenza HA. The amino acid sequence of VAX 125 (SEQ ID 1) is shown in Figure 1. VAX128A, also known as HL184 STF2.HA1-2 CA7, is a recombinant fusion protein that consists of Salmonella typhimurium flagellin type 2 (STF2), a TLR5 ligand, fused at its C-terminus to the globular head of the HA1 domain of the HA of Influenza A/California/07/2009 (H1N1) a pandemic strain of influenza. The nucleotide (SEQ ID 2) and amino acid (SEQ ID 3) sequences of VAX 128A are shown in Figures 4 and 5, respectively. VAX128B, also known as HL185 STF2.HA1-2 CA7, is an R3 fusion where the D3 domain of the flagellin has been removed and replaced with the globular head of the HA1 domain of the HA of Influenza A/California/07/2009 (H1N1). The nucleotide (SEQ ID 4) and amino acid (SEQ ID 5) sequences of VAX 128B are shown in Figures 6 and 7, respectively. VAX128C, also known as HL186 STF.2.HA1-2 CA 7, is a R32x fusion wherein the D3 domain of the flagellin has been removed and replaced with the globular head of the HA1 domain of the HA of Influenza A/California/07/2009 (H1N1) and the C-terminus of this flagellin is fused to the globular head of the HA1 domain of the HA of Influenza A/California/07/2009 (H1N1). Thus, the fusion protein contains two copies of the HA antigen per flagellin unit. The nucleotide (SEQ ID 6) and amino acid (SEQ ID 7) sequences of VAX 128B are shown in Figures 8 and 9, respectively. In VAX128C there are two copies of the HA globular head and the proportion of HA in the vaccine composition increases to 54% from 33% in the VAX128A construct.

about 4 $\mu$ g to about 50 $\mu$ g, 4 $\mu$ g to about 30 $\mu$ g, from about 4 $\mu$ g to about 20 $\mu$ g, from about 4 $\mu$ g to about 10 $\mu$ g, from about 4 $\mu$ g to about 8 $\mu$ g, from about 5 $\mu$ g to about 50 $\mu$ g, 5 $\mu$ g to about 30 $\mu$ g, from about 5 $\mu$ g to about 20 $\mu$ g, from about 5 $\mu$ g to about 10 $\mu$ g, from about 5 $\mu$ g to about 9 $\mu$ g, and from about 5 $\mu$ g to about 8 $\mu$ g. With respect to fusion protein compositions comprising flagellin and influenza antigen the dosage refers to the amount of protein present in the vaccine given to the human. Some of the protein quantity relates to the antigen and some of the protein quantity relates to the flagellin. For example, in VAX 125 and VAX 128A and VAX128B the HA1 antigen comprises about 33% of the molecular weight of the construct. In VAX128C there are two copies of the HA globular head and the proportion of HA in the vaccine increases to 54% from 33% in the VAX128A construct. In embodiments that use antigens other than HA it may be more useful to characterize the amount of the dosage by the amount of antigen, especially of the antigen is of a non-proteinaceous origin. In any event, the flagellin/antigen compositions of the present invention provide superior properties to the prior art compositions in treatment of the elderly.

With respect to compositions in which the flagellin and antigen are delivered via particles the dosage will depend on the type of particle used and the ratio of flagellin to antigen present in the composition. With respect to compositions in which flagellin and the antigen are present in ratios other than 1:1 the dosage will depend on the ratio of components. With respect to antigens other than influenza antigens the dosage will depend on the antigen used and the ratio of flagellin to the antigen. One of skill in the art may readily be able to determine the optimal dosing of the flagellin compositions based on the carrier, antigen and ratio of flagellin to antigen.

The antigen component of the fusion protein compositions of the present invention are preferably influenza antigens (influenza A, influenza B, influenza C antigen). In preferred embodiments of the compositions at least one member selected from the group consisting of a hemagglutinin influenza antigen (e.g., the fusion protein includes SEQ ID NO. 1 (Figure 1)), a matrix 2 (M2, such as an extodomain of M2, also referred to as "M2e") or a neuraminidase influenza antigen. The influenza antigen can include an H1N1 influenza antigen. In preferred embodiments, the antigen is fused to a flagellin molecule sequence such as described in WO 2009/128950 which is herein incorporated by reference. The compositions of the present invention may comprise one or more fusion proteins with one or more antigen sequences included in each fusion protein.

Advantages of Applicant's claimed methods include the ability to generate a protective immune response in an elderly population employing relatively low doses of antigens to infectious agents (e.g. influenza). The elderly are typically at high risk for disease consequent to exposure to an infectious agent, such as an influenza antigen, due, in part, to their inability to mount a suitable and sustainable immune response to an infectious antigen. A proposed approach to increase an elderly human's response to an antigen is to increase the dose of antigen and the frequency of dosing. However, such alternative treatment protocols have resulted in less than optimal immune responses to antigens and diminished the ability to provide protective immunity to disease consequent to exposure to antigens in elderly populations (See the tables herein provided concerning prior art products and studies). The methods employed herein improve immune responses in elderly populations so that an excess of 40% of the elderly population mount a suitable and sustainable immune response to an antigen administered in a relatively low dose, which also has the advantage of minimal side effects. The compositions of the present invention are more immunogenic and less reactogenic than prior art vaccines.

In one embodiment the human to be treated with the compositions and methods of the present invention is between 49 years old and about 64 years old. In another embodiment, the human may be older than 64 years old. In certain embodiments the compositions are administered to humans who are older than 55 years of age, or older than 60 years of age or older than 65 years of age or older than 70 years of age or older than 75 years of age or older than 80 years of age. The dose of compositions of the present invention may be selected to optimize the effects in the elderly while seeking to reduce any untoward side-effect. For example in the fusion protein compositions comprising flagellin and HA (as described in the case of VAX 125, VAX 128A, VAX 128B and VAX 128C) the dose may be selected to optimize the immunogenic response while attempting to keep reactogenicity low. At least one dose selected from the group consisting of a 0.1 $\mu$ g, 0.5 $\mu$ g, 1 $\mu$ g dose, 2 $\mu$ g dose, 3 $\mu$ g dose, 4 $\mu$ g dose, 5 $\mu$ g dose, 6 $\mu$ g dose, 7 $\mu$ g dose, 8 $\mu$ g dose, 9 $\mu$ g dose, 10 $\mu$ g dose, 15 $\mu$ g dose, 20 $\mu$ g dose, 25 $\mu$ g dose and a 30 $\mu$ g dose may be sufficient to induce an immune response in elderly humans. The dose of the fusion protein may be administered to the human within a range of doses including from about 0.1 $\mu$ g to about 500 $\mu$ g, 1 $\mu$ g to about 100 $\mu$ g, 1 $\mu$ g to about 50 $\mu$ g, from about 1 $\mu$ g to about 30 $\mu$ g, from about 1 $\mu$ g to about 25 $\mu$ g, from about 1 $\mu$ g to about 20 $\mu$ g, from about 1 $\mu$ g to about 15 $\mu$ g, from about 1 $\mu$ g to about 10 $\mu$ g, from about 2 $\mu$ g to about 50 $\mu$ g, 2 $\mu$ g to about 30 $\mu$ g, from about 2 $\mu$ g to about 20 $\mu$ g, from about 2 $\mu$ g to about 10 $\mu$ g, from about 2 $\mu$ g to about 8 $\mu$ g, from about 3 $\mu$ g to about 50 $\mu$ g, 3 $\mu$ g to about 30 $\mu$ g, from about 3 $\mu$ g to about 20 $\mu$ g, from about 3 $\mu$ g to about 10 $\mu$ g, from about 3 $\mu$ g to about 8 $\mu$ g, from about 3 $\mu$ g to about 5 $\mu$ g, from

The composition can be administered intramuscularly to the human in a single or in multiple doses. The method can further include the step of administering at least one subsequent dose of the flagellin/antigen composition to the human.

The immunogenic compositions for use according to the present invention may be delivered as  
5 a standard 0.5 ml injectable dose and contain from about 0.1 $\mu$ g to about 50 $\mu$ g of antigen. In a preferred embodiment of the immunogenic compositions for use according to the present invention is a standard 0.5 ml injectable dose and contains from about 3 $\mu$ g to about 20 $\mu$ g of antigen. The vaccine volume may be between 0.25 and 1.0 ml, suitably between 0.5 ml and 1.0 ml, in particular a standard 0.5ml. A vaccine dose according to the present invention may be provided in a smaller volume than conventional  
10 dosing. Low volume doses according to the present invention are suitably below 0.5ml, typically below 0.3ml and usually not less than 0.1 ml.

Accordingly, in one aspect of the invention it is provided for a composition, method or use as claimed herein wherein the immune response produced by administration of the composition in a human population where the humans are about 49 years old to about 64 years old or where the humans  
15 are older than 55 years of age, or older than 60 years of age or older than 65 years of age or older than 70 years of age or older than 75 years of age or older than 80 years of age and has a seroconversion rate of greater than 50%, greater than 60%, greater than 65% greater than 70%, greater than 75%, greater than 80%, greater than 85%, greater than 90%, greater than 95% or greater than 99%.

Accordingly, in one aspect of the invention it is provided for a composition, method or use as  
20 claimed herein wherein the immune response produced by administration of the composition in a human population where the humans are about 49 years old to about 64 years old or where the humans are older than 55 years of age, or older than 60 years of age or older than 65 years of age or older than 70 years of age or older than 75 years of age or older than 80 years of age and has a seroprotection rate of greater than 50%, greater than 60%, greater than 65%, greater than 70%, greater than 75%, greater  
25 than 80%, greater than 85%, greater than 90%, greater than 95% or greater than 99%.

Seroresponsive means an increase in HAI antibody titer of at least fourfold with a minimum post vaccination titer of 40.

Seroprotection means achievement of minimum post vaccination HAI titer of 40 among subjects  
30 with prevaccination titers of <40.

Seroconversion rate for anti-HA antibody response is defined as the proportion of subjects in each group having protective post-vaccination titer  $\geq 1:40$ . The seroprotection rate is the percentage of subjects who have an HAI titer before vaccination of  $< 1:10$  and  $\geq 1:40$  after vaccination. However, if the initial titer is  $\geq 1:10$  then there needs to be at least a fourfold increase in the amount of antibody after  
5 vaccination.

In another aspect of the invention it is provided for a composition, method or use as claimed herein wherein the immune response produced by administration of the compositions of the present invention induces functional (HAI) antibodies in the majority of elderly recipients in a dose dependent fashion. In certain embodiments the composition will induce a neutralizing antibody response of  
10 greater than a titer about 50 after 7 days or after 14 days or after 28 days. In other embodiments the composition will induce a neutralizing antibody response of greater than about a titer of 100 after 7 days or after 14 days or after 28 days. In other embodiments the composition will induce a neutralizing antibody response of greater than a titer of about 150 after 7 days or after 14 days or after 28 days. In other embodiments the composition will induce a neutralizing antibody response of greater than about  
15 200 after 7 days or after 14 days or after 28 days.

Accordingly, in one aspect of the invention it is provided for a composition, method or use as claimed herein wherein the immune response produced by administration of the composition in an elderly population meets or exceeds one of the following criteria:

- a seroconversion rate of greater than 50%, greater than 60%, greater than 70%, greater  
20 than 80%, greater than 90%, greater than 95% or greater than 99%.
- a seroprotection rate of greater than 50%, greater than 60%, greater than 70%, greater than 80%, greater than 90%, greater than 95% or greater than 99%.
- an average of four-fold or greater increase in neutralizing antibody titer at post vaccination.

An "effective amount" when referring to the amount of a composition and a fusion protein  
25 administered to the human, refers to that amount or dose of the composition that, when administered to the subject is an amount sufficient for therapeutic efficacy (e.g., an amount sufficient to stimulate an immune response in a subject, an amount sufficient to provide protective immunity in the subject).

The methods of the present invention can be accomplished by the administration of the compositions and fusion proteins of the invention by enteral or parenteral means. Specifically, the route of administration is by intramuscular injection of the composition and fusion protein. Other routes of administration are also encompassed by the present invention including intravenous,  
5 intradermal, interarterial, interperitoneal, intranasal, transdermal, suppositories or subcutaneous routes.

The compositions that include the fusion proteins can be administered alone or as admixtures with conventional excipients, for example, pharmaceutically, or physiologically, acceptable organic, or inorganic carrier substances suitable for enteral or parenteral application which do not  
10 deleteriously react with the composition. Suitable pharmaceutically acceptable carriers include water, salt solutions (such as Ringer's solution), alcohols, oils, gelatins and carbohydrates such as lactose, amylose or starch, fatty acid esters, hydroxymethylcellulose, and polyvinyl pyrrolidone. Such preparations can be sterilized and, if desired, mixed with auxiliary agents such as lubricants, preservatives, stabilizers, wetting agents, emulsifiers, salts for influencing osmotic pressure, buffers, coloring and/or aromatic  
15 substances and the like which do not deleteriously react with the compositions administered to the human. Preferred diluents for diluting the vaccines of the present invention include but are not limited to 150mM NaCl with histidine and trehalose.

The compositions, fusion proteins and proteins of the invention can be administered to a subject on a support that presents the compositions, proteins and fusion proteins of the invention to the  
20 immune system of the subject to generate an immune response in the subject. The presentation of the compositions, proteins and fusion proteins of the invention would preferably include exposure of antigenic portions of the fusion protein to generate antibodies. The support is biocompatible. "Biocompatible" as used herein, means that the support does not generate an immune response in the subject (e.g., the production of antibodies).

25 The dosage and frequency (single or multiple doses) administered to a subject can vary depending upon a variety of factors, including, for example, prior exposure to an infection consequent to exposure to the antigen: health, body weight, body mass index, and diet of the subject or health-related problems. Other therapeutic regimens or agents can be used in conjunction with the methods and compositions, proteins or polypeptides of the present invention.

The composition can be administered to the human in a single dose or in multiple doses, such as at least two doses. When multiple doses are administered to the subject, a second or third dose can be administered days (e.g., 1, 2, 3, 4, 5, 6, 7), weeks (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10), months (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10) or years (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10) after the initial dose. For example, a second dose of the composition can be administered about 7 days, about 14 days or about 28 days following administration of a first dose of the composition that includes the fusion protein.

Ranges may be expressed herein as from about one particular value, and/or to about another particular value. When such a range is expressed, another aspect includes from the one particular value and/or to the other particular value. Similarly, when values are expressed as approximations, by use of the antecedent about, it will be understood that the particular value forms another aspect. It will be further understood that the endpoints of each of the ranges are significant both in relation to the other endpoint, and independently of the other endpoint.

The dose of fusion protein is made in reference to microgram doses. The invention is generally directed to methods of treating elderly populations of human to stimulate immune responses to antigens, in particular a protective immune response, employing relatively low doses of the antigenic composition that include the antigen. A description of example embodiments of the invention follows.

#### Examples

##### Example 1

##### *Phase II, Open-Label, Escalating Dose-Ranging Study*

STF2.HA1(SI) (VAX125) is a recombinant fusion protein that consists of *Salmonella typhimurium* flagellin type 2 (STF2), a TLR5 ligand, fused at its C-terminus to the globular head (amino acids 62-284) of the HA1 domain of the HA of influenza A/Solomon Islands/3/2006 (H1N1) and has a molecular mass of 77,539 kDa (SEQ ID 1). Vaccine was supplied in glass vials at either 20 µg/mL or 2 µg/mL, and diluted in dilution buffer (150mM NaCl with histidine and trehalose) to the final concentration on the day of administration. Study materials were prepared by non-blinded pharmacists and provided to blinded clinical staff. Vaccine was administered at a final volume of 0.5 mL by deep intramuscular injection in the deltoid muscle.

A total of 120 community-living adults who were  $\geq 65$  years of age (the mean age was 72 with a range of 64-84) enrolled across the six dose groups. Subjects were healthy as ascertained by medical history, screening physical examination and screening laboratory analysis. Subjects with active medical conditions, abnormal screening laboratory tests (CBC and differential, and AST and ALT), known allergies to vaccine components, influenza vaccination within the previous 6 months, or receipt of other vaccines within 30 days were excluded from participation.

The study was conducted in an open-label, dose escalation design. Twenty subjects were enrolled in each dose group at up to 3 study sites. Subjects received a single dose at dose levels of 0.5  $\mu\text{g}$ , 1.0  $\mu\text{g}$ , 2.0  $\mu\text{g}$ , 3.0  $\mu\text{g}$ , 5  $\mu\text{g}$ , and 8  $\mu\text{g}$  (Table 1). Subjects were evaluated in the clinic following vaccination at 30 minutes, 4 hours, Day 1, and by phone interview at Day 3. Subjects enrolled in the 5 and 8  $\mu\text{g}$  groups remained under observation at the study site for four hours after vaccination. Subjects were further evaluated during clinic visits on study days 7, 14, and 28 following vaccination. Safety follow-up by telephone contact also occurred at 6 and 12 months after vaccination.

### ***Immunogenicity***

The ability of antibody generated in response to *E. coli*-derived hemagglutinin antigen to inhibit hemagglutination by egg-grown influenza virus is shown in Tables 2 and 3. The geometric mean titer

(GMT) of HAI antibody on day 28 after a single dose increased in a dose dependent manner, with the highest post-vaccination GMT seen in subjects who received 5 µg (Table 2). Four-fold or greater antibody responses were seen in the majority of subjects who received doses of 5 or 8 µg. Among subjects who received doses of 5 or 8 µg, a total of 30 (75%) of 40 subjects had four-fold or greater serum HAI antibody responses. In the 5 and 8 µg dose groups 18 (45%) subjects had titers of 1:40 or greater at the beginning of the study before vaccination. Among the 22 subjects with pre-vaccination serum HAI antibody of 1:40 or less, 21 (98%) achieved a titer of at least 1:40 by day 28 after vaccination (Table 3). The kinetics of the antibody titers by group in this study are shown in Figure 2.

The anti-flagellin response as assessed by IgG ELISA appears in Table 4. Levels of anti-flagellin IgG were low in these subjects prior to vaccination. VAX125 induced substantial increases in anti-flagellin antibodies. There was no apparent relationship between the level of anti-flagellin antibody detected prior to vaccination and either the frequency or severity of side effects, or the serum antibody response to the influenza hemagglutinin.

The immune response generated by VAX125 was compared to the H1N1 component of the standard (15 µg) and high dose (60 µg) Fluzone as reported by Falsey et al. (Table 5). The GMT increase in subjects 65 years and older after standard Fluzone increases by about 2-fold and after the high dose by about 4-fold. In contrast the GMT increase in subjects 65 years and older after VAX125 the 5 µg dose increases by more than 10-fold. This translates to higher seroconversion rates and seroprotection rates in the VAX125 groups.

**Table 2. Geometric mean (GMT) HAI antibody titers, mean fold response (MFR) among 120 subjects  $\geq$  65 years old who received a single dose of VAX125**

### ***Reactogenicity.***

Vaccine was well tolerated in all dose groups (Table 6). No side effect was graded as severe (3) or life-threatening (4) and there were serious no adverse events. Moderate arm pain was observed in

about 20% of subjects of subjects who received a dose of 2 µg or greater. Systemic adverse events were usually mild and did not appear to be dose-dependent.

C-reactive protein (CRP) levels were measured at baseline and on day 1 (Table 7). The mean fold increase in CRP showed a dose-dependence, with a mean increase of less than 5-fold in subjects receiving the two highest doses. At doses of 3 µg or greater 57% of 60 subjects experienced at least a 2-fold increase in CRP. However, the majority (or none) of CRP increases were not associated with local or systemic symptoms of greater than mild severity or for subjects in stage 1 associated with increases in IL-6, IL-8 or IL-10 (data not shown).

### Discussion

VAX125 was both safe and immunogenic at the dose range tested, but the elderly appear much less sensitive to the VAX125 in terms of immune and cytokine response. The peak GMT HAI titers in the 3 $\mu$ g elderly group was 160 which was similar to the 0.1 $\mu$ g dose in young adults. The peak titers in the 0.3 and 0.5 $\mu$ g dose in the young adults were higher than the elderly (Table 8). There is a four-fold or greater serum HAI responses in 61 of 96 (64%) subjects who received doses of 0.5  $\mu$ g or greater, including in 46 of 72 subjects who received doses from 0.5  $\mu$ g to 2  $\mu$ g. The GM HAI titer after a single 0.5  $\mu$ g dose of VAX125 was similar to the titer observed in the 5  $\mu$ g dose in subjects over 65 years, suggesting that it requires nearly a 10-fold increase in dose to obtain the same titer in the elderly.

**Table 8. Geometric mean HAI antibody titers, seroprotection and seroconversion rates for H1N1 Solomon Island among young adult subjects who received one IM dose of VAX125.**

HAI GMT						MFR		SR	SP

Table 9 is a comparison of the mean and maximum CRP values for healthy subjects older than about 65 years old and subjects 18-49 years old. The geometric means do not vary until you reach the 3µg group where the mean is nearly double in the young adults. The upper 95% confidence limit and the maximum value are both less in the elderly.

5 **Table 9. Comparison of CRP in elderly and young adults after VAX125.**

Dose (µg)	1		2		3	
Age group	>65	18-49	>65	18-49	>65	18-49
No. subjects	20	24	20	24	20	8
Geometric mean	2	2.2	2.2	2.4	3.4	5.9
Upper 95% CI	3.2	4.7	3.4	4.6	5	19.9
Maximum	11.9	43.7	13.7	33.2	13.5	83

While these data may suggest that the optimal dose in the elderly is greater than 3µg, doses as low as this still produce an HAI response to the H1N1 antigen that is better than the standard Fluzone TIV and is similar to the response observed with the high dose Fluzone formulation (Table 10).

10 **Table 10. Immunological response of VAX125 compared to standard dose and high dose Fluzone in elderly subjects 65 years or older.**

	VAX125		Fluzone TIV	
Dose of H1N1	2 µg	3 µg	15 µg	60 µg
No. of subjects	20	20	1252	2543
SP (%)	70	95	77	90
SC (%)	35	40	23	49
GMT HAI Titer	70	149	67	116

**Table 11 Comparative Seroresponse against H1N1 antigens in adults over 65 for VAX 125 and Fluzone standard dose and high dose**

	VAX 125 dose (µg)			Fluzone dose (µg)	
	3	5	8	15	60
Number of Subjects	20	20	20	1252	2543
GMT (H1N1)					
Prevaccination	51	19	30	29	29
Post vaccination	160	234	234	67	116
Fold Increase	3.1	12.6	7.7	2.3	4.1
Seroconversion (%)	40	80	65	23	49
Seroprotection (%)	95	95	100	77	90

**Table 12. Clinical Evaluation of VAX 125 Phase I**

			VAX 125 dose range (µg)		
	Timing	Control N=16	0.1-0.3 N=16	1-3 N=56	5-8 N=16
GMT	Day 0	91	99	102	50
	Day 14	87	190	672	698
	Day 28	84	258	640	640
GMT fold increase	At day 14	1.0	1.9	6.6	14.1
	At day 28	0.9	2.6	6.2	12.9
	Seroresponse*	0	5 (31%)	33 (59%)	12 (75%)
	Seroprotection	0 of 2	4 of 4	12 of 13 (92%)	5 of 6 (83%)

5 \*Seroresponse: increase in HAI antibody titer of at least fourfold with a minimum post vaccination titer of 40

\*\*Seroprotection: achievement of minimum post vaccination HAI titer of 40 among subjects with prevaccination titers of <40.

VAX125 induces functional (HAI) antibodies in the majority of elderly recipients in a dose dependent fashion. The 5.0 and 8.0 µg doses elicited high HAI GMT (226 and 234, respectively) and high GMT fold response (12.6 and 7.7, respectively) values. The 5.0 µg dose was the most immunogenic. The 5.0 µg and 8.0 µg doses elicited high seroconversion rates (80% and 65%, respectively) and high seroprotection rates (95% and 100%, respectively). The peak GMT values in healthy adults ≥ 65 were similar to those observed with 0.5 µg dose in young adults. This suggests that a high dose formulation is required for the elderly. The ability to produce a high dose influenza vaccine in *E. coli* for the elderly is unique to this product.

## Example 2

### *Construction and Expression of Vax 128A, Vax 128B and Vax 128C*

#### **Cloning and Expression**

*E. coli* clones producing each of the three vaccine candidates Vax 128A, Vax 128B and Vax 128C were produced in a similar manner, but with differences in plasmid preparation specific to each construct. Plasmids encoding for STF2.HA1 (CA07) and STF2R3.HA1 (CA07) were mutated from plasmids encoding for STF2.HA1 (CA04) and STF2R3.HA1 (CA04). The plasmid encoding for STF2R3.2xHA1 (CA07) was produced from the STF2.HA1 (CA07) and STF2R3.HA1 (CA07) plasmids. Details of the plasmid construction and clone selection follow. A plasmid map for the vaccine candidates is shown in Figure 3.

#### **10 Plasmid Construction for Vax 128A (STF2. HA1 (CA07))**

A multi step PCR procedure was performed to produce the plasmid encoding for STF2.HA1 (CA07). A plasmid encoding for STF2.HA1 (CA04) was initially produced, and then mutated to code for STF2.HA1 (CA07). To make STF2.HA1 (CA04), DNA encoding STF2 was fused with DNA encoding the HA1 globular head domain of the (CA04) HA protein. DNA encoding STF2 was amplified from the pET24a-STF2.HA1 FL plasmid. DNA encoding the HA globular head protein was synthesized by an outside vendor (DNA 2.0, Menlo Park, CA) and amplified by PCR. After gel purification of both the SFT2 and HA1 (CA07) DNA, the fragments were fused together. The final PCR product (DNA encoding the STF2.HA1 (CA04) fusion protein) was digested with restriction enzymes NdeI and EcoRI and ligated to the pET24a plasmid. Since there is only one residue difference between the HA portion of STF2.HA1-2 (CA04) and STF2.HA1 (CA07), STF2.HA1 (CA07) was made by site-directed mutagenesis of STF2.HA1 (CA04). The recombinant DNA sequence was confirmed by an outside vendor (Genewiz Inc.).

#### **Plasmid Construction for Vax 128B (STF2R3. HA1 (CA07))**

As with STF2.HA1 (CA07), a plasmid encoding for STF2R3.HA1 CA4 was initially produced and then mutated to code for STF2R3.HA1 (CA07). To make STF2R3.HA1 (CA04), DNA encoding portions of the N and C terminal sections of STF2 was fused with DNA encoding the HA1 globular head domain of the CA4 HA protein. This has the effect of replacing the D3 domain of STF2 with HA1-2 (CA04) in the fusion protein. DNA encoding for the portions of the N and C terminal sections of STF2 was PCR amplified from the pET24a-STF2.HA1 (CA04) plasmid. DNA encoding for HA1 (CA04) was PCR amplified from the same

plasmid. Gel purified STF2 and HA1 (CA04) fragments were fused, and the final PCR product was digested with restriction enzymes NdeI and EcoRI and ligated to the pET24a plasmid. Since there is only one residue difference between the HA portion of STF2R3.HA1 (CA04) and STF2R3.HA1 (CA07), STF2R3.HA1 (CA07) was made by site-directed mutagenesis of STF2R3.HA1 (CA04). The recombinant DNA sequence was confirmed by an outside vendor (Genewiz Inc.).

#### Plasmid Construction for Vax 128C (STF2R3. 2xHA1 (CA07))

The plasmid encoding for STF2R3.2xHA1 (CA07) was made from a fusion of the DNA from the STF2R3.HA1 (CA07) plasmid and the STF2.HA1 (CA07) plasmid. Both plasmids were digested separately with NdeI and MfeI enzymes. Specific fragments of the STF2R3.HA1 (CA07) (as insert) and STF2.HA1 (CA07) (as vector) were gel purified and ligated to form a complete DNA sequence encoding for STF2R3.2xHA1 (CA07). The common restriction site is in the C terminal section of STF2. The recombinant DNA sequence was confirmed by an outside vendor (Genewiz Inc.).

#### Cloning

The DNA was used to transform commercially available *E. coli* BLR(DE3) cells (Novagen, Cat. No. 69053). *E. coli* BLR(DE3) cells from Novagen are a recA derivative of a BL21 strain of *E. coli* that improves plasmid monomer yield and may help to stabilize included plasmids.. The cells are *lon* and *ompT* protease deficient, and are lysogenic for lambda prophage that contains an IPTG inducible T7 RNA polymerase. The resulting BLR(DE3) clones, were used to produce a research cell bank for each vaccine candidate. To generate the banks, a selected clone was grown in LB media, supplemented with 0.5% Glucose, and 25 µg/mL kanamycin. Cells were frozen in 1 mL cryovials at -60 to -80 °C following the addition of glycerol to 7% final concentration. In protein expression studies, proteins corresponding to the expected molecular weights of the vaccine candidates were easily visualized by Coomassie Blue staining and by Western blot analyses using an anti-flagellin monoclonal antibody.

#### Protein Production

The constructs described below are all comprised of combinations of *Salmonella typhimurium* *fliB* flagellin (STF2) and a portion of the globular head domain of the protective hemagglutinin antigen from the novel H1N1 emerging in 2009 (A/California 07/2009).

**Manufacture of VAX128A**

A pET24a plasmid encoding production of STF2.HA1-2 CA07 is used to transform commercially available *E. coli* BLR(DE3) cells. These cells are expanded to manufacture both research and cGMP master cell banks. To produce the target protein, a vial of banked cells was expanded in shake flasks using synthetic media and grown to a specific optical density. A specific amount of cells were then transferred to a bioreactor containing a different synthetic media. The bioreactor was run under automatic control (T=30C, pH = 7, DO >= 30%) in batch mode until the glucose was exhausted. At that point a synthetic feed media is added to the bioreactor at a specific flow rate. After three hours, target protein production was initiated in the culture by addition of IPTG to a concentration of 2 mM. The cells were harvested four hours after induction and the cell paste separated from the conditioned media by centrifugation. After freezing and thawing, the cells were re-suspended in a Tris acetate buffer and lysed by high pressure homogenization. The lysate supernatant was collected after centrifugation. Proteins were precipitated using 14% PEG, and then re-suspended in 6M urea at pH 4. After adjusting the solution pH to 8, the buffer was exchanged into a Tris/acetate buffer by TFF. Triton X-114 and PEG were added and the resulting solution separated into detergent and aqueous phases by centrifugation. The aqueous phase was retained and filtered. Proteins were denatured by addition of urea and diluted to a concentration of 2 grams per liter protein in a 6 molar urea solution at pH 8. Target protein was refolded in batch mode by a ten-fold dilution into a refolding buffer. Initial purification of active, monomeric vaccine was performed by bind and elute anion exchange chromatography, with target protein and impurity elution effected by increasing salt concentration in a step-wise fashion. After filtration and pH adjustment of the AEX eluate to 6.8, active, monomeric vaccine was further purified by utilizing a hydroxyapatite (CHT) chromatography media in binding mode. Elution of impurities and target protein was effected by increasing phosphate concentration in steps. After filtration, the material was buffer-exchanged into a formulation buffer by TFF and dilution, filtered, aliquoted, and stored at -70C. The resulting bulk drug substance was diluted to the target drug product concentration in the same formulation buffer and stored at -70C prior to administration.

**Manufacture of VAX128B**

A pET24a plasmid encoding production of STF2R3.HA1-2 CA07 was used to transform commercially available *E. coli* BLR(DE3) cells. These cells were expanded to manufacture both research and cGMP master cell banks. To produce the target protein, a vial of banked cells was expanded in

shaker flasks using synthetic media and grown to a specific optical density. A specific amount of cells were then transferred to a bioreactor containing a different synthetic media. The bioreactor was run under automatic control (T=30C, pH = 7, DO >= 30%) in batch mode until the glucose was exhausted. At that point a synthetic feed media was added to the bioreactor at a specific flow rate. After three hours, target protein production was initiated in the culture by addition of IPTG to a concentration of 2 mM. The cells were harvested four hours after induction and the cell paste separated from the conditioned media by centrifugation. After freezing and thawing, the cells were re-suspended in a Tris acetate buffer and lysed by high pressure homogenization. The lysate pellet was collected after centrifugation, re-suspended in a phosphate buffer, and collected again by subsequent centrifugation. The pellet resuspension and collection process was repeated and the washed pellet was solubilized in a 6M urea buffer at pH 8. After mixing, solubilized proteins were recovered by centrifugation and diluted to 2 grams protein per liter of solution. The target protein was refolded into its proper conformation by rapidly diluting the denatured proteins into a nine fold excess of refolding buffer under flow. The denatured protein solution and refolding buffer were mixed in line at a 1 to 9 flow rate ratio, held for an average of 30 minutes before loading on an anion exchange chromatography column. Active, monomeric vaccine was bound to the AEX media with target protein and impurity elution effected by increasing salt concentration in steps. After filtration, the anion exchange elution was diluted 10% with water and loaded onto a different anion exchange chromatography column for further purification. Elution of impurities and target protein was effected by increasing Tris/acetate concentration in steps. After filtration, the material was buffer-exchanged into a formulation buffer by TFF and dilution, filtered, aliquoted, and stored at -70C. The resulting bulk drug substance was diluted to the target drug product concentration in the same formulation buffer and stored at -70C prior to administration.

#### Manufacture of VAX128C

A pET24a plasmid encoding production of STF2R3.2xHA1-2 CA07 was used to transform commercially available *E. coli* BLR(DE3) cells. These cells were expanded to manufacture both research and cGMP master cell banks. To produce the target protein, a vial of banked cells was expanded in shaker flasks using synthetic media and grown to a specific optical density. A specific amount of cells were then transferred to a bioreactor containing a synthetic media. The bioreactor was run under automatic control (T=30C, pH = 7, DO >= 30%) in batch mode until the glucose was exhausted. At that point a synthetic feed media was added to the bioreactor at a specific flow rate. After three hours,

target protein production was initiated in the culture by addition of IPTG to a concentration of 2 mM. The cells were harvested four hours after induction and the cell paste separated from the conditioned media by centrifugation. After freezing and thawing, the cells were re-suspended in a Tris/acetate buffer and lysed by high pressure homogenization. The lysate pellet was collected after centrifugation, re-suspended in a phosphate buffer, and collected again by subsequent centrifugation. The pellet re-suspension and collection process was repeated and the washed pellet was solubilized in a 6M urea buffer at pH 8. After mixing, solubilized proteins were recovered by centrifugation and diluted to 2 grams protein per liter of solution. Target protein was refolded in batch mode by a ten-fold dilution into a refolding buffer. Initial purification of active, monomeric vaccine was performed by bind and elute anion exchange chromatography, with impurity and target protein elution effected by increasing salt concentration in steps. After filtration and pH adjustment of the AEX eluate to 6.8, active, monomeric vaccine was further purified by utilizing a hydroxyapatite (CHT) chromatography media in binding mode. Elution of impurities and target protein was effected by increasing phosphate concentration in a step-wise fashion. After filtration, the material was buffer exchanged into a formulation buffer by TFF and dilution, filtered, aliquoted, and stored at -70C. The resulting bulk drug substance was diluted to the target drug product concentration in the same formulation buffer and stored at -70C prior to administration.

#### Synthetic shake flask media

Component	Amount
Water	940 mL
KH <sub>2</sub> PO <sub>4</sub>	7.8 g/L
Citric Acid	1.0 g/L
(NH <sub>4</sub> ) <sub>2</sub> SO <sub>4</sub>	2.33 g/L
Trace Metals Solution	1.0 mL/L
Thiamine HCl	0.01 g/L
Glucose	10 g/L
MgSO <sub>4</sub>	1 g/L
CaCl <sub>2</sub>	0.04 g/L
Kanamycin	0.0075 g/L
10N NaOH	As needed to adjust final pH to 7.0-7.2

## Synthetic bioreactor media

Component	Amount
Water	As needed to obtained calculated final volume
$\text{KH}_2\text{PO}_4$	2.2 g/L
$(\text{NH}_4)_2\text{SO}_4$	4.5 g/L
Citric Acid	1.0 g/L
Trace Metals Solution	1.0 mL/L
Thiamine HCl	0.01 g/L
Antifoam	100 $\mu\text{L}$ per L
10N NaOH	As needed to adjust base MRBR to pH to 6.0-6.5
Glucose	20 g/L
$\text{MgSO}_4$	1 g/L
$\text{CaCl}_2$	0.04 g/L
Kanamycin	0.0075 g/L
10N NaOH Solution	As needed to adjust final MRBR to pH to 6.0-6.5

## Synthetic feed media

Component	Amount
Water	As needed to obtained calculated final volume
Dextrose	180.0 g/L
L-Alanine	40.0 g/L
$\text{KH}_2\text{PO}_4$	1.5 g/L
$(\text{NH}_4)_2\text{HPO}_4$	10.0 g/L
$\text{NaH}_2\text{PO}_4$	4.0 g/L
$(\text{NH}_4)_2\text{SO}_4$	5.0 g/L

Component	Amount
Citric Acid	4.0 g/L
Sulfuric Acid	As needed to adjust pH to 5.0-5.4
MgSO <sub>4</sub>	2.3 g/L
Trace Metals Solution	6 mL/L
CaCl <sub>2</sub>	2 g/L
Thiamine HCl	0.01 g/L
FeSO <sub>4</sub>	0.25 g/L
10N NaOH Solution	As needed to adjust pH to 5.95-6.05

## Trace Metals Solution

Component	Amount
Water	As needed to obtained calculated final volume
EDTA	5.0 g/L
FeSO <sub>4</sub> · 7H <sub>2</sub> O	10.0 g/L
ZnSO <sub>4</sub> · 7H <sub>2</sub> O	2.0 g/L
MnSO <sub>4</sub> · H <sub>2</sub> O	2.0 g/L
CoCl <sub>2</sub> · 6H <sub>2</sub> O	0.2 g/L
CuSO <sub>4</sub> · 5H <sub>2</sub> O	0.1 g/L
Na <sub>2</sub> MoO <sub>4</sub> · 2H <sub>2</sub> O	0.2 g/L
H <sub>3</sub> BO <sub>3</sub>	0.1 g/L
Sulfuric Acid	As needed to remove precipitate

## Formulation buffer (pH7)

Component	Amount
Tris	10 mM
Histidine	10 mM

Component	Amount
Trehalose	5% (w/v)
NaCl	150 mM
Polysorbate-80	0.02% (w/v)
EDTA	0.1 mM
Ethanol	0.5% (v/v)
WFI	q.s.

### Example 3

#### *Phase I Escalating Dose Ranging Study of Vax 128 A, B, C*

A Phase I escalating dose ranging study to evaluate the safety and immunogenicity of VAX128 A, B, and C H1N1 influenza vaccine constructs in healthy adults 18-49 years of age and in adults  $\geq 65$  years of age was conducted. These 3 novel influenza vaccine constructs are comprised of the globular head of the HA1 domain of the A/California/07, Novel H1N1 (VAX128) genetically fused to the TLR5 ligand, flagellin, and produced in *E. coli*. In Vax128A the HA1 was fused to the C-terminus of flagellin, while in VAX128B HA1 replaced the D3 domain of flagellin and in VAX128C HA1 was replaced the D3 domain and was fused to the C-terminus. Vaccine was supplied in glass vials at either 20  $\mu\text{g}/\text{mL}$  or 2  $\mu\text{g}/\text{mL}$ , and diluted in dilution buffer (150mM NaCl with histidine and trehalose) to the final concentration on the day of administration. Study materials were prepared by non-blinded pharmacists and provided to blinded clinical staff. Vaccine was administered at a final volume of 0.5 mL by deep intramuscular injection in the deltoid muscle.

116 healthy adult subjects 18-49 and 100 healthy adults  $\geq 65$  years old were enrolled in a double blind, placebo controlled clinical trial conducted at two centers. Subjects received one of the 3 VAX128 vaccine constructs or placebo in a dose escalation study in a ratio of 3:3:3:1. Vaccines were administered IM at doses ranging from 0.5-20  $\mu\text{g}$ . Subjects were followed for safety and sera were tested by hemagglutination-inhibition (HAI) against egg-grown virus on days 0, 7, 14, and 28. Serum C-reactive protein (CRP), cytokine levels, and anti-flagellin antibody were also assessed.

In young adults, the maximum tolerated dose (MTD) for VAX128A was 8 µg and VAX128B 16µg. VAX128C was safe at 20µg, the highest dose tested (Table 13). Serum antibody responses were seen by HAI after doses as low as 0.5 µg. Doses of 1.25 µg to 2.5 µg induced a GMT of 1:250 with over 90% seroconversion and seroprotection (Table 15a and 15b). In adults ≥ 65 years, all three vaccines were safe at the highest doses tested of 8 µg, 12 µg and 20 µg for VAX128A, B and C, respectively (Table 14). Doses of 2.5 to 4 µg were associated reciprocal HAI titers of 70-180 and doses of 8-16 µg were associated HAI titers of 60 to 370 (Table 16). Table 17 shows the immune response by age cohort and table 18 shows the response for each individual tested that was 65 year of age and older.

Altering the configuration of the HA1 and flagellin was used to produce influenza vaccines that are safe with a large therapeutic window. VAX128C with two copies of the HA1 globular head had the highest MTD and was the most immunogenic. The globular head of the influenza HA expressed in a prokaryotic system was able to induce a functional antibody response. Vigorous responses were seen at relatively low doses of HA antigen indicating that the addition of flagellin provided a substantial adjuvanting effect.

Within this disclosure, any indication that a feature is optional is intended provide adequate support (e.g., under 35 U.S.C. 112 or Art. 83 and 84 of EPC) for claims that include closed or exclusive or negative language with reference to the optional feature. Exclusive language specifically excludes the particular recited feature from including any additional subject matter. For example, if it is indicated that A can be drug X, such language is intended to provide support for a claim that explicitly specifies that A consists of X alone, or that A does not include any other drugs besides X. "Negative" language explicitly excludes the optional feature itself from the scope of the claims. For example, if it is indicated that element A can include X, such language is intended to provide support for a claim that explicitly specifies that A does not include X. Non-limiting examples of exclusive or negative terms include "only," "solely," "consisting of," "consisting essentially of," "alone," "without", "in the absence of (e.g., other items of the same type, structure and/or function)" "excluding," "not including", "not", "cannot," or any combination and/or variation of such language.

Similarly, referents such as "a," "an," "said," or "the," are intended to support both single and/or plural occurrences unless the context indicates otherwise. For example "a dog" is intended to include support for one dog, no more than one dog, at least one dog, a plurality of dogs, etc. Non-limiting

examples of qualifying terms that indicate singularity include "a single", "one", "alone", "only one", "not more than one", etc. Non-limiting examples of qualifying terms that indicate (potential or actual) plurality include "at least one", "one or more", "more than one", "two or more", "a multiplicity", "a plurality", "any combination of", "any permutation of", "any one or more of," etc. Claims or descriptions  
5 that include "or" between one or more members of a group are considered satisfied if one, more than one, or all of the group members are present in, employed in, or otherwise relevant to a given product or process unless indicated to the contrary or otherwise evident from the context.

Where ranges are given herein, the endpoints are included. Furthermore, it is to be understood  
10 that unless otherwise indicated or otherwise evident from the context and understanding of one of ordinary skill in the art, values that are expressed as ranges can assume any specific value or subrange within the stated ranges in different embodiments of the invention, to the tenth of the unit of the lower limit of the range, unless the context clearly dictates otherwise.

15 All publications and patents cited in this specification are herein incorporated by reference as if each individual publication or patent were specifically and individually indicated to be incorporated by reference. The citation of any publication is for its disclosure prior to the filing date and should not be construed as an admission that the present invention is not entitled to antedate such publication by virtue of prior invention.

20 While this invention has been particularly shown and described with references to example embodiments thereof, it will be understood by those skilled in the art that the various changes in form and details may be made therein without departing from the scope of the invention encompassed by the appended claims.

25

## Claims

What is claimed is:

1. A method of stimulating an immune response in a human, comprising the step of administering to the human a composition that includes a fusion protein comprising at least a portion of at least one flagellin and at least a portion of at least one antigen, wherein the fusion protein is administered to the human in a dose greater than about a 0.5µg dose and the human is at least 49 years old.
2. The method of claim 1, wherein administration of the composition to the human provides protective immunity against an infection consequent to exposure of the human to a source of antigen.
3. The method of claim 1, wherein the human is between 49 years old and about 64 years old.
4. The method of claim 1, wherein the human is at least 65 years old.
5. The method of claim 1, wherein the dose is at least one dose selected from the group consisting of a 0.5 µg dose, 1 µg dose, 2 µg dose, 3 µg dose, 4 µg dose, 5 µg dose, 6 µg dose, 7 µg dose, 8µg dose, 10µg dose, 15µg dose, 20µg dose, 25µg dose and a 30µg dose.
6. The method of claim 5, wherein the dose is at least one dose selected from the group consisting of a 0.5 µg dose, 1 µg dose, 2 µg dose, 3 µg dose, 4 µg dose, 5 µg dose, 6 µg dose, 7 µg dose, and 8µg dose.
7. The method of claim 5, wherein the dose is at least one dose selected from the group consisting of a 5 µg dose, 6 µg dose, 7 µg dose, 8µg dose, 10µg dose, 15µg dose, 20µg dose, 25µg dose and a 30µg dose.
8. The method of claim 1, wherein the dose is at least one dose selected from the group consisting of an 8µg dose, 10µg dose, 15µg dose, 20µg dose, 25µg dose and a 30µg dose.
9. The method of claim 1, wherein the antigen is an influenza antigen.
10. The method of claim 9, wherein the influenza antigen is a hemagglutinin influenza antigen.
11. The method of claim 9, wherein the influenza antigen is an influenza A antigen.

12. The method of claim 9, wherein the influenza antigen is an influenza B antigen.
13. The method of claim 9, wherein the influenza antigen is an influenza C antigen.
14. The method of claim 1, wherein the fusion protein is administered intramuscularly to the human.
- 5 15. The method of claim 1, further including the step of administering at least one subsequent dose of the fusion protein to the human.
16. The method of claim 8, wherein the fusion protein includes SEQ ID No. 1.
17. A method of stimulating an immune response in an elderly human population, comprising the step of administering to the human population a composition that includes a fusion protein  
10 comprising at least a portion of at least one flagellin and at least a portion of at least one antigen, wherein the seroresponse rate is at least 75%.
18. A method of stimulating an immune response in an elderly human population, comprising the step of administering to the human population a composition that includes a fusion protein  
15 comprising at least a portion of at least one flagellin and at least a portion of at least one antigen, wherein the seroprotection rate is at least 95%.
19. A method of stimulating an immune response in an elderly human population, comprising the step of administering to the human population a composition that includes a fusion protein  
comprising at least a portion of at least one flagellin and at least a portion of at least one antigen, wherein the seroconversion rate is at least 50%.
- 20 20. A method of stimulating an immune response in an elderly human population, comprising the step of administering to the human population a composition that includes a fusion protein  
comprising at least a portion of at least one flagellin and at least a portion of at least one influenza antigen.
- 25 21. A method of stimulating an immune response in a human, comprising the step of administering to the human a composition that includes comprising at least a portion of at least one flagellin and at least a portion of at least one antigen associated with a particle, wherein the human is at least 49 years old.

22. The method of claim 18, wherein the particle is a virosome, liposome, biodegradable microsphere, self-assembling peptide nanoparticle, virus-like particle or combinations thereof.
23. The method of claim 22, wherein the particle is a self-assembling peptide nanoparticle.
24. The method of claim 22, wherein the particle is a virosome.
- 5 25. The method of claim 19, wherein administration of the composition to the human provide protective immunity against an infection consequent to exposure of the human to a source of antigen.
26. The method of claim 19, wherein the human is between 49 years old and about 64 years old.
27. The method of claim 19, wherein the human is at least 65 years old.
- 10 28. The method of claim 19, wherein the dose is at least one dose selected from the group consisting of a 8 $\mu$ g dose, 10 $\mu$ g dose, 15 $\mu$ g dose, 20 $\mu$ g dose, 25 $\mu$ g dose and a 30 $\mu$ g dose.
29. The method of claim 19, wherein the antigen is an influenza antigen.
30. The method of claim 24, wherein the influenza antigen is a hemagglutinin influenza antigen
31. The method of claim 24, wherein the influenza antigen is an influenza A antigen.
- 15 32. The method of claim 24, wherein the influenza antigen is an influenza B antigen.
33. The method of claim 24, wherein the influenza antigen is an influenza C antigen.
34. A method of stimulating an immune response in an elderly human population, comprising the step of administering to the human population a composition comprising at least a portion of at least one flagellin and at least a portion of at least one antigen, wherein the seroresponse rate
- 20 is at least 75%.
35. A method of stimulating an immune response in an elderly human population, comprising the step of administering to the human population a composition comprising at least a portion of at least one flagellin and at least a portion of at least one antigen, wherein the seroprotection rate is at least 95%.

36. A method of stimulating an immune response in an elderly human population, comprising the step of administering to the human population a composition comprising at least a portion of at least one flagellin and at least a portion of at least one antigen, wherein the seroconversion rate is at least 50%.
- 5 37. A method of stimulating an immune response in an elderly human population, comprising the step of administering to the human population a composition comprising at least a portion of at least one flagellin and at least a portion of at least one influenza antigen.
38. The nucleic acid sequence as set forth in Seq ID 2.
39. The nucleic acid sequence as set forth in Seq ID 4.
- 10 40. The nucleic acid sequence as set forth in Seq ID 6.
41. The polypeptide sequence as set forth in Seq ID 3.
42. The polypeptide sequence as set forth in Seq ID 5.
43. The polypeptide sequence as set forth in Seq ID 7.
- 15 44. A method of stimulating an immune response in an elderly human population, comprising the step of administering to the human population a composition comprising at least 3 µg of SEQ ID No. 1, wherein the immune response produced by administration of the composition in an elderly population meets or exceeds one of the following criteria:
- a seroconversion rate of greater than 50%, greater than 60%, greater than 70%, greater than 80%, greater than 90%, greater than 95% or greater than 99%.
  - 20 - a seroprotection rate of greater than 50%, greater than 60%, greater than 70%, greater than 80%, greater than 90%, greater than 95% or greater than 99%.
  - an average four-fold or greater increase in neutralizing antibody titer at post vaccination.
