(54) Title: ANALOGUES FOR THE TREATMENT OR PREVENTION OF FLAVIVIRUS INFECTIONS
ANALOGUES FOR THE TREATMENT OR PREVENTION OF FLAVIVIRUS INFECTIONS

The present application claims the benefit under 35 U.S.C. § 119(e) of United States Provisional Application No. 61/290,030, filed December 24, 2009, and United States Provisional Application No. 61/316,998, filed March 24, 2010, both of which are hereby incorporated by reference in their entirety.

The present invention relates to novel compounds and a method for the treatment or prevention of Flavivirus infections using novel compounds.

Hepatitis is a disease occurring throughout the world. It is generally of viral nature, although there are other causes known. Viral hepatitis is by far the most common form of hepatitis. Nearly 750,000 Americans are affected by hepatitis each year, and out of those, more than 150,000 are infected with the hepatitis C virus ("HCV").

HCV is a positive-stranded RNA virus belonging to the Flaviviridae family and has close relationship to the pestiviruses that include hog cholera virus and bovine viral diarrhea virus (BVDV). HCV is believed to replicate through the production of a complementary negative-strand RNA template. Due to the lack of efficient culture replication system for the virus, HCV particles were isolated from pooled human plasma and shown, by electron microscopy, to have a diameter of about 50-60 nm. The HCV genome is a single-stranded, positive-sense RNA of about 9,600 bp coding for a polyprotein of 3009-3030 amino-acids, which is cleaved co- and post-translationally into mature viral proteins (core, E1, E2, p7, NS2, NS3, NS4A, NS4B, NS5A, NS5B). It is believed that the structural glycoproteins, E1 and E2, are embedded into a viral lipid envelope and form stable heterodimers. It is also believed that the structural core protein interacts with the viral RNA genome to form the nucleocapsid. The nonstructural proteins designated NS2 to NS5 include proteins with enzymatic functions involved in virus replication and protein processing including a polymerase, protease and helicase.

The main source of contamination with HCV is blood. The magnitude of the HCV infection as a health problem is illustrated by the prevalence among high-risk groups. For example, 60% to 90% of hemophiliacs and more than 80% of intravenous drug abusers in western countries are chronically infected with HCV. For intravenous drug abusers, the prevalence varies from about 28% to 70% depending on the population studied. The
proportion of new HCV infections associated with post-transfusion has been markedly reduced lately due to advances in diagnostic tools used to screen blood donors.

Combination of pegylated interferon plus ribavirin is the treatment of choice for chronic HCV infection. This treatment does not provide sustained viral response (SVR) in a majority of patients infected with the most prevalent genotype (1a and 1b). Furthermore, significant side effects prevent compliance to the current regimen and may require dose reduction or discontinuation in some patients.

There is therefore a great need for the development of anti-viral agents for use in treating or preventing Flavivirus infections.

![Diagram](image_url)
"Halogen atom or halo" is specifically a fluorine atom, chlorine atom, bromine atom or iodine atom.

The term "oxo" represents $=0$.

A dash ("-") that is not between two letters or symbols is used to indicate a point of attachment for a substituent. For example, $-\text{CONR}_\text{aR}_\text{b}$ is attached through the carbon of the amide.

A dash line ("-----") is used to indicate the point of attachment for the group. For example, A is attached through the carbon at position 1 and 4 in the following representation:

When there is a sulfur atom present, the sulfur atom can be at different oxidation levels, i.e., S, SO, or SO$_2$. All such oxidation levels are within the scope of the present invention.

The term "independently" means that a substituent can be the same or a different definition for each item.

In general, the term "substituted," whether preceded by the term "optionally" or not, refers to the replacement of hydrogen radicals on a carbon or nitrogen atom in a given structure with the radical of a specified substituent. Specific substituents are described above in the definitions and below in the description of compounds and examples thereof. Unless otherwise indicated, an optionally substituted group can have a substituent at each substitutable position of the group, and when more than one position in any given structure can be substituted with more than one substituent selected from a specified group, the substituent can be either the same or different at every position. For example, the language, "which is unsubstituted or substituted one or more times by R$^0$" means that when the group is substituted with more than one R$^0$ group, the R$^0$ groups can be different from each other. A ring substituent, such as a
heterocycle, can be bound to another ring, such as a cycloalkyl, to form a spiro-bicyclic ring system, e.g., both rings share one common atom.

As one of ordinary skill in the art will recognize, combinations of substituents envisioned by this invention are those combinations that result in the formation of stable or chemically feasible compounds. The term "stable", as used herein, refers to compounds that are not substantially altered when subjected to conditions to allow for their production, detection, and preferably their recovery, purification, and use for one or more of the purposes disclosed herein. In some embodiments, a stable compound or chemically feasible compound is one that is not substantially altered when kept at a temperature of 40°C or less, in the absence of moisture or other chemically reactive conditions, for at least a week. When two alkoxy groups are bound to the same atom or adjacent atoms, the two alkoxy groups can form a ring together with the atom(s) to which they are bound.

![Chemical structure](image)

In certain embodiment, a compound represented by:

also includes where the R group replaces the H on the nitrogen atom.

Additionally, unless otherwise stated, structures depicted herein are also meant to include compounds that differ only in the presence of one or more isotopically enriched atoms. For example, compounds of this invention, wherein one or more hydrogen atoms are replaced deuterium or tritium, or one or more carbon atoms are replaced by a $^{13}$C- or $^{14}$C-enriched carbon are within the scope of this invention. Such compounds are useful, for example, as analytical tools, probes in biological assays, or antiviral compounds with improved therapeutic profile.

The terms "host" or "patient" mean human male or female, for example child, adolescent or adult.
It will be appreciated that the amount of a compound of the invention required for use in treatment will vary not only with the particular compound selected but also with the route of administration, the nature of the condition for which treatment is required and the age and condition of the patient and will be ultimately at the discretion of the attendant physician or veterinarian. In general however a suitable dose will be in the range of from about 0.1 to about 750 mg/kg of body weight per day, for example, in the range of 0.5 to 60 mg/kg/day, or, for example, in the range of 1 to 20 mg/kg/day.

The desired dose may conveniently be presented in a single dose or as divided dose administered at appropriate intervals, for example as two, three, four or more doses per day.

The compound is conveniently administered in unit dosage form; for example containing 10 to 1500 mg, conveniently 20 to 1000 mg, most conveniently 50 to 700 mg of active ingredient per unit dosage form.

Ideally the active ingredient should be administered to achieve peak plasma concentrations of the active compound of from about 1 to about 75 μM, about 2 to 50 μM, about 3 to about 30 μM. This may be achieved, for example, by the intravenous injection of a 0.1 to 5% solution of the active ingredient, optionally in saline, or orally administered as a bolus containing about 1 to about 500 mg of the active ingredient. Desirable blood levels may be maintained by a continuous infusion to provide about 0.01 to about 5.0 mg/kg/hour or by intermittent infusions containing about 0.4 to about 15 mg/kg of the active ingredient.

When the compounds of the present invention or a pharmaceutically acceptable salts thereof is used in combination with a second therapeutic agent active against the same virus the dose of each compound may be either the same as or differ from that when the compound is used alone. Appropriate doses will be readily appreciated by those skilled in the art.

While it is possible that, for use in therapy, a compound of the invention may be administered as the raw chemical it is preferable to present the active ingredient as a pharmaceutical composition. The invention thus further provides a pharmaceutical composition comprising compounds of the present invention or a pharmaceutically acceptable derivative thereof together with one or more pharmaceutically acceptable
carriers therefore and, optionally, other therapeutic and/or prophylactic ingredients. The carrier(s) must be "acceptable" in the sense of being compatible with the other ingredients of the formulation and not deleterious to the recipient thereof.

Pharmaceutical compositions include those suitable for oral, rectal, nasal, topical (including buccal and sub-lingual), transdermal, vaginal or parenteral (including intramuscular, sub-cutaneous and intravenous) administration or in a form suitable for administration by inhalation or insufflation. The formulations may, where appropriate, be conveniently presented in discrete dosage units and may be prepared by any of the methods well known in the art of pharmacy. All methods include the step of bringing into association the active compound with liquid carriers or finely divided solid carriers or both and then, if necessary, shaping the product into the desired formulation.

Pharmaceutical compositions suitable for oral administration may conveniently be presented as discrete units such as capsules, cachets or tablets each containing a predetermined amount of the active ingredient; as a powder or granules; as a solution, a suspension or as an emulsion. The active ingredient may also be presented as a bolus, eectuary or paste. Tablets and capsules for oral administration may contain conventional excipients such as binding agents, fillers, lubricants, disintegrants, or wetting agents. The tablets may be coated according to methods well known in the art. Oral liquid preparations may be in the form of, for example, aqueous or oily suspensions, solutions, emulsions, syrups or elixirs, or may be presented as a dry product for constitution with water or other suitable vehicle before use. Such liquid preparations may contain conventional additives such as suspending agents, emulsifying agents, non-aqueous vehicles (which may include edible oils), or preservatives.

The compounds according to the invention may also be formulated for parenteral administration (e.g. by injection, for example bolus injection or continuous infusion) and may be presented in unit dose form in ampoules, pre-filled syringes, small volume infusion or in multi-dose containers with an added preservative. The compounds of this invention may be prepared in light of the specification using steps generally known to those of ordinary skill in the art. Those compounds may be analyzed by known methods, including but not limited to LCMS (liquid chromatography mass spectrometry) HPLC (high performance liquid chromatography) and NMR (nuclear magnetic resonance). It should be understood that the specific conditions shown below are only examples, and are not meant to limit the scope of the conditions that can be used for making compounds of this invention. Instead, this invention also includes conditions that would be apparent to those skilled in that art in light of this specification for making the compounds of this invention. Unless otherwise indicated, all variables in the following schemes are as defined herein. General Schemes:

Mass spec, samples were analyzed on a MicroMass Quattro Micro of MicroMass LCZ mass spectrometer operated in single MS mode with electrospray ionization. Samples were introduced into the mass spectrometer using chromatography. Mobile phase for all mass spec, analyses consisted of 10mM pH 7 ammonium acetate and a 1:1 acetonitrile-methanol mixture. Method A: Column gradient conditions were 5%-100% acetonitrile-methanol over 3.5 mins gradient time and 4.8 mins run time on an ACE5C8 3.0 x 75mm column. Flow rate was 1.2 ml/min. Method B: Column gradient were 5%-100% acetonitrile-methanol over 10 mins gradient time and 12 mins run time on a ACE5C8 4.6 x 150 mm column. Flow rate was 1.5 mL/min. As used herein, the term "Rt(min)" refers to the LCMS retention time, in minutes, associated with the compound. Unless otherwise indicated, the LCMS method utilized to obtain the reported retention time is as detailed above. If the Rt(min) is < 5 min method A was used, if the Rt(min) is >5 min then method B was used.

**General procedure 1:**

The diethynyl intermediate is prepared in 2 steps from the commercially available bis-halogenated aryl or heterocycle. A Sonogashira coupling with bis(trimethylsilylacetylene) using Cul and palladium catalysts in such solvents as DMF in presence of base such as TEA or DIPEA give the bis-trimethyl ethynyl silane intermediate. The silyl groups are hydrolyzed in presence of a base such as K$_2$CO$_3$ in MeOH to give the expected diethynyl intermediate.

The Sonogashira coupling reaction is a well established method for producing acetylene containing compounds. Conditions for such coupling are well known in the art and can be found for example in the examples of the present application, in Yamagushi et al. (Synlett 1999, No.5, 549-550), or in Tykwinski et al. Angew. Chem. Inte. Ed. 2003, 42, 1566-1 568.

**General procedure 2:**

The compound is formed from the diethynyl intermediate and the iodo or bromo imidazole intermediate by a Sonogashira coupling using Cul and palladium catalysts in solvents such as DMF in presence of base such as TEA or DIPEA.
In one embodiment, the halogen is iodo or bromo.

In one embodiment, the halogen is iodo.

**General procedure 3:**

Reduction of the triple bond is done under standard hydrogenation procedure as known by those of ordinary skill in the art. The compound having triple bonds is dissolved in a suitable solvent such as methanol and a catalytic amount of a 1M solution of HCl is added followed by a catalytic amount of 10% Pd/C. The reaction mixture is stirred at RT under 1 atmosphere of hydrogen until completion of the reaction, filtered and the filtrate concentrated to dryness to afford the alkyl derivatives.

**General procedure 4:**

Reduction of the triple bonds to double bonds could be done under standard hydrogenation procedure as known in the art. Such conditions are described for example in the following references:

Alternatively, the compound is formed from the diethynyl intermediate and the protected iodo or bromo imidazole intermediate by a Sonogoshira coupling using Cul and palladium catalysts in solvents such as DMF in presence of base such as TEA or DIPEA. Removal of the protecting group optionally followed by coupling with the complimentary functionalized X-R5’ or Y-R5 group can be accomplished under standard reaction conditions known in the art.

In one embodiment, the halogen is iodo or bromo.

In one embodiment, the halogen is iodo.

In one embodiment, the protecting group is tert-butoxycarbonyl.

Mass spec, samples were analyzed on a Micromass Platform LCZ mass spectrometer operated in single MS mode with electrospray ionization. Samples were introduced into the mass spectrometer using chromatography. Mobile phase for all mass spec, analyses consisted of H₂O+0.01%TFA and CH₃CN+0.01%TFA. Method: Column gradient conditions were 5%-85%CH₃CN+0.01%TFA in 20 minutes gradient time on a SymmetryShield RP18 3.5um, 2.1x50mm column. Flow rate was 0.5mL/minute. As used herein, the term "Rt(minute)" refers to the LCMS retention time, in minutes, associated with the compound. Unless otherwise indicated, the LCMS method utilized to obtain the reported retention time is detailed above.

Intermediate 18 : method A

(3S,5S)-tert-butyl 5-(5-iodo-1H-imidazol-2-yl)-3-methyl-2-oxopyrrolidine-1-carboxylate

Step I:
(2S,4S)-tert-butyl 2-formyl-4-methylpyrrolidine-1-carboxylate
4-Methyl- \( N \)-(t-butoxycarbonyl)- (2S)-prolinol is oxidized to (2S,4S)-tert-butyl 2-formyl-4-methylpyrrolidine-1-carboxylate under standard oxidizing conditions known in the art for oxidizing an alcohol to an aldehyde (e.g., TEMPO/bleach).

Step II:

The (2S,4S)-tert-butyl 2-formyl-4-methylpyrrolidine-1-carboxylate is converted to the (2S,4S)-tert-butyl 2-(1H-imidazol-2-yl)-4-methylpyrrolidine-1-carboxylate using ammonium hydroxide and glyoxal in methanol (see Intermediate 3, Step I).

Step III:
(2S,4S)-tert-butyl 2-(4,5-diido-1H-imidazol-2-yl)-4-methylpyrrolidine-1-carboxylate
The (2S,4S)-tert-butyl 2-(1H-imidazol-2-yl)-4-methylpyrrolidine-1-carboxylate is reacted with \( N \)-iodosuccinimide to afford the bis-iodoimidazole (2S,4S)-tert-butyl 2-(4,5-diido-1H-imidazol-2-yl)-4-methylpyrrolidine-1-carboxylate (see Intermediate 3, Step II).

Step IV:
(2S,4S)-tert-butyl 2-(5-iodo-1H-imidazol-2-yl)-4-methylpyrrolidine-1-carboxylate
The 4-iodo substituent of (2S,4S)-tert-butyl 2-(4,5-diiodo-1H-imidazol-2-yl)-4-methylpyrrolidine-1-carboxylate is selectively removed by metallation, preferably with isopropyl magnesium chloride, followed by a quench with a proton source such as water to afford the mono-iodoimidazole (2S,4S)-tert-butyl 2-(5-iodo-1H-imidazol-2-yl)-4-methylpyrrolidine-1-carboxylate (see Intermediate 3, Step III).

Intermediate 18: method B

Methyl N-[(1S)-1-[(2S,4S)-2-(5-iodo-1H-imidazol-2-yl)-4-methyl-pyrrolidine-1-carbonyl]-2-methyl-propyl]carbamate

Step I:

In a 2L Parr flask under nitrogen, a solution of (2S)-1-tert-butoxycarbonyl-4-methylene-pyrrolidine-2-carboxylic acid (175 g, 770.1 mmol) in ethanol (700 mL) is added Pt0$_2$ (5.250 g, 23.12 mmol). The suspension is purged 3 times, (vacuum/hydrogen) and stirred at rt on a Parr apparatus under 30-40 psi of hydrogen. The Initial H$_2$ consumption is rapid and then the reaction is completed after 60 minutes. The catalyst is decanted and the supernatant is cannulated in 1L Erlenmeyer, then filtered through Celite and washed with ethanol. The mother liquor is put aside. The reaction is repeated 7 times using a total of 8.8 g of Pt0$_2$. The reaction mixtures of the 7 runs are combined (ratio of cis/trans 3.6/1) and evaporated to a volume of 3 L. Isopropyl acetate (1.5 L) is added and 2 L of the solution is evaporated. Isopropyl acetate (1.5 L) is added and 1 L of the solution is evaporated. The compound is started to crystallize in the solution, heptane (1.5 liters) and isopropyl acetate (1L) are added and the suspension is stirred at rt for 1 hour and then at 0°C for 2 hours. The mixture is filtered and washed with a cold solution of 2:1 heptane/isopropyl acetate (1L). The cake is dried for 2 hours, then put in the
vacuum oven yielding (2S)-1-tert-butoxycarbonyl-4-methyl-pyrrolidine-2-carboxylic acid; 883.44 g (71% yield) as a pale gray crystalline powder, 9:1 (S:R).

The crude product (850 g) is recrystallized in isopropyl acetate (2 volume) and heptane (1 volume). The recrystallization process is repeated 2 times to reach a ratio of 23/1 (S:R).

Step II:

In a 22 L, 3 neck round bottom flask under nitrogen equipped with a thermocouple, an addition funnel and a mechanical stirrer (2S,4S)-1-tert-butoxycarbonyl-4-methyl-pyrrolidine-2-carboxylic acid (672 g, 2.931 mol) and THF (4 L) are added and cooled in an ice bath until the internal temperature is about 3°C. The Borane/THF solution (5.527 kg, 6.155 L of 1 M, 6.155 mol) is added dropwise over 3.5 hours using the addition funnel. An exotherm of 10°C and a very strong gas formation are occurred during the addition of the first 1800 mL. The reaction mixture is stirred overnight at room temp. TLC: (25% EtOAC/Hexane) shows no starting material. Then 1 L of a saturated aqueous solution of NH₄Cl is carefully added (dropwise) at 4°C. An exotherm of 20°C and a very strong gas formation are observed. H₂O (5000 mL) is added and the mixture is extracted with EtOAc (2 L), the phases are separated and the aqueous phase is re-extracted with EtOAc (2L). The organic phases are merged and the solvent is evaporated. The residual mixture is added EtOAc (3 L) and the phases are separated and dried over Na₂SO₄, filtered and concentrated to a small volume. The residual solution contains water and a white solid. The mixture is transferred to a 5L extraction funnel and added EtOAc (1L) and water (500 mL). The organic phase is dried over sodium sulfate and the mixture is stirred for 30 minutes, filtered and evaporated to dryness. The residue is purified by a plug of silica gel using 0 to 30% EtOAc/Hexanes as eluant to give tert-butyl (2S,4S)-2-(hydroxymethyl)-4-methyl-pyrrolidine-1-carboxylate (604 g, 2.806 mol, 95% yield).

Step III:

In a 12L of three-neck RBF under nitrogen equipped with a mechanical stirrer, a thermocouple and a 2L addition funnel, oxaly chloride (2.2 kg, 1.52 L of 2 M, 3.05 mol) and CH₂Cl₂ (2.1 L) are added. The solution is cooled to -78°C in an acetone/dry ice bath while stirring. The DMSO (476.6 g, 432.9 mL, 6.1 mol) is added dropwise using the addition funnel, while keeping the internal temp around -67±5°C. A solution of tert-butyl (2S,4S)-2-(hydroxymethyl)-4-methyl-pyrrolidine-1-carboxylate (262.65 g, 1.22 mol) in CH₂Cl₂ (1.8 L) is added and the mixture is stirred for 20 minutes at -75±5°C. Finally DIPEA
(1.57 kg, 2.13 L, 12.2 mol) is added over 90 minutes keeping the internal temp at -73 ± 2°C. The reaction mixture is stirred for 2 hours at -76±2°C and then the temperature is raised to room temp over 2 hours. A solution of HCl 1N (3400 ml) is slowly added using an addition funnel, an exotherm of 6°C is observed, the phases are separated (aqueous pH=8) and the HCl washing procedure is repeated until the pH of the aqueous phase is below 2. The organic phase is dried using Na₂SO₄, filtered and concentrated to give a yellow oil (300 g). The Swern reaction was repeated on the same scale and the two crude reactions are combined and purified together. The residue is purified by a plug of silica gel using 0 to 15% EtOAc in Hexanes as eluant to give tert-butyl (2S,4S)-2-formyl-4-methyl-pyrrolidine-1 -carboxylate (480 g, 2.25 mol, 92.2%) as a golden oil.  

Step IV:

In a 5L 3 neck RBF under nitrogen equipped with a thermocouple, a refrigerant and an addition funnel, tert-butyl (2S,4S)-2-formyl-4-methyl-pyrrolidine-1 -carboxylate (480 g, 2.25 mol) and MeOH (960 ml) are added while stirring an exotherm of +20°C is observed. NH₄OH (960.0 mL) is added, an exotherm of 12°C is noted. Oxaldehyde (91.37 g, 722.3 mL of 40 %w/v, 4.98 mol) is added over 39 minutes using the addition funnel. A very big exotherm up to 70°C is observed. The reaction mixture is stirred overnight at room temperature. In the morning the reaction mixture is all solidified with no apparent liquid. Water (1.5 L) is added and stirred for 1 hour. The suspension is filtered on a Buchner funnel and washed with water (~2L) until the mother liquor is pale brown. The wet solid is transferred in a 12L RBF, then water (3L) is added and the suspension is stirred for 2 hours, filtered and washed with water (1.5 L) and heptane (1.5 L) and then dried for 2 days in a vacuum oven at 45°C. The crude gray solid contains 8% of 2-(1H-imidazol-2-yl)-1 H-imidazole as a side product impurity. The solid is transferred into a 12L 5 neck RBF, ethyl acetate (4L) is added and the mixture is refluxed. The water is azeotroped with ethyl acetate (1.5 L). The hot solution is filtered to remove the insoluble 2-(1H-imidazol-2-yl)-1 H-imidazole. The remaining solution is evaporated to 1L and then the suspension is stirred in an ice/bath, filtered and washed with cold ethyl acetate to give tert-butyl (2S,4S)-2-(1 H-imidazol-2-yl)-4-methyl-pyrrolidine-1 -carboxylate (330g, 1.31 mol, 58% yield) as a pale gray solid, 99.4% pure.  

Step V:

In a 12L 4 neck RBF under nitrogen equipped with mechanical stirrer, a thermocouple a refrigerant and an addition funnel, tert-butyl (2S,4S)-2-(1 H-imidazol-2-yl)-4-methyl-pyrrolidine-1 -carboxylate (334.4 g, 1.331 mol) and CH₂Cl₂ (3.344 L) are added while stirring. The solution is cooled to below 5°C using an ice bath. NIS (628.8 g, 2.795 mol) is
added in 6 batches of 104.8 g each over 30 minutes while keeping the internal temperature below 5°C. The reaction mixture is stirred for 2.5 hours and then HPLC shows the completion of the reaction. A solution of 10% sodium thiosulfate solution (4 L) is added and the reaction mixture is stirred for 15 minutes and the phases are separated. The organic phase is transferred back in the 12L reactor, water (2 L) and CH₂Cl₂ (1 L) are added, the mixture is stirred for 15 minutes. The organic phase is dried over sodium sulfate, filtered and evaporated to dryness to afford tert-butyl (2S,4S)-2-(4,5-diiodo-1 H-imidazol-2-yl)-4-methyl-pyrrolidine-1-carboxylate, (646.3 g, 93% yield, 96% purity). ¹H NMR (400 MHz, dmso, 2.5:1 mixture of rotamers), peaks for the major rotamer: δ 12.70 (s, 1 H), 4.57 (dd, 1 H), 3.62 - 3.52 (m, 1 H), 2.95 (t, 1 H), 2.35 - 2.0 (m, 2 H), 1.50 (dd, 1 H), 1.10 (s, 9 H), 1.01 (d, 3 H).

Step VI:
In a 5L 3 neck round bottom flask under nitrogen equipped with a mechanical stirrer, LiCl (54.09 g, 1.276 mol) and THF (2.504 L) are added and stirred at rt overnight. In a 12L 3 neck round bottom flask under nitrogen equipped with a temperature reader, a mechanical stirrer and an 1L addition funnel, tert-butyl (2S,4S)-2-(4,5-diiodo-1 H-imidazol-2-yl)-4-methyl-pyrrolidine-1-carboxylate (642 g, 1.276 mol) and LiCl solution in THF are added while stirring. The reaction mixture is cooled down to -20°C. To the beige suspension is added dropwise a solution of methyl magnesium chloride in THF (425.3 mL of 3 M, 1.276 mol) over 60 minutes keeping the internal temperature between -17 and -20°C. The reaction mixture is stirred at the same temperature for 20 minutes. A solution of isopropyl magnesium chloride in THF (1.276 L of 2 M, 2.552 mol) is added dropwise over 70 minutes while keeping the internal temperature between -17 and -23°C, then the mixture is slowly warmed up to rt. TLC 50% ETOAC/Hexane shows that the reaction is completed. The reaction mixture is cooled down in an ice/water bath to -10°C and a 10% aq. NH₄Cl solution (2 L) is added dropwise. An exotherm of 35°C and gas formation are observed. Water (1 L) and ethyl acetate (2L) are added and the mixture is stirred for 30 minutes. Step II
To a solution of (2S)-2-carboxy-4-(hydroxymethyl)pyrrolidin-1-ium chloride (13.24 mmol) (from step I) in THF (20 mL) and water (6.6 mL) are sequentially added NaOH (7.408 mL of 2.5 M, 18.52 mmol) and tert-butoxycarbonyl tert-butyl carbonate (2.761 g, 2.906 mL, 12.65 mmol). The reaction mixture is stirred at room temperature overnight. NaOH (aqueous 2.5 M, 1.25 mL) is then added to bring the pH to 10-11. THF is evaporated and the residue is washed with ether (2 x 2 mL) and the residue is then acidified with 1M HCl to bring the pH to 1. The mixture is extracted by EtOAc (5 x 20 mL) and the combined
organic layers are dried over Na$_2$SO$_4$, filtered and concentrated to dryness to give (2S)-1-(tert-butoxycarbonyl)-4-(hydroxymethyl)pyrrolidine-2-carboxylic acid (1.848 g, 84 %).

Step III
To a solution of (2S)-1-(tert-butoxycarbonyl)-4-(hydroxymethyl)pyrrolidine-2-carboxylic acid (1775 mg, 7.237 mmol) in DMF (17.75 mL) are sequentially added imidazole (1.084 g, 15.92 mmol) followed by TBDMSI (2.291 g, 2.828 mL, 15.20 mmol). The mixture is stirred overnight at room temperature. The reaction mixture is extracted by EtOAc (5 x 70 mL) and the combined organic layers are washed with H$_2$O (3 x 35 mL), dried over Na$_2$SO$_4$, filtered and concentrated to dryness. The residue is purified by flash column chromatography on silica gel (0 to 20% methanol in CH$_2$Cl$_2$) to give a mixture of mono and bis-silylated product. The product is dissolved in 5:1 methanol (10 mL) water and stirred for 1 hour. The mixture is concentrated to dryness and the residue is purified by flash column chromatography on silica gel (0 to 20% methanol in CH$_2$Cl$_2$) to give (2S)-1-(tert-butoxycarbonyl)-4-(((tert-butyldimethylsilyl)oxy)methyl)pyrrolidine-2-carboxylic acid (1.239 g, 88 %).

The mixture is stirred for 1 hour, warmed to room temperature and stirred for another 2 hours. The mixture is then cooled in an ice bath and diluted with 10% aqueous NH$_4$Cl (5 mL) followed by 10 mL of water. The reaction mixture is extracted by EtOAc (3 x 20 mL) and the combined organic layers are washed with H$_2$O (2 x 5 mL), dried over Na$_2$SO$_4$, filtered and concentrated to dryness. The residue is purified by flash column chromatography on silica gel (6 to 50 % EtOAc in hexane) to give (2S)-tert-butyl 4-(((tert-butyldimethylsilyl)oxy)methyl)-2-(hydroxymethyl)pyrrolidine-1-carboxylate (775 mg, 75 %).

A solution of (2S)-4-[[tert-butyl(dimethyl)silyl]oxyethyl]-2-(hydroxymethyl)pyrrolidine-1-carboxylate (722 mg, 2.089 mmol) in CH$_2$Cl$_2$ (8 mL) is then added and the mixture is stirred for another 30 minutes. DIPEA (1.619 g, 2.182 mL, 12.53 mmol) is added and the mixture is stirred for 30 minutes, warmed to room temperature, stirred again for 1 hour and diluted with 1 M aqueous HCl (30 mL). The layers are separated and the aqueous layer is extracted by CH$_2$Cl$_2$ (2 x 20 mL). The
combined organic layers are dried over Na$_2$SO$_4$, filtered, and concentrated to dryness. The residue is purified by flash column chromatography on silica gel (6 to 40 % EtOAc in hexane) to give (2S)-tert-butyl 4-(((tert-butyldimethylsilyl)oxy)methyl)-2-formylpyrrolidine-1-carboxylate (647 mg, 90 %).

The mixture is warmed gently to avoid strong bubbling and refluxed for 2 hours. The reaction mixture is then cooled to room temperature, methanol is evaporated and the residue is dissolved with water (10 mL). The reaction mixture is extracted by CH$_2$Cl$_2$ (2 x 15 mL) and the combined organic layers are dried over Na$_2$SO$_4$, filtered and concentrated to dryness. Activity determination using the ELISA and the sub-genomic replicon 1a cell line

The cell line W11.8 containing the sub-genomic HCV replicon of genotype 1a is used to determine the potency of the drugs. The RNA replication in presence of different drug concentrations is indirectly measured in this cell line by the level of NS5A protein content upon drug treatment for four days. It is shown that the level of the NS5A protein correlates well with the level of HCV RNA in the replicon cell line. Cells are split twice a week in order to keep the confluence state below 85% of the culture flask surface area. The culture media used for cell passaging consists of DMEM-10% foetal bovine serum with 100 UI/mL penicillin, 100 µg/mL streptomycin, 2 mM glutamine, 1 mM sodium pyruvate, non-essential amino acids (1x) and 600 µg/mL of G418 final concentrations. Monolayer of the W11.8 cells is trypsinized and cells are counted. Cells are diluted at 50,000 cells/mL with complete DMEM without G418, then approximately 5,000 viable cells (100 µL) are plated per well in a white opaque 96-well microtiter plate. After an incubation period of 2 - 4 hours at 37 °C in a 5% CO2 incubator, compounds are added at various concentrations. Drugs are resuspended in DMSO at a stock concentration of 10 mM. Then, drugs are serially diluted at twice the final concentration in the same medium.

One volume (100 µL) of each drug dilution is then added to each well that contains cells. A control compound is used as an internal standard for each plate assay. Sixteen wells are used as control (0% inhibition) without drug. Eight wells are used as background control (100% inhibition) containing 2 µM (final concentration) of the control drug that was shown to inhibit the NS5A expression at = 100% and is nontoxic to the cells. Values from 100% inhibited wells were averaged and used as the background value. Cells are further incubated for four days at 37° C in a 5% CO2 incubator. Following the incubation time of four days, the media is removed and wells are washed once with 150 µL of PBS at room temperature for five minutes. Cells are then fixed for five minutes using 150 µL per well of cold (-20 °C) fixative solution (50% methanol / 50% acetone mix). Cells are then washed twice with 150 µL of PBS (phosphate buffered saline) per well, following the addition of 150 µL of blocking solution, cells are incubated for one hour at 37 °C to block non-specific sites. The blocking solution is removed and cells are washed twice with 150 µL of PBS per well and once with 150 µL of PBSTS solution (PBS / 0.1% Triton X-100 / 0.02% SDS) per well. Then, 50 µL of mouse monoclonal anti-NS5A antibody (Santa Cruz, Cat. No. sc-52417) is added in each well, diluted 1/1,000 in the blocking solution and incubated at 4 °C overnight. Next day, media is removed and plates are washed five
times with 150 µL of PBS per well with five-minute incubations at room temperature. Then 50 µL per well of peroxidase-conjugated donkey anti-mouse antibody (Jackson Immunoresearch, Cat. No. 715-036-150) diluted 1/10,000 in the blocking solution is added and incubated at room temperature for three hours on a shaker (500 rpm). Plates are washed four times with 150 µL of PBSTS solution per well and once with 150 µL of PBS. Then, substrate solution (100 µL, SuperSignal ELISA Pico Chemiluminescent Substrate, Fisher Cat. No.37069) is added in each well and plates are incubated 60 minutes at room temperature prior to reading the luminescence (relative light units) on the Analyst HT plate reader. The percentage of inhibition at each drug concentration tested (in duplicate) is calculated. The concentration required to reduce viral replication by 50% (IC₅₀) is then determined from dose response curves using nonlinear regression analysis with the GraphPad Prism software, version 2.0 (GraphPad Software Inc., San Diego, CA, USA).

The Huh-5.2 cells contain the highly cell culture-adapted replicon l₃⁵⁰luc-ubi-neo/NS3-375.1 construct that carries, in addition to the neomycin gene, an integrated copy to the firefly luciferase gene (Krieger, N; Lohmann, V; Bartenschlager, R. Enhancement of hepatitis C virus RNA replication by cell culture-adaptive mutations. J. Virol. 2001, 75, 4614-4624). This cell line allows measurement of HCV RNA replication and translation by measuring luciferase activity. It has been previously shown that the luciferase activity tightly follows the replicon RNA level in these cells (Krieger, N; Lohmann, V; Bartenschlager, R. Enhancement of hepatitis C virus RNA replication by cell culture-adaptive mutations. J. Virol. 2001, 75, 4614-4624).

The Huh- ET cell line has the same features as those mentioned for Huh-5.2 cell line, except that ET cells are more robust and contain an adaptative mutation in the HCV NS4B gene instead of NSSA. Both cell lines are maintained in cultures at a sub-confluent level (<85%) as the level of replicon RNA is highest in actively proliferating cells. The culture media used for cell passaging consist of DMEM (Gibco BRL Laboratories, Mississauga, ON, Canada) supplemented with 10% foetal bovine serum with 1%
penicillin/streptomycin, 1% glutamine, 1% sodium pyruvate, 1% non-essential amino acids, and 180 µg/ml of G418 final concentration. Cells are incubated at 37°C, in an atmosphere of 5% CO₂ and passaged twice a week to maintain sub-confluence.

Approximately 3000 viable Huh-7 cells (100 µl) are plated per well in a white opaque 96-well microtiter plate. The cell culture media used for the assay is the same as described above except that it contains no G418 and no phenol red. After an incubation period of 3-4 hours at 37°C in a 5% CO₂ incubator, compounds (100 µl) are added at various concentrations. Cells are then further incubated for 4 days at 37°C in a 5% CO₂ incubator. Thereafter, the culture media is removed and cells are lysed by the addition of 95 µl of the luciferase buffer (luciferin substrate in buffered detergent). Cell lysates are incubated at room temperature and protected from direct light for at least 10 minutes. Plates are read for luciferase counts using a luminometer (Wallac MicroBeta Trilux, Perkin Elmer™, MA, USA).

The 50% inhibitory concentrations (IC₅₀s) for inhibitory effect are determined from dose response curves using eleven concentrations per compound in duplicate. Curves are fitted to data points using nonlinear regression analysis, and IC₅₀s are interpolated from the resulting curve using GraphPad Prism software, version 2.0 (GraphPad Software Inc., San Diego, CA, USA).

Table 1C shows comparative data for exemplary compounds of formula (I) (entries 1-3) and formula (IA) (entries 4-5). As is shown in the table, the compounds having a substituent at the 4-position of the pyrrolidine ring (i.e. compounds of the invention where R₄ and R₅ are methyl). Data shows IC₅₀ values against the sub-genomic replicon 1a cell line.
