1. An elastomeric high molecular weight substantially amorphous propylene homopolymer including:

a heptane soluble fraction from 30% to 70%;

said heptane soluble fraction having a melting point between 100°C and 115°C and a heat of fusion less than 2.0 cal./gm.; and

a diethyl ether soluble fraction from 35% to 55%;

said diethyl ether soluble fraction having no detectable melting point above 40°C., and inherent viscosity less than 1.0 dl./g. and being substantially free of isotactic crystallinity;

said homopolymer characterized by a melting point between 145°C and 165°C, a melt viscosity at 190°C. greater than 200,000 cps, and a heat of fusion between 4 cal./gm/ and 10 cal./gm.

Invention Title:
AMORPHOUS ELASTOMERIC PROPYLENE HOMOPOLYMERS

Our Ref : 225816
POF Code: 118275/91934

The following statement is a full description of this invention, including
the best method of performing it known to applicant(s):

AMORPHOUS ELASTOMERIC PROPYLENE HOMOPOLYMERS

TECHNICAL FIELD

This invention relates to an elastomeric substantially amorphous propylene homopolymer. The polymer has properties which make it applicable for use as a thermoplastic elastomer in a variety of applications including films and film compositions.

5

BACKGROUND OF THE INVENTION

Crystalline and amorphous polypropylenes are materials that are used in a wide variety of applications and billions of pounds of polypropylene homopolymers and copolymers are produced on an annual basis. Amorphous polypropylene is generally regarded as being predominantly comprised of an atactic propylene polymer. Alternatively, crystalline polypropylene is considered to be polypropylene that is comprised prevailingly of syndiotactic or isotactic polypropylene. The difference between isotactic, syndiotactic and atactic polypropylenes lies in the stereochemistries of the polymers. The substituent methyl groups of isotactic polypropylene are located on one side of the extended chain that makes up the polymer whereas syndiotactic propylene has methyl groups that alternate regularly from side to side. The regularity of the isotactic and syndiotactic structures allows the molecules to fit together well, resulting in a highly crystalline material. The methyl groups of atactic polypropylene, on the other hand, are distributed randomly along the polymer chain. Atactic polypropylenes are generally gummy materials of little strength that are used in the production of adhesives. The structure of isotactic,

syndiotactic and atactic polypropylene is illustrated on p. 1248 of Organic Chemistry by Morrison and Boyd, fifth edition.

5 Highly crystalline isotactic polypropylenes make up the majority of commercially available polypropylenes. The isotactic structure results in polypropylene with high stiffness and good tensile strength. Crystalline polypropylene, however, generally has a high tensile set and is not suitable for those applications where elastomeric properties are desirable.

10 In the past, the manufacture of propylene homopolymers and copolymers using conventional polymerization techniques and unsupported catalysts resulted in the simultaneous production of substantial quantities of atactic polymer in addition to the desired highly crystalline and predominantly isotactic product. Various methods were used to separate and purify the two products and the atactic by-product was used commercially as a component in adhesive compounds, roofing materials, caulking compounds and the like. Over the last decade, however, major advances have been made in catalysts for the production of isotactic polypropylene. The use of highly active stereospecific catalysts has resulted in the

production of isotactic homopolymers and copolymers that
do not require purification or removal of the atactic or
low crystalline polymer. The development of novel high
molecular weight atactic propylene polymers has, however,
5 received much less attention. A fractionable elastomeric
polypropylene having a high molecular weight diethyl ether-
soluble fraction that has about 0.5% to about 5% isotactic
crystallinity and an inherent viscosity exceeding 1.5 is
disclosed in U.S. Pat. No. 4,335,225 to Collette et al.,
10 issued June 15, 1982. This polymer does not, however, have
the properties of the novel polymer of the present
invention.

SUMMARY OF THE INVENTION

The present invention provides a novel high molecular weight amorphous propylene homopolymer that has elastic properties. A diethyl ether soluble fraction of the polymer has no isotactic crystallinity and an inherent viscosity less than about 1.0 dl/g. The polymer is produced with a solid supported catalyst component and an organoaluminum component. The polymer of the present invention has a molecular weight such that the melt viscosity of the polymer is greater than 200,000 cps at 190°C and the melt flow rate (MFR) at 230°C is less than, ^{about} 80 g/10 minutes. The polymer is a general purpose thermoplastic elastomer adaptable to a wide variety applications including films, filaments, fibers, sheet, molded articles, and other applications where elastomeric properties are desireable. The polymer may also be blended with other homopolymers and copolymers to produce blends having useful properties.

DETAILED DESCRIPTION

In accordance with the present invention there is provided a substantially amorphous high molecular weight propylene homopolymer. The terminology "high molecular weight" as used herein refers to polymers having a melt viscosity at 190°C greater than 200,000 cps or a melt flow rate (MFR) at 230°C less than 80 g/10 minutes. The polymer includes a diethyl ether soluble fraction ^{substantially free of} ~~that exhibits no~~ isotactic crystallinity and an inherent viscosity less than about 1.0 dl/g.

Isotactic crystallinity, as referred to herein, is determined by ¹³C Nuclear Magnetic Resonance (NMR). The ¹³C spectra are obtained at 125°C using a JEOL FX270 NMR spectrometer operating at a ¹³C frequency of 67.8 MHz with a proton decoupling of 269.65 MHz. A 12 microsecond pulse width (approximately 65°) and a 2.1 second pulse repetition rate is used for quantification. The samples are run as a solution of 0.1 gm of polymer in 2 ml of a 90/10 by weight solution of 1,2,4-trichlorobenzene and D₆-benzene. N-phenyl-1-naphthylamine is used as an antioxidant (approximately 0.04M).

When a sample of polypropylene is tested for isotactic content as set forth above and then cooled to

ambient temperature and held for 24 hours there may be a reduction in the area under the mmmm pentad peak if there is crystallization of sufficiently long isotactic sequences. The decrease in mmmm intensity is attributed to immobilization of isotactic pentads by crystallization and thereby provides a measure of the fraction of polymer crystallized. An NMR rigidity parameter is defined by Collette et al., MACROMOLECULES 22, 1358 (1989) as:

$$R_{nmr} = F_h - F_l(1 - F_h)/(1 - F_l)$$

Where F_h and F_l are the mmmm pentad fractions at the higher and lower temperatures, respectively. The relationship between

R_{nmr} and crystallinity is given as:

$$R_{nmr} = 0.006 + 0.016(\% \text{ crystallinity})$$

An R_{nmr} of less than or equal to zero would, therefore, indicate the absence of isotactic crystallinity.

The inherent viscosity of the polymer is determined by placing a 0.05 gm sample in 100 ml. of decahydronaphthalene containing 0.1 g/l BHT (2,6-di-*t*-butyl-4-methyphenol) and heating the sample to 135°C under nitrogen as it is stirred with a magnetic stirrer for two hours. The mixture is poured through a filter stick into a Cannon-Ubbelohda viscometer and its efflux time is

measured at 135°C. and compared with that of the solvent alone. The inherent viscosity is then calculated as:

$$\text{Inherent viscosity} = (\ln T/T_0)/C$$

Where T is the efflux time of the mixture, T₀ is the efflux
5 time of the solvent and C is the concentration of the polymer in grams/deciliter.

The solubility of the homopolymer in the solvents referred to herein is determined by placing a sample (6 grams) into a cellulose thimble. The thimble is placed
10 into a vertical cylindrical chamber in a round bottom glass flask containing the solvent. The solvent is heated to boiling and solvent vapors rise through an outer zone surrounding the cylindrical chamber and are cooled in a reflux condenser. The condensed solvent drips onto the
15 thimble and extraction continues for 16 hours. The portion of the sample extracted is the soluble portion.

Melting points and heats of fusion are measured with a Perkin Elmer DSC-2C Differential Scanning Calorimeter (DSC). Melting point is determined according to ASTM
20 method D-3481. Melt flow rates are measured using a Tinius-Olsen extrusion plastometer in accordance with ASTM

~~method D-1238. The propylene homopolymer of the present invention has a melting point between about 145°C and about~~

method D-1238.

According to the present invention there is provided an elastomeric high molecular weight substantially amorphous propylene homopolymer including:

5 a heptane soluble fraction from 30% to 70%;

said heptane soluble fraction having a melting point between 100°C. and 115°C. and a heat of fusion less than 2.0 cal./gm.; and

a diethyl ether soluble fraction from 35% to 55%;

10 said diethyl ether soluble fraction having no detectable melting point above 40°C., and inherent viscosity less than 1.0 dl./g. and being substantially free of isotactic crystallinity;

said homopolymer characterized by a melting point
15 between 145°C. and 165°C., a melt viscosity at 190°C. greater than 200,000 cps, and a heat of fusion between 4 cal./gm/ and 10 cal./gm.

20

25

30

35

~~165°C and a heat of fusion of from about 4 cal/gm to about~~
10 cal/gm. The polymer has a melt viscosity of from about
200,000 cps to greater than about 2,000,000 cps at 190°C
and a melt flow rate of from about 4 gm/10 minutes to about
5 80 gm/10 minutes at 230°C.

The propylene homopolymer of the present
~~invention comprises from about 35% to about 55% of a~~

~~diethyl ether soluble fraction.~~ The diethyl ether soluble
fraction exhibits no ¹³C isotactic crystallinity and has an
10 inherent viscosity less than about 1.0 dl/g. The ether
soluble fraction has no detectable melting point above
40°C., a further indication of the absence of
crystallinity.

The propylene homopolymer of the present
15 invention comprises from about 30% to about 70% of a
heptane soluble fraction. The heptane soluble fraction of
the homopolymer has a melting point between about 100°C.
and about 110°C. and a heat of fusion less than about 2.0
cal/gm. The heptane insoluble fraction of the homopolymer
20 has a melting point between about 145°C. and 165°C. and a
heat of fusion between about 10 cal./gm. and about 20
cal/gm.

The homopolymer of the present invention is prepared by a process which comprises polymerizing propylene monomer at a temperature between about 120°F and about 175°F in the presence of a particular catalyst composition. Polymerization should be conducted at a pressure sufficient to maintain propylene in the liquid phase, usually pressures in the range between about 400 psig and about 550 psig are suitable. The preferred temperature is between about 130°F and about 150°F.

Close control of the hydrogen concentration during the preparation of the homopolymer of the present invention is important to produce a polymer with a melt viscosity at 190°C greater than 200,000 cps. Preferably, no hydrogen is introduced during polymerization, producing a polymer with a melt viscosity at 190°C greater than 2,000,000 cps.

The catalyst composition used to polymerize the amorphous high molecular propylene homopolymer contains a solid, supported catalyst component and an organoaluminum component. The supported catalyst component is comprised of an active transition metal compound such as titanium tetrahalide mixed with an enhanced support comprised of magnesium halide and aluminum trihalide. The molar ratio

of magnesium halide to aluminum trihalide is about 8:0.5-3.0 and preferably about 8:1.0-1.5.

5 The molar ratio of magnesium halide to titanium tetrahalide is between about 8:0.1-1.0 and preferably about 8:0.4-0.6. The preferred magnesium halide is magnesium chloride. An important step in the preparation of the solid supported catalyst component is the exclusion of electron donor compounds. Additionally, polymerization of the homopolymer with the catalyst should be carried out in the absence of added electron donors.

10 The catalyst system used to prepare the homopolymer is a composition of:

(A) a solid catalyst component produced by the method comprising:

15 (i) co-comminuting magnesium halide support base and aluminum trihalide in a molar ratio from about 8:0.5 to about 8:3 in the absence of added electron donor; and

20 (ii) then co-comminuting the product of step (i) in the absence of added electron donor with sufficient titanium tetrahalide to provide a molar ratio of magnesium

halide to titanium tetrahalide from about
8:0.4 to about 8:1; and

(B) a trialkylaluminum co-catalyst component having
from 1 to 9 carbon atoms in each alkyl group
in a sufficient quantity to provide an Al/Ti
ratio in the range from about 50:1 to about
600:1.

Thus, the modified method involves co-communiting
magnesium halide and aluminum trihalide in the absence of
an electron donor and then co-communiting the catalyst
support so formed with titanium tetrahalide, also in the
absence of an electron donor.

The solid catalyst component is used in conjunction
with an organoaluminum co-catalyst, which is a
trialkylaluminum wherein each alkyl group contains between
1 and 9 carbon atoms. Preferably, the alkyl groups are
ethyl groups. The invention will be described hereinafter
in connection with the preferred catalyst system. The
molar ratio of organoaluminum co-catalyst to titanium-
containing catalyst component, i.e., Al/Ti ratio should
range between about 50:1 and about 600:1, preferably
between about 90:1 and about 300:1.

The polymerization is carried out in a stirred reactor at average residence times between about 1 hour and about 3 hours. Sufficient catalyst quantities are fed to the reactor to result in a polymer solids concentration in the reactor slurry of from about 10 wt % to about 50 wt %. The reactor effluent is withdrawn from the reactor, and unreacted monomer and hydrogen is flashed from the polymer.

Various additives can be incorporated into the polymer, such as antioxidants, U.V. stabilizers, pigments, etc.

An additional benefit of the polymer of this invention is that since the polymer contains small quantities of catalyst residues due to the high productivity rates of the specific catalyst used in the polymerization, there is no need to remove these small amounts of catalysts from the polymer.

The invention will be further described with respect to the following examples; however, the scope of the invention is not to be limited thereby.

Example 1

The experiment was performed in a 1-liter, jacketed autoclave equipped with a magnetically coupled stirrer. The temperature of the autoclave was controlled using a

mixture of equal weights of glycol and water as the heat transfer fluid flowing the jacket of the autoclave. The temperature of the fluid was controlled with a microprocessor connected to an iron/constantin thermocouple inside the autoclave. Set point temperature was maintained at $\pm 0.2^{\circ}\text{C}$. Propylene monomer was polymerization grade passed through molecular sieve beds, as well as beds of copper catalyst for oxygen removal prior to use. Triethylaluminum (TEA) was purchased as a 25% W/W in normal heptane and used as is. A 1% W/W slurry of the solid catalyst component was prepared using degassed mineral oil. Prior to use, the autoclave was heated to 90°C . with a slow nitrogen purge for 30 minutes, cooled to 30°C ., and purged with propylene vapor. The alkyl solution and catalyst slurry were prepared in septum vials in dry boxes and introduced into the reactor using hypodermic syringes.

1.98 ml. of TEA (25%) and 1.71 ml. of 1% catalyst slurry (2.5% W/W titanium content) were added to the reactor. 0.6 liters of propylene monomer (300 gm.) was introduced using a sight gauge and nitrogen pressure. The reactor content was heated to 60°C . and maintained for two hours while stirring at 500 rpm. After two hours, the temperature was rapidly lower and the unreacted propylene

vented. The polymer was dried under vacuum at 40°C. overnight. Test results are set forth in Table 1 below.

Example 2

Polymerization of propylene homopolymer was
5 conducted in a large scale continuous pilot plant
operation. Propylene monomer and catalyst components were
separately and continuously charged to a stirred reactor,
the monomer feed rate corresponding to about a two hour
residence time in the reactor. The organoaluminum compound
10 of the catalyst system was a 5% W/W heptane solution of
triethylaluminum (TEA). The solid supported titanium
tetrachloride catalyst had a titanium content of about 2.5%
W/W and was pumped into the reactor as a 6% W/W mixture in
petrolatum. The two catalyst components were added at
15 rates directly proportional to the polymer production rate
and in amounts sufficient to maintain the polymer solids
concentration in the reactor slurry in a range from about
10% to about 15%. The reaction temperature was maintained
throughout at about 140°F. (60°C.). The catalyst
20 efficiency was calculated from the polymer slurry
withdrawal rate, solids content in the slurry, and the
titanium catalyst addition rate. The polymer was separated
from the unreacted monomer, stabilized with Irganox® 1010,

pelletized, and tested. Test result are set forth in Table 1 below.

Table 1

	Heat of fusion cal./gm. (heptane insoluble fraction)	17.0	17.6
20	<u>Comparative Examples 5 and 6</u>		

In order to illustrate the importance of hydrogen control in the preparation of the homopolymer of the present invention, propylene monomer was polymerized in the same manner as in Example 1, except that hydrogen was added at partial pressures of 45 and 70 psig respectively. The

polymers were tested and the results are set forth in Table 4 below.

Table 4

		<u>Example 5</u>	<u>Example 6</u>
5	H ₂ partial pressure (psig)	45	70
	Melt flow rate g/10 min. @ 230°C	fluid	fluid
	Melt viscosity cps @ 190°C.	6,300	1,730
10	Heptane soluble fraction wt. %	79.7	84.3
	Melting pt. °C (heptane soluble fraction)	115.5	134.8
15	Heat of Fusion cal./gm. (heptane soluble fraction)	2.3	3.1
	Melting pt. °C (heptane insoluble fraction)	151.4	152.2
	Heat of Fusion cal./gm. (heptane insoluble fraction)	21.3	21.5

20 Comparative Examples 5 and 6 illustrate that the
addition of excessive amounts of hydrogen results in the
production of polymers having undesirably high melt flow
rates and undesirably low melt viscosities.

25 While particular embodiments of the present
invention have been described, it will be apparent to those

skilled in the art that various changes and modification
can be made without departing from the spirit and scope of
the invention. The following claims are intended to cover
all such modifications that are within the scope of the
5 invention.

~

THE CLAIMS DEFINING THE INVENTION ARE AS FOLLOWS:

1. An elastomeric high molecular weight substantially amorphous propylene homopolymer including:

5 a heptane soluble fraction from 30% to 70%;
said heptane soluble fraction having a melting point between 100°C and 115°C and a heat of fusion less than 2.0 cal./gm.; and

a diethyl ether soluble fraction from 35% to 55%;
10 said diethyl ether soluble fraction having no detectable melting point above 40°C., and inherent viscosity less than 1.0 dl./g. and being substantially free of isotactic crystallinity;

said homopolymer characterized by a melting point
15 between 145°C and 165°C, a melt viscosity at 190°C. greater than 200,000 cps, and a heat of fusion between 4 cal./gm/ and 10 cal./gm.

2. The polymer of claim 1 wherein the homopolymer
20 includes from about 30% to about 70% of a heptane soluble fraction, the fraction having a melting point between about 100°C and 115°C and a heat of fusion less than about 2.0 cal./gm.

25

30

35

3. The homopolymer of claim 1 wherein the homopolymer is polymerized with a catalyst system comprising:

(A) a solid catalyst component prepared by:

- 5 (i) co-comminuting magnesium halide support base and aluminum trihalide in a molar ratio from about 8:0.5 to about 8:3 in the absence of added electron donor; and
- 10 (ii) then co-comminuting the product of step (i) in the absence of added electron donor with sufficient titanium tetrahalide to provide a molar ratio of magnesium halide to titanium tetrahalide from about 8:0.4 to about 8:1; and
- 15

(B) a trialkylaluminum co-catalyst component having from 1 to 9 carbon atoms in each alkyl group in a sufficient quantity to provide an Al/Ti ratio in the range from about 50:1 to about 600:1.

ABSTRACT

An elastomeric high molecular weight substantially amorphous propylene homopolymer having a melting point between about 145°C and 165°C, a melt viscosity at 190°C greater than 200,000 cps and a heat of fusion between about 4 cal./gm. and about 10 cal./gm. is disclosed. The polymer comprises from about 35% to about 55% of a diethyl ether soluble fraction, the fraction having an inherent viscosity less than about 1.0 dl/g and exhibiting substantially no isotactic crystallinity and from about 30% to about 70% of a heptane soluble fraction, the fraction having a melting point between about 100°C and 115°C and a heat of fusion less than about 2.0 cal./gm.
