(57) Abstract: This invention features systems and methods for the detection of analytes, and their use in the treatment and diagnosis of disease.

NMR SYSTEMS AND METHODS FOR THE RAPID DETECTION OF ANALYTES

Background of the Invention

This invention features assays and devices for the detection of analytes, and their use in the
treatment and diagnosis of disease.

Magnetic sensors have been designed to detect molecular interactions in a variety of media,
including biofluids, food products, and soil samples, among other media. Upon target binding, these
sensors cause changes in properties of neighboring water molecules (or any solvent molecule with free
hydrogens) of a sample, which can be detected by magnetic resonance (NMR/MRI) techniques. Thus, by
using these sensors in a liquid sample, it is possible to detect the presence, and potentially quantify the
amount, of an analyte at very low concentration. For example, small molecules, DNA, RNA, proteins,
carbohydrates, organisms, metabolites, and pathogens (e.g., viruses) can be detected using magnetic
sensors.

In general, magnetic sensors are magnetic particles that bind or otherwise link to their intended
molecular target to form clusters (aggregates). It is believed that when magnetic particles assemble into
clusters and the effective cross sectional area becomes larger (and the cluster number density is smaller),
the interactions with the water or other solvent molecules are altered, leading to a change in the measured
relaxation rates (e.g., T_2, T_1, T_2^*), susceptibility, frequency of precession, among other physical changes.
Additionally, cluster formation can be designed to be reversible (e.g., by temperature shift, chemical
cleavage, pH shift, etc.) so that "forward" or "reverse" (competitive and inhibition) assays can be
developed for detection of specific analytes. Forward (clustering) and reverse (declustering) types of
assays can be used to detect a wide variety of biologically relevant materials. The MRS (magnetic
resonance switch) phenomenon was previously described (see U.S. Patent Publication No. 20090029392).

Many diagnostic assays require sensitivity in the picomolar or subpicomolar range. In such
assays an equally low concentration of paramagnetic particles is employed. As a result, the binding
events leading to cluster formation can become a rate-limiting step in the completion of the assay as the
collision frequency of antigens, paramagnetic particles, and partially formed clusters is low in this
concentration range (see Baudry et al., Proc Natl Acad Sci USA, 103:16076 (2006)). The current
detection of infectious agents, nucleic acids, small molecules, biowarfare agents and organisms, and
molecular targets (biomarkers) or the combination of molecular and immunoassay targets usually requires
up-front sample preparation, time to analyze the sample, and single tests for each of the individual
analytes. There is a need for a rapid, commercially-realizable NMR-based analyte detection device
suitable for use with magnetic nanosensors having four unique features and qualities: 1) little to no
sample preparation, 2) multiplex detection across multiple molecular types, 3) rapid acquisition of
diagnostic information, and 4) accurate information for point-of-care clinical decision making.

Summary of the Invention

The invention features systems and methods for the detection of analytes.

The invention features a method for detecting the presence of an analyte in a liquid sample, the method including: (a) contacting a solution with magnetic particles to produce a liquid sample including from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the liquid sample (e.g., from 1×10^6 to 1×10^8, 1×10^7 to 1×10^8, 1×10^7 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{11}, or 1×10^{10} to 1×10^{13} magnetic particles per milliliter), wherein the magnetic particles have a mean diameter of from 150 nm to 699 nm (e.g., from 150 to 250, 200 to 350, 250 to 450, 300 to 500, 450 to 650, or from 500 to 699 nm), a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} mM^{-1}s^{-1} (e.g., from 1×10^8 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{10}, 1×10^9 to 1×10^{11}, or from 1×10^{10} to 1×10^{12} mM^{-1}s^{-1}), and binding moieties on their surface, the binding moieties operative to alter aggregation of the magnetic particles in the presence of the analyte or a multivalent binding agent; (b) placing the liquid sample in a device, the device including a support defining a well holding the liquid sample including the magnetic particles, the multivalent binding agent, and the analyte, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using one or more magnets and an RF pulse sequence; (c) exposing the sample to a bias magnetic field and an RF pulse sequence; (d) following step (c), measuring the signal; and (e) on the basis of the result of step (d), detecting the analyte. In certain embodiments, the magnetic particles are substantially monodisperse; exhibit nonspecific reversibility in the absence of the analyte and multivalent binding agent; and/or the magnetic particles further include a surface decorated with a blocking agent selected from albumin, fish skin gelatin, gamma globulin, lysozyme, casein, peptidase, and an amine-bearing moiety (e.g., amino polyethyleneglycol, glycine, ethylenediamine, or amino dextran). In particular embodiments, the liquid sample further includes a buffer, from 0.1% to 3% (w/w) albumin (e.g., from 0.1% to 0.5%, 0.3% to 0.7%, 0.5% to 1%, 0.8% to 2%, or from 1.5% to 3% (w/w) albumin), from 0.01% to 0.5% nonionic surfactant (e.g., from 0.01% to 0.05%, 0.05% to 0.1%, 0.05% to 0.2%, 0.1% to 0.3%, 0.2% to 0.4%, or from 0.3% to 0.5% nonionic surfactant), or a combination thereof. In still other embodiments, the magnetic particles include a surface decorated with 40 µg to 100 µg (e.g., 40 µg to 60 µg, 50 µg to 70 µg, 60 µg to 80 µg, or 80 µg to 100 µg,) of one or more proteins per milligram of the magnetic particles. The liquid sample can include a multivalent binding agent bearing a plurality of analytes conjugated to a polymeric scaffold. For example, the analyte can be creatinine, the liquid sample can include a multivalent binding agent bearing a plurality of creatinine conjugates, and the magnetic particles can include a surface decorated with creatinine antibodies. In another embodiment, the analyte can be tacrolimus, the liquid sample can include a multivalent binding agent bearing a plurality of tacrolimus conjugates, and the magnetic particles can include a surface decorated with tacrolimus antibodies. In particular embodiments of the method, step (d) includes measuring the T_2 relaxation response of the liquid sample, and wherein increasing agglomeration in the liquid sample produces an increase in the observed T_2 relaxation rate of the sample. In certain embodiments, the analyte is a target nucleic acid

(e.g., a target nucleic acid extracted from a leukocyte, or a pathogen).

The invention features a method for detecting the presence of an analyte in a liquid sample, the method including (a) contacting a solution with magnetic particles to produce a liquid sample including from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the liquid sample (e.g., from 1×10^6 to 1×10^8, 1×10^7 to 1×10^8, 1×10^7 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{11}, or 1×10^{10} to 1×10^{13} magnetic particles per milliliter), wherein the magnetic particles have a mean diameter of from 700 nm to 1200 nm (e.g., from 700 to 850, 800 to 950, 900 to 1050, or from 1000 to 1200 nm), a T_2 relaxivity per particle of from 1×10^9 to 1×10^{12} mM^{-1}s^{-1} (e.g., from 1×10^9 to 1×10^{10}, 1×10^9 to 1×10^{11}, or from 1×10^{10} to 1×10^{12} mM^{-1}s^{-1}), and have binding moieties on their surface, the binding moieties operative to alter an aggregation of the magnetic particles in the presence of the analyte; (b) placing the liquid sample in a device, the device including a support defining a well holding the liquid sample including the magnetic particles, the multivalent binding agent, and the analyte, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using one or more magnets and an RF pulse sequence; (c) exposing the sample to a bias magnetic field and an RF pulse sequence; (d) following step (c), measuring the signal; and (e) on the basis of the result of step (d), detecting the presence or concentration of an analyte. In certain embodiments, the magnetic particles are substantially monodisperse; exhibit nonspecific reversibility in the absence of the analyte and multivalent binding agent; and/or the magnetic particles further include a surface decorated with a blocking agent selected from albumin, fish skin gelatin, gamma globulin, lysozyme, casein, peptidase, and an amine-bearing moiety (e.g., amino polyethyleneglycol, glycine, ethylenediamine, or amino dextran). In particular embodiments, the liquid sample further includes a buffer, from 0.1% to 3% (w/w) albumin (e.g., from 0.1% to 0.5%, 0.3% to 0.7%, 0.5% to 1%, 0.8% to 2%, or from 1.5% to 3% (w/w) albumin), from 0.01% to 0.5% nonionic surfactant (e.g., from 0.01% to 0.05%, 0.05% to 0.1%, 0.05% to 0.2%, 0.1% to 0.3%, 0.2% to 0.4%, or from 0.3% to 0.5% nonionic surfactant), or a combination thereof. In still other embodiments, the magnetic particles include a surface decorated with 40 µg to 100 µg (e.g., 40 µg to 60 µg, 50 µg to 70 µg, 60 µg to 80 µg, or 80 µg to 100 µg,) of one or more proteins per milligram of the magnetic particles. The liquid sample can include a multivalent binding agent bearing a plurality of analytes conjugated to a polymeric scaffold. For example, the analyte can be creatinine, the liquid sample can include a multivalent binding agent bearing a plurality of creatinine conjugates, and the magnetic particles can include a surface decorated with creatinine antibodies. In another embodiment, the analyte can be tacrolimus, the liquid sample can include a multivalent binding agent bearing a plurality of tacrolimus conjugates, and the magnetic particles can include a surface decorated with tacrolimus antibodies. In particular embodiments of the method, step (d) includes measuring the T_2 relaxation response of the liquid sample, and wherein increasing agglomeration in the liquid sample produces an increase in the observed T_2 relaxation rate of the sample. In certain embodiments, the analyte is a target nucleic acid (e.g., a target nucleic acid extracted from a leukocyte, or a pathogen).

The invention further features a method for detecting the presence of a pathogen in a whole blood sample, the method including: (a) providing a whole blood sample from a subject; (b) mixing the whole blood sample with an erythrocyte lysis agent solution to produce disrupted red blood cells; (c) following step (b), centrifuging the sample to form a supernatant and a pellet, discarding some or all of the supernatant, and resuspending the pellet to form an extract, optionally washing the pellet (e.g., with TE buffer) prior to resuspending the pellet and optionally repeating step (c); (d) lysing cells of the extract to form a lysate; (e) placing the lysate of step (d) in a detection tube and amplifying a target nucleic acid in the lysate to form an amplified lysate solution including the target nucleic acid, wherein the target nucleic acid is characteristic of the pathogen to be detected; (f) following step (e), adding to the detection tube from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the amplified lysate solution (e.g., from 1×10^6 to 1×10^8, 1×10^7 to 1×10^8, 1×10^7 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{11}, or 1×10^{10} to 1×10^{13} magnetic particles per milliliter), wherein the magnetic particles have a mean diameter of from 700 nm to 1200 nm (e.g., from 700 to 850, 800 to 950, 900 to 1050, or from 1000 to 1200 nm), and binding moieties on their surface, the binding moieties operative to alter aggregation of the magnetic particles in the presence of the target nucleic acid or a multivalent binding agent; (g) placing the detection tube in a device, the device including a support defining a well for holding the detection tube including the magnetic particles and the target nucleic acid, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using one or more magnets and an RF pulse sequence; (h) exposing the sample to a bias magnetic field and an RF pulse sequence; (i) following step (h), measuring the signal from the detection tube; and (j) on the basis of the result of step (i), detecting the pathogen. In certain embodiments, steps (a) through (i) are completed within 4 hours (e.g., within 3.5 hours, 3.0 hours, 2.5 hours, 2 hours, 1.5 hours, or 1 hour). In another embodiment, step (i) is carried out without any prior purification of the amplified lysate solution (i.e., the lysate solution is unfractionated after it is formed). In particular embodiments, step c includes washing the pellet prior to resuspending the pellet to form the extract. In particular embodiments step (d) includes combining the extract with beads to form a mixture and agitating the mixture to form a lysate. The magnetic particles can include one or more populations having a first probe and a second probe conjugated to their surface, the first probe operative to bind to a first segment of the target nucleic acid and the second probe operative to bind to a second segment of the target nucleic acid, wherein the magnetic particles form aggregates in the presence of the target nucleic acid. Alternatively, the assay can be a disaggregation assay in which the magnetic particles include a first population having a first binding moiety on their surface and a second population having a second binding moiety on their surface, and the multivalent binding moiety including a first probe and a second probe, the first probe operative to bind to the first binding moiety and the second probe operative to bind to a second binding moiety, the binding moieties and multivalent binding moiety operative to alter an aggregation of the magnetic particles in the presence of the target nucleic acid. In certain embodiments, the magnetic particles are substantially monodisperse; exhibit nonspecific reversibility in the absence of the analyte and multivalent binding agent; and/or the

- 4 -

magnetic particles further include a surface decorated with a blocking agent selected from albumin, fish skin gelatin, gamma globulin, lysozyme, casein, peptidase, and an amine-bearing moiety (e.g., amino polyethyleneglycol, glycine, ethylenediamine, or amino dextran). In particular embodiments, the lysate further includes a buffer, from 0.1% to 3% (w/w) albumin (e.g., from 0.1% to 0.5%, 0.3% to 0.7%, 0.5%

5   to 1%, 0.8% to 2%, or from 1.5% to 3% (w/w) albumin), from 0.01% to 0.5% nonionic surfactant (e.g., from 0.01% to 0.05%, 0.05% to 0.1%, 0.05% to 0.2%, 0.1% to 0.3%, 0.2% to 0.4%, or from 0.3% to 0.5% nonionic surfactant), or a combination thereof. In still other embodiments, the magnetic particles include a surface decorated with 40 µg to 100 µg (e.g., 40 µg to 60 µg, 50 µg to 70 µg, 60 µg to 80 µg, or 80 µg to 100 µg,) of one or more proteins per milligram of the magnetic particles. The lysate can include

10   a multivalent binding agent bearing a plurality of analytes conjugated to a polymeric scaffold.

The invention features a method for detecting the presence of a target nucleic acid in a whole blood sample, the method including: (a) providing one or more cells from a whole blood sample from a subject; (b) lysing the cells to form a lysate; (c) amplifying a target nucleic acid in the lysate to form an amplified lysate solution comprising the target nucleic acid; (d) following step (c), adding to a detection

15   tube the amplified lysate solution and from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the amplified lysate solution, wherein the magnetic particles have a mean diameter of from 700 nm to 1200 nm and binding moieties on their surface, the binding moieties operative to alter aggregation of the magnetic particles in the presence of the target nucleic acid or a multivalent binding agent; (e) placing the detection tube in a device, the device including a support defining a well for holding the detection tube

20   including the magnetic particles and the target nucleic acid, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using one or more magnets and an RF pulse sequence; (f) exposing the sample to a bias magnetic field and an RF pulse sequence; (h) following step (f), measuring the signal from the detection tube; and (i) on the basis of the result of step (h), detecting the target nucleic acid. In particular

25   embodiments, the target nucleic acid is purified prior to step (d). In particular embodiments, step (b) includes combining the extract with beads to form a mixture and agitating the mixture to form a lysate. The magnetic particles can include one or more populations having a first probe and a second probe conjugated to their surface, the first probe operative to bind to a first segment of the target nucleic acid and the second probe operative to bind to a second segment of the target nucleic acid, wherein the

30   magnetic particles form aggregates in the presence of the target nucleic acid. Alternatively, the assay can be a disaggregation assay in which the magnetic particles include a first population having a first binding moiety on their surface and a second population having a second binding moiety on their surface, and the multivalent binding moiety including a first probe and a second probe, the first probe operative to bind to the first binding moiety and the second probe operative to bind to a second binding moiety, the binding

35   moieties and multivalent binding moiety operative to alter an aggregation of the magnetic particles in the presence of the target nucleic acid. In certain embodiments, the magnetic particles are substantially monodisperse; exhibit nonspecific reversibility in the absence of the analyte and multivalent binding

agent; and/or the magnetic particles further include a surface decorated with a blocking agent selected from albumin, fish skin gelatin, gamma globulin, lysozyme, casein, peptidase, and an amine-bearing moiety (e.g., amino polyethyleneglycol, glycine, ethylenediamine, or amino dextran). In particular embodiments, the lysate further includes a buffer, from 0.1% to 3% (w/w) albumin (e.g., from 0.1% to 0.5%, 0.3% to 0.7%, 0.5% to 1%, 0.8% to 2%, or from 1.5% to 3% (w/w) albumin), from 0.01% to 0.5% nonionic surfactant (e.g., from 0.01% to 0.05%, 0.05% to 0.1%, 0.05% to 0.2%, 0.1% to 0.3%, 0.2% to 0.4%, or from 0.3% to 0.5% nonionic surfactant), or a combination thereof. In still other embodiments, the magnetic particles optionally include a surface decorated with 40 μg to 100 μg (e.g., 40 μg to 60 μg, 50 μg to 70 μg, 60 μg to 80 μg, or 80 μg to 100 μg,) of one or more proteins per milligram of the magnetic particles. The lysate can include a multivalent binding agent bearing a plurality of analytes conjugated to a polymeric scaffold.

The invention further features a method for detecting the presence of a target nucleic acid in a whole blood sample, the method including: (a) providing an extract produced by lysing the red blood cells in a whole blood sample from a subject, centrifuging the sample to form a supernatant and a pellet, discarding some or all of the supernatant, and resuspending the pellet to form an extract, optionally washing the pellet (e.g., with TE buffer) prior to resuspending the pellet and optionally repeating the centrifuging, discarding, and washing of step (a); (b) lysing cells in the extract to form a lysate; (c) placing the lysate of step (b) in a detection tube and amplifying nucleic acids therein to form an amplified lysate solution including from 40% (w/w) to 95% (w/w) the target nucleic acid (e.g., from 40 to 60%, from 60 to 80%, or from 85 to 95% (w/w) target nucleic acid) and from 5% (w/w) to 60% (w/w) nontarget nucleic acid (e.g., from 5 to 20%, from 20 to 40%, or from 40 to 60% (w/w) nontarget nucleic acid); (d) following step (c), adding to the detection tube from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the amplified lysate solution, wherein the magnetic particles have a mean diameter of from 700 nm to 1200 nm and binding moieties on their surface, the binding moieties operative to alter aggregation of the magnetic particles in the presence of the target nucleic acid or a multivalent binding agent; (e) placing the detection tube in a device, the device including a support defining a well for holding the detection tube including the magnetic particles and the target nucleic acid, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using one or more magnets and an RF pulse sequence; (f) exposing the sample to a bias magnetic field and an RF pulse sequence; (g) following step (f), measuring the signal from the detection tube; and (h) on the basis of the result of step (g), detecting the target nucleic acid, wherein step (g) is carried out without any prior purification of the amplified lysate solution. In particular embodiments, step (b) includes combining the extract with beads to form a mixture and agitating the mixture to form a lysate. The magnetic particles can include one or more populations having a first probe and a second probe conjugated to their surface, the first probe operative to bind to a first segment of the target nucleic acid and the second probe operative to bind to a second segment of the target nucleic acid, wherein the magnetic particles form aggregates in the presence of the target nucleic acid. Alternatively,

the assay can be a disaggregation assay in which the magnetic particles include a first population having a first binding moiety on their surface and a second population having a second binding moiety on their surface, and the multivalent binding moiety including a first probe and a second probe, the first probe operative to bind to the first binding moiety and the second probe operative to bind to a second binding moiety, the binding moieties and multivalent binding moiety operative to alter an aggregation of the magnetic particles in the presence of the target nucleic acid. In certain embodiments, the magnetic particles are substantially monodisperse; exhibit nonspecific reversibility in the absence of the analyte and multivalent binding agent; and/or the magnetic particles further include a surface decorated with a blocking agent selected from albumin, fish skin gelatin, gamma globulin, lysozyme, casein, peptidase, and an amine-bearing moiety (e.g., amino polyethyleneglycol, glycine, ethylenediamine, or amino dextran). In particular embodiments, the lysate further includes a buffer, from 0.1% to 3% (w/w) albumin (e.g., from 0.1% to 0.5%, 0.3% to 0.7%, 0.5% to 1%, 0.8% to 2%, or from 1.5% to 3% (w/w) albumin), from 0.01% to 0.5% nonionic surfactant (e.g., from 0.01% to 0.05%, 0.05% to 0.1%, 0.05% to 0.2%, 0.1% to 0.3%, 0.2% to 0.4%, or from 0.3% to 0.5% nonionic surfactant), or a combination thereof. In still other embodiments, the magnetic particles include a surface decorated with 40 μg to 100 μg (e.g., 40 μg to 60 μg, 50 μg to 70 μg, 60 μg to 80 μg, or 80 μg to 100 μg,) of one or more proteins per milligram of the magnetic particles. The lysate can include a multivalent binding agent bearing a plurality of analytes conjugated to a polymeric scaffold.

The invention features a method for detecting the presence of a Candida species in a liquid sample, the method including: (a) lysing the Candida cells in the liquid sample; (b) amplifying a nucleic acid to be detected in the presence of a forward primer and a reverse primer, each of which is universal to multiple Candida species to form a solution including a Candida amplicon; (c) contacting the solution with magnetic particles to produce a liquid sample including from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the liquid sample (e.g., from 1×10^6 to 1×10^8, 1×10^7 to 1×10^8, 1×10^7 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{11}, or 1×10^{10} to 1×10^{13} magnetic particles per milliliter), wherein the magnetic particles have a mean diameter of from 700 nm to 1200 nm (e.g., from 700 to 850, 800 to 950, 900 to 1050, or from 1000 to 1200 nm), a T_2 relaxivity per particle of from 1×10^9 to 1×10^{12} mM^{-1}s^{-1} (e.g., from 1×10^8 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{10}, 1×10^9 to 1×10^{11}, or from 1×10^{10} to 1×10^{12} mM^{-1}s^{-1}), and binding moieties on their surface, the binding moieties operative to alter aggregation of the magnetic particles in the presence of the Candida amplicon or a multivalent binding agent; (d) placing the liquid sample in a device, the device including a support defining a well for holding the liquid sample including the magnetic particles and the Candida amplicon, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using one or more magnets and an RF pulse sequence; (e) exposing the sample to a bias magnetic field and an RF pulse sequence; (f) following step (e), measuring the signal; and (g) on the basis of the result of step (f), determining whether the Candida species was present in the sample. In certain embodiments, the magnetic particles are substantially monodisperse; exhibit nonspecific reversibility in the absence of the

analyte and multivalent binding agent; and/or the magnetic particles further include a surface decorated with a blocking agent selected from albumin, fish skin gelatin, gamma globulin, lysozyme, casein, peptidase, and an amine-bearing moiety (e.g., amino polyethyleneglycol, glycine, ethylenediamine, or amino dextran). In particular embodiments, the liquid sample further includes a buffer, from 0.1% to 3%

5 (w/w) albumin (e.g., from 0.1% to 0.5%, 0.3% to 0.7%, 0.5% to 1%, 0.8% to 2%, or from 1.5% to 3% (w/w) albumin), from 0.01% to 0.5% nonionic surfactant (e.g., from 0.01% to 0.05%, 0.05% to 0.1%, 0.05% to 0.2%, 0.1% to 0.3%, 0.2% to 0.4%, or from 0.3% to 0.5% nonionic surfactant), or a combination thereof. In still other embodiments, the magnetic particles include a surface decorated with 40 μg to 100 μg (e.g., 40 μg to 60 μg, 50 μg to 70 μg, 60 μg to 80 μg, or 80 μg to 100 μg,) of one or more

10 proteins per milligram of the magnetic particles. The liquid sample can include a multivalent binding agent bearing a plurality of analytes conjugated to a polymeric scaffold. The forward primer can include, for example, the sequence 5'-GGC ATG CCT GTT TGA GCG TC-3' (SEQ ID NO. 1). The reverse primer can include, for example, the sequence 5'-GCT TAT TGA TAT GCT TAA GTT CAG CGG GT-3' (SEQ ID NO. 2). In certain embodiments, (i) the Candida species is Candida albicans, the first probe

15 includes the oligonucleotide sequence 5'-ACC CAG CGG TTT GAG GGA GAA AC-3' (SEQ ID NO. 3), and the second probe includes the oligonucleotide sequence 5'-AAA GTT TGA AGA TAT ACG TGG TGG ACG TTA-3' (SEQ ID NO. 4); (ii) the Candida species is Candida krusei and the first probe and the second probe include an oligonucleotide sequence selected from: 5'-CGC ACG CGC AAG ATG GAA ACG-3' (SEQ ID NO. 5), 5'-AAG TTC AGC GGG TAT TCC TAC CT-3' (SEQ ID NO. 6), and

20 5'-AGC TTT TTG TTG TCT CGC AAC ACT CGC-3' (SEQ ID NO. 32); (iii) the Candida species is Candida glabrata, the first probe includes the oligonucleotide sequence: 5'-CTA CCA AAC ACA ATG TGT TTG AGA AG-3' (SEQ ID NO. 7), and the second probe includes the oligonucleotide sequence: 5'-CCT GAT TTG AGG TCA AAC TTA AAG ACG TCT G-3' (SEQ ID NO. 8); and (iv) the Candida species is Candida parapsilosis or Candida tropicalis and the first probe and the second probe include an

25 oligonucleotide sequence selected from: 5'-AGT CCT ACC TGA TTT GAG GTCNitIndAA-3' (SEQ ID NO. 9), 5'-CCG NitIndGG GTT TGA GGG AGA AAT-3' (SEQ ID NO. 10), AAA GTT ATG AAATAA ATT GTG GTG GCC ACT AGC (SEQ ID NO. 33), ACC CGG GGGTTT GAG GGA GAA A (SEQ ID NO. 34), AGT CCT ACC TGA TTT GAG GTC GAA (SEQ ID NO. 35), and CCG AGG GTT TGA GGG AGA AAT (SEQ ID NO. 36). In certain embodiments, steps (a) through (h) are

30 completed within 4 hours (e.g., within 3.5 hours, 3.0 hours, 2.5 hours, 2 hours, 1.5 hours, or 1 hour or less). In particular embodiments, the magnetic particles include two populations, a first population bearing the first probe on its surface, and the second population bearing the second probe on its surface. In another embodiment, the magnetic particles are a single population bearing both the first probe and the second probe on the surface of the magnetic particles. The magnetic particles can include one or more

35 populations having a first probe and a second probe conjugated to their surface, the first probe operative to bind to a first segment of the Candida amplicon and the second probe operative to bind to a second segment of the Candida amplicon, wherein the magnetic particles form aggregates in the presence of the

target nucleic acid. Alternatively, the assay can be a disaggregation assay in which the magnetic particles include a first population having a first binding moiety on their surface and a second population having a second binding moiety on their surface, and the multivalent binding moiety including a first probe and a second probe, the first probe operative to bind to the first binding moiety and the second probe operative to bind to a second binding moiety, the binding moieties and multivalent binding moiety operative to alter an aggregation of the magnetic particles in the presence of the Candida amplicon. In particular embodiments, the method can produce (i) a coefficient of variation in the T2 value of less than 20% on Candida positive samples; (ii) at least 95% correct detection at less than or equal to 5 cells/mL in samples spiked into 50 individual healthy patient blood samples; (iii) at least 95% correct detection less than or equal to 5 cells/mL in samples spiked into 50 indiviudal unhealthy patient blood samples; and/or (iv) greater than or equal to 80% correct detection in clinically positive patient samples (i.e., Candida positive by another technique, such as by cell culture) starting with 2mL of blood.

The invention features a method for detecting the presence of a Candida species in a whole blood sample sample, the method including: (a) providing an extract produced by lysing the red blood cells in a whole blood sample from a subject; (b) centrifuging the sample to form a supernatant and a pellet, discarding some or all of the supernatant; (c) washing the pellet (e.g., with TE buffer) by mixing the pellet with a buffer, agitating the sample (e.g., by vortexing), centrifuging the sample to form a supernatant and a pellet, discarding some or all of the supernatant; (d) optionally repeating steps (b) and (c); (e) bead beating the pellet to form a lysate in the presence of a buffer (e.g., TE buffer); (f) centrifuging the sample to form a supernatant containing the lysate; (g) amplifying nucleic acids in the lysate of step (f) to form a Candida amplicon; and (h) detecting the presence of the Candida amplicon, wherein , the method can produce (i) at least 95% correct detection at less than or equal to 5 cells/mL in samples spiked into 50 individual healthy patient blood samples; (ii) at least 95% correct detection less than or equal to 5 cells/mL in samples spiked into 50 indiviudal unhealthy patient blood samples; and/or (iii) greater than or equal to 80% correct detection in clinically positive patient samples (i.e., Candida positive by cell culture) starting with 2mL of blood at step(a).

The invention features a method for detecting the presence of a pathogen in a whole blood sample, the method including the steps of: (a) providing from 0.05 to 4.0 mL of the whole blood sample (e.g., from 0.05 to 0.25, 0.25 to 0.5, 0.25 to 0.75, 0.4 to 0.8, 0.5 to 0.75, 0.6 to 0.9, 0.65 to 1.25, 1.25 to 2.5, 2.5 to 3.5, or 3.0 to 4.0 mL of whole blood); (b) placing an aliquot of the sample of step (a) in a container and amplifying a target nucleic acid in the sample to form an amplified solution including the target nucleic acid, wherein the target nucleic acid is characteristic of the pathogen to be detected; (c) placing the amplified liquid sample in a detecting device; (d) on the basis of the result of step (c), detecting the pathogen, wherein the pathogen is selected from bacteria and fungi, and wherein the method is capable of detecting a pathogen concentration of 10 cells/mL (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 25, 30, 35, 40, 45, or 50 cells/mL) in the whole blood sample. The detecting device can detect the pathogen via an optical, fluorescent, mass, density, magnetic, chromatographic, and/or electrochemical

measurement of the amplified liquid sample. In certain embodiments, steps (a) through (d) are completed within 3 hours (e.g., within 3.2, 2.9, 2.7, 2.5, 2.3, 2.2, 2.1, 2.0, 1.9, 1.8, 1.7, 1.6, or 1.5 hours or 1 hour). In still other embodiments, step (c) is carried out without any prior purification of the amplified solution, and/or the liquid sample of step (c) includes whole blood proteins and non-target oligonucleotides. In
5   certain embodiments, the pathogen is selected from bacteria and fungi. The pathogen can be any bacterial or fungal pathogen described herein.

The invention also features a method for detecting the presence of a pathogen in a whole blood sample, the method including the steps of: (a) providing a whole blood sample from a subject; (b) mixing from 0.05 to 4.0 mL of the whole blood sample (e.g., from 0.05 to 0.25, 0.25 to 0.5, 0.25 to 0.75, 0.4 to
10 0.8, 0.5 to 0.75, 0.6 to 0.9, 0.65 to 1.25, 1.25 to 2.5, 2.5 to 3.5, or 3.0 to 4.0 mL of whole blood) with an erythrocyte lysis agent solution to produce disrupted red blood cells; (c) following step (b), centrifuging the sample to form a supernatant and a pellet, discarding some or all of the supernatant, and resuspending the pellet to form an extract, optionally washing the pellet (e.g., with TE buffer) prior to resuspending the pellet and optionally repeating step (c); (d) lysing cells of the extract to form a lysate; (e) placing the
15 lysate of step (d) in a container and amplifying a target nucleic acid in the lysate to form an amplified lysate solution including the target nucleic acid, wherein the target nucleic acid is characteristic of the pathogen to be detected; (f) following step (e), mixing the amplified lysate solution with from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the amplified lysate solution to form a liquid sample (e.g., from 1×10^6 to 1×10^8, 1×10^7 to 1×10^8, 1×10^7 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{11}, or 1×10^{10} to 1×10^{13}
20 magnetic particles per milliliter), wherein the magnetic particles have a mean diameter of from 150 nm to 1200 nm (e.g., from 150 to 250, 200 to 350, 250 to 450, 300 to 500, 450 to 650, 500 to 700 nm, 700 to 850, 800 to 950, 900 to 1050, or from 1000 to 1200 nm), a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} mM^{-1}s^{-1} (e.g., from 1×10^8 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{10}, 1×10^9 to 1×10^{11}, or from 1×10^{10} to 1×10^{12} mM^{-1}s^{-1}), and binding moieties on their surface, the binding moieties operative to alter
25 aggregation of the magnetic particles in the presence of the target nucleic acid or a multivalent binding agent; (g) placing the liquid sample in a device, the device including a support defining a well for holding the detection tube including the magnetic particles and the target nucleic acid, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using one or more magnets and an RF pulse sequence; (h) exposing the
30 sample to a bias magnetic field and an RF pulse sequence; (i) following step (h), measuring the signal from the liquid sample; and (j) on the basis of the result of step (i), detecting the pathogen, wherein the pathogen is selected from bacteria and fungi, and wherein the method is capable of detecting a pathogen concentration of 10 cells/mL (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 25, 30, 35, 40, 45, or 50 cells/mL) in the whole blood sample. In certain embodiments, steps (a) through (i) are completed within 3 hours (e.g.,
35 within 3.2, 2.9, 2.7, 2.5, 2.3, 2.2, 2.1, 2.0, 1.9, 1.8, 1.7, 1.6, 1.5, or 1or less hours). In still other embodiments, step (i) is carried out without any prior purification of the amplified lysate solution, and/or the liquid sample of step (i) includes whole blood proteins and non-target oligonucleotides. In certain

- 10 -

embodiments, the pathogen is selected from bacteria and fungi. The pathogen can be any bacterial or fungal pathogen described herein. In particular embodiments the method is capable of measuring a pathogen concentration of 10 cells/mL in the whole blood sample with a coefficient of variation of less than 15% (e.g., 10 cells/mL with a coefficient of variation of less than 15%, 10%, 7.5%, or 5%; or 25

5   cells/mL with a coefficient of variation of less than 15%, 10%, 7.5%, or 5%; or 50 cells/mL with a coefficient of variation of less than 15%, 10%, 7.5%, or 5%; or 100 cells/mL with a coefficient of variation of less than 15%, 10%, 7.5%, or 5%). In certain embodiments, the magnetic particles are substantially monodisperse; exhibit nonspecific reversibility in the absence of the analyte and multivalent binding agent; and/or the magnetic particles further include a surface decorated with a blocking agent

10   selected from albumin, fish skin gelatin, gamma globulin, lysozyme, casein, peptidase, and an amine-bearing moiety (e.g., amino polyethyleneglycol, glycine, ethylenediamine, or amino dextran). In particular embodiments, the liquid sample further includes a buffer, from 0.1% to 3% (w/w) albumin (e.g., from 0.1% to 0.5%, 0.3% to 0.7%, 0.5% to 1%, 0.8% to 2%, or from 1.5% to 3% (w/w) albumin), from 0.01% to 0.5% nonionic surfactant (e.g., from 0.01% to 0.05%, 0.05% to 0.1%, 0.05% to 0.2%,

15   0.1% to 0.3%, 0.2% to 0.4%, or from 0.3% to 0.5% nonionic surfactant), or a combination thereof. In still other embodiments, the magnetic particles include a surface decorated with 40 μg to 100 μg (e.g., 40 μg to 60 μg, 50 μg to 70 μg, 60 μg to 80 μg, or 80 μg to 100 μg,) of one or more proteins per milligram of the magnetic particles. The liquid sample can include a multivalent binding agent bearing a plurality of analytes conjugated to a polymeric scaffold. The method for monitoring can include any of the

20   magnetic assisted agglomeration methods described herein. The magnetic particles can include one or more populations having a first probe and a second probe conjugated to their surface, the first probe operative to bind to a first segment of the target nucleic acid and the second probe operative to bind to a second segment of the target nucleic acid, wherein the magnetic particles form aggregates in the presence of the target nucleic acid. Alternatively, the assay can be a disaggregation assay in which the magnetic

25   particles include a first population having a first binding moiety on their surface and a second population having a second binding moiety on their surface, and the multivalent binding moiety including a first probe and a second probe, the first probe operative to bind to the first binding moiety and the second probe operative to bind to a second binding moiety, the binding moieties and multivalent binding moiety operative to alter an aggregation of the magnetic particles in the presence of the target nucleic acid.

30   The invention further features a method for detecting the presence of a virus in a whole blood sample, the method including the steps of: (a) providing a plasma sample from a subject; (b) mixing from 0.05 to 4.0 mL of the plasma sample (e.g., from 0.05 to 0.25, 0.25 to 0.5, 0.25 to 0.75, 0.4 to 0.8, 0.5 to 0.75, 0.6 to 0.9, 0.65 to 1.25, 1.25 to 2.5, 2.5 to 3.5, or 3.0 to 4.0 mL of whole blood) with a lysis agent to produce a mixture comprising disrupted viruses; (c) placing the mixture of step (b) in a container and

35   amplifying a target nucleic acid in the filtrate to form an amplified filtrate solution including the target nucleic acid, wherein the target nucleic acid is characteristic of the virus to be detected; (d) following step (c), mixing the amplified filtrate solution with from 1×10^6 to 1×10^{13} magnetic particles per milliliter of

the amplified filtrate solution to form a liquid sample (e.g., from 1×10^6 to 1×10^8, 1×10^7 to 1×10^8, 1×10^7 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{11}, or 1×10^{10} to 1×10^{13} magnetic particles per milliliter), wherein the magnetic particles have a mean diameter of from 150 nm to 1200 nm (e.g., from 150 to 250, 200 to 350, 250 to 450, 300 to 500, 450 to 650, 500 to 700 nm, 700 to 850, 800 to 950, 900 to 1050, or from

5   1000 to 1200 nm), a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} mM^{-1}s^{-1} (e.g., from 1×10^8 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{10}, 1×10^9 to 1×10^{11}, or from 1×10^{10} to 1×10^{12} mM^{-1}s^{-1}), and binding moieties on their surface, the binding moieties operative to alter aggregation of the magnetic particles in the presence of the target nucleic acid or a multivalent binding agent; (e) placing the liquid sample in a device, the device including a support defining a well for holding the detection tube including the

10   magnetic particles and the target nucleic acid, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using one or more magnets and an RF pulse sequence; (f) exposing the liquid sample to a bias magnetic field and an RF pulse sequence; (g) following step (f), measuring the signal from the liquid sample; and (h) on the basis of the result of step (g), detecting the virus, wherein the method is capable of detecting

15   fewer than 100 virus copies (e.g., fewer than 80, 70, 60, 50, 40, 30, 20, or 10 copies) in the whole blood sample. In certain embodiments, steps (a) through (g) are completed within 3 hours (e.g., within 3.2, 2.9, 2.7, 2.5, 2.3, 2.2, 2.1, 2.0, 1.9, 1.8, 1.7, 1.6, 1.5 hours, or 1 hour or less). The virus can be any viral pathogen described herein. In certain embodiments, the magnetic particles are substantially monodisperse; exhibit nonspecific reversibility in the absence of the analyte and multivalent binding

20   agent; and/or the magnetic particles further include a surface decorated with a blocking agent selected from albumin, fish skin gelatin, gamma globulin, lysozyme, casein, peptidase, and an amine-bearing moiety (e.g., amino polyethyleneglycol, glycine, ethylenediamine, or amino dextran). In particular embodiments, the liquid sample further includes a buffer, from 0.1% to 3% (w/w) albumin (e.g., from 0.1% to 0.5%, 0.3% to 0.7%, 0.5% to 1%, 0.8% to 2%, or from 1.5% to 3% (w/w) albumin), from 0.01%

25   to 0.5% nonionic surfactant (e.g., from 0.01% to 0.05%, 0.05% to 0.1%, 0.05% to 0.2%, 0.1% to 0.3%, 0.2% to 0.4%, or from 0.3% to 0.5% nonionic surfactant), or a combination thereof. In still other embodiments, the magnetic particles include a surface decorated with 40 µg to 100 µg (e.g., 40 µg to 60 µg, 50 µg to 70 µg, 60 µg to 80 µg, or 80 µg to 100 µg,) of one or more proteins per milligram of the magnetic particles. The liquid sample can include a multivalent binding agent bearing a plurality of

30   analytes conjugated to a polymeric scaffold. The method for monitoring can include any of the magnetic assisted agglomeration methods described herein. The magnetic particles can include one or more populations having a first probe and a second probe conjugated to their surface, the first probe operative to bind to a first segment of the target nucleic acid and the second probe operative to bind to a second segment of the target nucleic acid, wherein the magnetic particles form aggregates in the presence of the

35   target nucleic acid. Alternatively, the assay can be a disaggregation assay in which the magnetic particles include a first population having a first binding moiety on their surface and a second population having a second binding moiety on their surface, and the multivalent binding moiety including a first probe and a

second probe, the first probe operative to bind to the first binding moiety and the second probe operative to bind to a second binding moiety, the binding moieties and multivalent binding moiety operative to alter an aggregation of the magnetic particles in the presence of the target nucleic acid.

In any of the systems and methods of the invention in which a PCR amplification is performed, the PCR method can be real time PCR for quantifying the amount of a target nucleic acid present in a sample.

The invention features a method of quantifying a target nucleic acid molecule in a sample by amplifying the target nucleic acid molecule (e.g., using PCR or isothermal amplification) in an amplification reaction mixture in a detection tube resulting in the production of amplicons corresponding to the target nucleic acid molecule, wherein the amplification reaction mixture includes (1) a target nucleic acid molecule, (2) biotin labeled amplification primers specific for the target nucleic acid molecule, and (3) avidin labeled superparamagnetic particles. In this method, the amplification is performed in a device including a support defining a well for holding the detection tube including the superparamagnetic particles and the target nucleic acid molecule, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the sample to a bias magnetic field created using one or more magnets and an RF pulse sequence. In this method, the amplification includes the following steps:

(a)   performing one or more cycles of amplification;

(b)   exposing the amplification reaction mixture to conditions permitting the aggregation or disaggregation of the avidin labeled superparamagnetic particles,

(c)   exposing the sample to a bias magnetic field and an RF pulse sequence;

(d)   following step (c), measuring the signal from the detection tube;

(e)   repeating steps (a)-(d) until a desired amount of amplification is obtained; and

(f)   on the basis of the result of step (d), quantifying the amplicons present at the corresponding cycle of amplification.

In this method, the initial quantity of target nucleic acid molecule in the sample is determined based on the quantity of amplicons determined at each cycle of the PCR.

The invention further features a method of quantifying a target nucleic acid molecule in a sample by amplifying the target nucleic acid molecule (e.g., using PCR or isothermal amplification) in an amplification reaction mixture in a detection tube resulting in the production of amplicons corresponding to the target nucleic acid molecule. In this method, the amplification reaction mixture includes (1) a target nucleic acid molecule, (2) amplification primers including a 5' overhang, wherein the amplification primers are specific for the target nucleic acid molecule, and (3) oligonucleotide labeled superparamagnetic particles, wherein the oligonucleotide label is substantially complementary to the 5' overhang of the amplification primers. In this method, the amplification is performed in a device including a support defining a well for holding the detection tube including the superparamagnetic particles and the target nucleic acid molecule, and having an RF coil disposed about the well, the RF coil

configured to detect a signal produced by exposing the sample to a bias magnetic field created using one or more magnets and an RF pulse sequence. In this method, the amplification includes the following steps:

(a)   performing one or more cycles of amplification;

(b)   exposing the amplification reaction mixture to conditions permitting the hybridization of the oligonucleotide labeled superparamagnetic particles with the 5' overhang;

(c)   exposing the sample to a bias magnetic field and an RF pulse sequence;

(d)   following step (c), measuring the signal from the detection tube;

(e)   repeating steps (a)-(d) until a desired amount of amplification is obtained; and

(f)   on the basis of the result of step (d), quantifying the amplicons present at the corresponding cycle of amplification.

In this method, the initial quantity of target nucleic acid molecule in the sample is determined based on the quantity of amplicons determined at each cycle of the amplification.

The invention further features a method of quantifying a target nucleic acid molecule in a sample by amplifying the target nucleic acid molecule (e.g., using PCR or isothermal amplification) in an amplification reaction mixture in a detection tube resulting in the production of amplicons corresponding to the target nucleic acid molecule. In this method the amplification reaction mixture includes (1) a target nucleic acid molecule, (2) amplification primers specific for the target nucleic acid molecule, and (3) oligonucleotide labeled superparamagnetic particles, wherein the oligonucleotide label contains a hairpin structure and a portion of the hairpin structure is substantially complementary to a portion of the nucleic acid sequence of the amplicons. In this method, the amplification is performed in a device including a support defining a well for holding the detection tube including the superparamagnetic particles and the target nucleic acid molecule, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the sample to a bias magnetic field created using one or more magnets and an RF pulse sequence. This amplification of this method includes the following steps:

(a)   performing one or more cycles of amplification;

(b)   exposing the amplification reaction mixture to conditions permitting the hybridization of the portion of the hairpin structure of (3) with the amplicons;

(c)   exposing the sample to a bias magnetic field and an RF pulse sequence;

(d)   following step (c), measuring the signal from the detection tube;

(e)   repeating steps (a)-(d) until a desired amount of amplification is obtained; and

(f)   on the basis of the result of step (d), quantifying the amplicons present at the corresponding cycle of amplification.

In this method, the initial quantity of target nucleic acid molecule in the sample is determined based on the quantity of amplicons determined at each cycle of the amplification.

The invention also features a method of quantifying a target nucleic acid molecule in a sample by amplifying the target nucleic acid molecule using PCR in an amplification reaction mixture in a detection

tube resulting in the production of amplicons corresponding to the target nucleic acid molecule. In this method, the amplification reaction mixture includes (1) a target nucleic acid molecule, (2) a polymerase with 5'exonuclease activity, (3) amplification primers specific for the target nucleic acid molecule, and (4) oligonucleotide tethered superparamagnetic particles, wherein the oligonucleotide tether connects at

5   least two superparamagnetic particles and the oligonucleotide tether is substantially complementary to a portion of the nucleic acid sequence of the amplicons. In this method, the amplification is performed in a device including a support defining a well for holding the detection tube including the superparamagnetic particles and the target nucleic acid molecule, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the sample to a bias magnetic field created using one

10   or more magnets and an RF pulse sequence. The amplification of this method includes the following steps:

(a)   performing one or more cycles of PCR under conditions permitting the hybridization of the oligonucleotide tether to an amplicon during the extension phase of the PCR, wherein during the extension phase of the PCR, the 5' exonuclease activity of the polymerase untethers the at

15   least two superparamagnetic particles permitting a decrease in superparamagnetic particle aggregation;

(b)   exposing the sample to a bias magnetic field and an RF pulse sequence;

(c)   following step (b), measuring the signal from the detection tube;

(d)   repeating steps (a)-(c) until the PCR is complete; and

20   (e)   on the basis of the result of step (c), quantifying the amplicons present at the corresponding cycle of PCR.

In this method, the initial quantity of target nucleic acid molecule in the sample is determined based on the quantity of amplicons determined at each cycle of the PCR.

The invention also features a method of quantifying a target nucleic acid molecule in a sample by

25   amplifying the target nucleic acid molecule (e.g., using PCR or isothermal amplification) in an amplification reaction mixture in a detection tube resulting in the production of amplicons corresponding to the target nucleic acid molecule. In this method, the amplification reaction mixture includes (1) a target nucleic acid molecule, (2) amplification primers specific for the target nucleic acid molecule, and (3) superparamagnetic particles labeled with a plurality of oligonucleotides, wherein a first group of the

30   plurality of oligonucleotides are substantially complementary to a portion of the nucleic acid sequence of the amplicons and substantially complementary to a second group of the plurality of oligonucleotides, wherein the first group of the plurality of oligonucleotides has a lesser hybridization affinity for the second group of the plurality of oligonucleotides than for the amplicons. In this method, the amplification is performed in a device including a support defining a well for holding the detection tube

35   including the superparamagnetic particles and the target nucleic acid molecule, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the sample to a

bias magnetic field created using one or more magnets and an RF pulse sequence. The amplification of this method includes the following steps:

(a) performing one or more cycles of amplification;

(b) exposing the amplification reaction mixture to conditions permitting the preferential hybridization of the first group of the plurality of oligonucleotides with the amplicons thereby permitting disaggregation of the superparamagnetic particles;

(c) exposing the sample to a bias magnetic field and an RF pulse sequence;

(d) following step (c), measuring the signal from the detection tube;

(e) repeating steps (a)-(d) until a desired amount of amplification is obtained; and

(f) on the basis of the result of step (d); quantifying the amplicons present at the corresponding cycle of amplification.

In this method, the initial quantity of target nucleic acid molecule in the sample is determined based on the quantity of amplicons determined at each cycle of the amplification.

The invention further features a method of quantifying a target nucleic acid molecule in a sample by amplifying the target nucleic acid molecule (e.g., using PCR or isothermal amplification) in an amplification reaction mixture in a detection tube resulting in the production of amplicons corresponding to the target nucleic acid molecule. In this method, the amplification reaction mixture includes (1) a target nucleic acid molecule, (2) amplification primers specific for the target nucleic acid molecule, and (3) superparamagnetic particles. In this method, the amplification is performed in a device including a support defining a well for holding the detection tube including the superparamagnetic particles and the target nucleic acid molecule, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the sample to a bias magnetic field created using one or more magnets and an RF pulse sequence. The amplification of this method including the following steps:

(a) performing one or more cycles of amplification;

(b) exposing the amplification reaction mixture to conditions permitting the aggregation or disaggregation of the superparamagnetic particles,

(c) exposing the sample to a bias magnetic field and an RF pulse sequence;

(d) following step (c), measuring the signal from the detection tube;

(e) repeating steps (a)-(d) until a desired amount of amplification is obtained; and

(f) on the basis of the result of step (d), quantifying the amplicons present at the corresponding cycle of amplification.

In this method, the initial quantity of target nucleic acid molecule in the sample is determined based on the quantity of amplicons determined at each cycle of the amplification.

In any of the foregoing methods of quantifying a target nucleic acid molecule, the detection tube can remained sealed throughout the amplification reaction. The superparamagnetic particles of these methods can be greater or less than 100 nm in diameter (e.g., 30 nm in diameter).

Also, in any of the foregoing methods of quantifying a target nucleic acid molecule, the methods can further include applying a magnetic field to the detection tube following the measuring the signal from the detection tube, resulting in the sequestration of the superparamagnetic particles to the side of the detection tube, and releasing the magnetic field subsequent to the completion of one or more additional

5   cycles of amplification.

Also, in any of the foregoing methods of quantifying a target nucleic acid molecule, the sample can, e.g., not include isolated nucleic acid molecules prior to step (a) (e.g., the sample can be whole blood or not contain a target nucleic acid molecule prior to step (a)).

The invention features a method of monitoring one or more analytes in a liquid sample derived

10   from a patient for the diagnosis, management, or treatment of a medical condition in a patient, the method including (a) combining with the liquid sample from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the liquid sample (e.g., from 1×10^6 to 1×10^8, 1×10^7 to 1×10^8, 1×10^7 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{11}, or 1×10^{10} to 1×10^{13} magnetic particles per milliliter), wherein the magnetic particles have a mean diameter of from 150 nm to 1200 nm (e.g., from 150 to 250, 200 to 350, 250 to 450, 300 to 500, 450 to

15   650, 500 to 700 nm, 700 to 850, 800 to 950, 900 to 1050, or from 1000 to 1200 nm), and a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} mM^{-1}s^{-1} (e.g., from 1×10^8 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{10}, 1×10^9 to 1×10^{11}, or from 1×10^{10} to 1×10^{12} mM^{-1}s^{-1}), and wherein the magnetic particles have binding moieties on their surfaces, the binding moieties operative to alter the specific aggregation of the magnetic particles in the presence of the one or more analytes or a multivalent binding agent; (b) placing the liquid

20   sample in a device, the device including a support defining a well for holding the liquid sample including the magnetic particles and the one or more analytes, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using one or more magnets and an RF pulse sequence; (c) exposing the sample to the bias magnetic field and the RF pulse sequence; (d) following step (c), measuring the signal; (e) on the basis of

25   the result of step (d), monitoring the one or more analytes; and (f) using the result of step (e) to diagnose, manage, or treat the medical condition. In one embodiment, the one or more analytes include creatinine. In another embodiment, the patient is immunocompromised, and the one or more analytes include an analyte selected from pathogen-associated analytes, antibiotic agents, antifungal agents, and antiviral agents (e.g., the one or more analytes can include Candida spp., tacrolimus, fluconazole, and/or

30   creatinine). In still another embodiment, the patient has cancer, and the one or more analytes are selected from anticancer agents, and genetic markers present in a cancer cell. The patient can have, or be at risk of, an infection, and the one or more analytes include an analyte selected from pathogen-associated analytes, antibiotic agents, antifungal agents, and antiviral agents. The patient can have an immunoinflammatory condition, and the one or more analytes include an analyte selected from

35   antiinflammatory agents and TNF-alpha. The patient can have heart disease, and the one or more analytes can include a cardiac marker. The patient can have HIV/AIDS, and the one or more analytes can include CD3, viral load, and AZT. In certain embodiments, the method is used to monitor the liver

- 17 -

function of the patient, and wherein the one or more analytes are selected from albumin, aspartate transaminase, alanine transaminase, alkaline phosphatase, gamma glutamyl transpeptidase, bilirubin, alpha fetoprotein, lactase dehydrogenase, mitochondrial antibodies, and cytochrome P450. For example, the one or more analytes include cytochrome P450 polymorphisms, and the ability of the patient to metabolize a drug is evaluated. The method can include identifying the patient as a poor metabolizer, a normal metabolizer, an intermediate metabolizer, or an ultra rapid metabolizer. The method can be used to determine an appropriate dose of a therapeutic agent in a patient by (i) administering the therapeutic agent to the patient; (ii) following step (i), obtaining a sample including the therapeutic agent or metabolite thereof from the patient; (iii) contacting the sample with the magnetic particles and exposing the sample to the bias magnetic field and the RF pulse sequence and detecting a signal produced by the sample; and (iv) on the basis of the result of step (iii), determining the concentration of the therapeutic agent or metabolite thereof. The therapeutic agent can be an anticancer agent, antibiotic agent, antifungal agent, or any therapeutic agent described herein. In any of the above methods of monitoring, the monitoring can be intermittent (e.g., periodic), or continuous. In certain embodiments, the magnetic particles are substantially monodisperse; exhibit nonspecific reversibility in the absence of the analyte and multivalent binding agent; and/or the magnetic particles further include a surface decorated with a blocking agent selected from albumin, fish skin gelatin, gamma globulin, lysozyme, casein, peptidase, and an amine-bearing moiety (e.g., amino polyethyleneglycol, glycine, ethylenediamine, or amino dextran). In particular embodiments, the liquid sample further includes a buffer, from 0.1% to 3% (w/w) albumin (e.g., from 0.1% to 0.5%, 0.3% to 0.7%, 0.5% to 1%, 0.8% to 2%, or from 1.5% to 3% (w/w) albumin), from 0.01% to 0.5% nonionic surfactant (e.g., from 0.01% to 0.05%, 0.05% to 0.1%, 0.05% to 0.2%, 0.1% to 0.3%, 0.2% to 0.4%, or from 0.3% to 0.5% nonionic surfactant), or a combination thereof. In still other embodiments, the magnetic particles include a surface decorated with 40 µg to 100 µg (e.g., 40 µg to 60 µg, 50 µg to 70 µg, 60 µg to 80 µg, or 80 µg to 100 µg,) of one or more proteins per milligram of the magnetic particles. The liquid sample can include a multivalent binding agent bearing a plurality of analytes conjugated to a polymeric scaffold. The method for monitoring can include any of the magnetic assisted agglomeration methods described herein.

The invention features a method of diagnosing sepsis in a subject, the method including (a) obtaining a liquid sample derived from the blood of a patient; (b) preparing a first assay sample by combining with a portion of the liquid sample from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the liquid sample (e.g., from 1×10^6 to 1×10^8, 1×10^7 to 1×10^8, 1×10^7 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{11}, or 1×10^{10} to 1×10^{13} magnetic particles per milliliter), wherein the magnetic particles have a mean diameter of from 150 nm to 1200 nm (e.g., from 150 to 250, 200 to 350, 250 to 450, 300 to 500, 450 to 650, 500 to 700 nm, 700 to 850, 800 to 950, 900 to 1050, or from 1000 to 1200 nm), and a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} mM^{-1}s^{-1} (e.g., from 1×10^8 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{10}, 1×10^9 to 1×10^{11}, or from 1×10^{10} to 1×10^{12} mM^{-1}s^{-1}), and wherein the magnetic particles have binding moieties on their surfaces, the binding moieties operative to alter the specific aggregation of the magnetic

particles in the presence of one or more pathogen-associated analytes or a multivalent binding agent; (c) preparing a second assay sample by combining with a portion of the liquid sample from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the liquid sample (e.g., from 1×10^6 to 1×10^8, 1×10^7 to 1×10^8, 1×10^7 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{11}, or 1×10^{10} to 1×10^{13} magnetic particles per milliliter), wherein

5   the magnetic particles have a mean diameter of from 150 nm to 1200 nm (e.g., from 150 to 250, 200 to 350, 250 to 450, 300 to 500, 450 to 650, 500 to 700 nm, 700 to 850, 800 to 950, 900 to 1050, or from 1000 to 1200 nm), and a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} mM^{-1}s^{-1} (e.g., from 1×10^8 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{10}, 1×10^9 to 1×10^{11}, or from 1×10^{10} to 1×10^{12} mM^{-1}s^{-1}), and wherein the magnetic particles have binding moieties on their surfaces, the binding moieties operative to

10   alter the specific aggregation of the magnetic particles in the presence of one or more analytes characteristic of sepsis selected from GRO-alpha, High mobility group-box 1 protein (HMBG-1), IL-1 receptor, IL-1 receptor antagonist, IL-1b, IL-2, IL-4, IL-6, IL-8, IL-10, IL-12, IL-13, IL-18, macrophage inflammatory protein (MIP-1), macrophage migration inhibitory factor (MIF), osteopontin, RANTES (regulated on activation, normal T-cell expressed and secreted; or CCL5), TNF-α, C-reactive protein

15   (CRP), CD64, monocyte chemotactic protein 1 (MCP-1), adenosine deaminase binding protein (ABP-26), inducible nitric oxide synthetase (iNOS), lipopolysaccharide binding protein, and procalcitonin; (d) placing each assay sample in a device, the device including a support defining a well for holding the liquid sample including the magnetic particles and the one or more analytes, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample

20   to a bias magnetic field created using one or more magnets and an RF pulse sequence; (e) exposing each assay sample to the bias magnetic field and the RF pulse sequence; (f) following step (e), measuring the signal produced by the first assay sample and the signal produced by the second assay sample; (g) on the basis of the result of step (f), monitoring the one or more analytes of the first assay sample and monitoring the one or more analytes of the second assay sample; and (h) using the results of step (g) to

25   diagnose the subject. In one embodiment, the one or more pathogen-associated analytes of the first assay sample are derived from a pathogen associated with sepsis selected from Acinetobacter baumannii, Aspergillus fumigatis, Bacteroides fragilis, B. fragilis, blaSHV, Burkholderia cepacia, Campylobacter jejuni/coli, Candida guilliermondii, C. albicans, C. glabrata, C. krusei, C. lusitaniae, C. parapsilosis, C. tropicalis, Clostridium pefringens, Coagulase negative Staph, Enterobacter aeraogenes, E. cloacae,

30   Enterobacteriaceae, Enterococcus faecalis, E. faecium, Escherichia coli, Haemophilus influenzae, Kingella Kingae, Klebsiella oxytoca, K. pneumoniae, Listeria monocytogenes, Mec A gene (MRSA), Morganella morgana, Neisseria meningitidis, Neisseria spp. non-meningitidis, Prevotella buccae, P. intermedia, P. melaninogenica, Propionibacterium acnes, Proteus mirabilis, P. vulgaris, Pseudomonas aeruginosa, Salmonella enterica, Serratia marcescens, Staphylococcus aureus, S. haemolyticus, S.

35   maltophilia, S. saprophyticus, Stenotrophomonas maltophilia, S. maltophilia, Streptococcus agalactie, S. bovis, S. dysgalactie, S. mitis, S. mutans, S. pneumoniae, S. pyogenes, and S. sanguinis. The one or more pathogen-associated analytes can be derived from treatment resistant strains of bacteria, such as

penicillin-resistant, methicillin-resistant, quinolone-resistant, macrolide-resistant, and/or vancomycin-resistant bacterial strains (e.g., methicillin resistant Staphylococcus aureus or vancomycin-resistant enterococci). In certain embodiments, the one or more analytes of the second assay sample are selected from GRO-alpha, High mobility group-box 1 protein (HMBG-1), IL-1 receptor, IL-1 receptor antagonist,

5   IL-1b, IL-2, IL-4, IL-6, IL-8, IL-10, IL-12, IL-13, IL-18, macrophage inflammatory protein (MIP-1), macrophage migration inhibitory factor (MIF), osteopontin, RANTES (regulated on activation, normal T-cell expressed and secreted; or CCL5), TNF-α, C-reactive protein (CRP), CD64, and monocyte chemotactic protein 1 (MCP-1). In a particular embodiment, the method further includes preparing a third assay sample to monitor the concentration of an antiviral agent, antibiotic agent, or antifungal agent

10   circulating in the blood stream of the subject. In certain embodiments, the subject can be an immunocompromised subject, or a subject at risk of becoming immunocompromised. In any of the above methods of monitoring, the monitoring can be intermittent (e.g., periodic), or continuous. In certain embodiments, the magnetic particles are substantially monodisperse; exhibit nonspecific reversibility in the absence of the analyte and multivalent binding agent; and/or the magnetic particles further include a

15   surface decorated with a blocking agent selected from albumin, fish skin gelatin, gamma globulin, lysozyme, casein, peptidase, and an amine-bearing moiety (e.g., amino polyethyleneglycol, glycine, ethylenediamine, or amino dextran). In particular embodiments, the liquid sample further includes a buffer, from 0.1% to 3% (w/w) albumin (e.g., from 0.1% to 0.5%, 0.3% to 0.7%, 0.5% to 1%, 0.8% to 2%, or from 1.5% to 3% (w/w) albumin), from 0.01% to 0.5% nonionic surfactant (e.g., from 0.01% to

20   0.05%, 0.05% to 0.1%, 0.05% to 0.2%, 0.1% to 0.3%, 0.2% to 0.4%, or from 0.3% to 0.5% nonionic surfactant), or a combination thereof. In still other embodiments, the magnetic particles include a surface decorated with 40 μg to 100 μg (e.g., 40 μg to 60 μg, 50 μg to 70 μg, 60 μg to 80 μg, or 80 μg to 100 μg,) of one or more proteins per milligram of the magnetic particles. The liquid sample can include a multivalent binding agent bearing a plurality of analytes conjugated to a polymeric scaffold. The method

25   for monitoring can include any of the magnetic assisted agglomeration methods described herein.

The invention further features a method of monitoring one or more analytes in a liquid sample derived from a patient for the diagnosis, management, or treatment of sepsis or SIRS in a patient, the method including: (a) combining with the liquid sample from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the liquid sample (e.g., from 1×10^6 to 1×10^8, 1×10^7 to 1×10^8, 1×10^7 to 1×10^9, 1×10^8 to

30   1×10^{10}, 1×10^9 to 1×10^{11}, or 1×10^{10} to 1×10^{13} magnetic particles per milliliter), wherein the magnetic particles have a mean diameter of from 150 nm to 1200 nm (e.g., from 150 to 250, 200 to 350, 250 to 450, 300 to 500, 450 to 650, 500 to 700 nm, 700 to 850, 800 to 950, 900 to 1050, or from 1000 to 1200 nm), and a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} mM^{-1}s^{-1} (e.g., from 1×10^8 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{10}, 1×10^9 to 1×10^{11}, or from 1×10^{10} to 1×10^{12} mM^{-1}s^{-1}), and wherein the magnetic

35   particles have binding moieties on their surfaces, the binding moieties operative to alter the specific aggregation of the magnetic particles in the presence of the one or more analytes or a multivalent binding agent; (b) placing the liquid sample in a device, the device including a support defining a well for holding

the liquid sample including the magnetic particles and the one or more analytes, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using one or more magnets and an RF pulse sequence; (c) exposing the sample to the bias magnetic field and the RF pulse sequence; (d) following step (c), measuring the signal;

5   (e) on the basis of the result of step (d), monitoring the one or more analytes; and (f) using the result of step (e) to diagnose, manage, or treat the sepsis or SIRS. The method can include (i) monitoring a pathogen-associated analyte, and (ii) monitoring a second analyte characteristic of sepsis selected from GRO-alpha, High mobility group-box 1 protein (HMBG-1), IL-1 receptor, IL-1 receptor antagonist, IL-1b, IL-2, IL-4, IL-6, IL-8, IL-10, IL-12, IL-13, IL-18, macrophage inflammatory protein (MIP-1),

10   macrophage migration inhibitory factor (MIF), osteopontin, RANTES (regulated on activation, normal T-cell expressed and secreted; or CCL5), TNF-α, C-reactive protein (CRP), CD64, monocyte chemotactic protein 1 (MCP-1), adenosine deaminase binding protein (ABP-26), inducible nitric oxide synthetase (iNOS), lipopolysaccharide binding protein, and procalcitonin. In certain embodiments, the pathogen-associated analyte is derived from a pathogen associated with sepsis selected from Acinetobacter

15   baumannii, Aspergillus fumigatis, Bacteroides fragilis, B. fragilis, blaSHV, Burkholderia cepacia, Campylobacter jejuni/coli, Candida guilliermondii, C. albicans, C. glabrata, C. krusei, C. Lusitaniae, C. parapsilosis, C. tropicalis, Clostridium pefringens, Coagulase negative Staph, Enterobacter aeraogenes, E. cloacae, Enterobacteriaceae, Enterococcus faecalis, E. faecium, Escherichia coli, Haemophilus influenzae, Kingella Kingae, Klebsiella oxytoca, K. pneumoniae, Listeria monocytogenes, Mec A gene

20   (MRSA), Morganella morgana, Neisseria meningitidis, Neisseria spp. non-meningitidis, Prevotella buccae, P. intermedia, P. melaninogenica, Propionibacterium acnes, Proteus mirabilis, P. vulgaris, Pseudomonas aeruginosa, Salmonella enterica, Serratia marcescens, Staphylococcus aureus, S. haemolyticus, S. maltophilia, S. saprophyticus, Stenotrophomonas maltophilia, S. maltophilia, Streptococcus agalactie, S. bovis, S. dysgalactie, S. mitis, S. mutans, S. pneumoniae, S. pyogenes, and S.

25   sanguinis. The pathogen-associated analyte can be derived from a treatment resistant strain of bacteria, such as penicillin-resistant, methicillin-resistant, quinolone-resistant, macrolide-resistant, and/or vancomycin-resistant bacterial strains (e.g., methicillin resistant Staphylococcus aureus or vancomycin-resistant enterococci). In particular embodiments, the second analytes is selected from GRO-alpha, High mobility group-box 1 protein (HMBG-1), IL-1 receptor, IL-1 receptor antagonist, IL-1b, IL-2, IL-4, IL-6,

30   IL-8, IL-10, IL-12, IL-13, IL-18, macrophage inflammatory protein (MIP-1), macrophage migration inhibitory factor (MIF), osteopontin, RANTES (regulated on activation, normal T-cell expressed and secreted; or CCL5), TNF-α, C-reactive protein (CRP), CD64, and monocyte chemotactic protein 1 (MCP-1). In a particular embodiment, the method further includes preparing a third assay sample to monitor the concentration of an antiviral agent, antibiotic agent, or antifungal agent circulating in the blood stream of

35   the subject. In certain embodiments, the subject can be an immunocompromised subject, or a subject at risk of becoming immunocompromised. In any of the above methods of monitoring, the monitoring can be intermittent (e.g., periodic), or continuous. In certain embodiments, the magnetic particles are

substantially monodisperse; exhibit nonspecific reversibility in the absence of the analyte and multivalent binding agent; and/or the magnetic particles further include a surface decorated with a blocking agent selected from albumin, fish skin gelatin, gamma globulin, lysozyme, casein, peptidase, and an amine-bearing moiety (e.g., amino polyethyleneglycol, glycine, ethylenediamine, or amino dextran). In particular embodiments, the liquid sample further includes a buffer, from 0.1% to 3% (w/w) albumin (e.g., from 0.1% to 0.5%, 0.3% to 0.7%, 0.5% to 1%, 0.8% to 2%, or from 1.5% to 3% (w/w) albumin), from 0.01% to 0.5% nonionic surfactant (e.g., from 0.01% to 0.05%, 0.05% to 0.1%, 0.05% to 0.2%, 0.1% to 0.3%, 0.2% to 0.4%, or from 0.3% to 0.5% nonionic surfactant), or a combination thereof. In still other embodiments, the magnetic particles include a surface decorated with 40 µg to 100 µg (e.g., 40 µg to 60 µg, 50 µg to 70 µg, 60 µg to 80 µg, or 80 µg to 100 µg,) of one or more proteins per milligram of the magnetic particles. The liquid sample can include a multivalent binding agent bearing a plurality of analytes conjugated to a polymeric scaffold. The method for monitoring can include any of the magnetic assisted agglomeration methods described herein.

In a related aspect, the invention features a method for assisting the specific agglomeration of magnetic particles in a liquid sample, the method including: (i) providing a liquid sample including one or more analytes and the magnetic particles, wherein the magnetic particles have binding moieties on their surfaces, the binding moieties operative to alter the specific aggregation of the magnetic particles in the presence of the one or more analytes or a multivalent binding agent; (ii) exposing the liquid sample to a magnetic field; (iii) removing the liquid sample from the magnetic field; and (iv) repeating step (ii).

The invention further features a method for assisting the specific agglomeration of magnetic particles in a liquid sample by (i) providing a liquid sample including one or more analytes and the magnetic particles, wherein the magnetic particles have binding moieties on their surfaces, the binding moieties operative to alter the specific aggregation of the magnetic particles in the presence of the one or more analytes or a multivalent binding agent; (ii) applying a magnetic field gradient to the liquid sample for a time sufficient to cause concentration of the magnetic particles in a first portion of the liquid sample, the magnetic field gradient being aligned in a first direction relative to the liquid sample; (iii) following step (ii), applying a magnetic field to the liquid sample for a time sufficient to cause concentration of the magnetic particles in a second portion of the liquid sample, the magnetic field being aligned in a second direction relative to the liquid sample; and (iv) optionally repeating steps (ii) and (iii). In certain embodiments, the angle between the first direction and the second direction relative to the liquid sample is between 0° and 180° (e.g., from 0° to 10°, 5° to 120°, 20° to 60°, 30° to 80°, 45° to 90°, 60° to 120°, 80° to 135°, or from 120° to 180°).

The invention features a method for assisting the specific agglomeration of magnetic particles in a liquid sample by (i) providing a liquid sample including one or more analytes and the magnetic particles, wherein the magnetic particles have binding moieties on their surfaces, the binding moieties operative to alter the specific aggregation of the magnetic particles in the presence of the one or more analytes or a multivalent binding agent; (ii) applying a magnetic field gradient to the liquid sample for a time sufficient

to cause concentration of the magnetic particles in a first portion of the liquid sample; (iii) following step (ii), agitating the liquid sample; and (iv) repeating step (ii). In certain embodiments, step (iii) includes vortexing the liquid sample, or mixing the sample using any method described herein.

The invention also features a method for assisting the specific agglomeration of magnetic particles in a liquid sample by (i) providing a liquid sample including one or more analytes and the magnetic particles, wherein the magnetic particles have binding moieties on their surfaces, the binding moieties operative to alter the specific aggregation of the magnetic particles in the presence of the one or more analytes or a multivalent binding agent; and (ii) exposing the liquid sample to a gradient magnetic field and rotating the gradient magnetic field about the sample, or rotating the sample within the gradient magnetic field. The sample can be rotated slowly. In certain embodiments, the sample is rotated at a rate of 0.0333 Hz, or less (e.g., from 0.000833 Hz to 0.0333 Hz, from 0.00166 Hz to 0.0333 Hz, or from 0.00333 Hz to 0.0333 Hz). In other embodiments, the method further includes (iii) following step (ii), agitating the liquid sample; and (iv) repeating step (ii).

In any of the above methods for assisting specific agglomeration step (ii) can be repeated from 1 to 100 times (e.g., repeated 1, 2, 3, 4, 5, 6, 7, 8, 9, or 10 times, from 10 to 20 times, or from 80 to 100 times). In particular embodiments, the one or more magnets providing the magnetic field gradient within the liquid sample have a maximum field strength of from 0.01T to 10T (e.g., from 0.01T to 0.05T, 0.05T to 0.1T, 0.1T to 0.5T, 0.5T to 1T, 1T to 3T, or from 3T to 10T) and wherein the gradient magnetic field varies from 0.1mT/mm to 10T/mm across the liquid sample (e.g., from 0.1mT/mm to 0.5mT/mm, 0.3mT/mm to 1mT/mm, 0.5mT/mm to 5mT/mm, 5mT/mm to 20mT/mm, 10mT/mm to 100mT/mm, 100mT/mm to 500mT/mm, 500mT/mm to 1T/mm, or from 1T/mm to 10T/mm). In certain embodiments of any of the above methods for assisting specific agglomeration, step (ii) includes applying the magnetic field gradient to the liquid sample for a period of from 1 second to 5 minutes (e.g., from 1 to 20 seconds, from 20 to 60 seconds, from 30 seconds to 2 minutes, from 1 minutes to 3 minutes, or from 2 minutes to 5 minutes). In particular embodiments, (i) the liquid sample includes from 1×10^5 to 1×10^{15} of the one or more analytes per milliliter of the liquid sample (e.g., from 1×10^5 to 1×10^6, 1×10^6 to 1×10^8, 1×10^7 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{12}, or 1×10^{11} to 1×10^{15} analytes per milliliter); (ii) the liquid sample includes from 1×10^6 to 1×10^{13} of the magnetic particles per milliliter of the liquid sample (e.g., from 1×10^6 to 1×10^8, 1×10^7 to 1×10^8, 1×10^7 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{11}, or 1×10^{10} to 1×10^{13} magnetic particles per milliliter); (iii) the magnetic particles have a T_2 relaxivity per particle of from 1×10^4 to 1×10^{12} $mM^{-1}s^{-1}$ (e.g., from 1×10^4 to 1×10^7, 1×10^6 to 1×10^{10}, 1×10^7 to 1×10^9, 1×10^8 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{10}, 1×10^9 to 1×10^{11}, or from 1×10^{10} to 1×10^{12} $mM^{-1}s^{-1}$); (iv) the magnetic particles have an average diameter of from 150 nm to 1200 nm (e.g., from 150 to 250, 200 to 350, 250 to 450, 300 to 500, 450 to 650, 500 to 700 nm, 700 to 850, 800 to 950, 900 to 1050, or from 1000 to 1200 nm); (v) the magnetic particles are substantially monodisperse; (vi) the magnetic particles in the liquid sample exhibit nonspecific reversibility in the absence of the one or more analytes and multivalent binding agent; (vii) the magnetic particles further include a surface decorated with a blocking agent

selected from albumin, fish skin gelatin, gamma globulin, lysozyme, casein, peptidase, and an amine-bearing moiety (e.g., amino polyethyleneglycol, glycine, ethylenediamine, or amino dextran); (viii) the liquid sample further includes a buffer, from 0.1% to 3% (w/w) albumin (e.g., from 0.1% to 0.5%, 0.3% to 0.7%, 0.5% to 1%, 0.8% to 2%, or from 1.5% to 3% (w/w) albumin), from 0.01% to 0.5% nonionic

5   surfactant (e.g., from 0.01% to 0.05%, 0.05% to 0.1%, 0.05% to 0.2%, 0.1% to 0.3%, 0.2% to 0.4%, or from 0.3% to 0.5% nonionic surfactant), or a combination thereof; and/or (ix) the magnetic particles include a surface decorated with 40 μg to 100 μg (e.g., 40 μg to 60 μg, 50 μg to 70 μg, 60 μg to 80 μg, or 80 μg to 100 μg,) of one or more proteins per milligram of the magnetic particles.

The invention features a system for the detection of one or more analytes, the system including:

10   (a) a first unit including (a1) a permanent magnet defining a magnetic field; (a2) a support defining a well for holding a liquid sample including magnetic particles and the one or more analytes and having an RF coil disposed about the well, the RF coil configured to detect a signal by exposing the liquid sample to a bias homogenous magnetic field created using the permanent magnet and an RF pulse sequence; and (a3) one or more electrical elements in communication with the RF coil, the electrical elements configured to

15   amplify, rectify, transmit, and/or digitize the signal; and (b) one or more second units including (b1) a permanent magnet adjacent a first sample position for holding a liquid sample and configured to apply a first gradient magnetic field to the liquid sample. The one or more second units can further include a second permanent magnet adjacent a second sample position for holding a liquid sample and configured to apply a second gradient magnetic field to the liquid sample, the second magnetic field aligned to apply

20   a gradient magnetic field to the sample from a direction different from the direction of the first field gradient, and a means for moving a liquid sample from the first sample position to the second sample position. In certain embodiments, the one or more second units is incapable of measuring a signal (e.g., incapable of measuring an NMR relaxation rate), and/or lacks an RF coil, or a means for producing an RF pulse. In certain embodiments, the angle between the first direction and the second direction relative to

25   the liquid sample is between 0° and 180° (e.g., from 0° to 10°, 5° to 120°, 20° to 60°, 30° to 80°, 45° to 90°, 60° to 120°, 80° to 135°, or from 120° to 180°). The system can further include a sample holder for holding the liquid sample and configured to move the liquid sample from the first position to the second position. In particular embodiments, the system includes an array of the one or more second units for assisting the agglomeration of an array of samples simultaneously. For example, the array can be

30   configured to rotate one or more liquid from a first position in which a magnetic field is applied to the side of a sample to a second position in which a magnetic field is applied to the bottom of a sample. The system can include a cartridge unit, an agitation unit, a centrifuge, or any other system component described herein. For example, the system can further include (c) a third unit including a removable cartridge sized to facilitate insertion into and removal from the system and having a compartment

35   including one or more populations of magnetic particles having binding moieties on their surfaces, wherein the binding moieties are operative to alter an aggregation of the magnetic particles in the presence of the one or more analytes. In particular embodiments, the removable cartridge is a modular

cartridge including (i) a reagent module for holding one or more assay reagents; and (ii) a detection module including a detection chamber for holding a liquid sample including magnetic particles and one or more analytes, wherein the reagent module and the detection module can be assembled into the modular cartridge prior to use, and wherein the detection chamber is removable from the modular cartridge. The

5   modular cartridge can further include an inlet module, wherein the inlet module, the reagent module, and the detection module can be assembled into the modular cartridge prior to use, and wherein the inlet module is sterilizable. In another embodiment, the system can further include a system computer with processor for implementing an assay protocol and storing assay data, and wherein the removable cartridge further includes (i) a readable label indicating the analyte to be detected, (ii) a readable label indicating

10   the assay protocol to be implemented, (iii) a readable label indicating a patient identification number, (iv) a readable label indicating the position of assay reagents contained in the cartridge, or (v) a readable label including instructions for the programmable processor.

The invention further features a system for the detection of one or more analytes, the system including: (a) a first unit including (a1) a permanent magnet defining a magnetic field; (a2) a support

15   defining a well for holding a liquid sample including magnetic particles and the one or more analytes and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using the permanent magnet and an RF pulse sequence; and (a3) one or more electrical elements in communication with the RF coil, the electrical elements configured to amplify, rectify, transmit, and/or digitize the signal; and (b) a second unit including a

20   removable cartridge sized to facilitate insertion into and removal from the system, wherein the removable cartridge is a modular cartridge including (i) a reagent module for holding one or more assay reagents; and (ii) a detection module including a detection chamber for holding a liquid sample including the magnetic particles and the one or more analytes, wherein the reagent module and the detection module can be assembled into the modular cartridge prior to use, and wherein the detection chamber is removable

25   from the modular cartridge. The modular cartridge can further include an inlet module, wherein the inlet module, the reagent module, and the detection module can be assembled into the modular cartridge prior to use, and wherein the inlet module is sterilizable. In certain embodiments, the system further includes a system computer with processor for implementing an assay protocol and storing assay data, and wherein the removable cartridge further includes (i) a readable label indicating the analyte to be detected, (ii) a

30   readable label indicating the assay protocol to be implemented, (iii) a readable label indicating a patient identification number, (iv) a readable label indicating the position of assay reagents contained in the cartridge, or (v) a readable label including instructions for the programmable processor. The system can include a cartridge unit, an agitation unit, a centrifuge, or any other system component described herein.

The invention features an agitation unit for the automated mixing of a liquid sample in a sample

35   chamber, including a motor for providing a rotational driving force to a motor shaft coupled to a drive shaft, the driveshaft having a first end coupled to the motor shaft and a second end coupled to a plate bearing a sample holder for holding the sample chamber, the draft shaft including a first axis coaxial to

the motor shaft, and a second axis that is offset and parallel to the motor shaft, such that the second axis of the driveshaft, the plate, and the sample holder are driven in an orbital path, wherein the motor includes an index mark and/or other position sensing means such as an optical, magnetic or resitive position encoder for positioning the sample chamber in a predetermined position following the mixing or a sensor

5   which tracks the sample's position throughout its path.

The invention features a system for the detection of one or more analytes, the system including: (a) a first unit including (a1) a permanent magnet defining a magnetic field; (a2) a support defining a well for holding a liquid sample including magnetic particles and the one or more analytes and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid

10   sample to a bias magnetic field created using the permanent magnet and an RF pulse sequence; and (a3) one or more electrical elements in communication with the RF coil, the electrical elements configured to amplify, rectify, transmit, and/or digitize the signal; and (b) a second unit for the automated mixing of a liquid sample in a sample chamber, including a motor for providing a rotational driving force to a motor shaft coupled to a drive shaft, the driveshaft having a first end coupled to the motor shaft and a second

15   end coupled to a plate bearing a sample holder for holding the sample chamber, the draft shaft including a first axis coaxial to the motor shaft, and a second axis that is offset and parallel to the motor shaft, such that the second axis of the driveshaft, the plate, and the sample holder are driven in an orbital path, wherein the motor includes an index mark and/or other position sensing means such as an optical, magnetic or resitive position encoder for positioning the sample chamber in a predetermined position

20   following the mixing or a sensor which tracks the sample's position throughout its path.

In certain embodiments, the system further includes a robotic arm for placing the sample chamber in, and removing the sample chamber from, the agitation unit.

The invention further features a system for the detection of one or more analytes, the system including: (a) a first unit including (a1) a permanent magnet defining a magnetic field; (a2) a support

25   defining a well for holding a liquid sample including magnetic particles and the one or more analytes and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using the permanent magnet and an RF pulse sequence; and (a3) one or more electrical elements in communication with the RF coil, the electrical elements configured to amplify, rectify, transmit, and/or digitize the signal; and (b) a centrifuge including a motor

30   for providing a rotational driving force to a drive shaft, the drive shaft having a first end coupled to the motor and a second end coupled to a centrifuge rotor bearing a sample holder for holding the sample chamber, wherein the motor includes an index mark and/or other position sensing means such as an optical, magnetic or resitive position encoder for positioning the sample chamber in a predetermined position following the centrifuging of the sample or a sensor which tracks the sample's position

35   throughout its path.

The invention further features a system for the detection of one or more analytes, the system including: (a) a disposable sample holder defining a well for holding a liquid sample and having an RF

coil contained within the disposable sample holder and disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using the permanent magnet and an RF pulse sequence, wherein the disposable sample holder includes one or more fusable links; and (b) an MR reader including (b1) a permanent magnet defining a magnetic field; (b2) an

5   RF pulse sequence and detection coil; (b3) one or more electrical elements in communication with the RF coil, the electrical elements configured to amplify, rectify, transmit, and/or digitize the signal; and (b4) one or more electrical elements in communication with the fusable link and configured to apply excess current to the fusable link, causing the link to break and rendering the coil inoperable following a predetermined working lifetime. In certain embodiments, the electrical element in communication with

10   the RF coil is inductively coupled to the RF coil.

The invention features a system for the detection of creatinine, tacrolimus, and Candida, the system including: (a) a first unit including (a1) a permanent magnet defining a magnetic field; (a2) a support defining a well for holding a liquid sample including magnetic particles and the creatinine, tacrolimus, and Candida and having an RF coil disposed about the well, the RF coil configured to detect

15   signal produced by exposing the liquid sample to a bias magnetic field created using the permanent magnet and an RF pulse sequence; and (a3) an electrical element in communication with the RF coil, the electrical element configured to amplify, rectify, transmit, and/or digitize the signal; and (b) a second unit including a removable cartridge sized to facilitate insertion into and removal from the system, wherein the removable cartridge is a modular cartridge including (i) a plurality of reagent modules for holding one or

20   more assay reagents; and (ii) a plurality of detection module including a detection chamber for holding a liquid sample including the magnetic particles and the creatinine, tacrolimus, and Candida, wherein the plurality of reagent modules includes (i) a first population of magnetic particles having a mean diameter of from 150 nm to 699 nm (e.g., from 150 to 250, 200 to 350, 250 to 450, 300 to 500, 450 to 650, or from 500 to 699 nm), a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} mM^{-1}s^{-1} (e.g., from 1×10^8 to 1×10^9,

25   1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{10}, 1×10^9 to 1×10^{11}, or from 1×10^{10} to 1×10^{12} mM^{-1}s^{-1}), and creatinine antibodies conjugated to their surface; (ii) a multivalent binding agent bearing a plurality of creatinine conjugates designed to form aggregates with the first population of magnetic particles in the absence of creatinine; (iii) a second population of magnetic particles having a mean diameter of from 150 nm to 699 nm (e.g., from 150 to 250, 200 to 350, 250 to 450, 300 to 500, 450 to 650, or from 500 to 699 nm), a T_2

30   relaxivity per particle of from 1×10^8 to 1×10^{12} mM^{-1}s^{-1} (e.g., from 1×10^8 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{10}, 1×10^9 to 1×10^{11}, or from 1×10^{10} to 1×10^{12} mM^{-1}s^{-1}), and tacrolimus antibodies conjugated to their surface; (iv) a multivalent binding agent bearing a plurality of tacrolimus conjugates designed to form aggregates with the second population of magnetic particles in the absence of tacrolimus; (v) a third population of magnetic particles have a mean diameter of from 700 nm to 1200 nm (e.g., from 700 to 850,

35   800 to 950, 900 to 1050, or from 1000 to 1200 nm), a T_2 relaxivity per particle of from 1×10^9 to 1×10^{12} mM^{-1}s^{-1} (e.g., from 1×10^8 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{10}, 1×10^9 to 1×10^{11}, or from 1×10^{10} to 1×10^{12} mM^{-1}s^{-1}), and having a first probe and a second probe conjugated to their surface selected to form

aggregates in the presence of a Candida nucleic acid, the first probe operative to bind to a first segment of the Candida nucleic acid and the second probe operative to bind to a second segment of the Candida nucleic acid. In certain embodiments, the magnetic particles are substantially monodisperse; exhibit nonspecific reversibility in the absence of the analyte and multivalent binding agent; and/or the magnetic

5   particles further include a surface decorated with a blocking agent selected from albumin, fish skin gelatin, gamma globulin, lysozyme, casein, peptidase, and an amine-bearing moiety (e.g., amino polyethyleneglycol, glycine, ethylenediamine, or amino dextran). In particular embodiments, the liquid sample further includes a buffer, from 0.1% to 3% (w/w) albumin (e.g., from 0.1% to 0.5%, 0.3% to 0.7%, 0.5% to 1%, 0.8% to 2%, or from 1.5% to 3% (w/w) albumin), from 0.01% to 0.5% nonionic

10   surfactant (e.g., from 0.01% to 0.05%, 0.05% to 0.1%, 0.05% to 0.2%, 0.1% to 0.3%, 0.2% to 0.4%, or from 0.3% to 0.5% nonionic surfactant), or a combination thereof. In still other embodiments, the magnetic particles include a surface decorated with 40 μg to 100 μg (e.g., 40 μg to 60 μg, 50 μg to 70 μg, 60 μg to 80 μg, or 80 μg to 100 μg,) of one or more proteins per milligram of the magnetic particles. The liquid sample can include a multivalent binding agent bearing a plurality of analytes conjugated to a

15   polymeric scaffold. In another embodiment, the liquid sample includes from 1×10^6 to 1×10^{13} of the magnetic particles per milliliter of the liquid sample (e.g., from 1×10^6 to 1×10^8, 1×10^7 to 1×10^8, 1×10^7 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{11}, or 1×10^{10} to 1×10^{13} magnetic particles per milliliter).
The invention features a method for measuring the concentration of creatinine in a liquid sample, the method including: (a) contacting a solution with (i) magnetic particles to produce a liquid sample

20   including from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the liquid sample (e.g., from 1×10^6 to 1×10^8, 1×10^7 to 1×10^8, 1×10^7 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{11}, or 1×10^{10} to 1×10^{13} magnetic particles per milliliter), wherein the magnetic particles have a mean diameter of from 150 nm to 1200 nm (e.g., from 150 to 250, 200 to 350, 250 to 450, 300 to 500, 450 to 650, 500 to 700 nm, 700 to 850, 800 to 950, 900 to 1050, or from 1000 to 1200 nm), a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} mM^{-1}s^{-1}

25   (e.g., from 1×10^8 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{10}, 1×10^9 to 1×10^{11}, or from 1×10^{10} to 1×10^{12} mM^{-1}s^{-1}), and creatinine antibodies conjugated to their surface, and (ii) a multivalent binding agent bearing a plurality of creatinine conjugates designed to form aggregates with the magnetic particles in the absence of creatinine; (b) placing the liquid sample in a device, the device including a support defining a well for holding the liquid sample including the magnetic particles, the multivalent binding agent, and the

30   creatinine, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using one or more magnets and an RF pulse sequence; (c) exposing the sample to a bias magnetic field and an RF pulse sequence; (d) following step (c), measuring the signal; and (e) on the basis of the result of step (d), determining the concentration of creatinine in the liquid sample. In certain embodiments, the magnetic particles are

35   substantially monodisperse; exhibit nonspecific reversibility in the absence of the analyte and multivalent binding agent; and/or the magnetic particles further include a surface decorated with a blocking agent selected from albumin, fish skin gelatin, gamma globulin, lysozyme, casein, peptidase, and an amine-

bearing moiety (e.g., amino polyethyleneglycol, glycine, ethylenediamine, or amino dextran). In particular embodiments, the liquid sample further includes a buffer, from 0.1% to 3% (w/w) albumin (e.g., from 0.1% to 0.5%, 0.3% to 0.7%, 0.5% to 1%, 0.8% to 2%, or from 1.5% to 3% (w/w) albumin), from 0.01% to 0.5% nonionic surfactant (e.g., from 0.01% to 0.05%, 0.05% to 0.1%, 0.05% to 0.2%,

5   0.1% to 0.3%, 0.2% to 0.4%, or from 0.3% to 0.5% nonionic surfactant), or a combination thereof. In still other embodiments, the magnetic particles include a surface decorated with 40 μg to 100 μg (e.g., 40 μg to 60 μg, 50 μg to 70 μg, 60 μg to 80 μg, or 80 μg to 100 μg,) of one or more proteins per milligram of the magnetic particles. The liquid sample can include a multivalent binding agent bearing a plurality of analytes conjugated to a polymeric scaffold.

10   The invention features a multivalent binding agent including two or more creatinine moieties covalently linked to a scaffold. In certain embodiments, the multivalent binding agent is a compound of formula (I):
$$(A)_n-(B) \quad (I)$$

wherein (A) is

15

(B) is a polymeric scaffold covalently attached to each (A), m is an integer from 2 to 10, and n is an integer from 2 to 50.

The invention features a solution including from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the solution (e.g., from 1×10^6 to 1×10^8, 1×10^7 to 1×10^8, 1×10^7 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to

20   1×10^{11}, or 1×10^{10} to 1×10^{13} magnetic particles per milliliter), wherein the magnetic particles have a mean diameter of from 150 nm to 600 nm (e.g., from 150 to 250, 200 to 350, 250 to 450, 300 to 500, 450 to 650, or from 500 to 600 nm), a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} mM^{-1}s^{-1} (e.g., from 1×10^8 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{10}, 1×10^9 to 1×10^{11}, or from 1×10^{10} to 1×10^{12} mM^{-1}s^{-1}), and a surface bearing creatinine conjugate (A), wherein (A) is selected from:

, and

,

and m is an integer from 2 to 10.

The invention further features solution including from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the solution (e.g., from 1×10^6 to 1×10^8, 1×10^7 to 1×10^8, 1×10^7 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{11}, or 1×10^{10} to 1×10^{13} magnetic particles per milliliter), wherein the magnetic particles have a mean diameter of from 150 nm to 600 nm (e.g., from 150 to 250, 200 to 350, 250 to 450, 300 to 500, 450 to 650, or from 500 to 600 nm), a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} $mM^{-1}s^{-1}$ (e.g., from 1×10^8 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{10}, 1×10^9 to 1×10^{11}, or from 1×10^{10} to 1×10^{12} $mM^{-1}s^{-1}$), and a surface bearing antibodies having affinity for the creatinine conjugate:

,

wherein (B) is a polymeric scaffold.

The invention further features a method for measuring the concentration of tacrolimus in a liquid sample, the method including: (a) contacting a solution with (i) magnetic particles to produce a liquid sample including from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the liquid sample (e.g., from 1×10^6 to 1×10^8, 1×10^7 to 1×10^8, 1×10^7 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{11}, or 1×10^{10} to 1×10^{13} magnetic particles per milliliter), wherein the magnetic particles have a mean diameter of from 150 nm to 1200 nm (e.g., from 150 to 250, 200 to 350, 250 to 450, 300 to 500, 450 to 650, 500 to 700 nm, 700 to 850, 800 to 950, 900 to 1050, or from 1000 to 1200 nm), a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} $mM^{-1}s^{-1}$ (e.g., from 1×10^8 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{10}, 1×10^9 to 1×10^{11}, or from 1×10^{10} to 1×10^{12} $mM^{-1}s^{-1}$), and tacrolimus antibodies conjugated to their surface, and (ii) a multivalent binding agent bearing a plurality of tacrolimus conjugates designed to form aggregates with the magnetic particles in the absence of tacrolimus; (b) placing the liquid sample in a device, the device including a

support defining a well for holding the liquid sample including the magnetic particles, the multivalent binding agent, and the tacrolimus, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using one or more magnets and an RF pulse sequence; (c) exposing the sample to a bias magnetic field and an RF

5   pulse sequence; (d) following step (c), measuring the signal; and (e) on the basis of the result of step (d), determining the concentration of tacrolimus in the liquid sample. In certain embodiments, the magnetic particles are substantially monodisperse; exhibit nonspecific reversibility in the absence of the analyte and multivalent binding agent; and/or the magnetic particles further include a surface decorated with a blocking agent selected from albumin, fish skin gelatin, gamma globulin, lysozyme, casein, peptidase,

10   and an amine-bearing moiety (e.g., amino polyethyleneglycol, glycine, ethylenediamine, or amino dextran). In particular embodiments, the liquid sample further includes a buffer, from 0.1% to 3% (w/w) albumin (e.g., from 0.1% to 0.5%, 0.3% to 0.7%, 0.5% to 1%, 0.8% to 2%, or from 1.5% to 3% (w/w) albumin), from 0.01% to 0.5% nonionic surfactant (e.g., from 0.01% to 0.05%, 0.05% to 0.1%, 0.05% to 0.2%, 0.1% to 0.3%, 0.2% to 0.4%, or from 0.3% to 0.5% nonionic surfactant), or a combination thereof.

15   In still other embodiments, the magnetic particles include a surface decorated with 40 μg to 100 μg (e.g., 40 μg to 60 μg, 50 μg to 70 μg, 60 μg to 80 μg, or 80 μg to 100 μg,) of one or more proteins per milligram of the magnetic particles. The liquid sample can include a multivalent binding agent bearing a plurality of analytes conjugated to a polymeric scaffold.

The invention features a multivalent binding agent including two or more tacrolimus moieties,

20   including tacrolimus metabolites described herein or structurally similar compounds for which the antibody has affinity covalently linked to a scaffold. In certain embodiments, the multivalent binding agent is a compound of formula (II):
$$(A)_n\text{-}(B) \quad (II)$$

wherein (A) is

25

(B) is a polymeric scaffold covalently attached to each (A), and n is an integer from 2 to 50.

The invention features a solution including from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the solution (e.g., from 1×10^6 to 1×10^8, 1×10^7 to 1×10^8, 1×10^7 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{11}, or 1×10^{10} to 1×10^{13} magnetic particles per milliliter), wherein the magnetic particles have a mean

30   diameter of from 150 nm to 600 nm (e.g., from 150 to 250, 200 to 350, 250 to 450, 300 to 500, 450 to 650, or from 500 to 600 nm), a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} mM^{-1}s^{-1} (e.g., from

1×10^8 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{10}, 1×10^9 to 1×10^{11}, or from 1×10^{10} to 1×10^{12} mM^{-1}s^{-1}), and a surface bearing antibodies having affinity for the tacrolimus conjugate:

wherein (B) is a polymeric scaffold.

In an embodiment of any of the above solutions, (i) the magnetic particles are substantially monodisperse; (ii) the magnetic particles exhibit nonspecific reversibility in plasma; (iii) the magnetic particles further include a surface decorated with a blocking agent selected from albumin, fish skin gelatin, gamma globulin, lysozyme, casein, peptidase, and an amine-bearing moiety (e.g., amino polyethyleneglycol, glycine, ethylenediamine, or amino dextran); (iv) the liquid sample further includes a buffer, from 0.1% to 3% (w/w) albumin (e.g., from 0.1% to 0.5%, 0.3% to 0.7%, 0.5% to 1%, 0.8% to 2%, or from 1.5% to 3% (w/w) albumin), from 0.01% to 0.5% nonionic surfactant (e.g., from 0.01% to 0.05%, 0.05% to 0.1%, 0.05% to 0.2%, 0.1% to 0.3%, 0.2% to 0.4%, or from 0.3% to 0.5% nonionic surfactant), or a combination thereof; and/or (iv) the magnetic particles include a surface decorated with 40 μg to 100 μg (e.g., 40 μg to 60 μg, 50 μg to 70 μg, 60 μg to 80 μg, or 80 μg to 100 μg,) of one or more proteins per milligram of the magnetic particles. The solutions can be used in any of the systems or methods described herein.

The invention features a removable cartridge sized to facilitate insertion into and removal from a system of the invention, wherein the removable cartridge includes one or more chambers for holding a plurality of reagent modules for holding one or more assay reagents, wherein the reagent modules include (i) a chamber for holding from 1×10^6 to 1×10^{13} magnetic particles (e.g., from 1×10^6 to 1×10^8, 1×10^7 to 1×10^8, 1×10^7 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{11}, or 1×10^{10} to 1×10^{13} magnetic particles) having a mean diameter of from 100 nm to 699 nm (e.g., from 150 to 250, 200 to 350, 250 to 450, 300 to 500, 450 to 650, or from 500 to 699 nm), a T$_2$ relaxivity per particle of from 1×10^8 to 1×10^{12} mM^{-1}s^{-1} (e.g., from 1×10^8 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{10}, 1×10^9 to 1×10^{11}, or from 1×10^{10} to 1×10^{12} mM^{-1}s^{-1}), and binding moieties on their surfaces, the binding moieties operative to alter the specific aggregation of the magnetic particles in the presence of the one or more analytes or a multivalent binding agent; and (ii) a chamber for holding a buffer. In a related aspect, the invention features a removable cartridge sized to facilitate insertion into and removal from a system of the invention, wherein the removable cartridge comprises one or more chambers for holding a plurality of reagent modules for holding one or more assay reagents, wherein the reagent modules include (i) a chamber for holding from 1×10^6 to 1×10^{13} magnetic particles (e.g., from 1×10^6 to 1×10^8, 1×10^7 to 1×10^8, 1×10^7 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{11}, or

1×10^{10} to 1×10^{13} magnetic particles) having a mean diameter of from 700 nm to 1200 nm (e.g., from 700 to 850, 800 to 950, 900 to 1050, or from 1000 to 1200 nm), a T_2 relaxivity per particle of from 1×10^9 to 1×10^{12} mM^{-1}s^{-1} (e.g., from 1×10^9 to 1×10^{10}, 1×10^9 to 1×10^{11}, or from 1×10^{10} to 1×10^{12} mM^{-1}s^{-1}), and oligonucleotide binding moieties on their surfaces, the oligonucleotide binding moieties operative to alter the specific aggregation of the magnetic particles in the presence of the one or more analytes; and (ii) a chamber for holding a buffer. The magnetic particles can be any described herein, decorated with any binding moieties described herein, for detecting any analyte described herein. In particular embodiments of the removable cartridges, the magnetic particles and buffer are together in a single chamber withing the cartridge. In still other embodiments, the buffer includes from 0.1% to 3% (w/w) albumin, from 0.01% to 0.5% nonionic surfactant, a lysis agent, or a combination thereof. The removable cartridge can further include a chamber including beads for lysing cells; a chamber including a polymerase; and/or a chamber including a primer.

The invention features a removable cartridge sized to facilitate insertion into and removal from a system of the invention, wherein the removable cartridge includes one ore more chambers for holding a plurality of reagent modules for holding one or more assay reagents, wherein the reagent modules include (i) a chamber for holding from 1×10^8 to 1×10^{10} magnetic particles having a mean diameter of from 100 nm to 350 nm, a T_2 relaxivity per particle of from 5×10^8 to 1×10^{10} mM^{-1}s^{-1}, and binding moieties on their surfaces (e.g., antibodies, conjugated analyte), the binding moieties operative to alter the specific aggregation of the magnetic particles in the presence of the one or more analytes or a multivalent binding agent; and (ii) a chamber for holding a buffer including from 0.1% to 3% (w/w) albumin (e.g., from 0.1% to 0.5%, 0.3% to 0.7%, 0.5% to 1%, 0.8% to 2%, or from 1.5% to 3% (w/w) albumin), from 0.01% to 0.5% nonionic surfactant (e.g., from 0.01% to 0.05%, 0.05% to 0.1%, 0.05% to 0.2%, 0.1% to 0.3%, 0.2% to 0.4%, or from 0.3% to 0.5% nonionic surfactant), or a combination thereof. In one embodiment, the magnetic particles and buffer are together in a single chamber withing the cartridge.

In any of the systems, kits, cartridges, and methods of the invention, the liquid sample can include from 1×10^8 to 1×10^{10} magnetic particles having a mean diameter of from 100 nm to 350 nm, a T_2 relaxivity per particle of from 5×10^8 to 1×10^{10} mM^{-1}s^{-1}, and binding moieties on their surfaces (e.g., antibodies, conjugated analyte), the binding moieties operative to alter the specific aggregation of the magnetic particles in the presence of the one or more analytes or a multivalent binding agent.

In any of the systems, kits, cartridges, and methods of the invention for detection of any analyte in a whole blood sample, the disruption of the red blood cells can be carried out using an erythrocyte lysis agent (i.e., a lysis buffer, or a nonionic detergent). Erythrocyte lysis buffers which can be used in the methods of the invention include, without limitation, isotonic solutions of ammonium chloride (optionally including carbonate buffer and/or EDTA), and hypotonic solutions. Alternatively, the erythrocyte lysis agent can be an aqueous solutions of nonionic detergents (e.g., nonyl phenoxypolyethoxylethanol (NP-40), 4-octylphenol polyethoxylate (Triton-X100), Brij-58, or related nonionic surfactants, and mixtures thereof). The erythrocyte lysis agent disrupts at least some of the red blood cells, allowing a large

fraction of certain components of whole blood (e.g., certain whole blood proteins) to be separated (e.g., as supernatant following centrifugation) from the white blood cells, yeast cells, and/or bacteria cells present in the whold blood sample. Following Erythrocyte lysis and centrifugation, the resulting pellet is reconstituted to form an extract.

5   The methods, kits, cartridges, and systems of the invention can be configured to detect a predetermined panel of pathogen-associated analytes. For example, the panel can be a candida fungal panel configured to individually detect three or more of Candida guilliermondii, C. albicans, C. glabrata, C. krusei, C. Lusitaniae, C. parapsilosis, and C. tropicalis. In another embodiment, the panel can be a bacterial panel configured to individually detect three or more of coagulase negative Staphylococcus,

10   Enterococcus faecalis, E. faecium, Pseudomonas aeruginosa, Staphylococcus aureus, and Escherichia coli. In a particular embodiment, the panel can be a viral panel configured to individually detect three or more of Cytomegalovirus (CMV), Epstein Barr Virus, BK Virus, Hepatitis B virus, Hepatitis C virus, Herpes simplex virus (HSV), HSV1, HSV2, Respiratory syncytial virus (RSV), Influenza; Influenza A, Influenza A subtype H1, Influenza A subtype H3, Influenza B, Human Herpes Virus 6, Human Herpes

15   Virus 8, Human Metapneumovirus (hMPV), Rhinovirus, Parainfluenza 1, Parainfluenza 2, Parainfluenza 3, and Adenovirus. The panel can be a bacterial panel configured to individually detect three or more of E. coli, CoNS (coagulase negative staph), Pseudomonas aeruginosa, S. aureus, E. faecium, E. faecalis, and Klebsiella pneumonia. The panel can be a bacterial panel configured to individually detect three or more of A. fumigates, and A. flavum. The panel can be a bacterial panel configured to individually detect

20   three or more of Acinetobacter baumannii, Enterobacter aeraogenes, Enterobacter cloacae, Klebsiella oxytoca, Proteus mirabilis, Serratia marcescens, Staphylococcus haemolyticus, Stenotro-phomonas maltophilia, Streptococcus agalactie, Streptococcus mitis, Streptococcus pneumonia, and Streptococcus pyogenes. The panel can be a meningitis panel configured to individually detect three or more of Streptococcus pneumonia, H. influenza, Neisseria Meningitis, HSV1, HSV2, Enterovirus, Listeria, E.

25   coli, Group B Streptococcus. The panel can be configured to individually detect three or more of N. gonnorrhoeae, S. aureus, S. pyogenes, CoNS, and Borrelia burgdorferi. The panel can be configured to individually detect three or more of C. Difficile, Toxin A, and Toxin B. The panel can be a pneumonia panel configured to individually detect three or more of Streptococcus pneumonia, MRSA, Legionella, C. pneumonia, and Mycoplasma Pneumonia. The panel can be configured to individually detect three or

30   more of treatment resistant mutations selected from mecA, vanA, vanB, NDM-1, KPC, and VIM. The panel can be configured to individually detect three or more of H. influenza, N. gonnorrhoeae, H. pylori, Campylobacter, Brucella, Legionella, and Stenotrophomonas maltophilia. The panel can be configured to detect total viral load caused by CMV, EBV, BK Virus, HIV, HBV, and HCV. The panel can be configured to detect fungal load and/or bacterial load. Viral load determination can be using a standard

35   curve and measuring the sample against this standard curve or some other method of quantitation of the pathogen in a sample. The quantitative measuring method may include real-time PCR, competitive PCR (ratio of two cometiting signals) or other methods mentioned here. The panel can be configured to detect

immune response in a subject by monitoring PCT, MCP-1, CRP, GRO-alpha, High mobility group-box 1 protein (HMBG-1), IL-1 receptor, IL-1 receptor antagonist, IL-1b, IL-2, IL-4, IL-6, IL-8, IL-10, IL-12, IL-13, IL-18, macrophage inflammatory protein (MIP-1), macrophage migration inhibitory factor (MIF), osteopontin, RANTES (regulated on activation, normal T-cell expressed and secreted; or CCL5), Th1,

5   Th17, and/or TNF-α. The panel can be configured to individually detect three or more of Ehrlichea, Mycobacterium, Syphillis, Borrelia burgdorferi, Cryptococcus, Histoplasma, and Blastomyces. The panel can be an influenza panel configured to individually detect three or more of Influenza A, Influenza B, RSV, Parainfluenza, Meta-pneumovirus, Rhinovirus, and Adenovirus.

       The methods, kits, cartridges, and systems of the invention can be configured to reduce sample to

10   sample variablility by determining a magnetic resonance signal prior to and after hybridization. The addition of derivatized nanoparticles to the sample prior to methods to enhance clustering may provide a baseline, internal T_2 signal that can either be subtracted or used to modify the T_2 signal after analyte-derivatized particle binding and clustering. This method may also be used to determine or manage cartridge to cartridge variability.

15   The terms "aggregation," "agglomeration," and "clustering" are used interchangeably in the context of the magnetic particles described herein and mean the binding of two or more magnetic particles to one another, e.g., via a multivalent analyte, multimeric form of analyte, antibody, nucleic acid molecule, or other binding molecule or entity. In some instances, magnetic particle agglomeration is reversible.

20   By "analyte" is meant a substance or a constituent of a sample to be analyzed. Exemplary analytes include one or more species of one or more of the following: a protein, a peptide, a polypeptide, an amino acid, a nucleic acid, an oligonucleotide, RNA, DNA, an antibody, a carbohydrate, a polysaccharide, glucose, a lipid, a gas (e.g., oxygen or carbon dioxide), an electrolyte (e.g., sodium, potassium, chloride, bicarbonate, BUN, magnesium, phosphate, calcium, ammonia, lactate), a lipoprotein,

25   cholesterol, a fatty acid, a glycoprotein, a proteoglycan, a lipopolysaccharide, a cell surface marker (e.g., CD3, CD4, CD8, IL2R, or CD35), a cytoplasmic marker (e.g., CD4/CD8 or CD4/viral load), a therapeutic agent, a metabolite of a therapeutic agent, a marker for the detection of a weapon (e.g., a chemical or biological weapon), an organism, a pathogen, a pathogen byproduct, a parasite (e.g., a protozoan or a helminth), a protist, a fungus (e.g., yeast or mold), a bacterium, an actinomycete, a cell

30   (e.g., a whole cell, a tumor cell, a stem cell, a white blood cell, a T cell (e.g., displaying CD3, CD4, CD8, IL2R, CD35, or other surface markers), or another cell identified with one or more specific markers), a virus, a prion, a plant component, a plant by-product, algae, an algae by-product, plant growth hormone, an insecticide, a man-made toxin, an environmental toxin, an oil component, and components derived therefrom. As used herein, the term "small molecule" refers to a drug, medication, medicament, or other

35   chemically synthesized compound that is contemplated for human therapeutic use. As used herein, the term "biologic" refers to a substance derived from a biological source, not synthesized and that is contemplated for human therapeutic use. A "biomarker" is a biological substance that can be used as an

indicator of a particular disease state or particular physiological state of an organism, generally a biomarker is a protein or other native compound measured in bodily fluid whose concentration reflects the presence or severity or staging of a disease state or dysfunction, can be used to monitor therapeutic progress of treatment of a disease or disorder or dysfunction, or can be used as a surrogate measure of

5   clinical outcome or progression. As used herein, the term "metabolic biomarker" refers to a substance, molecule, or compound that is synthesized or biologically derived that is used to determine the status of a patient or subject's liver or kidney function. As used herein, the term "genotyping" refers to the ability to determine genetic differences in specific genes that may or may not affect the phenotype of the specific gene. As used herein, the term "phenotype" refers to the resultant biological expression, (metabolic or

10   physiological) of the protein set by the genotype. As used herein, the term "gene expression profiling" refers to the ability to determine the rate or amount of the production of a gene product or the activity of gene transcription in a specific tissue, in a temporal or spatial manner. As used herein, the term "proteomic analysis" refers to a protein pattern or array to identify key differences in proteins or peptides in normal and diseased tissues. Additional exemplary analytes are described herein. The term analyte

15   further includes components of a sample that are a direct product of a biochemical means of amplification of the initial target analyte, such as the product of a nucleic acid amplification reaction.

By an "isolated" nucleic acid molecule is meant a nucleic acid molecule that is removed from the environment in which it naturally occurs. For example, a naturally-occurring nucleic acid molecule present in the genome of cell or as part of a gene bank is not isolated, but the same molecule, separated

20   from the remaining part of the genome, as a result of, e.g., a cloning event, amplification, or enrichment, is "isolated." Typically, an isolated nucleic acid molecule is free from nucleic acid regions (e.g., coding regions) with which it is immediately contiguous, at the 5' or 3' ends, in the naturally occurring genome. Such isolated nucleic acid molecules can be part of a vector or a composition and still be isolated, as such a vector or composition is not part of its natural environment.

25   As used herein, "linked" means attached or bound by covalent bonds, non-covalent bonds, and/or linked via Van der Waals forces, hydrogen bonds, and/or other intermolecular forces.

The term "magnetic particle" refers to particles including materials of high positive magnetic susceptibility such as paramagnetic compounds, superparamagnetic compounds, and magnetite, gamma ferric oxide, or metallic iron.

30   As used herein, "nonspecific reversibility" refers to the colloidal stability and robustness of magnetic particles against non-specific aggregation in a liquid sample and can be determined by subjecting the particles to the intended assay conditions in the absence of a specific clustering moiety (i.e., an analyte or an agglomerator). For example, nonspecific reversibility can be determined by measuring the T_2 values of a solution of magnetic particles before and after incubation in a uniform

35   magnetic field (defined as <5000 ppm) at 0.45T for 3 minutes at 37 °C. Magnetic particles are deemed to have nonspecific reversibility if the difference in T_2 values before and after subjectng the magnetic particles to the intended assay conditions vary by less than 10% (e.g., vary by less than 9%, 8%, 6%, 4%,

3%, 2%, or 1%). If the difference is greater than 10%, then the particles exhibit irreversibility in the buffer, diluents, and matrix tested, and manipulation of particle and matrix properties (e.g., coating and buffer formulation) may be required to produce a system in which the particles have nonspecific reversibility. In another example, the test can be applied by measuring the T_2 values of a solution of

5   magnetic particles before and after incubation in a gradient magnetic field 1Gauss/mm-10000Gauss/mm.

As used herein, the term "NMR relaxation rate" refers to a measuring any of the following in a sample T_1, T_2, T_1/T_2 hybrid, T_{1rho}, T_{2rho}, and T_2^*. The systems and methods of the invention are designed to produce an NMR relaxation rate characteristic of whether an analyte is present in the liquid sample. In some instances the NMR relaxation rate is characteristic of the quantity of analyte present in the liquid

10   sample.

As used herein, the term "T_1/T_2 hybrid" refers to any detection method that combines a T_1 and a T_2 measurement. For example, the value of a T_1/T_2 hybrid can be a composite signal obtained through the combination of, ratio, or difference between two or more different T_1 and T_2 measurements. The T_1/T_2 hybrid can be obtained, for example, by using a pulse sequence in which T_1 and T_2 are alternatively

15   measured or acquired in an interleaved fashion. Additionally, the T_1/T_2 hybrid signal can be acquired with a pulse sequence that measures a relaxation rate that is comprised of both T_1 and T_2 relaxation rates or mechanisms.

A "pathogen" means an agent causing disease or illness to its host, such as an organism or infectious particle, capable of producing a disease in another organism, and includes but is not limited to

20   bacteria, viruses, protozoa, prions, yeast and fungi or pathogen by-products. "Pathogen by-products" are those biological substances arising from the pathogen that can be deleterious to the host or stimulate an excessive host immune response, for example pathogen antigen/s, metabolic substances, enzymes, biological substances, or toxins.

By "pathogen-associated analyte" is meant an analyte characteristic of the presence of a pathogen

25   (e.g., a bacterium, fungus, or virus) in a sample. The pathogen-associated analyte can be a particular substance derived from a pathogen (e.g., a protein, nucleic acid, lipid, polysaccharide, or any other material produced by a pathogen) or a mixture derived from a pathogen (e.g., whole cells, or whole viruses). In certain instances, the pathogen-associated analyte is selected to be characteristic of the genus, species, or specific strain of pathogen being detected. Alternatively, the pathogen-associated analyte is

30   selected to ascertain a property of the pathogen, such as resistance to a particular therapy. For example, the pathogen-associated analyte can be a gene, such as a Van A gene or Van B gene, characteristic of vancomycin resistance in a number of different bacterial species.

By "pulse sequence" or "RF pulse sequence" is meant one or more radio frequency pulses to be applied to a sample and designed to measure, e.g., certain NMR relaxation rates, such as spin echo

35   sequences. A pulse sequence may also include the acquisition of a signal following one or more pulses to minimize noise and improve accuracy in the resulting signal value.

As used herein, the term "signal" refers to an NMR relaxation rate, frequency shift, susceptibility measurement, diffusion measurement, or correlation measurements.

As used herein, reference to the "size" of a magnetic particle refers to the average diameter for a mixture of the magnetic particles as determined by microscopy, light scattering, or other methods.

5   As used herein, the term "substantially monodisperse" refers to a mixture of magnetic particles having a polydispersity in size distribution as determined by the shape of the distribution curve of particle size in light scattering measurements. The FWHM (full width half max) of the particle distribution curve less than 25% of the peak position is considered substantially monodisperse. In addition, only one peak should be observed in the light scattering experiments and the peak position should be within one

10   standard deviation of a population of known monodisperse particles.

By "T_2 relaxivity per particle" is meant the average T_2 relaxivity per particle in a population of magnetic particles.

As used herein, "unfractionated" refers to an assay in which none of the components of the sample being tested are removed following the addition of magnetic particles to the sample and prior to

15   the NMR relaxation measurement.

It is contemplated that units, systems, methods, and processes of the claimed invention encompass variations and adaptations developed using information from the embodiments described herein. Throughout the description, where units and systems are described as having, including, or including specific components, or where processes and methods are described as having, including, or

20   including specific steps, it is contemplated that, additionally, there are units and systems of the present invention that consist essentially of, or consist of, the recited components, and that there are processes and methods according to the present invention that consist essentially of, or consist of, the recited processing steps. It should be understood that the order of steps or order for performing certain actions is immaterial, unless otherwise specified, so long as the invention remains operable. Moreover, in many instances two

25   or more steps or actions may be conducted simultaneously.

Other features and advantages of the invention will be apparent from the following detailed description, the drawings, and the claims.

Brief Description of the Drawings

30   Figure 1A is a schematic diagram of an NMR unit for detection of a signal response of a sample to an RF pulse sequence, according to an illustrative embodiment of the invention.

Figure 1B depicts a typical coil configuration surrounding a sample tube for measuring a relaxation signal in a 20 μL sample.

Figures 2A-2E illustrate micro coil geometries which can be used in NMR (for excitation and/or

35   detection); designs include, but are not limited to a wound solenoid coil (Figure 2A), a planar coil (Figure 2B), a MEMS solenoid coil (Figure 2C), a MEMS Helmholz coil (Figure 2D), and a saddle coil (Figure 2E), according to an illustrative embodiment of the invention. Three dimensional lithographic coil

fabrication of well characterized coils used in MR detection is also established and can be used for these applications, Demas et al. "Electronic characterization of lithographically patterned microcoils for high sensitivity NMR detection" J Magn Reson 200:56 (2009).

Figure 3 is a drawing depicting an aggregation assay of the invention. The magnetic particles
5   (dots) are coated with a binding agent (i.e., antibody, oligo, etc.) such that in the presence of analyte, or multivalent binding agent, aggregates are formed. The dotted circles represent the diffusion sphere or portion of the total fluid volume that a solution molecule may experience via its diffusion during a T_2 measurement (the exact path travelled by a water molecule is random, and this drawing is not to scale). Aggregation (right hand side) depletes portions of the sample from the microscopic magnetic non-
10   uniformities that disrupt the water's T_2 signal, leading to an increase in T_2 relaxation.

Figures 4A-4E are a series of graphs depicting the dependence of transverse relaxivity (R_2) (Figure 4A) or T2 (Figures 4B-4E) on particle diameter and particle aggregation. Figure 4A is a graph depicting the motional averaging regime (light line, left side); the R_2 ($1/T_2$) measured by a CPMG sequence increases as particle size increases because the refocusing pulses are ineffective to counteract
15   the dephasing effects of the particles. As the system transitions to the visit limited regime (dark line, right side) the refocusing pulses begin to become effective and the R_2 decreases as particle size increases. For homogeneous magnetic fields, the $R_2{}^*$ in the motional averaging regime matches the R_2 and the $R_2{}^*$ reaches a constant value in the visit limited regime. In a homogenous field, when the $R_2{}^*$ is less than the R_2 of either the motional averaging regime or visit limited regime the system is in the static dephasing
20   regime. The empty circle represents the R_2 of a solution of 100% dispersed particles (diameter = 15 nm) and the solid circle represents a solution of 100% clustered particles (diameter = 200 nm). This is an example of how to interpret these curves for clustering reactions. The conditions for this curve are 0.1 mM Fe, $\Delta\omega = 8.85 \times 10^6$, $D = 2.5 \times 10^{-5}$ m²/s, and $\tau_{CP} = 0.25$ ms. Figure 4B is a graph depicting the same light and dark curves plotted in terms of T_2 and diameter, on a linear scale. In this figure the black dashed
25   line represents the $T_2{}^*$ measured in a non-uniform magnetic field where $T_2{}^*$ is always lower than T_2 and doesn't reflect the particle size. The data points are the same as well. Figure 4C is a graph depicting the monodisperse clustering model and showing that T_2 will follow the curve as analyte is added because the average diameter of the population particles will cover all intermediate diameters between the initial and final states. Figure 4D is a graph depicting the polydisperse model and showing that the T_2 will transition
30   between the two points on this curve when particles form clusters of specific sizes. The response curve . will be linear with regard to analyte addition, but non-linear with regard to volume fraction of clusters, because particles transition between state 1 and state 2. The slope of the response curve is directly proportional to the sensitivity of the assay. Figure 4E is a graph showing the two regimes for particle aggregation and T_2 affects based on particle size and how clustering assays in the different regimes map
35   onto the T_2 versus diameter curves (i) for the motional averaging regime T_2 decreases when particles cluster; and (ii) for the slow motion regime T_2 increases when particles cluster. Under the conditions shown in these models, the boundary between the two regimes is ca. 100 nm diameter particles. When

small magnetic particles form aggregates under 100 nm in diameter, the result is a decrease in T_2 upon aggregate formation. When magnetic particles at or above 100 nm in diameter form larger aggregates, the result is an increase in T_2 upon aggregate formation.

Figures 5A-5C are drawings depicting different assay formats for the assays of the invention.

5   Figure 5A depicts an agglomerative sandwich immunoassay in which two populations of magnetic particles are designed to bind to two different epitopes of an analyte. Figure 5B depicts a competitive immunoassay in which analyte in a liquid sample binds to a multivalent binding agent (a multivalent antibody), thereby inhibiting aggregation. Figure 5C depicts a hybridization-mediated agglomerative assay in which two populations of particles are designed to bind to the first and second portions of a

10   nucleic acid target, respectively.

Figure 6 illustrates a modular cartridge concept in sections that can be packaged and stored separately. This is done, for example, so that the inlet module (shown elevated with inverted Vacutainer tube attached) can be sterilized while the reagent holding module in the middle is not. This allows the component containing reagents to be the only refrigerated component.

15   Figures 7A-7F depict a Vacutainer inlet module. Figure 7A shows it in the inverted position after the user has removed the closure from the Vacutainer tube and placed the cartridge onto it. Figure 7B shows the molded in path that the blood will follow out of the Vacutainer and into the sample loading region once the cartridge is turned right side up. The foil seal can be the bottom side of the channels, forming an inexpensively molded part with closed channels. Figure 7C is a cutaway view showing the

20   vent tube which allows air to enter into the vial as the blood leaves and fills the sample region. Figures 7D-7F depict an inlet module for sample aliquoting designed to interface with uncapped vacutainer tubes, and to aliquot two a sample volume that can be used to perform, for example, a candida assay. The inlet module has two hard plastic parts, that get ultrasonically welded together and foil sealed to form a network of channels to allow a flow path to form into the first well overflow to the second sample well.

25   A soft vacutainer seal part is used to for a seal with the vacutainer. It has a port for sample flow, and a venting port, to allow the flow to occur.

Figure 8 depicts the sample inlet module with the foil seal removed. On the top, one can see the small air inlet port to the left, the larger sample well in the center and a port which connects them together. This port provides a channel through which air can flow once the foil seal is pierced. It also

30   provides an overflow into the body of the module to allow excess blood to drain away and not spill over. This effectively meters the blood sample to the volume contained in the sample well.

Figures 9A-9C depict a reagent module. Figure 9A depicts the module of the cartridge that is intended to hold reagents and consumables for use during the assay. On the left are sealed pre-dispensed aliquots of reagents. On the right is a 2.8 ml conical bottomed centrifuge tube that is used for initial

35   centrifugation of the blood. The other holes can be filled as need with vials, microcentrifuge tubes, and pipette tips. Figure 9B is a cutaway view of the reagent module showing the holders for the pre-aliquoted reagent tips, including the feature at the bottom into which the tips are pressed to provide a seal. Figure

9C depicts three representative pipette tips into which reagents can be pre-dispensed, and then the backs sealed. The tips are pressed into the sample holder to provide a seal.

Figures 10A and 10B depict an alternative design of the modular cartridge, showing a detection module with a recessed well for use in assays that require PCR. Cross-contamination from PCR products is controlled in two ways. First, the seals that are on the detection tubes are designed to seal to a pipette tip as it penetrates. Second, the instrument provides air flow through the recessed well by means of holes in the well to ensure that any aerosol is carried down and does not travel throughout the machine.

Figure 11 depicts a detection module of cartridge showing detection tubes and one of the holes used to ensure air flow down and over the tubes during pipetting to help prevent aerosol escape.

Figure 12 depicts a bottom view of the detection module, showing the bottom of the detection tubes and the two holes used to ensure airflow. An optional filter can be inserted here to capture any liquid aerosol and prevent it from entering the machine. This filter could also be a sheet of a hydrophobic material like Gore-tex that will allow air but not liquids to escape.

Figures 13A-13C depict a detection tube. Figure 13A is a view of the detection tube. The tube itself could be an off the shelf 200 microliter PCR tube, while the cap is a custom molded elastomer part that provides a pressure resistant duckbill seal on the inside and a first seal to the pipette tip from the top. The seal is thus a make-break type of seal, where one seal is made before the other is broken. Figure 13B depicts the custom molded seal component. Note the circular hole into which the pipette tip is inserted and the duckbill seal below, which provides a second seal that resists pressure developed in the tube. Figure 13C depicts the seal showing the duckbill at bottom and the hole at top.

Figures 14A-14C depict a cartridge for performing a multiplexed assay. Figure 14A shows a reagent strip for the cartridge. The oval holes are the supports for the detection modules, and these are constructed separately and then placed into the holes. The detection wells could be custom designed or commercially available. Figure 14B shows the detection module for the cartridge depicted in Figure 14A. In this example, the detection module contains two detection chambers, but could contain any number of chambers as required by the assay and as the detection system (the MR reader) is designed to accept. Figure 14C depicts an alternate footprint for the modular multiplexed cartridge. This cartridge includes 3 detection modules that are molded as part of the reagent strip, and these portions are popped out of the frame and individually processed at other units (i.e., the NMR unit and/or magnetic assisted agglomeration (MAA) unit) within the assay system.

Figure 15 is a scheme depicting one embodiment of the cycling gradient magnetic assisted agglomeration (gMAA) method of the invention. Two magnets are placed in two positions such that if the sample tube is placed close to the a region of strong magnetic field gradient produced by the first magnet, the magnetic particles will be drawn towards the direction of the field gradient produced by the first magnet, the sample tube is then placed next to the second magnet producing a field gradient, and the magnetic particles are drawn to the direction of the field gradient produced by second magnet. The cycle can be repeated until the aggregation reaction reaches a steady state (as observed by the change in the

NMR relaxation rate of the sample); a smaller number of cycles can be used as well. A single magnet used to produce a field gradient can also be used, while for cycling the sample tube can be moved relative to the magnetic field gradient.

Figure 16 is a scheme depicting a homogenous magnetic assisted agglomeration (hMAA) setup. On the left hand side, the magnetic particles are shown as dots in a partially clustered state. When exposed to a homogeneous magnetic field, as depicted on the right hand side, clustering of the magnetic particles is promoted as the magnetic particles form chains along the direction of the field produced by the hMAA setup. On the right hand side, the two magnets are represented by bars, to depict the formation of a standard dipole field. hMAA can also be used to evaluate the nonspecific reversibility of a magnetic particle to assess its utility in an assay of the invention.

Figure 17 depicts a gradient MAA unit configured to apply a gradient magnetic field to the side and to the bottom of a sample. The specific setup has magnets with a surface field of approximately 0.7 T, while the produced gradient is in the order of 0.25 T/mm. Similar gMAA units, covering a much bigger range of fields and gradients can be used.

Figures 18A-18C depict a gradient MAA unit configured to apply a gradient magnetic field to the side and to the bottom of an array of samples. Figure 18A depicts the gMAA unit array of 32 bottom magnets and 40 side magnets (32 functional, 8 used to balance the stray magnetic fields seen by all sample), each with a field strength of about 0.5T, used for assisting agglomeration in an array of samples simultaneously. Figures 18B-18C depict a top view (Figure 18B) and side view (Figure 18C) of a setup for the automation of the an automated gMAA unit wherein a plate gMAA along with a configuration for containing an array of samples is cycled between the bottom and side magnet positions by a robotic systems, within a temperature controlled array. The magnets are stationary, while the plate holding the sample tubes moves through a preset trajectory. An exemplary field strength on the surface of individual magnets is 0.4-0.5 T, with a gradient in the order of 0.1T/mm.

Figures 19A-19B depict a top view (Figure 19A) and side view (Figure 19B) of a homogenous MAA unit configured to apply a homogenous magnetic field to an array samples. Field strengths from 0.2-0.7T can be used with homogeneity from 500 to 5000 ppm over the sample tube region.

Figure 20 is a drawing of a vortexer which includes the following components: (i) a sample support, (ii) a main plate, (iii) four linkages, (iv) linear rail and carriage system (x2), (v) a support for driveshaft and rails, (vi) coupling and driveshaft, (vii) a mounting plate, and (viii) a drive motor.

Figure 21 is a drawing of a compact vortexer which includes the following components: (i) a sample support, (ii) a main plate, (iii) two linkages, (iv) linear rail and carriage system, (v) a support for linear rail, (vi) support for driveshaft, (vii) coupling and driveshaft, (viii) a mounting plate, and (ix) a drive motor.

Figures 22A and 22B depict portions of a vortexer. Figure 22A is a drawing depicting the bottom portion (i.e., the drive motor, coupling, and drive shaft) of a vortexer of the invention. The motor includes an index mark and/or other position sensing means such as an optical, magnetic or resitive

position encoder that allows the motor to find a specific point in its rotation. These index marks are used to home the system, and ensure that the sample can be returned to a known position after mixing and allows the vortexer to be easily accessed by robotic actuators, and thus integrated into an automated system. In lieu of index marks, external home switches or position tracking sensors could be employed.

5   Figure 22B is a drawing depicting the guide mechanism of a vortexer of the invention. The main plate is connected to the offset axis of the drive shaft and is free to rotate. The plate follows the orbital path around and dictated by the motor shaft.

Figures 23A-23C are a series of drawings depicting a vortexer utilizing a planetary belt drive. Figure 23A is an overall view showing the vortexer configured for one large tube. Figure 23B is a section

10   view showing two tube holders for small tubes. Figure 23C is an overall view of vortexer showing four tubes and a close up of planetary belt drive mechanism.

Figure 24 is a drawing depicting the components of the creatinine competitive assay of Example 6. A magnetic particle decorated with creatinine is used in combination with a creatinine antibody to form an aggregating system. The creatinine present in a liquid sample competes with the magnetic

15   particles for the antibody, leading to a reduction in aggregation with increasing creatinine concentration. The change in aggregation is observed as a change in the T_2 relaxation rate of the hydrogen nuclei in the water molecules of the liquid sample. By comparing the observed T_2 relaxation rate of the liquid sample to a standard curve, the concentration of creatinine is determined.

Figures 25A-25C are a series of graphs showing the response curve for creatinine competitive

20   assays. Figure 25A is a graph showing a standard curve for the creatinine competitive assay of Example 6 correlating the observed T_2 relaxation rate with the concentration of creatinine in the liquid sample. Figure 25B shows the T_2 response of a creatinine-decorated particle with 2 different preparations of antibody. Preparation 1 is pre-production (with aggregated antibody) and Preparation 2 is production purified (no aggregated antibody present). Figure 25C shows the T_2 response of a creatinine-decorated

25   particle with unaggregated antibody, biotinylated antibody and deliberately multimerized antibody, and confirms the increased clustering ability of multi-valent agglomerating agents.

Figure 26 is a graph showing the specific clustering achieved, as determined via T_2 relaxation rates, with various methods of gMAA as described in Example 10. In Figure 26 (i) "control" is gMAA (magnet exposure + vortex, repeat) in which the relative position of the sample and the magnetic field

30   direction are unchanged with each cycle; (ii) "twist" is gMAA (magnet exposure + rotation within magnet, repeat) with rotating tube ca. 90° relative to the gradient magnet with each cycle; (iii) "180° turn" is gMAA (magnet exposure + remove tube from magnet, rotate, place back in magnet, repeat) with rotating tube ca. 180° relative to the gradient magnet with each cycle; and "remove 5 s" is removal of tube from magnet, 5 seconds rest (no rotation), repeat. The results show that the rate at which a steady

35   state degree of agglomeration, and stable T_2 reading, is achieved is expedited by cycling between the two or more positions over a number of gMAA treatments. Further, field gradient combinations, cycling field (side or bottom) to null or side field to bottom, field (side or bottom) to vortex are also iterations that can

be used for gMAA. Exposure or dwell times (either on the field or away), and number of cycles can be varied to optimize assisted aggregation for a specific assay (not shown).

Figure 27 is a graph showing the response curve for the creatinine competitive assay for samples processed with alternating side-bottom magnet gMAA as described in Example 11.

5   Figure 28 is a drawing depicting the tacrolimus competitive assay architecture of Example 9.

Figure 29 is a graph showing a standard curve for the tacrolimus competitive assay of Example 9 correlating the observed T_2 relaxation rate observed for a liquid sample with the concentration of tacrolimus in the liquid sample.

Figures 30A-30B are graphs depicting the degree to which gMAA assisted aggregation is

10   dependent upon temperature and dwell time in the assay of Example 11. Figure 30A is a graph showing that the degree of aggregation as determined by measuring the T_2 response of the sample is increased with increasing dwell time at room temperature. Figure 30B is a graph showing that the degree of aggregation as determined by measuring the T_2 response of the sample is increased with increasing gMAA dwell time at 37 °C. As shown in Figures 30A and 30B, increasing temperature and increasing dwell time enhance

15   the extent of gMAA assisted aggregation as observed by changes in the observed T_2.

Figure 31 is a graph showing that the degree of aggregation as determined by measuring the T_2 response of the sample is increased with increasing the number of gMAA cycles in the assay of Example 13.

Figure 32 is a drawing depicting the Candida agglomerative sandwich assay architecture of

20   Example 14.

Figure 33 is a graph depicting a creatinine inhibition curve (see Example 7) for using an antibody coated particle and an amino-dextran-creatinine multivalent binding agent to induce clustering by competing with any target analyte (creatinine) present in the sample to cause particle clustering. The binding agent used is a 40kDa dextran with ~10 creatinines per dextran molecule.

25   Figure 34 is a graph depicting the evaluation of Tac-dextran conjugates for clustering ability (see Example 8) by performing a titration. As observed, that increased molecular weight of Tac-dextran results in the improved T_2 signal.

Figure 35 is a graph depicting the evaluation of Tac-dextran conjugates for clustering ability (see Example 8) by performing a titration. As observed, higher substitution improved T_2 signal.

30   Figure 36 is a graph depicting the evaluation of Tac-BSA conjugates for clustering ability (see Example 8) by performing a titration similar to that used for the Tac-dextran conjugates. As observed, clustering performance varies with the tacrolimus substitution ratio.

Figure 37 is a graph depicting the results of T_2 assays for detecting anti-biotin antibody using prepared magnetic particles in blood and PBS matrices as described in Example 1.

35   Figure 38 is a graph depicting results of T_2 assays for detecting anti-biotin antibody using prepared magnetic particles with (open circle) and without (filled circle) a protein block as described in Examples 8 and 9.

Figure 39 is a graph depicting results of T_2 assays for detecting anti-biotin antibody using prepared magnetic particles having a BSA block (dark filled diamond, square, triangle) or an FSG block (light gray X's and circle) as described in Example 2.

Figures 40A-40B are schematics of provided particle coatings.

5   Figures 41A-41B depict results of T_2 assays for detecting biotin in a competitive assay format described in Example 4. Figure 41A depicts experimental results in buffer; while Figure 41B depicts experimental results in lysed blood.

Figure 42 is a sketch of a system of the invention including an NMR unit, a robotic arm, a hMAA unit, a gMAA unit, two agitation units, a centrifuge, and a plurality of heating blocks.

10   Figures 43A-43D are images depicting various fluid transfer units which can be used in the systems of the invention.

Figures 44A and 44B are sketches showing how a system of the invention can be designed to regulate the temperature of the working space.

Figures 45A and 45B are sketches depicting an NMR unit having a separate casing for regulation

15   of the temperature at the site of the NMR measurement, and useful where tight temperature control is needed for precision of the measurement. The temperature control configuration depicted in this figure is one of many different ways to control temperature.

Figure 46A is a table and 46B is a graph depicting the repeatability of Candida measurements by methods of the invention over a period of eight days. To determine the repeatability of the T2

20   measurement on C. albicans infected human whole blood, we conducted an eight day study in which the same donor spiked and amplified sample was hybridized to the superparamagnetic particles (n=3) each day and the resulting T2 values were recorded (see Example 17). The within run precision is shown in Figure 46A and in general is tight with the CV's of all measurands less than 12%. The repeatability observed over the course of eight days is shown in Figure 46B (Mean T2 values +/- the 95% confidence

25   intervals measured from the same donor spiked and amplified samples over the course of eight days) with the CVs less than 10% across the range of Candida concentrations and 6% for the negative control.

Figure 47 is a scheme describing the work flow for detection of a bacterial or fungal pathogen in a whole blood sample (see Examples 14 and 17).

Figures 48A and 48B are graphs depicting results from donor samples. Figure 48A is a graph

30   depicting the results obtained from 16 experiments designed to assess the assay's performance in 6 different donor blood samples spiked with a range of C. albicans cells (see Example 17). Each data point is the mean +/- the 95% confidence interval (n=48). At the lowest test concentration (10 cells/mL), we failed to detect Candida albicans 37% of the time (6 out of 16 experiments); however at 100 cells/mL Candida albicans was detected 100% of the time. This suggests the assay can robustly detect at C.

35   albicans concentrations greater than or equal to 100 cells/mL with no major inhibition of performance introduced through the donor blood samples. Figure 48B is a graph depicting the results obtained from 7 experiments designed to assess the assay's performance in 6 different donor blood samples spiked with a

range of C. krusei cells (see Example 17). Each data point is the mean +/- the 95% confidence interval (n=21). We do not detect at 10 cells/mL in any of the experimental runs but detect at 100 cells/mL for all experimental runs. This suggests the LOD between 10 and 100 cells/mL.

Figure 49 is a dot diagram showing the T2 values measured for five C. albicans clinical isolates spiked into 400 µL whole blood at concentrations spanning 0 to 1E4 cells/mL. The plotted results are the mean +/- 1SD. The data indicates despite the scatter of absolute T2 values obtained among the different isolates, at 50 cells/mL all values are above that of the no Candida control (3 replicate measurements from 20 independent assays, total of 60 different clustering reactions).

Figures 50A and 50B are ROC plots of T2 results generated at 10 cells/mL (Figure 50A) and 50 cells/mL (Figure 50B). The area under the curve at 10 cells/mL is 0.72 (95CI= 0.56 to 0.88) while at 50 cells/mL the area under the curve is 0.98 (95CI= 0.95 to 1.001). The area under the curve is often used to quantify the diagnostic accuracy; in this case our ability to discriminate between a Candidemic patient with an infection of 10 cells/mL or 50 cells/mL versus a patient with no Candidemia. At 10 cells/mL the area under the curve is 0.72 which means that if the T2 assay was run on a randomly chosen person with Candidemia at a level of infection of 10 cells/mL, there is an 72% chance their T2 value would be higher than a person with no Candidemia. The clinical accuracy of the test is much higher at 50 cells/mL with the area under the curve at 0.98. Again indicating that in a person with Candidemia at this level of infection, the T2 assay would give a value higher than a sample from a patient without Candidemia 98% of the time. See Example 17.

Figure 51 is a graph depicting the sensitivity of the assay using the standard thermocycle (~3 hours turnaround time) and a process that combines the annealing/elongation steps (~2 hours, 13 minutes turnaround time). Combining the annealing and elongation step in the thermocycling reduces the total assay TAT to 2.25 hours without compromising assay sensitivity.

Figure 52 is a graph depicting the change in T_2 signal with PCR cycling (see Example 18). The results demonstrate that the methods and systems of the invention can be used to perform real time PCR and provide quantitative information about the amount of target nucleic acid present in a sample.

Figure 53 is a series of photographs showing a simple magnetic separator/PCR block insert.

Figure 54 is an image showing the quantity of DNA generated by amplification of (1) 100 copies of genomic C. albicans amplified in the presence of 3' and 5' C. albicans single probe nanoparticles; particles were held on the side wall during PCR via magnetic field, (2) 100 copies of genomic C. albicans amplified without nanoparticles, and (3) 100 copies of genomic C. albicans amplified in the presence of 3' and 5' C.albicans single probe nanoparticles; no magnetic field.

Figures 55A-55E are schematic views of a sample tube containing an immobilized portion of magnetizable metal foam (shaded), magnetic particles (circles), and analyte (triangles). a magnetizable metal foam, e.g., made of nickel, may be inserted into a conduit and immobilized by exposure to heat, which shrinks the conduit around the metal foam, resulting in a tight seal. A sample containing magnetic particles and analytes is then introduced at one end of the conduit (Figure 55A). Next, the conduit is

exposed to a magnet (Figure 55B), and the magnetic particles are attracted to the metal foam and become magnetically trapped within its pores, or crevices. The average diameter of the pores in the metal foam is, e.g., between 100-1000 microns. Analyte molecules can be carried to the metal foam via binding to a magnetic particle, or the fluid can be forced through the metal foam to reach trapped magnetic particles.

5   While trapped in the metal foam, the magnetic particles have enhanced interactions, as they are now confined and are closer to other magnetic particles, and cluster formation is enhanced. The metal foam is then demagnetized (Figure 55C), i.e., the magnetic field of the metal foam becomes negligible. The magnetic particles and analyte cluster complexes largely remain in the metal foam, as the diffusion of magnetic particle clusters is relatively low, although some natural diffusion of the analyte in to and out of

10   the metal foam occurs (Figure 55D). Alternatively, the magnetizable metal foam (hollow cylinder) is free floating in the sample tube with the magnetic particles (circles), and analyte (stars). The magnetization and demagnetization of the free floating metal foam is used to increase the rate of aggregate formation.

         Figure 56A depicts a rotary gMAA configuration. The Rotary gMAA can include three configurations for varying magnetic field exposures – side-bottom; side-null and bottom-null (see

15   Example 21).

         Figure 56B is a graph comparing T2 signal as a function of various rotary gMAA configurations for varying magnetic field exposures to a sample at a given agglomerator concentration. The rotary side-bottom configuration provided the highest T2 signal at a given agglomerator concentration, followed by the comparison side-bottom plate configuration. Rotary side-null provides equivalent signal to the plate

20   side-bottom; and the bottom-null produces the lowest signal (see Example 21).

         Figure 57 is a table depicting the T2MR results for 32 clinical specimens indicates fourteen specimens are Candida positive. The test identifies four specimens containing C. krusei or C. glabrata, seven specimens containing C. albicans or C. tropicalis, and three containing C. parapsilosis. A solid black line indicates the decision threshold (T2=128 msec) (see Example 22).

25

Detailed Description

         The invention features systems, devices, and methods for the rapid detection of analytes or determination of analyte concentration in a sample. The systems and methods of the invention employ magnetic particles, an NMR unit, optionally one or more MAA units, optionally one or more incubation

30   stations at different temperatures, optionally one or more vortexer, optionally one or more centrifuges, optionally a fluidic manipulation station, optionally a robotic system, and optionally one or more modular cartridges. The systems, devices, and methods of the invention can be used to assay a biological sample (e.g., blood, sweat, tears, urine, saliva, semen, serum, plasma, cerebrospinal fluid (CSF), feces, vaginal fluid or tissue, sputum, nasopharyngeal aspirate or swab, lacrimal fluid, mucous, or epithelial swab

35   (buccal swab), tissues, organs, bones, teeth, or tumors, among others). Alternatively, the systems, devices, and methods of the invention are used to monitor an environmental condition (e.g., plant growth hormone, insecticides, man-made or environmental toxins, nucleic acid sequences that are important for

insect resistance/susceptibility, algae and algae by-products), as part of a bioremediation program, for use in farming plants or animals, or to identify environmental hazards. Similarily, the systems, devices, and methods of the invention are used to detect and monitor biowarfare or biological warfare agents, such as ricin, Salmonella typhimurium, botulinum toxin, aflatoxin, mycotoxins, Francisella tularesis, small pox,

5   anthrax, or others.

The magnetic particles can be coated with a binding moiety (i.e., antibody, oligo, etc.) such that in the presence of analyte, or multivalent binding agent, aggregates are formed. Aggregation depletes portions of the sample from the microscopic magnetic non-uniformities that disrupt the solvent's T_2 signal, leading to an increase in T_2 relaxation (see Figure 3).

10   The T_2 measurement is a single measure of all spins in the ensemble, measurements lasting typically 1-10 seconds, which allows the solvent to travel hundreds of microns, a long distance relative to the microscopic non-uniformities in the liquid sample. Each solvent molecule samples a volume in the liquid sample and the T_2 signal is an average (net total signal) of all (nuclear spins) on solvent molecules in the sample; in other words, the T_2 measurement is a net measurement of the entire environment

15   experienced by a solvent molecule, and is an average measurement of all microscopic non-uniformities in the sample.

The observed T_2 relaxation rate for the solvent molecules in the liquid sample is dominated by the magnetic particles, which in the presence of a magnetic field form high magnetic dipole moments. In the absence of magnetic particles, the observed T_2 relaxation rates for a liquid sample are typically long (i.e.,

20   T_2 (water) = ~2000 ms, T_2 (blood) = ~1500 ms). As particle concentration increases, the microscopic non-uniformities in the sample increase and the diffusion of solvent through these microscopic non-uniformities leads to an increase in spin decoherence and a decrease in the T_2 value. The observed T_2 value depends upon the particle concentration in a non-linear fashion, and on the relaxivity per particle parameter.

25   In the aggregation assays of the invention, the number of magnetic particles, and if present the number of agglomerant particles, remain constant during the assay. The spatial distribution of the particles change when the particles cluster. Aggregation changes the average "experience" of a solvent molecule because particle localization into clusters is promoted rather than more even particle distributions. At a high degree of aggregation, many solvent molecules do not experience microscopic

30   non-uniformities created by magnetic particles and the T_2 approaches that of solvent. As the fraction of aggregated magnetic particles increases in a liquid sample, the observed T_2 is the average of the non-uniform suspension of aggregated and single (unaggregated) magnetic particles. The assays of the invention are designed to maximize the change in T_2 with aggregation to increase the sensitivity of the assay to the presence of analytes, and to differences in analyte concentration.

35   In designing magnetic relaxation switch (MRSw) biosensors, it is important to consider the relaxation mechanisms of the magnetic particles. First, in the case of superparamagnetic particles the solvent longitudinal and transverse relaxivities (defined as $R_1 = 1/T_1$ and $R_2 = 1/T_2$, respectively) are a

function of particle size. Furthermore, R_2 and R_2^* (where $R_2^*=1/T_2^*$, $R_2^*=R_2+\Delta\omega_F$, where $\Delta\omega_F$ is dephasing due to field inhomgeneities) increase with particle diameter until about 100 nm, and then R_2 decreases with increasing particle size and the R_2^* reaches a plateau for uniform fields (see Figure 4A). Superparamagnetic particles are typically divided into categories of strongly magnetized and weakly

5 magnetized particles, based on the relative magnitude of the precession frequency difference between nuclei at the surface of the particle and nuclei distant from the particle, $\Delta\omega$, and the inter-echo delay of the CPMG detection sequence, τ_{CP}. $\Delta\omega$ is essentially a relative measure of the effect of the dipolar magnetic field generated by a superparamagnetic particle on the resonant frequency of hydrogen nuclei in adjacent water molecules. When the product $\Delta\omega\tau_{CP} > 1$ then the particles are classified as strongly

10 magnetized and when $\Delta\omega\tau_{CP} < 1$ then the particles are classified as weakly magnetized. For typical relaxometers, τ_{CP} is no shorter than tens of microseconds, so $\Delta\omega$ must be less than 10^5 for the particles to be within the weakly magnetized regime. Most superparamagnetic particles used for MRSw assays have a surface dephasing $\Delta\omega$ of approximately 1×10^7, therefore they are classified as strongly magnetized. This means that the inter-echo delay is always longer than the amount of dephasing that occurs at the

15 surface of a particle.

Another characteristic of superparamagnetic particle solutions that is used to differentiate physical behavior is the diffusion time, or travel time, of water (τ_D) relative to the inter-echo time of the pulse sequence, τ_{CP}. Particle solutions are in the long echo limit when the τ_D is significantly less than that τ_{CP}. τ_D can be determined by the relationship:

20
$$\tau_D = \frac{R^2}{D} \quad (1),$$

where τ_D is the time it takes a water molecule to diffuse the distance of a particle radius, R, and D the diffusion constant of water, 10^{-9} m^2/s. τ_D can be thought of as the time it takes a water molecule to pass a hemisphere of a particle, or a flyby time. When τ_D is much larger than τ_{CP}, then the particle system is within the "short echo limit". Typical CPMG sequences have echo times on the order of hundreds of

25 microseconds to several milliseconds. Therefore, the "short echo limit" cannot be approached unless the particle diameter approaches 1000 nm. The most common MRSw biosensors are within the "long echo limit" because the length of the inter-echo delays ($\tau_{CP} > 0.25$ ms) is longer than the time it takes a water molecule to diffuse past the hemisphere of a particle (0.2 - 100 microseconds).

As the particle size of a solution of superparamagnetic particles at fixed iron concentration is

30 increased there is an initial increase in R_2, then a plateau and later decrease (Figure 4A). The regime on the left hand side of the curve is been termed the motional averaging regime, the regime in the middle is been termed the static dephasing regime, and the regime on the right is been termed the visit limited, or slow motion regime. The boundaries between the motional averaging and visit limited regimes can be determined by generating plots such as that shown in Figure 4A, or they can be determined by the

35 relationship between $\Delta\omega$ and τ_D. If $\Delta\omega\tau_D < 1$, then the system is in the motional averaging regime; if

$\Delta\omega\tau_D > 1$, then the system is in the visit limited regime (also termed the slow motion regime). As the diameter of the particles increases in the motional averaging regime the refocusing echos in the CPMG pulse sequence cannot efficiently refocus the magnetization that has been dephased by the particles, hence the increase in R_2 (or decrease in T_2). In other words, the refocusing pulses cannot compensate for

5   increased dephasing by larger particles. The flat region of the static dephasing regime is due to the R_2 being limited by R_2^*. The decreasing R_2 with increasing diameter in the visit limited regime results in the refocusing pulses being able to refocus the dephasing caused by the particles. Also apparent in Figure 4A is that the R_2 in the slow motion regime exhibits a dependence on the inter-echo delay of the spin echo sequence.

10   In a homogenous magnetic field, one can determine which regime applies to a sample by comparing the R_2 to the R_2^*; the two values are identical in the motional averaging or static dephasing regime and they are different in the visit limited regime. However, in cases of inhomogeneous fields, such as those present on benchtop and portable MR devices, the T_2^* is dominated by the field gradient. In fact, the measured T_2^* value is not indicative of the particle or particle cluster size state (Figure 4B).

15   The shape of the R_2 response as particles agglomerated generally matches the expected trend for the increase in average particle size. The similarity between the R_2 of particle agglomerates and that of spherical particles suggests that one can equate particle aggregates and spherical shapes. Even though this assumption may seem to be in contradiction with the fractal nature of particle agglomerates, the shape of the particle aggregates observed by the magnetic resonance measurement is determined by the

20   ensemble of diffusing water molecules in solution, which can be approximated by the radius of hydration measured by light scattering.

     The analytical models for R_2 can be applied to magnetic relaxation biosensors to aid in the design of biosensor assays. Conveniently, these models accurately predict the dependence of R_2 on parameters that a biosensor designer can control—iron concentration, temperature, magnetic susceptibility, and

25   particle size. Additionally, these analytical models allow for predictive modeling of the dependence of T_2 relaxation on these parameters. Results are not entirely quantitative, but the general trends and response curves predicted by these models can be instructive. One useful model is the chemical exchange model for strongly magnetized spheres:

$$1/T_2 = \frac{(4/9)V\tau_D(\Delta\omega_r)^2}{1 + (4/9)^2(\tau_D/\tau_{CP})^2\alpha^5} \quad (2)$$

30

$$\alpha = \left[\frac{\Delta\omega\tau_{CP}}{a + b\Delta\omega\tau_{CP}V}\right]^{1/3} \quad (3)$$

where $1/T_2$ is the transverse relaxivity, V the volume fraction of iron in solution, τ_D the diffusion, or flyby time, $\Delta\omega_r$ the frequency shift at the surface of a particle relative to bulk solution, τ_{CP} one half the inter-echo delay in a CPMG sequence, and a and b are derived constants ($a = 1.34$ and $b = 0.99$). Equations (2) and (3) can be used to generate a curve that describes the dependence of R_2 on particle sizes, as shown by

the light and dark lines in Figures 4A and 4B (dark line on right side of the curve; light line on left side of the curve).

A modification of Equation 2 can be used to generate a plot that is more intuitive to an assay developer. This plot is in terms of T_2 and particle diameter with linear units rather than logarithmic units (Figure 2). As discussed above, magnetic relaxation biosensor assays function due to a transition between dispersed and clustered states. For a given agglomerative assay, the measured T_2 can follow one of two pathways over the course of an analyte titration. The population of dispersed particles can cluster in a uniform manner leading to an increase in average particle size that is proportional to the amount of analyte that has been added. This type of agglomeration is termed the monodisperse model because it would lead to a monodisperse intermediate population of particles. In this case, T_2 would be expected to decrease as particle size increases as long as the system is within the motional averaging regime. As the system approaches and enters the visit limited regime the T_2 would increase with particle size (Figure 4C).

A different type of agglomeration that may occur is one in which the addition of analyte seeds the self-assembly of clusters, a process with energetics similar to crystal formation or fractal aggregation. For this model one would expect a preferred size for particle clusters that depended on the conditions of the solution. Systems that followed this model would exhibit polydisperse intermediate populations; one would find a mixture of particles with discrete sizes. Given two discrete populations, dispersed particles and clustered particles, the system would transition between the T_2 value of the starting monodisperse population of unclustered particles and the final T_2 value of the fully clustered particles. For both models, full titration may lead to a monodisperse solution of clustered particles. Although the exact energetics, kinetics, and thermodynamics of particle agglomeration will depend on characteristics of the assay system such as valency and binding affinities, these two models are instructive in understanding the dependencies and possible scenarios one may encounter during MRSw biosensor design.

There are two regimes for particle clustering and T_2 affects based on particle size (see Figure 4D, the boundary is typically ca. 100 nm diameter particles). For any given assay of a liquid sample the particle count for 250 nm sized magnetic particles can be ca. 1×10^7 particles, whereas for 30 nm sized magnetic particles can be ca. 1×10^{13}. This is because the smaller particles have a lower relaxivity per particle (for the same type of material), resulting in an inherent sensitivity disadvantage. In a typical assay of the invention, the magnetic particles are selected such that T_2 increases with an increase in the fraction of aggregated particles.

The assay of the invention can be designed to change the direction of T_2 in the presence of analyte (see Figures 5A-5C). For example, the assay can be an agglomerative sandwich immunoassay in which two populations of magnetic particles bind to different epitopes of an analyte (see Figure 5A); a competitive assay in which analyte competes with a multivalent binding agents to inhibit the aggregation of magnetic particles (see Figure 5B); or a hybridization-mediated agglomeration in which two populations of magnetic particles bind to a first and second portion of an oligonucleotide (see Figure 5C).

Additional competitive format might include when two particles binding moieties bind without agglomerator (e..g. the DNA oligonucleotides are designed so that two nanoparticles have two different oligos and they can anneal together and when heated the analyte or amplicon or target DNA competes or disrupts the np annealing).

5   Other formats for carrying out the assays of the invention can be used, such as: (i) a target sample can be incubated in the presence of a magnetic particle that has been decorated with binding moieties specific to a target analyte and a multivalent binding agent, in an inhibition assay the binding of the analyte to the magnetic particles blocks agglomeration of the magnetic particles with the multivalent binding agent; (ii) a target sample can be incubated in the presence of a magnetic particle that has been

10   decorated with binding moieties specific to a target analyte and a multivalent binding agent, in a disaggregation assay the analyte is exposed to a pre-formed aggregate of the multivalent binding agent and the magnetic particle and the analyte displaces the multivalent binding agent to reduce aggregation in the liquid sample; or (iii) a target sample can be incubated in the presence of a magnetic particle that has been decorated with binding moieties specific to a target analyte and the target analyte itself to form a

15   self-assembling single population of magnetic particles, in an inhibition assay or disaggregation assay the presence the binding of the analyte to the magnetic particles blocks the self agglomeration of the magnetic particles; or (iv) a target sample can be incubated in the presence of a soluble agglomerating agent and a magnetic particle decorated with the analyte or analog of the analyte, in an inhibition assay the presence of the analyte binds the soluble agglomerating agent blocking the agglomeration of the

20   particles.

Where a multivalent binding agent (agglomerant) is employed, multiple analytes are linked to a carrier (e.g., a simple synthetic scaffold, or a larger carrier protein or polysaccharide, such as BSA, transferrin, or dextran).

25   **Magnetic particles**

The magnetic particles described herein include those described, e.g., in U.S. Patent No. 7,564,245 and U.S. Patent Application Publication No. 2003-0092029, each of which is incorporated herein by reference. The magnetic particles are generally in the form of conjugates, that is, a magnetic particle with one or more binding moieties (e.g., an oligonucleotide, nucleic acid, polypeptide, or

30   polysaccharide) linked thereto. The binding moiety causes a specific interaction with a target analyte. The binding moiety specifically binds to a selected target analyte, for example, a nucleic acid, polypeptide, or polysaccharide. In some instances, binding causes aggregation of the conjugates, resulting in a change, e.g., a decrease (e.g., in the case of smaller magnetic particles) or an increase (e.g., in the case of larger magnetic particles) in the spin-spin relaxation time (T2) of adjacent water protons in

35   an aqueous solution (or protons in a non-aqueous solvent). Alternatively, the analyte binds to a preformed aggregate in a competitive disaggregation assay (e.g., an aggregate formed from a multivalent binding agent and magnetic particles), or competes with a multivalent binding agent for binding moieties

on the magnetic particles in an inhibition assay (i.e., the formation of aggregates is inhibited in the presence of the analyte).

The conjugates have high relaxivity owing to the superparamagnetism of their iron, metal oxide, or other ferro or ferrimagnetic nanomaterials. Iron, cobalt, and nickel compounds and their alloys, rare earth elements such as gadolinium, and certain intermetallics such as gold and vanadium are ferromagnets can be used to produce superparamagnetic particles. The magnetic particles can be monodisperse (a single crystal of a magnetic material, e.g., metal oxide, such as superparamagnetic iron oxide, per magnetic particle) or polydisperse (e.g., a plurality of crystals per magnetic particle). The magnetic metal oxide can also include cobalt, magnesium, zinc, or mixtures of these metals with iron. Important features and elements of magnetic particles that are useful to produce conjugates include: (i) a high relaxivity, i.e., strong effect on water (or other solvent) relaxation, (ii) a functional group to which the binding moiety can be covalently attached, (iii) a low non-specific binding of interactive moieties to the magnetic particle, and/or (iv) stability in solution, i.e., the magnetic particles remain suspended in solution, not precipitated and/or the nps retain their ability to be employed in the described method (i.e. the nps have a shelf life).

The magnetic particles may be linked to the binding moieties via functional groups. In some embodiments, the magnetic particles can be associated with a polymer that includes functional groups selected, in part, to enhance the magnetic particles nonspecific reversibility. The polymer can be a synthetic polymer, such as, but not limited to, polyethylene glycol or silane, natural polymers, or derivatives of either synthetic or natural polymers or a combination of these. The polymer may be hydrophilic. In some embodiments, the polymer "coating" is not a continuous film around the magnetic metal oxide, but is a "mesh" or "cloud" of extended polymer chains attached to and surrounding the metal oxide. The polymer can include polysaccharides and derivatives, including dextran, pullanan, carboxydextran, carboxmethyl dextran, and/or reduced carboxymethyl dextran. The metal oxide can be a collection of one or more crystals that contact each other, or that are individually entrapped or surrounded by the polymer.

Alternatively, the magnetic particles can be associated with non-polymeric functional group compositions. Methods of synthesizing stabilized, functionalized magnetic particles without associated polymers are described, for example, in Halbreich et al., Biochimie, 80:379 (1998).

The magnetic particles typically include metal oxide mono and polycrystals of about 1-25 nm, e.g., about 3-10 nm, or about 5 nm in diameter per crystal. The magnetic particles can also include a polymer component in the form of a core and/or coating, e.g., about 5 to 20 nm thick or more. The overall size of the magnetic particles can be, e.g., from 20 to 50 nm, from 50 to 200 nm, from 100 to 300 nm, from 250 to 500 nm, from 400 to 600 nm, from 500 to 750 nm, from 700 to 1,200 nm, from 1,000 to 1,500 nm, or from 1,500 to 2,000 nm.

The magnetic particles may be prepared in a variety of ways. It is preferred that the magnetic particle have functional groups that link the magnetic particle to the binding moiety. Carboxy

functionalized magnetic particles can be made, for example, according to the method of Gorman (see PCT Publication No. WO00/61191). In this method, reduced carboxymethyl (CM) dextran is synthesized from commercial dextran. The CM-dextran and iron salts are mixed together and are then neutralized with ammonium hydroxide. The resulting carboxy functionalized magnetic particles can be used for

5   coupling amino functionalized oligonucleotides. Carboxy-functionalized magnetic particles can also be made from polysaccharide coated magnetic particles by reaction with bromo or chloroacetic acid in strong base to attach carboxyl groups. In addition, carboxy-functionalized particles can be made from amino-functionalized magnetic particles by converting amino to carboxy groups by the use of reagents such as succinic anhydride or maleic anhydride.

10   Magnetic particle size can be controlled by adjusting reaction conditions, for example, by using low temperature during the neutralization of iron salts with a base as described in U.S. Patent No. 5,262,176. Uniform particle size materials can also be made by fractionating the particles using centrifugation, ultrafiltration, or gel filtration, as described, for example in U.S. Patent No. 5,492,814.

Magnetic particles can also be synthesized according to the method of Molday (Molday, R. S. and

15   D. MacKenzie, "Immunospecific ferromagnetic iron-dextran reagents for the labeling and magnetic separation of cells," J. Immunol. Methods, 52:353 (1982)), and treated with periodate to form aldehyde groups. The aldehyde-containing magnetic particles can then be reacted with a diamine (e.g., ethylene diamine or hexanediamine), which will form a Schiff base, followed by reduction with sodium borohydride or sodium cyanoborohydride.

20   Dextran-coated magnetic particles can be made and cross-linked with epichlorohydrin. The addition of ammonia reacts with epoxy groups to generate amine groups, see Hogemann, D., et al., Improvement of MRI probes to allow efficient detection of gene expression Bioconjug. Chem., 11:941 (2000), and Josephson et al., "High-efficiency intracellular magnetic labeling with novel superparamagnetic-Tat peptide conjugates," Bioconjug. Chem., 10:186 (1999). This material is known as

25   cross-linked iron oxide or "CLIO" and when functionalized with amine is referred to as amine-CLIO or NH_2-CLIO. Carboxy-functionalized magnetic particles can be converted to amino-functionalized magnetic particles by the use of water-soluble carbodiimides and diamines such as ethylene diamine or hexane diamine.

The magnetic particles can be formed from a ferrofluid (i.e., a stable colloidal suspension of

30   magnetic particles). For example, the magnetic particle can be a composite of including multiple metal oxide crystals of the order of a few tens of nanometers in size and dispersed in a fluid containing a surfactant, which adsorbs onto the particles and stabilizes them, or by precipitation, in a basic medium, of a solution of metal ions. Suitable ferrofluids are sold by the company Liquids Research Ltd. under the references: WHKS1S9 (A, B or C), which is a water-based ferrofluid including magnetite (Fe_3O_4), having

35   particles 10 nm in diameter; WHJS1 (A, B or C), which is an isoparaffin-based ferrofluid including particles of magnetite (Fe_3O_4) 10 nm in diameter; and BKS25 dextran, which is a water-based ferrofluid stabilized with dextran, including particles of magnetite (Fe_3O_4) 9 nm in diameter. Other suitable

ferrofluids for use in the systems and methods of the invention are oleic acid-stabilized ferrofluids available from Ademtech, which include ca. 70% weight α-Fe$_2$O$_3$ particles (ca. 10 nm in diameter), 15% weight octane, and 15% weight oleic acid.

5   The magnetic particles are typically a composite including multiple metal oxide crystals and an organic matrix, and having a surface decorated with functional groups (i.e., amine groups or carboxy groups) for the linking binding moieties to the surface of the magnetic particle. For example, the magnetic particles useful in the methods of the invention include those commercially available from Dynal, Seradyn, Kisker, Miltenyi Biotec, Chemicell, Anvil, Biopal, Estapor, Genovis, Thermo Fisher Scientific, JSR micro, Invitrogen, and Ademtech, as well as those described in U.S. Patent Nos.

10   4,101,435; 4,452,773; 5,204,457; 5,262,176; 5,424,419; 6,165,378; 6,866,838; 7,001,589; and 7,217,457, each of which is incorporated herein by reference.

         Avidin or streptavidin can be attached to magnetic particles for use with a biotinylated binding moiety, such as an oligonucleotide or polypeptide (see, e.g., Shen et al., "Magnetically labeled secretin retains receptor affinity to pancreas acinar cells," Bioconjug. Chem., 7:311 (1996)). Similarly, biotin can

15   be attached to a magnetic particle for use with an avidin-labeled binding moiety. Alternatively, the binding moiety is covalently linked to the surface of the magnetic particle; the particles may be decorated with IgG molecules; the particles may be decorated with anti his antibodies; or the particles may be decorated with his-tagged FAbs.

         Low molecular weight materials can be separated from the magnetic particles by ultra-filtration,

20   dialysis, magnetic separation, or other means prior to use. For example, unreacted binding moieties and linking agents can be separated from the magnetic particle conjugates by magnetic separation or size exclusion chromatography. In certain instances the magnetic particles can be fractionated by size to produce mixtures of particles of a particular size range and average diameter.

         For certain assays requiring high sensitivity, analyte detection using T$_2$ relaxation assays can

25   require selecting a proper particle to enable sufficiently sensitive analyte-induced agglomeration. Higher sensitivities can be achieved using particles that contain multiple superparamagnetic iron oxide cores (5-15 nm diameter) within a single larger polymer matrix or ferrofluid assembly (100 nm-1200 nm total diameter, such as particles having an average diameter of 100 nm, 200 nm, 250 nm, 300 nm, 500 nm, 800 nm, or 1000 nm), or by using a higher magnetic moment materials or particles with higher density, and/or

30   particles with higher iron content. Without being limited by theory, it is postulated these types of particles provided a sensitivity gain of over 100× due to a much higher number of iron atoms per particle, which is believed to lead to an increase in sensitivity due to the decreased number of particles present in the assay solution and possibly a higher amount of superparamagnetic iron affected by each clustering event.

35   Relaxivity per particle and particle size is one useful term for selecting an optimal particle for high sensitivity assays. Ideally, this term will be as large as possible. Relaxivity per particle is a measure of the effect of each particle on the measured T$_2$ value. The larger this number, the fewer the number of

particles needed to elicit a given T_2 response. Furthermore, lowering the concentration of particles in the reactive solution can improve the analytical sensitivity of the assay. Relaxivity per particle can be a more useful parameter in that the iron density and relaxivity can vary from magnetic particle to magnetic particle, depending upon the components used to make the particles (see Table 1). Relaxivity per particle is proportional to the saturation magnetization of a superparamagnetic material.

Table 1.

Hydroynamic Diameter (nm)	# Metal Atoms per Particle	Relaxivity per Particle $(mM^{-1} s^{-1})$
10-30	1.0E+03 – 1.0E+06	1.0E+6 – 1.0E+11
10-50	8.0E+02 – 4.0E+04	1.0E+04 – 4.0E+06
10-50	1.0E+04 – 5.0E+05	1.0E+06 – 1.0E+08
50-100	1.0E+04 – 1.0E+07	1.0E+06 – 1.0E+09
100-200	5.0E+06 – 5.0E+07	5.0E+08 – 8.0E+09
200-300	1.0E+07 – 1.0E+08	3.0E+09 – 1.0E+10
300-500	5.0E+07 – 1.0E+09	7.0E+09 – 5.0E+10
500-800	1.0E+08 – 4.1E+09	1.0E+10 – 5.0E+11
800-1000	5.0E+08 – 5.0E+09	5.0E+10 – 5.0E+11
1000-1200	1.0E+09 – 7.0E+09	1.0E+11– 1.0E+12

The base particle for use in the systems and methods of the invention can be any of the commercially available particles identified in Table 2.

The magnetic particles for use in the systems and methods of the invention can have a hydrodynamic diameter from 10 nm to 1200 nm, and containing on average from $8 \times 10^2 - 1 \times 10^{10}$ metal atoms per particle, and having a relaxivity per particle of from $1 \times 10^4 - 1 \times 10^{13}$ mM^{-1}s^{-1}. The magnetic particles used in the systems and methods of the invention can be any of the designs, composites, or sources described above, and can be further modified has described herein for use as a magnetic resonance switch.

In addition to relaxivity per particle, several other practical issues must be address in the selection and design of magnetic particles for high analytical sensitivity assays.

For example, the use of large particles (i.e., 1000 nm or greater) may be desired to maximize iron content and the relaxivity per particle. However, we have observed that particles of this size tend to settle rapidly out of solution. We have observed that particle settling does not typically interfere with the assay if magnetic particle sizes are kept below 500 nm. When use of a particle above 500 nm in the described assays or smaller particles with high density are employed, settling is monitored and effect on T_2 measurement is determined. We have found a magnetic particle size of about 100-300 nm particle to be ideal for stability in terms of settling, even after functionalization (increasing the hydrodynamic diameter to 300 nm by approximately 50 nm), and to afford the high sensitivity enabled by a high relaxivity per particle. Particle density certainly plays a role in buoyancy. As such, the relative density of the solution and particles plays an important role in settling of the particle. Accordingly, a possible solution to this problem is the use of buoyant magnetic particles (i.e., a hollow particle, or particle containing both a low density matrix and high density metal oxide). Settling may affect the T_2 detection, thus, solution additives may be employed to change the ratio of the particle to solution density. T_2 detection can be impacted by settling if there is a significant portioning of the superparamagentic material from the measured volume of liquid. Settling can be assessed by diluting the particles to a concentration such that UV-Vis absorbance at 410 nm is between 0.6-0.8 absorbance units and then monitoring the absorbance for 90 minutes. If settling occurs, the difference between the initial and final absorbances divided by the initial absorbance will be greater than 5%. If % settling is above 5% then the particle is typically not suitable for use in assays requiring high analytical sensitivity. The magnetic particles used in the assays of the invention can be, but are not limited to, nonsettling magnetic particles. High settling represents handling difficulties and may lead to reproducibility issues.

For magnetic particles on the order of 100 nm or larger, the multiple superparamagnetic iron oxide crystals that typically include the particle core results in a net dipole moment when in the presence of external magnetic fields, i.e. the dipole monment is a sufficient force to overcome Brownian motion. Nonspecific reversibility is a measure of the colloidal stability and robustness against non-specific aggregation. Nonspecific reversibility is assessed by measuring the T_2 values of a solution of particles

before and after incubation in a uniform magnetic field (defined as <5000 ppm). Starting T_2 values are typically 200 ms for a particle with an iron concentration of 0.01mM Fe. If the difference in T_2 values before and after incubation in the uniform magnetic field is less than 20 ms, the samples are deemed reversible. Further, 10% is a threshold allowing starting T_2 measurements to reflect assay particle

5   concentration. If the difference is greater than 10%, then the particles exhibit irreversibility in the buffer, diluents, and matrix tested. The MAA reversibility of the magnetic particles can be altered as described herein. For example, colloidal stability and robustness against non-specific aggregation can be influenced by the surface characteristics of the particles, the binding moieties, the assay buffer, the matrix and the assay processing conditions. Maintenance of colloidal stability and resistance to non-specific biding can

10 be altered by conjugation chemistry, blocking methods, buffer modifications, and/or changes in assay processing conditions.

We have observed that a very important attribute for robust and reproducible assays is the monodispersity in the size distribution of the magnetic particles used, a distinction observed in polydisperse particles post-coating versus monodisperse particle pre-coating. Polydisperse batches of

15 magnetic particles can lack reproducibility and compromise sensitivity. Polydisperse samples can also present problems in terms of achieving uniform coatings. For certain highly sensitive assays it is desirable that the magnetic particles be substantially monodisperse in size distribution (i.e., having a polydispersity index of less than about 0.8 - 0.9). Alternatively, the assays of the invention can be designed to accommodate the use of polydisperse magnetic particles.

20   Given that the assays of the invention require monitoring a shift in the clustering states of the agglomeration assays and that measuring a change in clustering likely requires a significant fraction of clustered particles (e.g., thought to be >1-10%), the total number of particles in an assay should be minimized to enable the highest sensitivity. However, sufficient number of particles must be present to allow utilization of the T_2 detection dynamic range. We have found that the highest sensitivity is

25 observed when the number of magnetic particles (or molar equivalent) is approximately on the same order of magnitude of the number (or molar equivalent) of the analyte being detected, and the magnitude of the number (or molar equivalent) multivalent binding agents employed (i.e., in an inhibition assay).

For proteinaceous samples it may also be required to modify the magnetic particle surface to reduce non-specific binding of background proteins to the magnetic particles. Non-specific binding of

30 background proteins to particles can induce or impede particle clustering, resulting in false signals and/or false lack of signals. For example, in some instances the surface of the magnetic particle can include blocking agents covalently linked to the surface of the magnetic particle which reduce non-specific binding of background proteins. There are a variety of agents that one could use to achieve the desired effect, and in some cases, it is a combination of agents that is optimal (see Table 3; exemplary particles,

35 coatings, and binding moieties).

Table 3.

Base Particle	Coating	Binding Moiety
NP-COOH:	amino Dextran	Small molecule

NP-SA:	none	biotinylated Ab
	biotinylated amino PEG	Antibody
NP-SA:	biotinylated amino PEG	small molecule
NP-anti-species:	none	Antibody
NP-Ni:	none	his-tagged antibody

Thus, we have found a protein block may be required to achieve assay activity and sensitivity, particularly in proteinaceous samples (e.g., plasma samples or whole blood samples), that is comparable to results in nonproteinaceous buffer samples. Some commonly used protein blockers which may be used in provided preparations include, e.g., bovine serum albumin (BSA), fish skin gelatin (FSG), bovine gamma globulin (BGG), lysozyme, casein, peptidase, or non-fat dry milk. In certain embodiments a magnetic particle coating includes BSA or FSG. In other embodiments, a combination of coatings are combinations of those exemplary coatings listed in Table 3.

Furthermore, nonspecific binding can be due to lipids or other non-proteinaceous molecules in the biological sample. For non-proteinaceous mediated non-specific binding, changes in pH and buffer ionic strength maybe selected to enhance the particle repulsive forces, but not enough to limit the results of the intended interactions.

Assay reagents

The assays of the invention can include reagents for reducing the non-specific binding to the magnetic particles. For example, the assay can include one or more proteins (e.g., albumin, fish skin gelatin, lysozyme, or transferrin); low molecular weight (<500 Daltons) amines (e.g., amino acids,

glycine, ethylamine, or mercaptoethanol amine); and/or water soluble non-ionic surface active agents (e.g., polyethyleneglycol, Tween® 20, Tween® 80, Pluronic®, or Igepal®) (see Table 4).

Table 4.

Blocking Agents
PEG
BSA- Bovine serum albumin
HSA - Human serum albumin
FSG - Fish skin gelatin
Lysozyme
Transferrin
Glycine or other small amine containing molecules
Ethylamine
Mercaptoethanol amine
Tween 20
Tween 80
Pluronic
Igepal
Triton X-100
Other surfactants/detergents

The surfactant may be selected from a wide variety of soluble non-ionic surface active agents including surfactants that are generally commercially available under the IGEPAL trade name from GAF Company. The IGEPAL liquid non-ionic surfactants are polyethylene glycol p-isooctylphenyl ether compounds and are available in various molecular weight designations, for example, IGEPAL CA720, IGEPAL CA630, and IGEPAL CA890. Other suitable non-ionic surfactants include those available under the trade name TETRONIC 909 from BASF Wyandotte Corporation. This material is a tetra-functional block copolymer surfactant terminating in primary hydroxyl groups. Suitable non-ionic surfactants are also available under the VISTA ALPHONIC trade name from Vista Chemical Company and such materials are ethoxylates that are non-ionic biodegradables derived from linear primary alcohol blends of various molecular weights. The surfactant may also be selected from poloxamers, such as polyoxyethylene-polyoxypropylene block copolymers, such as those available under the trade names Synperonic PE series (ICI), Pluronic® series (BASF), Supronic, Monolan, Pluracare, and Plurodac, polysorbate surfactants, such as Tween® 20 (PEG-20 sorbitan monolaurate), and glycols such as ethylene glycol and propylene glycol.

Such non-ionic surfactants may be selected to provide an appropriate amount of detergency for an assay without having a deleterious effect on assay reactions. In particular, surfactants may be included in a reaction mixture for the purpose of suppressing non-specific interactions among various ingredients of

the aggregation assays of the invention. The non-ionic surfactants are typically added to the liquid sample prior in an amount from 0.01% (w/w) to 5% (w/w).

The non-ionic surfactants may be used in combination with one or more proteins (e.g., albumin, fish skin gelatin, lysozyme, or transferrin) also added to the liquid sample prior in an amount from 0.01% (w/w) to 5% (w/w).

Furthermore, the assays, methods, and cartridge units of the invention can include additional suitable buffer components (e.g., Tris base, selected to provide a pH of about 7.8 to 8.2 in the reaction milieu); and chelating agents to scavenge cations (e.g., EDTA disodium, ethylene diamine tetraacetic acid (EDTA), citric acid, tartaric acid, glucuronic acid, saccharic acid or suitable salts thereof).

Binding moieties

In general, a binding moiety is a molecule, synthetic or natural, that specifically binds or otherwise links to, e.g., covalently or non-covalently binds to or hybridizes with, a target molecule, or with another binding moiety (or, in certain embodiments, with an aggregation inducing molecule). For example, the binding moiety can be an antibody directed toward an antigen or any protein-protein interaction. Alternatively, the binding moiety can be a polysaccharide that binds to a corresponding target or a synthetic oligonucleotide that hybridizes to a specific complementary nucleic acid target. In certain embodiments, the binding moieties can be designed or selected to serve, when bound to another binding moiety, as substrates for a target molecule such as enzyme in solution.

Binding moieties include, for example, oligonucleotide binding moieties (DNA, RNA, or substituted or derivatized nucleotide substitutes), polypeptide binding moieties, antibody binding moieties, aptamers, and polysaccharide binding moieties.

Oligonucleotide binding moieties

In certain embodiments, the binding moieties are oligonucleotides, attached/linked to the magnetic particles using any of a variety of chemistries, by a single, e.g., covalent, bond, e.g., at the 3' or 5' end to a functional group on the magnetic particle. Such binding moieties can be used in the systems, devices, and methods of the invention to detect mutations (e.g., SNPs, translocations, large deletions, small deletions, insertions, substitutions) or to monitor gene expression (e.g., the presence of expression, or changes in the level of gene expression, monitoring RNA transcription), or CHP analysis characteristic of the presence of a pathogen, disease state, or the progression of disease.

An oligonucleotide binding moiety can be constructed using chemical synthesis. A double-stranded DNA binding moiety can be constructed by enzymatic ligation reactions using procedures known in the art. For example, a nucleic acid (e.g., an oligonucleotide) can be chemically synthesized using naturally occurring nucleotides or variously modified nucleotides designed to increase the biological stability of the molecules or to increase the physical stability of the duplex formed between the complementary strands, e.g., phosphorothioate derivatives and acridine substituted nucleotides can be

used. The nucleic acid also can be produced biologically using an expression vector into which a nucleic acid has been subcloned.

One method uses at least two populations of oligonucleotide magnetic particles, each with strong effects on water (or other solvent) relaxation. As the oligonucleotide-magnetic particle conjugates react with a target oligonucleotide, they form aggregates (e.g., clusters of magnetic particles). Upon prolonged standing, e.g., overnight at room temperature, the aggregates form large clusters (micron-sized clusters). Using the methods of the invention, the formation of large clusters can be accomplished more quickly by employing multiple cycles of magnetic assisted agglomeration. Magnetic resonance is used to determine the relaxation properties of the solvent, which are altered when the mixture of magnetic oligonucleotide magnetic particles reacts with a target nucleic acid to form aggregates.

Certain embodiments employ a mixture of at least two types of magnetic metal oxide magnetic particles, each with a specific sequence of oligonucleotide, and each with more than one copy of the oligonucleotide attached, e.g., covalently, per magnetic particle. For example, the assay protocol may involve preparing a mixture of populations of oligonucleotide-magnetic particle conjugates and reacting the mixture with a target nucleic acid. Alternatively, oligonucleotide-magnetic particle conjugates can be reacted with the target in a sequential fashion. Certain embodiments feature the use of magnetic resonance to detect the reaction of the oligonucleotide-magnetic particle conjugates with the target nucleic acid. When a target is present, the dispersed conjugates self-assemble to form small aggregates.

For example, oligonucleotide binding moieties can be linked to the metal oxide through covalent attachment to a functionalized polymer or to non-polymeric surface-functionalized metal oxides. In the latter method, the magnetic particles can be synthesized according to the method of Albrecht et al., Biochimie, 80:379 (1998). Dimercapto-succinic acid is coupled to the iron oxide and provides a carboxyl functional group.

In certain embodiments, oligonucleotides are attached to magnetic particles via a functionalized polymer associated with the metal oxide. In some embodiments, the polymer is hydrophilic. In certain embodiments, the conjugates are made using oligonucleotides that have terminal amino, sulfhydryl, or phosphate groups, and superparamagnetic iron oxide magnetic particles bearing amino or carboxy groups on a hydrophilic polymer. There are several methods for synthesizing carboxy and amino derivatized-magnetic particles.

In one embodiment, oligonucleotides are attached to a particle via ligand-protein binding interaction, such as biotin-streptavidin, where the ligand is covalently attached to the oligonucleotide and the protein to the particle, or vice versa. This approach can allow for more rapid reagent preparation.

Other forms of oligonucleotides may be used. For example, aptamers are single-stranded RNA or DNA oligonucleotides 15 to 60 base in length that in solution form intramolecular interactions that fold the linear nucleic acid molecule into a three dimensional complex that then can bind with high affinity to specific molecular targets; often with equilibrium constants in the range of 1 pM to 1 nM which is similar

to some monoclonal antibodies-antigen interactions. Aptamers can specifically bind to other nucleic acid molecules, proteins, small organic compounds, small molecules, and cells (organisms or pathogens).

5   Polypeptide binding moieties

In certain embodiments, the binding moiety is a polypeptide (i.e., a protein, polypeptide, or peptide), attached, using any of a variety of chemistries, by a single covalent bond in such a manner so as to not affect the biological activity of the polypeptide. In one embodiment, attachment is done through the thiol group of single reactive cysteine residue so placed that its modification does not affect the

10   biological activity of the polypeptide. In this regard the use of linear polypeptides, with cysteine at the C-terminal or N-terminal end, provides a single thiol in a manner similar to which alkanethiol supplies a thiol group at the 3' or 5' end of an oligonucleotide. Similar bifunctional conjugation reagents, such as SPDP and reacting with the amino group of the magnetic particle and thiol group of the polypeptide, can be used with any thiol bearing binding moiety. The types of polypeptides used as binding moieties can be

15   antibodies, antibody fragments, and natural and synthetic polypeptide sequences. The peptide binding moieties have a binding partner, that is, a molecule to which they selectively bind.

Use of peptides as binding moieties offers several advantages. For example, polypeptides can be engineered to have uniquely reactive residues, distal from the residues required for biological activity, for attachment to the magnetic particle. The reactive residue can be a cysteine thiol, an N-terminal amino

20   group, a C-terminal carboxyl group or a carboxyl group of aspartate or glutamate, etc. A single reactive residue on the peptide is used to insure a unique site of attachment. These design principles can be followed with chemically synthesized peptides or biologically produced polypeptides.

The binding moieties can also contain amino acid sequences from naturally occurring (wild-type) polypeptides or proteins. For example, the natural polypeptide may be a hormone, (e.g., a cytokine, a

25   growth factor), a serum protein, a viral protein (e.g., hemagglutinin), an extracellular matrix protein, a lectin, or an ectodomain of a cell surface protein. Another example is a ligand binding protein, such as streptavidin or avidin that bind biotin. In general, the resulting binding moiety-magnetic particle is used to measure the presence of analytes in a test media reacting with the binding moiety.

Additionally, a polypeptide binding moiety can be used in a universal reagent configuration,

30   where the target of the binding moiety (e.g., small molecule, ligand, or binding partner) is pre-attached to the target analyte to create a labeled analyte that, in the presence of the polypeptide decorated particles, induces clustering.

Examples of protein hormones which can be utilized as binding moieties include, without limitation, platelet-derived growth factor (PDGF), which binds the PDGF receptor; insulin-like growth

35   factor-I and -II (Igf) ,which binds the Igf receptor; nerve growth factor (NGF), which binds the NGF receptor; fibroblast growth factor (FGF), which binds the FGF receptor (e.g., aFGF and bFGF); epidermal growth factor (EGF), which binds the EGF receptor; transforming growth factor (TGF, e.g., TGFα and

- 64 -

TGF-β), which bind the TGF receptor; erythropoietin, which binds the erythropoitin receptor; growth hormone (e.g., human growth hormone), which binds the growth hormone receptor; and proinsulin, insulin, A-chain insulin, and B-chain insulin, which all bind to the insulin receptor.

Receptor binding moieties are useful for detecting and imaging receptor clustering on the surface of a cell. Useful ectodomains include those of the Notch protein, Delta protein, integrins, cadherins, and other cell adhesion molecules.

Antibody binding moieties

Other polypeptide binding moieties include immunoglobulin binding moieties that include at least one immunoglobulin domain, and typically at least two such domains. An "immunoglobulin domain" refers to a domain of an antibody molecule, e.g., a variable or constant domain. An "immunoglobulin superfamily domain" refers to a domain that has a three-dimensional structure related to an immunoglobulin domain, but is from a non-immunoglobulin molecule. Immunoglobulin domains and immunoglobulin superfamily domains typically include two β-sheets formed of about seven β-strands, and a conserved disulfide bond (see, e.g., Williams and Barclay Ann. Rev Immunol., 6:381 (1988)). Proteins that include domains of the Ig superfamily domains include T cell receptors, CD4, platelet derived growth factor receptor (PDGFR), and intercellular adhesion molecule (ICAM).

One type of immunoglobulin binding moiety is an antibody. The term "antibody," as used herein, refers to a full-length, two-chain immunoglobulin molecule and an antigen-binding portion and fragments thereof, including synthetic variants. A typical antibody includes two heavy (H) chain variable regions (abbreviated herein as VH), and two light (L) chain variable regions (abbreviated herein as VL). The VH and VL regions can be further subdivided into regions of hypervariability, termed "complementarity determining regions" (CDR), interspersed with regions that are more conserved, termed "framework regions" (FR). The extent of the framework region and CDR's has been precisely defined (see, Kabat, E. A., et al. (1991) Sequences of Proteins of Immunological Interest, Fifth Edition, U.S. Department of Health and Human Services, NIH Publication No. 91-3242, and Chothia et al., J. Mol. Biol., 196:901 (1987)). Each VH and VL is composed of three CDR's and four FRs, arranged from amino-terminus to carboxy-terminus in the following order: FR1, CDR1, FR2, CDR2, FR3, CDR3, and FR4.

An antibody can also include a constant region as part of a light or heavy chain. Light chains can include a kappa or lambda constant region gene at the COOH-terminus (termed CL). Heavy chains can include, for example, a gamma constant region (IgG1, IgG2, IgG3, IgG4; encoding about 330 amino acids). A gamma constant region can include, e.g., CH1, CH2, and CH3. The term "full-length antibody" refers to a protein that includes one polypeptide that includes VL and CL, and a second polypeptide that includes VH, CH1, CH2, and CH3.

The term "antigen-binding fragment" of an antibody, as used herein, refers to one or more fragments of a full-length antibody that retain the ability to specifically bind to a target. Examples of antigen-binding fragments include, but are not limited to: (i) an Fab fragment, a monovalent fragment

consisting of the VL, VH, CL and CH1 domains; (ii) an F(ab')$_2$ fragment, a bivalent fragment including two Fab fragments linked by a disulfide bridge at the hinge region; (iii) an Fd fragment consisting of the VH and CH1 domains; (iv) an Fv fragment consisting of the VL and VH domains of a single arm of an antibody, (v) a dAb fragment (Ward et al., Nature 341:544 (1989)), which consists of a VH domain; and

5   (vi) an isolated complementarity determining region (CDR). Furthermore, although the two domains of the Fv fragment, VL and VH, are coded for by separate genes, they can be joined, using recombinant methods, by a synthetic linker that enables them to be made as a single protein chain in which the VL and VH regions pair to form monovalent molecules (known as single chain Fv (scFv); see e.g., Bird et al., Science 242:423 (1988); and Huston et al., Proc. Natl. Acad. Sci. USA, 85:5879 (1988)). Such single

10   chain antibodies are also encompassed within the term "antigen-binding fragment."

A single domain antibody (sdAb, nanobody) is an antibody fragment consisting of a single monomeric variable antibody domain, and may also be used in the systems and methods of the invention. Like a whole antibody, sdAbs are able to bind selectively to a specific antigen. With a molecular weight of only 12–15 kDa, single domain antibodies are much smaller than common antibodies (150–160 kDa)

15   which are composed of two heavy protein chains and two light chains, and even smaller than Fab fragments (~50 kDa, one light chain and half a heavy chain) and single-chain variable fragments (~25 kDa, two variable domains, one from a light and one from a heavy chain).

Polysaccharide binding moieties

20   In certain embodiments, the binding moiety is a polysaccharide, linked, for example, using any of a variety of chemistries, by a single bond, e.g., a covalent bond, at one of the two ends, to a functional group on the magnetic particle. The polysaccharides can be synthetic or natural. Mono-, di-, tri- and polysaccharides can be used as the binding moiety. These include, e.g., glycosides, N-glycosylamines, O-acyl derivatives, O-methyl derivatives, osazones, sugar alcohols, sugar acids, sugar phosphates when used

25   with appropriate attachment chemistry to the magnetic particle.

A method of accomplishing linking is to couple avidin to a magnetic particle and react the avidin-magnetic particle with commercially available biotinylated polysaccharides, to yield polysaccharide-magnetic particle conjugates. For example, sialyl Lewis based polysaccharides are commercially available as biotinylated reagents and will react with avidin-CLIO (see Syntesome, Gesellschaft fur

30   medizinische Biochemie mbH.). The sialyl Lewis x tetrasaccharide (Sle^x) is recognized by proteins known as Selectins, which are present on the surfaces of leukocytes and function as part of the inflammatory cascade for the recruitment of leukocytes.

Still other targeting moieties include a non-proteinaceous element, e.g., a glycosyl modification (such as a Lewis antigen) or another non-proteinaceous organic molecule. Another method is covalent

35   coupling of the protein to the magnetic particle.

Another feature of the methods includes identification of specific cell types, for hematological or histopatholgical investigations for example CD4/CD3 cell counts and circulating tumor cells using any of the binding moieties described above.

Multivalent binding agents

The assays of the invention can include a multivalent binding agent (i) bearing multiple analytes are linked to a carrier (e.g., a simple synthetic scaffold, or a larger carrier protein or polysaccharide, such as BSA, transferrin, or dextran), or bearing multiple epitopes for binding to, for example, two or more populations of magnetic particles to form an aggregate.

Where a multivalent binding agent is employed, multiple analytes can be linked to a carrier (e.g., a simple synthetic scaffold, or a larger carrier protein or polysaccharide, such as BSA, transferrin, or dextran). Alternatively, the multivalent binding agent can be a nucleic acid designed to bind to two or more populations of magnetic particles. Such multivalent binding agents act as agglomerants and the assay architecture is characterized by a competition between the analyte being detected and the multivalent binding agent (e.g., in an inhibition assay, competition assay, or disaggregation assay).

The functional group present in the analyte can be used to form a covalent bond with the carrier. Alternatively, the analyte can be derivatized to provide a linker (i.e., a spacer separating the analyte from the carrier in the conjugate) terminating in a functional group (i.e., an alcohol, an amine, a carboxyl group, a sulfhydryl group, or a phosphate group), which is used to form the covalent linkage with the carrier.

The covalent linking of an analyte and a carrier may be effected using a linker which contains reactive moieties capable of reaction with such functional groups present in the analyte and the carrier. For example, a hydroxyl group of the analyte may react with a carboxyl group of the linker, or an activated derivative thereof, resulting in the formation of an ester linking the two.

Examples of moieties capable of reaction with sulfhydryl groups include α-haloacetyl compounds of the type XCH_2CO- (where X=Br, Cl or I), which show particular reactivity for sulfhydryl groups, but which can also be used to modify imidazolyl, thioether, phenol, and amino groups as described by Gurd, Methods Enzymol. 11:532 (1967). N-Maleimide derivatives are also considered selective towards sulfhydryl groups, but may additionally be useful in coupling to amino groups under certain conditions. Reagents such as 2-iminothiolane (Traut et al., Biochemistry 12:3266 (1973)), which introduce a thiol group through conversion of an amino group, may be considered as sulfhydryl reagents if linking occurs through the formation of disulphide bridges.

Examples of reactive moieties capable of reaction with amino groups include, for example, alkylating and acylating agents. Representative alkylating agents include:

(i) α-haloacetyl compounds, which show specificity towards amino groups in the absence of reactive thiol groups and are of the type XCH_2CO- (where X=Cl, Br or I), for example, as described by Wong, Biochemistry 24:5337 (1979); (ii) N-maleimide derivatives, which may react with amino groups either

through a Michael type reaction or through acylation by addition to the ring carbonyl group, for example, as described by Smyth et al., J. Am. Chem. Soc. 82:4600 (1960) and Biochem. J. 91:589 (1964); (iii) aryl halides such as reactive nitrohaloaromatic compounds; (iv) alkyl halides, as described, for example, by McKenzie et al., J. Protein Chem. 7:581 (1988); (v) aldehydes and ketones capable of Schiff's base formation with amino groups, the adducts formed usually being stabilized through reduction to give a stable amine; (vi) epoxide derivatives such as epichlorohydrin and bisoxiranes, which may react with amino, sulfhydryl, or phenolic hydroxyl groups; (vii) chlorine-containing derivatives of s-triazines, which are very reactive towards nucleophiles such as amino, sufhydryl, and hydroxyl groups; (viii) aziridines based on s-triazine compounds detailed above, e.g., as described by Ross, J. Adv. Cancer Res. 2:1 (1954), which react with nucleophiles such as amino groups by ring opening; (ix) squaric acid diethyl esters as described by Tietze, Chem. Ber. 124:1215 (1991); and (x) α-haloalkyl ethers, which are more reactive alkylating agents than normal alkyl halides because of the activation caused by the ether oxygen atom, as described by Benneche et al., Eur. J. Med. Chem. 28:463 (1993).

Representative amino-reactive acylating agents include: (i) isocyanates and isothiocyanates, particularly aromatic derivatives, which form stable urea and thiourea derivatives respectively; (ii) sulfonyl chlorides, which have been described by Herzig et al., Biopolymers 2:349 (1964); (iii) acid halides; (iv) active esters such as nitrophenylesters or N-hydroxysuccinimidyl esters; (v) acid anhydrides such as mixed, symmetrical, or N-carboxyanhydrides; (vi) other useful reagents for amide bond formation, for example, as described by M. Bodansky, Principles of Peptide Synthesis, Springer-Verlag, 1984; (vii) acylazides, e.g. wherein the azide group is generated from a preformed hydrazide derivative using sodium nitrite, as described by Wetz et al., Anal. Biochem. 58:347 (1974); and (viii) imidoesters, which form stable amidines on reaction with amino groups, for example, as described by Hunter and Ludwig, J. Am. Chem. Soc. 84:3491 (1962). Aldehydes and ketones may be reacted with amines to form Schiff's bases, which may advantageously be stabilized through reductive amination. Alkoxylamino moieties readily react with ketones and aldehydes to produce stable alkoxamines, for example, as described by Webb et al., Bioconjugate Chem. 1:96 (1990).

Examples of reactive moieties capable of reaction with carboxyl groups include diazo compounds such as diazoacetate esters and diazoacetamides, which react with high specificity to generate ester groups, for example, as described by Herriot, Adv. Protein Chem. 3:169 (1947). Carboxyl modifying reagents such as carbodiimides, which react through O-acylurea formation followed by amide bond formation, may also be employed.

It will be appreciated that functional groups in the analyte and/or the carrier may, if desired, be converted to other functional groups prior to reaction, for example, to confer additional reactivity or selectivity. Examples of methods useful for this purpose include conversion of amines to carboxyls using reagents such as dicarboxylic anhydrides; conversion of amines to thiols using reagents such as N-acetylhomocysteine thiolactone, S-acetylmercaptosuccinic anhydride, 2-iminothiolane, or thiol-containing succinimidyl derivatives; conversion of thiols to carboxyls using reagents such as α-haloacetates;

conversion of thiols to amines using reagents such as ethylenimine or 2-bromoethylamine; conversion of carboxyls to amines using reagents such as carbodiimides followed by diamines; and conversion of alcohols to thiols using reagents such as tosyl chloride followed by transesterification with thioacetate and hydrolysis to the thiol with sodium acetate.

5 So-called zero-length linkers, involving direct covalent joining of a reactive chemical group of the analyte with a reactive chemical group of the carrier without introducing additional linking material may, if desired, be used in accordance with the invention. Most commonly, however, the linker will include two or more reactive moieties, as described above, connected by a spacer element. The presence of such a spacer permits bifunctional linkers to react with specific functional groups within the analyte

10 and the carrier, resulting in a covalent linkage between the two. The reactive moieties in a linker may be the same (homobifunctional linker) or different (heterobifunctional linker, or, where several dissimilar reactive moieties are present, heteromultifunctional linker), providing a diversity of potential reagents that may bring about covalent attachment between the analyte and the carrier.

Spacer elements in the linker typically consist of linear or branched chains and may include a C_{1-}

15 $_{10}$ alkyl, a heteroalkyl of 1 to 10 atoms, a C_{2-10} alkene, a C_{2-10} alkyne, C_{5-10} aryl, a cyclic system of 3 to 10 atoms, or $-(CH_2CH_2O)_nCH_2CH_2-$, in which n is 1 to 4.

Typically, a multivalent binding agent will include 2, 3, 4, 5, 6, 7, 8, 15, 50, or 100 (e.g., from 3 to 100, from 3 to 30, from 4 to 25, or from 6 to 20) conjugated analytes. The multivalent binding agents are typically from 10 kDa to 200 kDa in size and can be prepared as described in the Examples.

20

Analytes

Embodiments of the invention include devices, systems, and/or methods for detecting and/or measuring the concentration of one or more analytes in a sample (e.g., a protein, a peptide, an enzyme, a polypeptide, an amino acid, a nucleic acid, an oligonucleotide, a therapeutic agent, a metabolite of a

25 therapeutic agent, RNA, DNA, circulating DNA (e.g., from a cell, tumor, pathogen, or fetus), an antibody, an organism, a virus, bacteria, a carbohydrate, a polysaccharide, glucose, a lipid, a gas (e.g., oxygen and/or carbon dioxide), an electrolyte (e.g., sodium, potassium, chloride, bicarbonate, BUN, magnesium, phosphate, calcium, ammonia, and/or lactate), general chemistry molecules (creatinine, glucose), a lipoprotein, cholesterol, a fatty acid, a glycoprotein, a proteoglycan, and/or a

30 lipopolysaccharide). The analytes may include identification of cells or specific cell types. The analyte(s) may include one or more biologically active substances and/or metabolite(s), marker(s), and/or other indicator(s) of biologically active substances. A biologically active substance may be described as a single entity or a combination of entities. The term "biologically active substance" includes without limitation, medications; vitamins; mineral supplements; substances used for the treatment, prevention,

35 diagnosis, cure or mitigation of disease or illness; or substances which affect the structure or function of the body; or pro-drugs, which become biologically active or more active after they have been placed in a predetermined physiological environment; or biologically toxic agents such as those used in biowarfare

including organisms such as anthrax, ebola, Salmonella typhimurium, Marburg virus, plague, cholera, Francisella tulariesis (tularemia), brucellosis, Q fever, Bolivian hemorrhagic fever, Coccidioides mycosis, glanders, Melioidosis, Shigella, Rocky Mountain spotted fever, typhus, Psittacosis, yellow fever, Japanese B encephalitis, Rift Valley fever, and smallpox; naturally-occurring toxins that can be used as

5   weapons include ricin, aflatoxin, SEB, botulinum toxin, saxitoxin, and many mycotoxins. Analytes may also include organisms such as Candida albicans, Candida glabrata, Candida krusei, Candida parapsilosis, Candida tropicalis, Coagulase negative Staphalococcus, Enterococcus faecalis, Enterococcus faecium, Escherichia coli, Klebsiella pneumonia, Pseudomonas aeruginosa, Staphylococcus aureus, Acinetobacter baumannii, Aspergillus fumigates, Bacteroides fragilis, Bacteroides fragilis, blaSHV, Burkholderia

10   cepacia, Campylobacter jejuni/coli, Candida guilliermondii, Candida lusitaniae, Clostridium pefringens, Enterobacter aeraogenesl, Enterobacter cloacae, Enterobacteriaceae spp., Haemophilus influenza, Kingella kingae, Klebsiella oxytoca, Listeria monocytogenes, Mec A gene-bearing bacteria (MRSA), Morganella morgana, Neisseria meningitides, Neisseria spp., non-meningitidis, Prevotella buccae, Prevotella intermedia, Prevotella melaninogenica, Propionibacterium acnes, Proteus mirabilis, Proteus

15   vulgaris, Salmonella enteric, Serratia marcescens, Staphylococcus haemolyticus, Staphylococcus maltophilia, Staphylococcus saprophyticus, Stenotrophomonas maltophilia, Stenotrophomonas maltophilia, Streptococcus agalactie, Streptococcus bovis, Streptococcus dysgalactie, Streptococcus mitis, Streptococcus mutans, Streptococcus pneumonia, Streptococcus pyogenes, Streptococcus sanguinis, Van A gene, Van B gene. Analytes may also include viral organisms such as dsDNA viruses (e.g.,

20   adenoviruses, herpes viruses, poxviruses); ssDNA viruses (+)sense DNA (e.g., parvoviruses); dsRNA viruses (e.g., reoviruses); (+)ssRNA viruses (+)sense RNA (e.g., picornaviruses, togaviruses); (−)ssRNA viruses (−)sense RNA (e.g., orthomyxoviruses, rhabdoviruses); ssRNA-RT viruses (+)sense RNA with DNA intermediate in life-cycle (e.g., retroviruses); and dsDNA-RT viruses (e.g., hepadnaviruses).

Opportunistic infections which can be detected using the systems and methods of the invention

25   include, without limitation, fungal, viral, bacterial, protozoan infections, such as: 1) fungal infections, such as those by Candida spp. (drug resistant and non-resistant strains), C. albicans, C. krusei, C. glabrata, and Aspergillus fumigates; 2) gram negative infections, such as those by E. coli, Stenotrophomonas maltophilia, Klebsiella pneumonia/oxytoca, and Pseudomonas aeruginosa; and 3) gram positive infections, such as those by Staphylococcus spp., S. aureus, S. pneumonia, Enterococcus ssp. (E faecalis

30   and E. faecium). The infection can be by coagulase negative staphylococcus, Corynebacterium spp., Fusobacterium spp., Morganella morganii, Pneumocystis jirovecii (previously known as Pneumocystis carinii), F. hominis, S. pyogenes, Pseudomonas aeruginosa, polyomavirus JC polyomavirus (the virus that causes progressive multifocal leukoencephalopathy), Acinetobacter baumanni, Toxoplasma gondii, cytomegalovirus, Aspergillus spp., Kaposi's Sarcoma, Cryptosporidium spp., Cryptococcus neoformans,

35   and Histoplasma capsulatum.

Non-limiting examples of broad categories of analytes which can be detected using the devices, systems, and methods of the invention include, without limitation, the following therapeutic categories:

anabolic agents, antacids, anti-asthmatic agents, anti-cholesterolemic and anti-lipid agents, anti-coagulants, anti-convulsants, anti-diarrheals, anti-emetics, anti-infective agents, anti-inflammatory agents, anti-manic agents, anti-nauseants, anti-neoplastic agents, anti-obesity agents, anti-pyretic and analgesic agents, anti-spasmodic agents, anti-thrombotic agents, anti-uricemic agents, anti-anginal agents,

5   antihistamines, anti-tussives, appetite suppressants, biologicals, cerebral dilators, coronary dilators, decongestants, diuretics, diagnostic agents, erythropoietic agents, expectorants, gastrointestinal sedatives, hyperglycemic agents, hypnotics, hypoglycemic agents, ion exchange resins, laxatives, mineral supplements, mucolytic agents, neuromuscular drugs, peripheral vasodilators, psychotropics, sedatives, stimulants, thyroid and anti-thyroid agents, uterine relaxants, vitamins, and prodrugs.

10   More specifically, non-limiting examples of analytes which can be detected using the devices, systems, and methods of the invention include, without limitation, the following therapeutic categories: analgesics, such as nonsteroidal anti-inflammatory drugs, opiate agonists and salicylates; antihistamines, such as H_1-blockers and H_2-blockers; anti-infective agents, such as anthelmintics, antianaerobics, antibiotics, aminoglycoside antibiotics, antifungal antibiotics, cephalosporin antibiotics, macrolide

15   antibiotics, miscellaneous β-lactam antibiotics, penicillin antibiotics, quinolone antibiotics, sulfonamide antibiotics, tetracycline antibiotics, antimycobacterials, antituberculosis antimycobacterials, antiprotozoals, antimalarial antiprotozoals, antiviral agents, antiretroviral agents, scabicides, and urinary anti-infectives; antineoplastic agents, such as alkylating agents, nitrogen mustard aklylating agents, nitrosourea alkylating agents, antimetabolites, purine analog antimetabolites, pyrimidine analog

20   antimetabolites, hormonal antineoplastics, natural antineoplastics, antibiotic natural antineoplastics, and vinca alkaloid natural antineoplastics; autonomic agents, such as anticholinergics, antimuscarinic anticholinergics, ergot alkaloids, parasympathomimetics, cholinergic agonist parasympathomimetics, cholinesterase inhibitor parasympathomimetics, sympatholytics, alpha-blocker sympatholytics, beta-blocker sympatholytics, sympathomimetics, and adrenergic agonist sympathomimetics; cardiovascular

25   agents, such as antianginals, beta-blocker antianginals, calcium-channel blocker antianginals, nitrate antianginals, antiarrhythmics, cardiac glycoside antiarrhythmics, class I antiarrhythmics, class II antiarrhythmics, class III antiarrhythmics, class IV antiarrhythmics, antihypertensive agents, alpha-blocker antihypertensives, angiotensin-converting enzyme inhibitor (ACE inhibitor) antihypertensives, beta-blocker antihypertensives, calcium-channel blocker antihypertensives, central-acting adrenergic

30   antihypertensives, diuretic antihypertensive agents, peripheral vasodilator antihypertensives, antilipemics, bile acid sequestrant antilipemics, HMG-COA reductase inhibitor antilipemics, inotropes, cardiac glycoside inotropes, and thrombolytic agents; dermatological agents, such as antihistamines, anti-inflammatory agents, corticosteroid anti-inflammatory agents, antipruritics/local anesthetics, topical anti-infectives, antifungal topical anti-infectives, antiviral topical anti-infectives, and topical antineoplastics;

35   electrolytic and renal agents, such as acidifying agents, alkalinizing agents, diuretics, carbonic anhydrase inhibitor diuretics, loop diuretics, osmotic diuretics, potassium-sparing diuretics, thiazide diuretics, electrolyte replacements, and uricosuric agents; enzymes, such as pancreatic enzymes and thrombolytic

enzymes; gastrointestinal agents, such as antidiarrheals, antiemetics, gastrointestinal anti-inflammatory agents, salicylate gastrointestinal anti-inflammatory agents, antacid anti-ulcer agents, gastric acid-pump inhibitor anti-ulcer agents, gastric mucosal anti-ulcer agents, H_2-blocker anti-ulcer agents, cholelitholytic agents, digestants, emetics, laxatives and stool softeners, and prokinetic agents; general anesthetics, such

5   as inhalation anesthetics, halogenated inhalation anesthetics, intravenous anesthetics, barbiturate intravenous anesthetics, benzodiazepine intravenous anesthetics, and opiate agonist intravenous anesthetics; hematological agents, such as antianemia agents, hematopoietic antianemia agents, coagulation agents, anticoagulants, hemostatic coagulation agents, platelet inhibitor coagulation agents, thrombolytic enzyme coagulation agents, and plasma volume expanders; hormones and hormone

10   modifiers, such as abortifacients, adrenal agents, corticosteroid adrenal agents, androgens, anti-androgens, antidiabetic agents, sulfonylurea antidiabetic agents, antihypoglycemic agents, oral contraceptives, progestin contraceptives, estrogens, fertility agents, oxytocics, parathyroid agents, pituitary hormones, progestins, antithyroid agents, thyroid hormones, and tocolytics; immunobiologic agents, such as immunoglobulins, immunosuppressives, toxoids, and vaccines; local anesthetics, such as amide local

15   anesthetics and ester local anesthetics; musculoskeletal agents, such as anti-gout anti-inflammatory agents, corticosteroid anti-inflammatory agents, gold compound anti-inflammatory agents, immuno-suppressive anti-inflammatory agents, nonsteroidal anti-inflammatory drugs (NSAIDs), salicylate anti-inflammatory agents, skeletal muscle relaxants, neuromuscular blocker skeletal muscle relaxants, and reverse neuromuscular blocker skeletal muscle relaxants; neurological agents, such as anticonvulsants,

20   barbiturate anticonvulsants, benzodiazepine anticonvulsants, anti-migraine agents, anti-parkinsonian agents, anti-vertigo agents, opiate agonists, and opiate antagonists; ophthalmic agents, such as anti-glaucoma agents, beta-blocker anti-gluacoma agents, miotic anti-glaucoma agents, mydriatics, adrenergic agonist mydriatics, antimuscarinic mydriatics, ophthalmic anesthetics, ophthalmic anti-infectives, ophthalmic aminoglycoside anti-infectives, ophthalmic macrolide anti-infectives, ophthalmic quinolone

25   anti-infectives, ophthalmic sulfonamide anti-infectives, ophthalmic tetracycline anti-infectives, ophthalmic anti-inflammatory agents, ophthalmic corticosteroid anti-inflammatory agents, and ophthalmic nonsteroidal anti-inflammatory drugs (NSAIDs); psychotropic agents, such as antidepressants, heterocyclic antidepressants, monoamine oxidase inhibitors (MAOIs), selective serotonin re-uptake inhibitors (SSRIs), tricyclic antidepressants, antimanics, antipsychotics, phenothiazine

30   antipsychotics, anxiolytics, sedatives, and hypnotics, barbiturate sedatives and hypnotics, benzodiazepine anxiolytics, sedatives, and hypnotics, and psychostimulants; respiratory agents, such as antitussives, bronchodilators, adrenergic agonist bronchodilators, antimuscarinic bronchodilators, expectorants, mucolytic agents, respiratory anti-inflammatory agents, and respiratory corticosteroid anti-inflammatory agents; toxicology agents, such as antidotes, heavy metal antagonists/chelating agents, substance abuse

35   agents, deterrent substance abuse agents, and withdrawal substance abuse agents; minerals; and vitamins, such as vitamin A, vitamin B, vitamin C, vitamin D, vitamin E, and vitamin K.

     Examples of classes of biologically active substances from the above categories which can be detected using the devices, systems, and methods of the invention include, without limitation, nonsteroidal anti-inflammatory drugs (NSAIDs) analgesics, such as diclofenac, ibuprofen, ketoprofen, and naproxen; opiate agonist analgesics, such as codeine, fentanyl, hydromorphone, and morphine;

5   salicylate analgesics, such as aspirin (ASA) (enteric coated ASA); H_1-blocker antihistamines, such as clemastine and terfenadine; H_2-blocker antihistamines, such as cimetidine, famotidine, nizadine, and ranitidine; anti-infective agents, such as mupirocin; antianaerobic anti-infectives, such as chloramphenicol and clindamycin; antifungal antibiotic anti-infectives, such as amphotericin b, clotrimazole, fluconazole, and ketoconazole; macrolide antibiotic anti-infectives, such as azithromycin

10   and erythromycin; miscellaneous beta-lactam antibiotic anti-infectives, such as aztreonam and imipenem; penicillin antibiotic anti-infectives, such as nafcillin, oxacillin, penicillin G, and penicillin V; quinolone antibiotic anti-infectives, such as ciprofloxacin and norfloxacin; tetracycline antibiotic anti-infectives, such as doxycycline, minocycline, and tetracycline; antituberculosis antimycobacterial anti-infectives such as isoniazid (INH), and rifampin; antiprotozoal anti-infectives, such as atovaquone and dapsone;

15   antimalarial antiprotozoal anti-infectives, such as chloroquine and pyrimethamine; anti-retroviral anti-infectives, such as ritonavir and zidovudine; antiviral anti-infective agents, such as acyclovir, ganciclovir, interferon alfa, and rimantadine; alkylating antineoplastic agents, such as carboplatin and cisplatin; nitrosourea alkylating antineoplastic agents, such as carmustine (BCNU); antimetabolite antineoplastic agents, such as methotrexate; pyrimidine analog antimetabolite antineoplastic agents, such as fluorouracil

20   (5-FU) and gemcitabine; hormonal antineoplastics, such as goserelin, leuprolide, and tamoxifen; natural antineoplastics, such as aldesleukin, interleukin-2, docetaxel, etoposide (VP-16), interferon alfa, paclitaxel, and tretinoin (ATRA); antibiotic natural antineoplastics, such as bleomycin, dactinomycin, daunorubicin, doxorubicin, and mitomycin; vinca alkaloid natural antineoplastics, such as vinblastine and vincristine; autonomic agents, such as nicotine; anticholinergic autonomic agents, such as benztropine

25   and trihexyphenidyl; antimuscarinic anticholinergic autonomic agents, such as atropine and oxybutynin; ergot alkaloid autonomic agents, such as bromocriptine; cholinergic agonist parasympathomimetics, such as pilocarpine; cholinesterase inhibitor parasympathomimetics, such as pyridostigmine; alpha-blocker sympatholytics, such as prazosin; 9-blocker sympatholytics, such as atenolol; adrenergic agonist sympathomimetics, such as albuterol and dobutamine; cardiovascular agents, such as aspirin (ASA)

30   (enteric coated ASA); i-blocker antianginals, such as atenolol and propranolol; calcium-channel blocker antianginals, such as nifedipine and verapamil; nitrate antianginals, such as isosorbide dinitrate (ISDN); cardiac glycoside antiarrhythmics, such as digoxin; class I antiarrhythmics, such as lidocaine, mexiletine, phenytoin, procainamide, and quinidine; class II antiarrhythmics, such as atenolol, metoprolol, propranolol, and timolol; class III antiarrhythmics, such as amiodarone; class IV antiarrhythmics, such as

35   diltiazem and verapamil; alpha-blocker antihypertensives, such as prazosin; angiotensin-converting enzyme inhibitor (ACE inhibitor) antihypertensives, such as captopril and enalapril; beta-blocker antihypertensives, such as atenolol, metoprolol, nadolol, and propanolol; calcium-channel blocker

antihypertensive agents, such as diltiazem and nifedipine; central-acting adrenergic antihypertensives, such as clonidine and methyldopa; diurectic antihypertensive agents, such as amiloride, furosemide, hydrochlorothiazide (HCTZ), and spironolactone; peripheral vasodilator antihypertensives, such as hydralazine and minoxidil; antilipemics, such as gemfibrozil and probucol; bile acid sequestrant

5   antilipemics, such as cholestyramine; HMG-CoA reductase inhibitor antilipemics, such as lovastatin and pravastatin; inotropes, such as amrinone, dobutamine, and dopamine; cardiac glycoside inotropes, such as digoxin; thrombolytic agents, such as alteplase (TPA), anistreplase, streptokinase, and urokinase; dermatological agents, such as colchicine, isotretinoin, methotrexate, minoxidil, tretinoin (ATRA); dermatological corticosteroid anti-inflammatory agents, such as betamethasone and dexamethasone;

10   antifungal topical anti-infectives, such as amphotericin B, clotrimazole, miconazole, and nystatin; antiviral topical anti-infectives, such as acyclovir; topical antineoplastics, such as fluorouracil (5-FU); electrolytic and renal agents, such as lactulose; loop diuretics, such as furosemide; potassium-sparing diuretics, such as triamterene; thiazide diuretics, such as hydrochlorothiazide (HCTZ); uricosuric agents, such as probenecid; enzymes such as RNase and DNase; thrombolytic enzymes, such as alteplase,

15   anistreplase, streptokinase and urokinase; antiemetics, such as prochlorperazine; salicylate gastrointestinal anti-inflammatory agents, such as sulfasalazine; gastric acid-pump inhibitor anti-ulcer agents, such as omeprazole; H_2-blocker anti-ulcer agents, such as cimetidine, famotidine, nizatidine, and ranitidine; digestants, such as pancrelipase; prokinetic agents, such as erythromycin; opiate agonist intravenous anesthetics such as fentanyl; hematopoietic antianemia agents, such as erythropoietin, filgrastim (G-CSF),

20   and sargramostim (GM-CSF); coagulation agents, such as antihemophilic factors 1-10 (AHF 1-10); anticoagulants, such as warfarin; thrombolytic enzyme coagulation agents, such as alteplase, anistreplase, streptokinase and urokinase; hormones and hormone modifiers, such as bromocriptine; abortifacients, such as methotrexate; antidiabetic agents, such as insulin; oral contraceptives, such as estrogen and progestin; progestin contraceptives, such as levonorgestrel and norgestrel; estrogens such as conjugated

25   estrogens, diethylstilbestrol (DES), estrogen (estradiol, estrone, and estropipate); fertility agents, such as clomiphene, human chorionic gonadatropin (HCG), and menotropins; parathyroid agents such as calcitonin; pituitary hormones, such as desmopressin, goserelin, oxytocin, and vasopressin (ADH); progestins, such as medroxyprogesterone, norethindrone, and progesterone; thyroid hormones, such as levothyroxine; immunobiologic agents, such as interferon beta-1b and interferon gamma-1b;

30   immunoglobulins, such as immune globulin IM, IMIG, IGIM and immune globulin IV, IVIG, IGIV; amide local anesthetics, such as lidocaine; ester local anesthetics, such as benzocaine and procaine; musculoskeletal corticosteroid anti-inflammatory agents, such as beclomethasone, betamethasone, cortisone, dexamethasone, hydrocortisone, and prednisone; musculoskeletal anti-inflammatory immunosuppressives, such as azathioprine, cyclophosphamide, and methotrexate; musculoskeletal

35   nonsteroidal anti-inflammatory drugs (NSAIDs), such as diclofenac, ibuprofen, ketoprofen, ketorlac, and naproxen; skeletal muscle relaxants, such as baclofen, cyclobenzaprine, and diazepam; reverse neuromuscular blocker skeletal muscle relaxants, such as pyridostigmine; neurological agents, such as

nimodipine, riluzole, tacrine and ticlopidine; anticonvulsants, such as carbamazepine, gabapentin, lamotrigine, phenytoin, and valproic acid; barbiturate anticonvulsants, such as phenobarbital and primidone; benzodiazepine anticonvulsants, such as clonazepam, diazepam, and lorazepam; anti-parkisonian agents, such as bromocriptine, levodopa, carbidopa, and pergolide; anti-vertigo agents, such

5   as meclizine; opiate agonists, such as codeine, fentanyl, hydromorphone, methadone, and morphine; opiate antagonists, such as naloxone; beta-blocker anti-glaucoma agents, such as timolol; miotic anti-glaucoma agents, such as pilocarpine; ophthalmic aminoglycoside antiinfectives, such as gentamicin, neomycin, and tobramycin; ophthalmic quinolone anti-infectives, such as ciprofloxacin, norfloxacin, and ofloxacin; ophthalmic corticosteroid anti-inflammatory agents, such as dexamethasone and prednisolone;

10   ophthalmic nonsteroidal anti-inflammatory drugs (NSAIDs), such as diclofenac; antipsychotics, such as clozapine, haloperidol, and risperidone; benzodiazepine anxiolytics, sedatives and hypnotics, such as clonazepam, diazepam, lorazepam, oxazepam, and prazepam; psychostimulants, such as methylphenidate and pemoline; antitussives, such as codeine; bronchodilators, such as theophylline; adrenergic agonist bronchodilators, such as albuterol; respiratory corticosteroid anti-inflammatory agents, such as

15   dexamethasone; antidotes, such as flumazenil and naloxone; heavy metal antagonists/chelating agents, such as penicillamine; deterrent substance abuse agents, such as disulfiram, naltrexone, and nicotine; withdrawal substance abuse agents, such as bromocriptine; minerals, such as iron, calcium, and magnesium; vitamin B compounds, such as cyanocobalamin (vitamin B_{12}) and niacin (vitamin B_3); vitamin C compounds, such as ascorbic acid; and vitamin D compounds, such as calcitriol; recombinant

20   beta-glucan; bovine immunoglobulin concentrate; bovine superoxide dismutase; the formulation including fluorouracil, epinephrine, and bovine collagen; recombinant hirudin (r-Hir), HIV-1 immunogen; human anti-TAC antibody; recombinant human growth hormone (r-hGH); recombinant human hemoglobin (r-Hb); recombinant human mecasermin (r-IGF-1); recombinant interferon beta-la; lenograstim (G-CSF); olanzapine; recombinant thyroid stimulating hormone (r-TSH); topotecan;

25   acyclovir sodium; aldesleukin; atenolol; bleomycin sulfate, human calcitonin; salmon calcitonin; carboplatin; carmustine; dactinomycin, daunorubicin HCl; docetaxel; doxorubicin HCl; epoetin alfa; etoposide (VP-16); fluorouracil (5-FU); ganciclovir sodium; gentamicin sulfate; interferon alfa; leuprolide acetate; meperidine HCl; methadone HCl; methotrexate sodium; paclitaxel; ranitidine HCl; vinblastin sulfate; and zidovudine (AZT).

30   Further specific examples of biologically active substances from the above categories which can be detected using the devices, systems, and methods of the invention include, without limitation, antineoplastics such as androgen inhibitors, antimetabolites, cytotoxic agents, and immunomodulators; anti-tussives such as dextromethorphan, dextromethorphan hydrobromide, noscapine, carbetapentane citrate, and chlorphedianol hydrochloride; antihistamines such as chlorpheniramine maleate,

35   phenindamine tartrate, pyrilamine maleate, doxylamine succinate, and phenyltoloxamine citrate; decongestants such as phenylephrine hydrochloride, phenylpropanolamine hydrochloride, pseudoephedrine hydrochloride, and ephedrine; various alkaloids such as codeine phosphate, codeine

sulfate and morphine; mineral supplements such as potassium chloride, zinc chloride, calcium carbonates, magnesium oxide, and other alkali metal and alkaline earth metal salts; ion exchange resins such as cholestryramine; anti-arrhythmics such as N-acetylprocainamide; antipyretics and analgesics such as acetaminophen, aspirin and ibuprofen; appetite suppressants such as phenyl-propanolamine hydrochloride

5   or caffeine; expectorants such as guaifenesin; antacids such as aluminum hydroxide and magnesium hydroxide; biologicals such as peptides, polypeptides, proteins and amino acids, hormones, interferons or cytokines, and other bioactive peptidic compounds, such as interleukins 1-18 including mutants and analogues, RNase, DNase, luteinizing hormone releasing hormone (LHRH) and analogues, gonadotropin releasing hormone (GnRH), transforming growth factor-beta(TGF-beta), fibroblast growth factor (FGF),

10   tumor necrosis factor-alpha & beta (TNF-alpha & beta), nerve growth factor (NGF), growth hormone releasing factor (GHRF), epidermal growth factor (EGF), fibroblast growth factor homologous factor (FGFHF), hepatocyte growth factor (HGF), insulin growth factor (IGF), invasion inhibiting factor-2 (IIF-2), bone morphogenetic proteins 1-7 (BMP 1-7), somatostatin, thymosin-α-1, T-globulin, superoxide dismutase (SOD), complement factors, hGH, tPA, calcitonin, ANF, EPO and insulin; and anti-infective

15   agents such as antifungals, anti-virals, antiseptics and antibiotics.

Biologically active substances which can be detected using the devices, systems, and methods of the invention also include radiosensitizers, such as metoclopramide, sensamide or neusensamide (manufactured by Oxigene); profiromycin (made by Vion); RSR13 (made by Allos); Thymitaq (made by Agouron), etanidazole or lobenguane (manufactured by Nycomed); gadolinium texaphrin (made by

20   Pharmacyclics); BuDR/Broxine (made by NeoPharm); IPdR (made by Sparta); CR2412 (made by Cell Therapeutic); LIX (made by Terrapin); or the like.

Biologically active substances which can be detected using the devices, systems, and methods of the invention include, without limitation, medications for the gastrointestinal tract or digestive system, for example, antacids, reflux suppressants, antiflatulents, antidoopaminergics, proton pump inhibitors, H_2-

25   receptor antagonists, cytoprotectants, prostaglandin analogues, laxatives, antispasmodics, antidiarrheals, bile acid sequestrants, and opioids; medications for the cardiovascular system, for example, beta-receptor blockers, calcium channel blockers, diuretics, cardiac glycosides, antiarrhythmics, nitrate, antianginals, vascoconstrictors, vasodilators, peripheral activators, ACE inhibitors, angiotensin receptor blockers, alpha blockers, anticoagulants, heparin, HSGAGs, antiplatelet drugs, fibrinolytics, anti-hemophilic factors,

30   haemostatic drugs, hypolipaemic agents, and statins; medications for the central nervous system, for example, hypnotics, anaesthetics, antipsychotics, antidepressants, anti-emetics, anticonvulsants, antiepileptics, anxiolytics, barbiturates, movement disorder drugs, stimulants, benzodiazepine, cyclopyrrolone, dopamine antagonists, antihistamine, cholinergics, anticholinergics, emetics, cannabinoids, 5-HT antigonists; medications for pain and/or consciousness, for example, NSAIDs,

35   opioids and orphans such as paracetamol, tricyclic antidepressants, and anticonvulsants; for musculo-skeletal disorders, for example, NSAIDs, muscle relaxants, and neuromuscular drug anticholinersterase; medications for the eye, for example, adrenergic neurone blockers, astringents, ocular lubricants, topical

anesthetics, sympathomimetics, parasympatholytics, mydriatics, cycloplegics, antibiotics, topical antibiotics, sulfa drugs, aminoglycosides, fluoroquinolones, anti-virals, anti-fungals, imidazoles, polyenes, NSAIDs, corticosteroids, mast cell inhibitors, adrenergic agnoists, beta-blockers, carbonic anhydrase inhibitors/hyperosmotiics, cholinergics, miotics, parasympathomimetics, prostaglandin,

5   agonists/prostaglandin inhibitors, nitroglycerin; medications for the ear, nose and oropharynx, for example, sympathomimetics, antihistamines, anticholinergics, NSAIDs, steroids, antiseptics, local anesthetics, antifungals, cerumenolytics; medications for the respiratory system, for example, bronchodilators, NSAIDs, anti-allergics, antitussives, mucolytics, decongestants, corticosteroids, beta-receptor antagonists, anticholinergics, steroids; medications for endocrine problems, for example,

10   androgen, antiandrogen, gonadotropin, corticosteroids, growth hormone, insulin, antidiabetics, thyroid hormones, antithyroid drugs, calcitonin, diphosponate, and vasopressin analogues; medications for the reproductive system or urinary system, for example, antifungals, alkalising agents, quinolones, antibiotics, cholinergics, anticholinergics, anticholinesterase, antispasmodics, 5-alpha reductase inhibitor, selective alpha-1 blockers, and sildenafil; medications for contraception, for example, oral contraceptives,

15   spermicides, and depot contraceptives; medications for obstetrics and gynacology, for example, NSAIDs, anticholinergics, haemostatic drugs, antifibrinolytics, hormone replacement therapy, bone regulator, beta-receptor agonists, follicle stimulating hormone, luteinising hormone, LHRH gamolenic acid, gonadotropin release inhibitor, progestogen, dopamine agonist, oestrogen, prostaglandin, gonadorelin, clomiphene, tammoxifen, and diethylstilbestrol; medications for the skin, for example, emollients, anti-

20   pruritics, antifungals, disinfectants, scabicide, pediculicide, tar products, vitamin A derivatives, vitamin D analogue, keratolytics, abrasives, systemic antibiotics, topical antibiotics, hormones, desloughing agents, exudate absorbents, fibrinolytics, proteolytics, sunscreens, antiperspirants, and corticosteroids; medications for infections and infestations, for example, antibiotics, antifungals, antileprotics, antituberculous drugs, antimalarials, anthelmintics, amoebicide, antivirals, antiprotozoals, and antiserum;

25   medications for the immune system, for example, vaccines, immunoglobulin, immunosuppressants, interferon, monoclonal antibodies; medications for allergic disorders, for example, anti-allergics, antihistamines, and NSAIDs; medications for nutrition, for example, tonics, iron preparations, electrolytes, vitamins, anti-obesity drugs, anabolic drugs, haematopoietic drugs, and food product drugs; medications for neoplastic disorders, for example, cytotoxic drugs, sex hormones, aromatase inhibitors,

30   somatostatin inhibitors, recombinant interleukins, G-CSF, and erythropoietin; medications for diagnostics, for example, contrast agents; and medications for cancer (anti-cancer agents).

Examples of pain medications (e.g., analgesics) which can be detected using the devices, systems, and methods of the invention include opioids such as buprenorphine, butorphanol, dextropropoxyphene, dihydrocodeine, fentanyl, diamorphine (heroin), hydromorphone, morphine, nalbuphine, oxycodone,

35   oxymorphone, pentazocine, pethidine (meperidine), and tramadol; salicylic acid and derivatives such as acetylsalicylic acid (aspirin), diflunisal, and ethenzamide; pyrazolones such as aminophenazone,

metamizole, and phenazone; anilides such as paracetamol (acetaminophen), phenacetin; and others such as ziconotide and tetradyrocannabinol.

Examples of blood pressure medications (e.g., antihypertensives and diuretics) which can be detected using the devices, systems, and methods of the invention include antiadrenergic agents such as clonidine, doxazosin, guanethidine, guanfacine, mecamylamine, methyldopa, moxonidinie, prazosin, rescinnamine, and reserpine; vasodilators such as diazoxide, hydralazine, minoxidil, and nitroprusside; low ceiling diuretics such as bendroflumethiazide, chlorothiazide, chlortalidone, hydrochlorothiazide, indapamide, quinethazone, mersalyl, metolazone, and theobromine; high ceiling diuretics such as bumetanide, furosemide, and torasemide; potassium-sparing diuretics such as amiloride, eplerenone, spironolactone, and triamterene; and other antihypertensives such as bosentan and ketanserin.

Examples of anti-thrombotics (e.g., thrombolytics, anticoagulants, and antiplatelet drugs) which can be detected using the devices, systems, and methods of the invention include vitamin K antagonists such as acenocoumarol, clorindione, dicumarol, diphenadione, ethyl biscoumacetate, phenprocoumon, phenindione, tioclomarol, and warfarin; heparin group (platelet aggregation inhibitors) such as antithrombin III, bemiparin, dalteparin, danaparoid, enoxaparin, heparin, nadroparin, parnaparin, reviparin, sulodexide, and tinzaparin; other platelet aggregation inhibitors such as abciximab, acetylsalicylic acid (aspirin), aloxiprin, beraprost, ditazole, carbasalate calcium, cloricromen, clopidogrel, dipyridamole, epoprostenol, eptifibatide, indobufen, iloprost, picotamide, prasugrel, ticlopidine, tirofiban, treprostinil, and triflusal; enzymes such as alteplase, ancrod, anistreplase, brinase, drotrecogin alfa, fibrinolysin, procein C, reteplase, saruplase, streptokinase, tenecteplase, and urokinase; direct thrombin inhibitors such as argatroban, bivalirudin, desirudin, lepirudin, melagatran, and ximelagatran; other antithrombotics such as dabigatran, defibrotide, dermatan sulfate, fondaparinux, and rivaroxaban; and others such as citrate, EDTA, and oxalate.

Examples of anticonvulsants which can be detected using the devices, systems, and methods of the invention include barbiturates such as barbexaclone, metharbital, methylphenobarbital, phenobarbital, and primidone; hydantoins such as ethotoin, fosphenytoin, mephenytoin, and phenytoin; oxazolidinediones such as ethadione, paramethadione, and trimethadione; succinimides such as ethosuximide, mesuximide, and phensuximide; benzodiazepines such as clobazam, clonazepam, clorazepate, diazepam, lorazepam, midazolam, and nitrazepam; carboxamides such as carbamazepine, oxcarbazepine, rufinamide; fatty acid derivatives such as valpromide and valnoctamide; carboxylic acids such as valproic acid, tiagabine; GABA analogs such as gabapentin, pregabalin, progabide, and givabatrin; monosaccharides such as topiramate; aromatic allyllic alcohols such as stiripentol; ureas such as phenacemide and pheneturide; carbamates such as emylcamate, felbamate, and meprobamate; pyrrolidines such as brivaracetam, levetiracetam, nefiracetam, and seletracetam; sulfa drugs such as acetazolamide, ethoxzolamide, sultiame, and zonisamide; propionates such as beclamide; aldehydes such as paraldehyde; and bromides such as potassium bromide.

Examples of anti-cancer agents which can be detected using the devices, systems, and methods of the invention include acivicin; aclarubicin; acodazole hydrochloride; acronine; adriamycin; adozelesin; aldesleukin; altretamine; ambomycin; ametantrone acetate; aminoglutethimide; amsacrine; anastrozole; anthramycin; asparaginase; asperlin; azacitidine; azetepa; azotomycin; batimastat; benzodepa;

5   bicalutamide; bisantrene hydrochloride; bisnafide dimesylate; bizelesin; bleomycin sulfate; brequinar sodium; bropirimine; busulfan; cactinomycin; calusterone; caracemide; carbetimer; carboplatin; carmustine; carubicin hydrochloride; carzelesin; cedefingol; chlorambucil; cirolemycin; cisplatin; cladribine; crisnatol mesylate; cyclophosphamide; cytarabine; dacarbazine; dactinomycin; daunorubicin hydrochloride; decitabine; dexormaplatin; dezaguanine; dezaguanine mesylate; diaziquone; docetaxel;

10   doxorubicin; doxorubicin hydrochloride; droloxifene; droloxifene citrate; dromostanolone propionate; duazomycin; edatrexate; eflornithine hydrochloride; elsamitrucin; enloplatin; enpromate; epipropidine; epirubicin hydrochloride; erbulozole; esorubicin hydrochloride; estramustine; estramustine phosphate sodium; etanidazole; etoposide; etoposide phosphate; etoprine; fadrozole hydrochloride; fazarabine; fenretinide; floxuridine; fludarabine phosphate; fluorouracil; flurocitabine; fosquidone; fostriecin sodium;

15   gemcitabine; gemcitabine hydrochloride; hydroxyurea; idarubicin hydrochloride; ifosfamide; ilmofosine; interferon alfa-2a; interferon alfa-2b; interferon alfa-n1; interferon alfa-n3; interferon beta-I a; interferon gamma-I b; iproplatin; irinotecan hydrochloride; lanreotide acetate; letrozole; leuprolide acetate; liarozole hydrochloride; lometrexol sodium; lomustine; losoxantrone hydrochloride; masoprocol; maytansine; mechlorethamine hydrochloride; megestrol acetate; melengestrol acetate; melphalan; menogaril;

20   mercaptopurine; methotrexate; methotrexate sodium; metoprine; meturedepa; mitindomide; mitocarcin; mitocromin; mitogillin; mitomalcin; mitomycin; mitosper; mitotane; mitoxantrone hydrochloride; mycophenolic acid; nocodazole; nogalamycin; ormaplatin; oxisuran; paclitaxel; pegaspargase; peliomycin; pentamustine; peplomycin sulfate; perfosfamide; pipobroman; piposulfan; piroxantrone hydrochloride; plicamycin; plomestane; porfimer sodium; porfiromycin; prednimustine; procarbazine

25   hydrochloride; puromycin; puromycin hydrochloride; pyrazofurin; riboprine; rogletimide; safingol; safingol hydrochloride; semustine; simtrazene; sparfosate sodium; sparsomycin; spirogermanium hydrochloride; spiromustine; spiroplatin; streptonigrin; streptozocin; sulofenur; talisomycin; tecogalan sodium; tegafur; teloxantrone hydrochloride; temoporfin; teniposide; teroxirone; testolactone; thiamiprine; thioguanine; thiotepa; tiazofurin; tirapazamine; topotecan hydrochloride; toremifene citrate;

30   trestolone acetate; triciribine phosphate; trimetrexate; trimetrexate glucuronate; triptorelin; tubulozole hydrochloride; Uracil mustard; rredepa; vapreotide; verteporfin; vinblastine sulfate; vincristine sulfate; vindesine; vindesine sulfate; vinepidine sulfate; vinglycinate sulfate; vinleurosine sulfate; vinorelbine tartrate; vinrosidine sulfate; vinzolidine sulfate; vorozole; zeniplatin; zinostatin; and zorubicin hydrochloride.

35   Other biologically active substances which can be detected using the devices, systems, and methods of the invention include those mentioned in Basic and Clinical Pharmacology (LANGE Basic Science), Katzung and Katzung, ISBN 0071410929, McGraw-Hill Medical, 9th edition (2003).

Medical conditions

Embodiments of the invention may be used in the monitoring of one or more analytes in the diagnosis, management, and/or treatment of any of a wide range of medical conditions. Various

5   categories of medical conditions include, for example, disorders of pain; of alterations in body temperature (e.g., fever); of nervous system dysfunction (e.g., syncope, myalgias, movement disorders, numbness, sensory loss, delirium, dementia, memory loss, or sleep disorders); of the eyes, ears, nose, and throat; of circulatory and/or respiratory functions (e.g., dysplnea, pulmonary edema, cough, hemoptysis, hypertension, myocardial infarctions, hypoxia, cyanosis, cardiovascular collapse, congestive heart failure,

10   edema, or shock); of gastrointestinal function (e.g., dysphagia, diarrhea, constipation, GI bleeding, jaundice, ascites, indigestion, nasusea, vomiting); of renal and urinary tract function (e.g., acidosis, alkalosis, fluid and electrolyte imbalances, azotemia, or urinary abnormalities); of sexual function and reproduction (e.g., erectile dysfunction, menstrual disturbances, hirsutism, virilization, infertility, pregnancy associated disorders and standard measurements); of the skin (e.g., eczema, psoriasis, acne,

15   rosacea, cutaneous infection, immunological skin diseases, or photosensitivity); of the blood (e.g., hematology); of genes (e.g., genetic disorders); of drug response (e.g., adverse drug responses); and of nutrition (e.g., obesity, eating disorders, or nutritional assessment). Other medical fields with which embodiments of the invention find utility include oncology (e.g., neoplasms, malignancies, angiogenesis, paraneoplasic syndromes, or oncologic emergencies); hematology (e.g., anemia, hemoglobinopathies,

20   megalooblastic anemias, hemolytic anemias, aplastic anemia, myelodysplasia, bone marrow failure, polycythemia vera, myloproliferative diseases, acute myeloid leukemia, chronic myeloid leukemia, lymphoid malignancies, plasma cell disorders, transfusion biology, or transplants); hemostasis (e.g., disorders of coagulation and thrombosis, or disorders of the platelet and vessel wall); and infectious diseases (e.g., sepsis, septic shock, fever of unknown origin, endocardidtis, bites, burns, osteomyelitis,

25   abscesses, food poisoning, pelvic inflammatory disease, bacterial (e.g., gram positive, gram negative, miscellaneous (nocardia, actimoyces, mixed), mycobacterial, spirochetal, rickettsia, or mycoplasma); chlamydia; viral (DNA, RNA), fungal and algal infections; protozoal and helminthic infections; endocrine diseases; nutritional diseases; and metabolic diseases.

Other medical conditions and/or fields with which embodiments of the invention find utility

30   include those mentioned in Harrison's Principles of Internal Medicine, Kasper et al., ISBN 0071402357, McGraw-Hill Professional, 16th edition (2004), as well as those mentioned in Robbins Basic Pathology, Kumar, Cotran, and Robbins, eds., ISBN 1416025340, Elsevier, 7th edition (2005).

Medical tests (e.g., blood tests, urine tests, and/or other human or animal tissue tests) that may be performed using various embodiments of the invention described herein include, for example, general

35   chemistry tests (e.g., analytes include albumin, blood urea nitrogen, calcium, creatinine, magnesium, phosphorus, total protein, and/or uric acid); electrolyte tests (e.g., analytes include sodium, potassium, chloride, and/or carbon dioxide); diabetes tests (e.g., analytes include glucose, hemoglobin A1C, and/or

microalbumin); lipids tests (e.g., analytes include apolipoprotein A1, apolipoprotein B, cholesterol, triglyceride, low density lipoprotein cholesteral, and/or high density lipoprotein cholesterol); nutritional assessment (e.g., analytes include albumin, prealbumin, transferrin, retinol binding protein, alpha1-acid glycoprotein, and/or ferritin); hepatic tests (e.g., analytes include alanine transaminase, albumin, alkaline

5   phosphatase, aspartate transaminase, direct bilirubin, gamma glutamyl transaminase, lactate dehydrogenase, immunoglobulin A, immunoglobulin G, immunoglobulin M, prealbumin, total bilirubin, and/or total protein); cardiac tests (e.g., analytes include apolipoprotein A1, apolipoprotein B, cardiac troponin-1, creatine kinase, creatine kinase MB isoenzyme, high sensitivity CRP, mass creatine kinase MB isoenzyme myoglobin, and/or N-terminal pro-brain natriuretic peptide); tests for anemia (e.g.,

10   analytes include ferritin, folate, homocysteine, haptoglobin, iron, soluble transferrin receptor, total iron binding capacity, transferrin, and/or vitamin B12); pancreatic tests (e.g., analytes include amylase and/or lipase); nephropathies (e.g., analytes include albumin, alpha1-microglobulin, alpha2-macroglobulin, beta2-microglobulin, cystatin C, retinol binding protein, and/or transferrin); bone tests (e.g., analytes include alkaline phosphatase, calcium, and/or phosphorous); cancer marker monitoring (e.g., analytes

15   include total PSA); thyroid tests (e.g., analytes include free thyroxine, free triiodothyronine, thyroxine, thyroid stimulating hormone, and/or triiodothyronine); fertility tests (e.g., analytes include beta-human chorionic gonadotropin); therapeutic drug monitoring (e.g., analytes include carbamazepine, digoxin, digitoxin, gentamicin, lidocaine, lithium, N-acetyl procainamide, phenobarbital, phenytoin, procainamide, theophylline, tobramycin, valproic acid, and/or vancomycin); immunosuppressive drugs (e.g., analytes

20   include cyclosporine A, sirolimus, and/or tacrolimus); tests for complement activity and/or autoimmune disease (e.g., analytes include C3 complement, C4 complement, C1 inhibitor, C-reactive protein, and/or rheumatoid fator); polyclonal/monoclonal gammopathies (e.g., analytes include immunoglobulin A, immunoglobulin G, immunoglobulin M, 1 g light chains types kappa and/or lambda, immunoglobulin G subclasses 1, 2, 3, and/or 4); tests for infectious disease (e.g., analytes include antistreptolysin O); tests

25   for inflammatory disorders (e.g., analytes include alpha1-acid glycoprotein, alpha1-antitrypsin, ceruloplasmin, C-reactive protein, and/or haptoglobin); allergy testing (e.g., analytes include immunoglobulin E); urine protein tests (e.g., analytes include alpha1-microglobulin, immunoglobulin G, 1 g light chains type kappa and/or lambda, microalbumin, and/or urinary/cerebrospinal fluid protein); tests for protein--CSF (e.g., analytes include immunoglobulin G and/or urinary/cerebrospinal fluid

30   protein); toxicology tests (e.g., analytes include serum acetaminophen, serum barbiturates, serum benzodiazepines, serum salicylate, serum tricyclic antidepressants, and/or urine ethyl alcohol); and/or tests for drugs of abuse (e.g., analytes include amphetamine, cocaine, barbiturates, benzodiazepines, ecstasy, methadone, opiate, phencyclidine, tetrahydrocannabinoids, propoxyphene, and/or methaqualone). Specific cancer markers that can be detected using the methods, devices, cartridges, and kits of the

35   invention include, without limitation, 17-beta-hydroxysteroid dehydrogenase type 1, Abl interactor 2, Actin-related protein 2/3 complex subunit 1A, Albumin, Aldolase A, Alkaline phosphatase, placental type, Alpha 1 antitrypsin, Alpha -1-acid glycoprotein 1, Alpha -2-HS-glycoprotein, Alpha lactalbumin,

Alpha-2-macroglobulin, Alpha-fetoprotein (AFP), Angiogenin ribonuclease RNase A family 5,
Angiopoietin 1, Angiopoietin 2, Antigen identified by monoclonal antibody Ki-67, Antileukoproteinase
1(SLPI), Apolipoprotein A1, ATP7B, β2-microglobulin, B-cell CLL/lymphoma 2, BCL2-associated X
protein, BRCA1, BRCA2, BrMS1, Butyrate -induced transcript 1, CA15.3/CA27-29, Cancer antigen 125,

5   Cancer antigen 15.3, Cancer antigen 19.9, Cancer antigen 602, Cancer antigen 72-4/TAG-72, Cancer
associated galactotransferase antigen, Cancer associated serum antigen (CASA), Carcinoembryonic
antigen (CEA), Catenin beta 1, Cathepsin D, Cathepsin member 8, CC chemokine 4 (HCC-4), CCL21
(small inducible cytokine A21), CCL5, CD15, CD24, CD34, CD44, Cell division protein kinase 5,
ceruloplasmin, Cervical cancer 1 protooncogene protein p40, c-Ets1, Chaparonin containing TCP1,

10   subunit 3, Chemokine (c-c motif) ligan 4 small inducible cytokine A4 (CCL4, MIP-1-beta), Chemokine
ligand 5, Chitinase-3 like protein 1 (YKL-40), Chloride intracellular channel 4 (CLIC4),
Choriogonadotropin beta chain, Claudin-3, Claudin-4, clusterin, Coagulation factor II (prothrombin),
Coagulation factor III, Coagulation factor XIII a chain, Coagulation factor XIII b chain, Collagen I c-
terminal peptide, Colony stimulating factor 2, Colony stimulating factor 3, Complement component 3, c-

15   reactive protein, Creatinine kinase brain (CKB), CTD small phosphatase-like, CyclinD1, Cyclin
dependent kinase 6 (CDK 6), Cyclin-dependent kinase inhibitor 1 (p21), Cyclooxygenase -1, Cytochrome
c oxidase Va, Cytochrome c-1, Desmin, Dystroglycan 1, Endoglin, Endothelin 1, Epidermal growth factor
receptor (EGFR), Epidermal growth factor (EGF), Erythropoietin, E-selectin, EST translocation variant 4
(EST 4), Extracellular matrix metalloproteinase inducer (EMMPRIN), Ferritin H, Ferritin L, Fibroblast

20   growth factor 2, fibronectin, Fit-3 ligand, Fluorodeoxyglucose-PET (FDG-PET) with CA125, Fms-related
tyrosine kinase 1 (VEGFR-1), GADD45A, Geminin, Glyphosate N-acetyltransferase, Granulin-epithelin
precursor (GEP), Growth differentiation factor 15, Haptoglobin 1, Haptoglobulin-a-subunit, HE4 (human
epidiymis protein), Her2, HER2-neu, hK10, hK11, hK13, hk6, hk7, hK8, HLA class II Doβ, hLMH1,
hLMH2, HNF-1β, Human chorionic gonadotropin-β subunit, Human chorionic gonadotrpin (hCG),

25   IGFBP-2, IL-2R alpha (soluble interleukin 2 receptor alpha), Immunoglobulins, Immunosuppressive
acidic protein (IAP), Indoleamine 2,3-dioxygenase, Insulin-like growth factor binding protein 1, Insulin-
like growth factor binding protein 2, Insulin-like growth factor binding protein 3, Integrin α-V, Integrin

Other analytes which can be detected using the devices, systems, and methods of the invention

30   include those mentioned in the Tietz Textbook of Clinical Chemistry and Molecular Diagnostics, Burtis, Ashwood, and Bruns, ISBN 0721601898, Elsevier, 4th edition (2006).

The methods, kits, cartridges, and systems of the invention can be configured to detect a predetermined combination panel of analytes that may be used to understand the medical condition of the subject. For example, a combination panel may include detection of pathogens, therapaeutic agents used

35   to treat the suspected pathogen/s, and a potential biomarker to monitor the therapeutic pharmacologic progress (efficacy or pharmacokinetic), or monitoring the presence of the pathogen or pathogen by-products. Further, one could envision a disease treatment panel configured for use to detect a disease or a

disease biomarker, the level or concentration of a therapeutic drug for use in treating the suspected disease, a potential biomarker to monitor the therapeutic pharmacologic progress (efficacy or pharmacokinetic), and general chemistry biomarker or other physiological marker of the disease or effect of treatment. In this way, panels of analyte detection can be used to inform and lead to appropriate

5   medical decision making.

For example, the systems and methods of the invention can be used to monitor immuno-compromised subjects following allogenic transplantation. In transplant subjects that receive solid organ, bone marrow, hematopoietic stem cell, or other allogeneic donations, there is a need to monitor the immune status, organ function, and if necessary, rapidly and accurately identify opportunistic infections.

10   Tacrolimus (also FK-506, Prograf, or Fujimycin) is an immunosuppressive drug whose main use is after allogeneic organ transplant to reduce the activity of the subject's immune system and so lower the risk of organ rejection. It reduces interleukin-2 (IL-2) production by T-cells. It is also used in a topical preparation in the treatment of severe atopic dermatitis (eczema), severe refractory uveitis after bone marrow transplants, and the skin condition vitiligo. It is a 23-membered macrolide lactone discovered in

15   1984 from the fermentation broth of a Japanese soil sample that contained the bacteria Streptomyces tsukubaensis. It has similar immunosuppressive properties to cyclosporin, but is much more potent in equal volumes. Immunosuppression with tacrolimus was associated with a significantly lower rate of acute rejection compared with cyclosporin-based immunosuppression (30.7% vs. 46.4%) in one study. Long term outcome has not been improved to the same extent. Tacrolimus is normally prescribed as part

20   of a post-transplant cocktail including steroids, mycophenolate and IL-2 receptor inhibitors. Dosages are titrated to target blood levels. Side effects can be severe and include infection, cardiac damage, hypertension, blurred vision, liver and kidney problems, seizures, tremors, hyperkalemia, hypomagnesaemia, hyperglycemia, diabetes mellitus, itching, insomnia, and neurological problems such as confusion, loss of appetite, weakness, depression, cramps, and neuropathy. In addition tacrolimus may

25   potentially increase the severity of existing fungal or infectious conditions such as herpes zoster or polyoma viral infections, and certain antibiotics cross-react with tacrolimus.

Measuring serum creatinine is a simple test and it is the most commonly used indicator of renal function. A rise in blood creatinine levels is observed only with marked damage to functioning nephrons. Therefore, this test is not suitable for detecting early stage kidney disease. A better estimation of kidney

30   function is given by the creatinine clearance test. Creatinine clearance can be accurately calculated using serum creatinine concentration and some or all of the following variables: sex, age, weight, and race as suggested by the American Diabetes Association without a 24 hour urine collection. Some laboratories will calculate the creatinine clearance if written on the pathology request form; and, the necessary age, sex, and weight are included in the subject information.

35   There is a need to monitor creatinine and tacrolimus levels from the same blood sample from a subject as the monitoring of the drug concentration and the renal function can assist and guide the physician to optimal therapy post-transplantation. Optimizing therapy is a tight balance of preventing

rejection but also to ensure immune function to fight opportunistic infections and overall results in enhanced subject compliance to the immunosuppressive therapy. In large part, transplant recipients succumb to transplant rejection, graft versus host disease, or opportunistic infections. In the first two, immunosuppressive agents can ablate or inhibit the reactions. However, if the subject has an underlying

5 infection, then clinical management is challenging. For a specific example, a heart, lung transplant subject presenting with fever of unknown origin enters a health care facility. The subject is started on broad spectrum antibiotics until the culture results are known. If the condition worsens, and the culture reveals a specific infection, for example candida, a specific antifungal, fluconazole, can be administered to the known subject. However, this antifungal may alter the levels of the immunosuppressive agent

10 given to almost all allogenic transplant recipients, tacrolimus. Upon testing for both tacrolimus and creatinine levels, the physician halts the tacrolimus, believing that the fluconazole will defeat the infection, and in a rapid manner. Under this regimen, the subject may worsen if the candida species is resistant to fluconazole, and the subject is then started on an appropriate anti-fungal agent. However, since the tacrolimus may be halted, the immunosuppressive therapy is unmanaged and the subject may

15 become unresponsive to any additional therapy and death may ensue. Thus, if there was a test to simultaneously monitor creatinine (kidney function), tacrolimus blood levels, and accurate identification of opportunistic infections, the above subject may have been saved.

The systems and methods of the invention can include a multiplexed, no sample preparation, single detection method, automated system to determine the drug level, the toxicity or adverse effect

20 determinant, and the pathogen identification having a critical role in the immunocompromised subject setting. For example, a cartridge having portals or wells containing 1) magnetic particles having creatinine specific antibodies decorated on their surface, 2) magnetic particles having tacrolimus specific antibodies on their surface, and 3) magnetic particles having specific nucleic acid probes to identify pathogen species could be employed to rapidly determine and provide clinical management values for a

25 given transplant subject. Opportunistic infections that can be monitored in such subjects, and any other patient populations at risk of infection, include, without limitation, fungal; candida (resistant and non-resistant strains); gram negative bacterial infections (e.g., E. coli, stenotrophomonas maltophilia, Klebsiella pneumonia/oxytoca, or Pseudomonas aeruginosa); and gram positive bacterial infections (e.g., Staphylococcus species: S. aureus, S. pneumonia, E. faecalis, and E. faecium). Other opportunistic

30 infections that can be monitored include coaglulase negative staphylococcus, Corynebacterium spp., Fusobacterium spp., and Morganella morganii, and viral organisms, such as CMV, BKV, EBC, HHV-6, HIV, HCV, HBV, and HAV.

The systems and methods of the invention can also be used to monitor and diagnose cancer patients as part of a multiplexed diagnostic test. One specific form of cancer, colorectal cancer, has

35 demonstrated positive promise for personalized medical treatment for a specific solid tumor. Pharmacogenetic markers can be used to optimize treatment of colorectal and other cancers. Significant individual genetic variation exists in drug metabolism of 5FU, capecitabine, irinotecan, and oxaliplatin

that influences both the toxicity and efficacy of these agents. Examples of genetic markers include UGT1A1*28 leads to reduced conjugation of SN-38, the active metabolite of irinotecan, resulting in an increased rate of adverse effects, especially neutropenia. To a lesser extent, increased 5-FU toxicity is predicted by DPYD*2A. A variable number of tandem repeats polymorphism in the thymidylate

5   synthase enhancer region, in combination with a single nucleotide polymorphism C>G, may predict poorer response to 5-FU. Efficacy of oxaliplatin is influenced by polymorphisms in components of DNA repair systems, such as ERCC1 and XRCC1. Polymorphic changes in the endothelial growth factor receptor probably predict cetuximab efficacy. Furthermore, the antibody-depended cell-mediated cytotoxic effect of cetuximab may be reduced by polymorphisms in the immunoglobin G fragment C

10   receptors. Polymorphic changes in the VEGF gene and the hypoxia inducible factor 1alpha gene are also believed to play a role in the variability of therapy outcome. Thus, identification of such polymorphisms in subjects can be used to assist physicians with treatment decisions. For example, PCR-based genetics tests have been developed to assist physicians with therapeutic treatment decisions for subjects with non-small cell lung cancer (NSCLC), colorectal cancer (CRC) and gastric cancer. Expression of ERCC1, TS,

15   EGFR, RRM1, VEGFR2, HER2, and detection of mutations in KRAS, EGFR, and BRAF are available for physicians to order to identify the optimal therapeutic option. However, these PCR tests are not available on site, and thus the sample must be delivered to the off-site laboratory. These solid tumors are often biopsied and FFPE (Formalin-Fixed, Paraffin-Embedded (tissue)) samples are prepared. The systems and methods of the invention can be used without the 5-7 day turnaround to get the data and

20   information and use of fixed samples required for existing methods. The systems and methods of the invention can provide a single platform to analyze samples, without sample prep, for multiple analyte types, as in cancer for chemotherapeutic drugs, genpotyping, toxicity and efficacy markers can revolutionize the practice of personalized medicine and provide rapid, accurate diagnostic testing.

The systems and methods of the invention can also be used to monitor and diagnose neurological

25   disease, such as dementia (a loss of cognitive ability in a previously-unimpaired person) and other forms of cognitive impairment. Without careful assessment of history, the short-term syndrome of delirium (often lasting days to weeks) can easily be confused with dementia, because they have all symptoms in common, save duration, and the fact that delirium is often associated with over-activity of the sympathetic nervous system. Some mental illnesses, including depression and psychosis, may also produce symptoms

30   that must be differentiated from both delirium and dementia. Routine blood tests are also usually performed to rule out treatable causes. These tests include vitamin B12, folic acid, thyroid-stimulating hormone (TSH), C-reactive protein, full blood count, electrolytes, calcium, renal function, and liver enzymes. Abnormalities may suggest vitamin deficiency, infection or other problems that commonly cause confusion or disorientation in the elderly. The problem is complicated by the fact that these cause

35   confusion more often in persons who have early dementia, so that "reversal" of such problems may ultimately only be temporary. Testing for alcohol and other known dementia-inducing drugs may be indicated. Acetylcholinesterase inhibitors-Tacrine (Cognex), donepezil (Aricept), galantamine

(Razadyne), and rivastigmine (Exelon) are approved by the United States Food and Drug Administration (FDA) for treatment of dementia induced by Alzheimer disease. They may be useful for other similar diseases causing dementia such as Parkinsons or vascular dementia. N-methyl-D-aspartate blockers include memantine (Namenda), which is a drug representative of this class. It can be used in combination with acetylcholinesterase inhibitors. Amyloid deposit inhibitors include minocycline and clioquinoline, which are antibiotics that may help reduce amyloid deposits in the brains of persons with Alzheimer disease. Depression is frequently associated with dementia and generally worsens the degree of cognitive and behavioral impairment. Antidepressants effectively treat the cognitive and behavioral symptoms of depression in subjects with Alzheimer's disease, but evidence for their use in other forms of dementia is weak. Many subjects with dementia experience anxiety symptoms. Although benzodiazepines like diazepam (Valium) have been used for treating anxiety in other situations, they are often avoided because they may increase agitation in persons with dementia and are likely to worsen cognitive problems or are too sedating. Buspirone (Buspar) is often initially tried for mild-to-moderate anxiety. There is little evidence for the effectiveness of benzodiazepines in dementia, whereas there is evidence for the effectiveness of antipsychotics (at low doses). Selegiline, a drug used primarily in the treatment of Parkinson's disease, appears to slow the development of dementia. Selegiline is thought to act as an antioxidant, preventing free radical damage. However, it also acts as a stimulant, making it difficult to determine whether the delay in onset of dementia symptoms is due to protection from free radicals or to the general elevation of brain activity from the stimulant effect. Both typical antipsychotics (such as haloperidol) and atypical antipsychotics such as (risperidone) increases the risk of death in dementia-associated psychosis. This means that any use of antipsychotic medication for dementia-associated psychosis is off-label and should only be considered after discussing the risks and benefits of treatment with these drugs, and after other treatment modalities have failed. In the UK around 144,000 dementia sufferers are unnecessarily prescribed antipsychotic drugs, around 2000 subjects die as a result of taking the drugs each year. Dementia can be broadly categorized into two groups: cortical dementias and subcortical dementias. Cortical dementias include: Alzheimer's disease, vascular dementia (also known as multi-infarct dementia), including Binswanger's disease, dementia with Lewy bodies (DLB), alcohol-induced persisting dementia, Korsakoff's syndrome, Wernicke's encephalopathy, frontotemporal lobar degenerations (FTLD), including Pick's disease, frontotemporal dementia (or frontal variant FTLD), semantic dementia (or temporal variant FTLD), progressive non-fluent aphasia, Creutzfeldt-Jakob disease, dementia pugilistica, Moyamoya disease, thebestia (often mistaken for a cancer), posterior cortical atrophy or Benson's syndrome. Subcortical dementias include dementia due to Huntington's disease, dementia due to hypothyroidism, dementia due to Parkinson's disease, dementia due to vitamin B1 deficiency, dementia due to vitamin B12 deficiency, dementia due to folate deficiency, dementia due to syphilis, dementia due to subdural hematoma, dementia due to hypercalcaemia, dementia due to hypoglycemia, AIDS dementia complex, pseudodementia (a major depressive episode with prominent cognitive symptoms), aubstance-induced persisting dementia (related to psychoactive use and formerly

absinthism), dementia due to multiple etiologies, fementia due to other general medical conditions (i.e., end stage renal failure, cardiovascular disease etc.), or dementia not otherwise specified (used in cases where no specific criteria is met). Alzheimer's disease is a common form of dementia. There are three companies that a currently offer for research only diagnostic testing of proteins (Satoris), splice variants

5   (Exonhit), or protein expression levels (Diagenic) in subjects suffering from dementia, Lewy Body disease, or mild cognitive impairment. Since dementia is fundamentally associated with many neurodegenerative diseases, the ability to test for these proteins, as biomarkers of the disease, along with drug or drug metabolite levels in a single platform will assist a physician to adjust the dosage, alter a regimen, or generally monitor the progression of the disease. These tests are currently run off-site at

10   locations far from the subject and care giver. Thus, to have the ability to monitor the drug levels and the biomarker in the same detection system, on-site will provide a huge advantage to this debilitating and devastating disease. The method of the invention can be a multiplexed, no sample preparation, single detection method, automated system to determine the drug level, the toxicity or adverse effect determinant, and the potential biomarker of the progression of the disease. For example, a cartridge

15   having portals or wells containing 1) magnetic particles having protein biomarker specific antibodies decorated on their surface, 2) magnetic particles having specific antibodies on their surface, and 3) magnetic particles having nucleic acid specific probes to identify protein expression levels could be employed to rapidly determine and provide clinical management values for a given dementia subject.

The systems and methods of the invention can also be used to monitor and diagnose infectious

20   disease in a multiplexed, automated, no sample preparation system. Examples of pathogens that may be detected using the devices, systems, and methods of the invention include, e.g., Candida (resistant and non-resistant strains), e.g., C. albicans, C. glabrata, C. krusei, C. tropicalis, and C. parapsilosis; A. fumigatus; E. coli, Stenotrophomonas maltophilia, Klebsiella pneumonia/oxytoca, P. aeruginosa; Staphylococcus spp. (e.g., S. aureus or S. pneumonia); E. faecalis, E. faecium, Coaglulase negative

25   staphylococcus spp., Corynebacterium spp., Fusobacterium spp., Morganella morganii, Pneumocystis jirovecii, previously known as pneumocystis carinii, F. hominis, streptococcus pyogenes, Pseudomonas aeruginosa, Polyomavirus JC polyomavirus (the virus that causes progressive multifocal leukoencephalopathy), Acinetobacter baumanni, Toxoplasma gondii, Cytomegalovirus, Aspergillus spp., Kaposi's Sarcoma, cryptosporidium, Cryptococcus neoformans, and Histoplasma capsulatum, among

30   other bacteria, yeast, fungal, virus, prion, mold, actinomycetes, protozoal, parasitic, protist and helminthic infectious organisms.

The systems and methods of the invention can be used to identify and monitor the pathogenesis of disease in a subject, to select therapeutic interventions, and to monitor the effectiveness of the selected treatment. For example, for a patient having or at risk of a viral infection, the systems and methods of the

35   invention can be used to identify the infectious virus, viral load, and to monitor white cell count and/or biomarkers indicative of the status of the infection. The identity of the virus can be used to select an appropriate therapy. The therapeutic intervention (e.g., a particular antiviral agent) can be monitored as

well to correlate the treatment regiman to the circulating concentration of antiviral agent and viral load to ensure that the patient is responding to treatment.

The systems and methods of the invention can be used to monitor a viral infection in a subject, e.g., with a viral panel configured to detect Cytomegalovirus (CMV), Epstein Barr Virus, BK Virus,

5 Hepatitis B virus, Hepatitis C virus, Herpes simplex virus (HSV), HSV1, HSV2, Respiratory syncytial virus (RSV), Influenza; Influenza A, Influenza A subtype H1, Influenza A subtype H3, Influenza B, Human Herpes Virus 6, Human Herpes Virus 8, Human Metapneumovirus (hMPV), Rhinovirus, Parainfluenza 1, Parainfluenza 2, Parainfluenza 3, and Adenovirus. The methods of the invention can be used to monitor a suitable therapy for the subject with a viral infection (e.g., Abacavir, Aciclovir,

10 Acyclovir, Adefovir, Amantadine, Amprenavir, Ampligen, Arbidol, Atazanavir, Atripla, Boceprevir, Cidofovir, Combivir, Darunavir, Delavirdine, Didanosine, Docosanol, Edoxudine, Efavirenz, Emtricitabine, Enfuvirtide, Entecavir, Famciclovir, Fomivirsen, Fosamprenavir, Foscarnet, Fosfonet, Ganciclovir, Ibacitabine, Imunovir, Idoxuridine, Imiquimod, Indinavir, Inosine, Integrase inhibitor, Interferon type III, Interferon type II, Interferon type I, Interferon α, Interferon β, Lamivudine, Lopinavir,

15 Loviride, Maraviroc, Moroxydine, Methisazone, Nelfinavir, Nevirapine, Nexavir, Nucleoside analogues, Oseltamivir (Tamiflu), Peginterferon alfa-2a, Penciclovir, Peramivir, Pleconaril, Podophyllotoxin, Raltegravir, Reverse transcriptase inhibitor, Ribavirin, Rimantadine, Ritonavir, Pyramidine, Saquinavir, Stavudine, Tea tree oil, Tenofovir, Tenofovir disoproxil, Tipranavir, Trifluridine, Trizivir, Tromantadine, Truvada, Valaciclovir (Valtrex), Valganciclovir, Vicriviroc, Vidarabine, Viramidine, Zalcitabine,

20 Zanamivir (Relenza), or Zidovudine), and to monitor the circulating concentration of the therapeutic administered to the subject.

The systems and methods of the invention can also be used to monitor HIV/AIDS patients. When clinicians suspect acute infection (e.g., in a subject with a report of recent risk behavior in association with symptoms and signs of the acute retroviral syndrome), a test for HIV RNA is usually performed.

25 High levels of HIV RNA detected in plasma through use of sensitive amplification assays (PCR, bDNA, or NASBA), in combination with a negative or indeterminate HIV antibody test, support the diagnosis of acute HIV infection. Low-level positive PCR results (<5000 copies/mL) are often not diagnostic of acute HIV infection and should be repeated to exclude a false-positive result. HIV RNA levels tend to be very high in acute infection; however, a low value may represent any point on the upward or downward slope

30 of the viremia associated with acute infection. Plasma HIV RNA levels during seroconversion do not appear significantly different in subjects who have acute symptoms versus those who are asymptomatic. Viremia occurs approximately 2 weeks prior to the detection of a specific immune response. Subjects diagnosed with acute HIV infection by HIV RNA. Fever and flu- or mono-like symptoms are common in acute HIV infection but are nonspecific rash, mucocutaneous ulcers, or pharyngeal candidiasis and

35 meningismus are more specific and should raise the index of suspicion testing still require antibody testing with confirmatory Western blot 3 to 6 weeks later.

Subjects undergoing HIV testing who are not suspected to be in the acute stages of infection should receive HIV antibody testing according to standard protocol. Antibody test results that are initially negative should be followed up with HIV antibody testing at 3 months to identify HIV infection in individuals who may not yet have seroconverted at the time of initial presentation. Plasma HIV RNA

5   levels indicate the magnitude of HIV replication and its associated rate of CD4+ T cell destruction, while CD4+ T-cell counts indicate the extent of HIV-induced immune damage already suffered. Regular, periodic measurement of plasma HIV RNA levels and CD4+ T-cell counts is necessary to determine the risk of disease progression in an HIV-infected individual and to determine when to initiate or modify antiretroviral treatment regimens.

10   As rates of disease progression differ among individuals, treatment decisions should be individualized by level of risk indicated by plasma HIV RNA levels and CD4+ T-cell counts. Current WHO guidelines and recommendations for HIV therapy includes a combination of the following drugs, AZT (zidovudine), 3TC (lamivudine), ABC (abacavir), ATV (atazanavir), d4T (stavudine), ddI (didanosine), NVP (nevirapine), EFV (efavirenz), FTC (emtricitabine), LPV (lopinavir), RTV (ritonavir),

15   TDF (tenofovir disoproxil fumarate) in established regimens. Drug therapy for HIV is to commence in subjects who have a CD4 count < 350 cell/mm3 irrespective of clinical symptoms. At least one of the four following regimens for antiretroviral naïve subjects is begun: 1) AZT + 3TC + EFV, 2) AZT + 3TC + NVP, 3) TDF + 3TC or FTC +EFV, or 4) TDF + 3TC or FTC + NVP. These regimens avoid d4T (stavudine) to limit the disfiguring, unpleasant, and potentially life-threatening toxicities of this drug.

20   Treatment failure is usually determined by viral load, a persistent value of 5,000 copies/ml confirms treatment failure. In cases whereby viral load measurement is not available, immunological criteria (CD4 cell count) can be used to determine therapeutic progress. In cases of treatment failure, a boosted protease inhibitor plus two nucleoside analogs are added to the regimen and is considered second line antiretroviral therapy. ATV plus low dose RTV, or LPV with low dose RTV is also considered second

25   line therapy. Often the goal in treatment failure cases is simpler timed regimens and fixed doses.

For subjects failing the second line treatment regimens should be maintained on a tolerated regimen for the duration. The use of potent combination antiretroviral therapy to suppress HIV replication to below the levels of detection of sensitive plasma HIV RNA assays limits the potential for selection of antiretroviral-resistant HIV variants, the major factor limiting the ability of antiretroviral

30   drugs to inhibit virus replication and delay disease progression. Therefore, maximum achievable suppression of HIV replication should be the goal of therapy. The most effective means to accomplish durable suppression of HIV replication is the simultaneous initiation of combinations of effective anti-HIV drugs with which the subject has not been previously treated and that are not cross-resistant with antiretroviral agents with which the subject has been treated previously. Each of the antiretroviral drugs

35   used in combination therapy regimens should always be used according to optimum schedules and dosages. The available effective antiretroviral drugs are limited in number and mechanism of action, and

cross-resistance between specific drugs has been documented. Therefore, any change in antiretroviral therapy increases future therapeutic constraints.

Monitoring HIV/AIDS subjects for viral load, drug levels, CD4 cell counts, and toxicity patterns in a single platform diagnostic method would provide distinct advantages to a subject. The systems and methods of the invention can be used in a multiplexed, no sample preparation, single detection method, automated system to determine the drug level, the toxicity or adverse effect determinants, and the potential biomarker of the progression of the disease. For example, a cartridge having portals or wells containing 1) magnetic particles having CD4 cell specific antibodies decorated on their surface, 2) magnetic particles having toxicity biomarker specific antibodies on their surface, and 3) magnetic particles having nucleic acid specific probes to identify viral load levels could be employed to rapidly determine and provide clinical management values for a given HIV/AIDS subject.

The systems and methods of the invention can also be used to monitor and diagnose immune disease in a subject (e.g., Crohn's disease, ileitis, enteritis, inflammatory bowel disease, irritable bowel syndrome, ulcerative colitis, as well as non-gastrointestinal immune disease). The relatively recent development of genetically engineered agents has the potential to alter the treatment of immune disease radically, and Remicade (also known as Infliximab, an anti-TNF antibody) was introduced as a new therapeutic class with high efficacy, rapid onset of action, prolonged effect, and improved tolerance. However these agents are expensive and at least one-third of the eligible patients fail to show any useful response. Finding a means to predict those who will respond, and to anticipate relapse is, therefore, of obvious importance. T helper-type 1 (Th1) lymphocytes orchestrate much of the inflammation in Crohn's disease mainly via production of TNF-alpha, which appears to play a pivotal role as a pro-inflammatory cytokine. It exerts its effects through its own family of receptors (TNFR1 and TNFR2), the end results of which include apoptosis, c-Jun N-terminal kinase/stress-activated protein kinase (JNK/SAPK) activation and NF-kappaB activation. Activated NF-kappaB enters the nucleus and induces transcription of genes associated with inflammation, host defense and cell survival. The promoter region of the TNF gene lies between nucleotides -1 and -1300, and encompasses numerous polymorphic sites associated with potential binding sites for various transcription factors. Carriers of the TNF allele 2 (TNF2) (which contains a single base-pair polymorphism at the -308 promoter position) produce slightly more TNF-alpha in their intestinal mucosa than non-TNF2 carriers. TNF polymorphisms also appear to influence the nature and frequency of extra-intestinal manifestations of inflammatory bowel disease (IBD). A number of routes of inhibition of TNF are being investigated. Most extensively evaluated is the use of remicade. Several large controlled trials indicate that remicade has a role in treating patients with moderate to severely active Crohn's disease and in fistulating Crohn's disease. Small studies have shown possible associations between poor response to remicade and increasing mucosal levels of activated NF-kappaB, homozygosity for the polymorphism in exon 6 of TNFR2 (genotype Arg196Arg), positivity for perinuclear antineutrophil cytoplasmic antibodies (ANCA), and with the presence of increased numbers of activated lamina propia mononuclear cells producing interferon-gamma and TNF-alpha. Thus,

monitoring Crohn's disease patients for TNF-alpha and toxicity patterns in a single platform diagnostic method would have distinct advantages. The method of the invention can be a multiplexed, no sample preparation, single detection method, automated system to determine the drug level, the toxicity or adverse effect determinants, and the potential biomarker of the progression of the disease. For example, a

5   cartridge having portals or wells containing 1) magnetic particles having anti-TNF-alpha specific antibodies decorated on their surface, 2) magnetic particles having toxicity biomarker specific antibodies on their surface, and 3) magnetic particles having specific probes to identify disease markers of progression could be employed to rapidly determine and provide clinical management values for a given Crohn's disease patient.

10   The systems and methods of the invention can also be used to monitor and diagnose infectious disease and inflammation in a multiplexed, automated, no sample preparation system. Such systems and methods could be used to monitor, for example, bacteremia, sepsis, and/or Systemic Inflammatory Response Syndrome (SIRS). Early diagnosis is clinically important as this type of infection, if left untreated, can lead to organ dysfunction, hypoperfusion, hypotension, refractory (septic) shock/SIRS

15   shock, and/or Multiple Organ Dysfunction Syndrome (MODS). For a typical patient, many bacterial or fungal infections are the result of incubation at the time of admission to a healthcare setting and are termed healthcare-associated infections (HAI), also known as nosocomial, hospital-acquired or hospital-onset infections. Healthcare-associated infections are most commonly caused by viral, bacterial, and fungal pathogens and are commonly transmitted via wounds, invasive devices (catheters, tracheostomy,

20   intubation, surgical drains) or ventilators and are found as urinary tract infections, surgical site infections, or a form of pneumonia. Within hours after admission, a patient's flora begins to acquire characteristics of the surrounding bacterial pool. Most infections that become clinically evident after 48 hours of hospitalization are considered hospital-acquired and the pathogens should be investigated in all febrile patients who are admitted for a nonfebrile illness or those who develop clinical deterioration unexplained

25   by the initial diagnosis. More careful and selective use of antimicrobial agents, such as antibiotics, is also desirable to decrease the selection pressure for the emergence of resistant strains. Infections that occur after the patient is discharged from the hospital can be considered healthcare-associated if the organisms were acquired during the hospital stay. Patient-related risk factors for invasion of colonizing pathogen include severity of illness, underlying immunocompromised state and/or the length of in-patient stay.

30   Risk factors for the development of catheter-associated bloodstream infections in neonates include catheter hub colonization, exit site colonization, catheter insertion after the first week of life, duration of parenteral nutrition, and extremely low birth weight (<1000 g) at the time of catheter insertion. In patients in the PICU risks, for catheter-associated bloodstream infections increase with neutropenia, prolonged catheter dwell time (>7 days), use of percutaneously placed CVL (higher than tunneled or

35   implanted devices), and frequent manipulation of lines. Candida infections are increasingly important pathogens in the NICU. Risk factors for the development of candidemia in neonates include gestational age less than 32 weeks, 5-min Apgar scores of less than 5, shock, disseminated intravascular

coagulopathy, prior use of intralipids, parenteral nutrition administration, CVL use, H2 blocker administration, intubation, or length of stay longer than 7 days. Risk factors for the development of ventilator-associated pneumonia (VAP) in pediatric patients include reintubation, genetic syndromes, immunodeficiency, and immunosuppression. In neonates, a prior episode of bloodstream infection is a

5   risk factor for the development of VAP. Risk factors for the development of healthcare-associated urinary tract infection in pediatric patients include bladder catheterization, prior antibiotic therapy, and cerebral palsy. Among the categories of bacteria most known to infect immunocompromised patients are MRSA (Methicillin resistant Staphylococcus aureus), gram-positive bacteria and Helicobacter, which is gram-negative. While there are antibiotic drugs that can treat diseases caused by Gram-positive MRSA,

10   there are currently few effective drugs for Acinetobacter. Common pathogens in bloodstream infections are coagulase-negative staphylococci, Enterococcus, and Staphylococcus aureus. In addition, Candida albicans and pathogens for pneumonia such as Pseudomonas aeruginosa, Staphylococcus aureus, Klebsiella pneumoniae, and Haemophilus influenza account for many infections. Pathogens for urinary tract infections include Escherichia coli, Candida albicans, and Pseudomonnas aeruginosa. Gram-

15   negative enteric organisms are additionally common in urinary tract infections. Surgical site infections include Staphylococcus aureus, Pseudomonas aeruginosa, and coagulase-negative staphylococci. The infectious agent can be selected from, without limitation, pathogens associated with sepsis, such as Acinetobacter baumannii, Aspergillus fumigatis, Bacteroides fragilis, B. fragilis, blaSHV, Burkholderia cepacia, Campylobacter jejuni/coli, Candida guilliermondii, C. albicans, C. glabrata, C. krusei, C.

20   Lusitaniae, C. parapsilosis, C. tropicalis, Clostridium pefringens, Coagulase negative Staph, Enterobacter aeraogenes, E. cloacae, Enterobacteriaceae, Enterococcus faecalis, E. faecium, Escherichia coli, Haemophilus influenzae, Kingella Kingae, Klebsiella oxytoca, K. pneumoniae, Listeria monocytogenes, Mec A gene (MRSA), Morganella morgana, Neisseria meningitidis, Neisseria spp. non-meningitidis, Prevotella buccae, P. intermedia, P. melaninogenica, Propionibacterium acnes, Proteus mirabilis, P.

25   vulgaris, Pseudomonas aeruginosa, Salmonella enterica, Serratia marcescens, Staphylococcus aureus, S. haemolyticus, S. maltophilia, S. saprophyticus, Stenotrophomonas maltophilia, S. maltophilia, Streptococcus agalactie, S. bovis, S. dysgalactie, S. mitis, S. mutans, S. pneumoniae, S. pyogenes, and S. sanguinis; or any other infectious agent described herein. In certain instances, the method and system will be designed to ascertain whether the infectious agent bears a Van A gene or Van B gene

30   characteristic of vancomycin resistance; mecA for methicillin resistance, NDM-1 and ESBLfor more general resistance to beta-lactams.

Sepsis or septic shock are serious medical conditions that are characterized by a whole-body inflammatory state (systemic inflammatory response syndrome or SIRS) and the presence of a known or suspected infection. Sepsis is defined as SIRS in the presence of an infection, septic shock is defined as

35   sepsis with refractory arterial hypotension or hypoperfusion abnormalities in spite of adequate fluid resuscitation, and severe sepsis is defined as sepsis with organ dysfunction, hypoperfusion, or hypotension. In addition to symptoms related to the provoking infection, sepsis is characterized by

presence of acute inflammation present throughout the entire body, and is, therefore, frequently associated with fever and leukocytosis or low white blood cell count and lower-than-average temperature, and vomiting. It is currently believed that sepsis is the host's immune response to an infection and it is thought that this response causes most of the symptoms of sepsis, resulting in hemodynamic

5   consequences and damage to organs. SIRS is characterized by hemodynamic compromise and resultant metabolic derangement. Outward physical symptoms of this response frequently include a high heart rate (above 90 beats per minute), high respiratory rate (above 20 breaths per minute), elevated WBC count (above 12,000) and elevated or lowered body temperature (under 36 °C (97 °F) or over 38 °C (100 °F)). Sepsis is differentiated from SIRS by the presence of a known pathogen. For example, SIRS and a

10   positive blood culture for a pathogen indicates the presence of sepsis. Without a known infection, it's not possible to classify the above symptoms as sepsis, only SIRS. SIRS causes widespread activation of acute-phase proteins, affecting the complement system and the coagulation pathways, which then cause damage to the vasculature as well as to the organs. Various neuroendocrine counter-regulatory systems are then activated as well, often compounding the problem. Even with immediate and aggressive

15   treatment, this may progress to multiple organ dysfunction syndrome and eventually death. The laboratory component of sepsis diagnosis can include several markers are considered at once and/or measured serially. A number of studies have examined the value of combining currently available markers like GRO-alpha, High mobility group-box 1 protein (HMBG-1), IL-1 receptor, IL-1 receptor antagonist, IL-1b, IL-2, IL-4, IL-6, IL-8, IL-10, IL-12, IL-13, IL-18, macrophage inflammatory protein

20   (MIP-1), macrophage migration inhibitory factor (MIF), osteopontin, RANTES (regulated on activation, normal T-cell expressed and secreted; or CCL5), TNF-α, C-reactive protein (CRP), CD64, and monocyte chemotactic protein 1 (MCP-1). Additionally, the systems and methods can be designed to monitor certain proteins characteristic of sepsis, such as adenosine deaminase binding protein (ABP-26), inducible nitric oxide synthetase (iNOS), lipopolysaccharide binding protein (LBP), and procalcitonin (PCT).

25   Sepsis is usually treated in the intensive care unit with intravenous fluids and antibiotics. If fluid replacement is insufficient to maintain blood pressure, specific vasopressor medications can be used. Mechanical ventilation and dialysis may be needed to support the function of the lungs and kidneys, respectively. To guide therapy, a central venous catheter and an arterial catheter may be placed. Sepsis patients may require preventive measures for deep vein thrombosis, stress ulcers and pressure ulcers, and

30   some patients may benefit from tight control of blood sugar levels with insulin (targeting stress hyperglycemia), low-dose corticosteroids, or activated drotrecogin alfa (recombinant protein C). For an immunocompromised patient, or a patient with a suspected infection that may be experiencing sepsis or SIRS, such methods and systems of the invention provide a diagnostic platform for the rapid identification of one or more pathogens, and whether or not the pathogens are resistant to certain therapies

35   (for the selection of an appropriate antimicrobial therapy). The platform as described allows for the simultaneous determination of the levels of the factors (e.g., GRO-alpha, High mobility group-box 1 protein (HMBG-1), IL-1 receptor, IL-1 receptor antagonist, IL-1b, IL-2, IL-4, IL-6, IL-8, IL-10, IL-12,

IL-13, IL-18, macrophage inflammatory protein (MIP-1), macrophage migration inhibitory factor (MIF), osteopontin, RANTES (regulated on activation, normal T-cell expressed and secreted; or CCL5), TNF-α, C-reactive protein (CRP), CD64, and monocyte chemotactic protein 1 (MCP-1)) and/or proteins (e.g., adenosine deaminase binding protein (ABP-26), inducible nitric oxide synthetase (iNOS),

5   lipopolysaccharide binding protein (LBP), and procalcitonin (PCT)) thought to be involved in SIRS, allowing for the optimization for the treatment of sepsis and SIRS. Thus, this platform reduces the empirical protocols and/or use of non-specific/general antimicrobials that may or may not be targeting the specific pathogen and/or the underlying system dysfunction for a given patient. This platform allows for rapid and accurate diagnoses, which can point to effective therapy, providing a key component to a

10   physician's decision making and reducing morbidity and mortality.

        To determine whether a patient has sepsis, it is necessary to identify the presence of a pathogen. To most effectively treat a patient, the earliest initiation of appropriate therapy is critical. Antimicrobial and other treatments for sepsis rely on the classification of pathogens at multiple levels, including the identification of an agent as 1) bacterial, viral, fungal, parasitic or otherwise; 2) gram positive, gram

15   negative, yeast, or mold, 3) species, and 4) susceptibility.

        Each of these levels of specificity improves the time to initiation of appropriate therapy, and each step further down the track will lead to a narrowing of therapeutic agents to the most specific set. Without absolute susceptibility data, empiric approaches to care rely on the information available about the pathogen (at whichever level) and the pattern of pathogen frequency and susceptibility trends in the

20   hospital of another site of care. Thus, certain categories of pathogens are frequently presumed to be causative until there are more data to refine the pairing of pathogen and therapy. Specifically, these targets fall into the ESKAPE category (which is a series of resistant pathogens) and the SPACE category, which is a set of high virulence pathogens that require isolation of patients.

        In addition to identifying these pathogens in multiple sample types (blood, tissue, urine, etc.),

25   another method to distinguish symptomatic patients, for instance, patients with systemic inflammatory syndrome, or SIRS, from septic patients, is to use biomarkers that correlate either individually or via an index, to identify patients with infection. In cases where infections are not detected due to antimicrobial therapy interference with diagnostics, immune system control of the therapy, or otherwise, these biomarkers, which can be multiple types of analytes (cytokines, metabolites, DNA, RNA/gene

30   expression, etc.) will indicate infection and thus sepsis.

        To generate the diagnostic information required for both the presence of an infection and some level of species identification, one panel could be: (i) gram positiive clusters (e.g., S. aureus, and CoNS (coagulase negative staph)); (ii) gram positive chains/pairs (e.g., Strep spp., mitis, pneumonia spp., agalactiae spp., pyogenes spp., Enterococcus spp.(E. faecium, E. fecalis); (iii) gram negative rods (e.g., E.

35   coli, Proteus spp., Klebsiella spp., Serratia spp., Acinetobacter spp., Stenotrophomonas spp.); (iv) SPACE (e.g., Serratia spp., Pseudomonas spp., Acinetobacter spp., Citrobacter spp., Enterobacter spp.); (v) Pseudomonas (e.g., Pseudomonas spp.); (vi) ESKAPE (E. faecium, Staphylococcus aureas, Klebsiella

spp., Acinetobacter spp., Pseudomonas spp., Enterobacter spp.); and (vii) Pan-Bacterial (all bacterial species).

This panel should be used in conjunction with a fungal assay for full coverage. The categories represent the information required for an effective intervention with appropriate therapy, given that each

5   site of care will have an empirically derived approach based on a positive response to gram +, gram -, etc. The species identified in each category represent those that would fit under each heading, but are not comprehensive. Further, a pan-bacterial marker is included to cover any species that is not covered by the diagnostic method employed for each category. Further, the combination of results will also give an indication of the species, although not fully, if included as described above. Cross-referencing positives

10 and negatives by category allow a process of elimination approach to identify some of the species, probabilistically.

In addition to pathogen panels, a standalone or companion test could be performed for biomarkers that can indicate sepsis. Examples of these markers are below, and may be used individually or in combination: IL-1β, GRO-alpha, High mobility group-box 1 protein (HMBG-1), IL-1 receptor, IL-1

15 receptor antagonist, IL-1b, IL-2, IL-4, IL-6, IL-8, IL-10, IL-12, IL-13, IL-18, macrophage inflammatory protein (MIP-1), macrophage migration inhibitory factor (MIF), osteopontin, RANTES (regulated on activation, normal T-cell expressed and secreted; or CCL5), IL-10, GM-CSF, MCP-1, TNF-α, hsCRP, PCT, LFB, and lactate.

The systems and methods of the invention can also be used to monitor and diagnose heart disease

20 in a subject, such as a myocardial infarction. Cardiac markers or cardiac enzymes are proteins that leak out of injured myocardial cells and are used to assess cardiac injury. Cardiac markers include, without limitation, the enzymes SGOT, LDH, the MB subtype of the enzyme creatine kinase, and cardiac troponins (T and I). The cardiac troponins T and I which are released within 4–6 hours of an attack of myocardial infarction (and remain elevated for up to 2 weeks) have nearly complete tissue specificity and

25 are now the preferred markers for assessing myocardial damage. Elevated troponins in the setting of chest pain may accurately predict a high likelihood of a myocardial infarction in the near future. The diagnosis of myocardial infarction is typically based upon subject history, ECG, and cardiac markers. When damage to the heart occurs, levels of cardiac markers rise over time, which is why blood tests for them are taken over a 24-hour period. Because these enzyme levels are not elevated immediately

30 following a heart attack, patients presenting with chest pain are generally treated with the assumption that a myocardial infarction has occurred and then evaluated for a more precise diagnosis. A MI is a medical emergency which requires immediate medical attention. Treatment attempts to salvage as much myocardium as possible and to prevent further complications, thus the phrase "time is muscle". Oxygen, aspirin, and nitroglycerin are usually administered as soon as possible. Thus, in the acute setting,

35 monitoring Troponin I and T, as well as potential other biomarkers of cardiac ischemia, in addition to drug therapy and toxicity patterns in a single platform diagnostic method would have distinct advantages. The systems and methods of the invention can be used to provide a multiplexed, no sample preparation,

single detection method, automated system to determine the drug level, the toxicity or adverse effect
determinants, and the potential biomarker of the progression of the disease. For example, a cartridge
having portals or wells containing 1) magnetic particles having anti-troponin I or troponin T specific
antibodies decorated on their surface, 2) magnetic particles having toxicity biomarker specific antibodies
5   on their surface, and 3) magnetic particles having specific probes to identify disease markers of
progression could be employed to rapidly determine and provide clinical management values for a given
myocardial infarction patient.

One or more multi-well cartridges can be configured for use in the systems and methods of the
invention and prepared with at least one whole blood sample from the patient; magnetic particles for
10   detecting each of the analytes to be detected (one or more small molecules; one or more metabolites of
the one or more small molecules; metabolic biomarker such as described for the hepatic function panel);
and dilution and wash buffers. Liver function tests are done on a patient's serum or plasma sample and
clinical biochemistry laboratory blood analysis furnishes crucial data regarding the condition of the
patient's liver. A "hepatic function panel" is a blood test wherein low or high levels of one or more
15   enzymes may point to liver diseases or damage. For example, the hepatic function panel can include one
or more of the following analyte detection assays: one or more small molecules; one or more metabolites
of the one or more small molecules; a biologic, metabolic biomarkers; genotyping, gene expression
profiling; and proteomic analysis.

A hepatic function panel can include analysis of one or more of the following proteins in a patient
20   or subject biological sample: 1) albumin (the major constituent of the total protein in the liver; while the
remnant is called globulin; albumin must be present as 3.9 to 5.0 g/dL, hypoalbuminaemia indicates poor
nutrition, lower protein catabolism, cirrhosis or nephrotic syndrome); 2) aspartate transaminase (AST)
(also known as serum glutamic oxaloacetic transaminase or aspartate aminotransferase , is an enzyme in
liver parenchymal cells and is normally 10 to 34 IU/L; elevated levels are indicative of acute liver
25   damage); 3) alanine transaminase (ALT) (also known as serum glutamic pyruvic transaminase or alanine
aminotransferase, is an enzyme is present in hepatocytes at levels between 8 to 37 IU/L; elevated levels
are indicative of acute liver damage in viral hepatitis or paracetamol overdose; the ratio of AST to ALT is
used to differentiate between the reasons of liver damage); 4) alkaline phosphatase (ALP) (an enzyme that
is present in the cells lining the biliary ducts of the liver; the normal range is 44 to 147 IU/L and the level
30   rises in case of infiltrative diseases of the liver, intrahepatic cholestasis or large bile duct obstruction); 5)
Gamma glutamyl transpeptidase (GGT) (a more sensitive marker for cholestatic damage than ALP, is
very specific to the liver; the standard range is 0 to 51 IU/L; both acute and chronic alcohol toxicity raise
GGT; the reason of an isolated elevation in ALP can be detected by GGT); 6) total bilirubin (TBIL) (an
increase in the total bilirubin can lead to jaundice and can be attributed to cirrhosis, viral hepatitis,
35   hemolytic anemias, or internal hemorrhage); 7) direct bilirubin; 8) prothrombin time (PTT) (hepatic cell
damage and bile flow obstruction can cause changes to blood clotting time); 9) alpha-fetoprotein test
(elevated levels indicate hepatitis or cancer); 10) lactate dehydrogenase; and 11) mitochondrial antibodies

(if present may indicate chronic active hepatitis, primary biliary cirrhosis, or other autoimmune disorders). The proteins described above would be analyzed in the hepatic function panel using the systems and methods of the invention.

An additional hepatic function panel may include genotyping of cytochrome P450 enzymes. The cytochrome P450 superfamily (CYP) is a large and diverse group of enzymes. The function of most CYP enzymes is to catalyze the oxidation of organic substances. The substrates of CYP enzymes include metabolic intermediates such as lipids and steroidal hormones, as well as xenobiotic substances such as drugs and other toxic chemicals. CYPs are the major enzymes involved in drug metabolism and bioactivation, accounting for ca. 75% of the total metabolism. Most drugs undergo biotransformation and are eventually excreted from the body; and many require bioactivation to form the active compound. The CYP enzymes that metabolize many medications include CYP3A4/5 (36%), CYP2D6 (19%), CYP2C8/9 (16%), and CYP1A2 (11%).

Cytochrome P450 genotyping tests are used to determine how well a patient or subject metabolizes a drug. The results of cytochrome P450 tests can be used to divide individuals into four main types:

(i) Poor metabolizers. Certain drugs are metabolized more slowly than normal and the medication will have a longer half life and possibly increase the likelihood that it will cause side effects.

(ii) Normal metabolizers. Drugs will be metabolized at an average rate and thus is indicative that there is a benefit from treatment and points to fewer side effects than are other individuals who don't metabolize those particular medications as well.

(iii) Intermediate metabolizers. Drugs may or may not be metabolized at an average rate. At least one gene involved in drug metabolism is suspected to function abnormally. There then is a predisposition to metabolize certain drugs differently.

(iv) Ultra rapid metabolizers. Drugs are metabolized faster and more efficiently than the average. Since the metabolic rate is higher than average, some medications are inactivated sooner or are excreted sooner than normal and the medication may not have the desired efficacy.

Currently, genotyping the genes responsible for these enzymes across a population has been shown that polymorphic differences in these enzymes can lead to variation in efficacy and toxicity of some drugs. Assessing cytochrome P450 status in a patient sample can be accomplished by measuring the enzyme activity of the sample, or determining if a genetic difference occurs in one of the genes of this metabolic system in the genome. Genotyping requires a cell sample representative of the patient or subject's genome and the analysis is aimed at determining genetic differences in these clinically important genes. Alternatively, CYP450 enzyme phenotyping (identifying enzymatic metabolizer status) can be accomplished by administering a test enzyme substrate to a patient and monitoring parent substrate and metabolite concentrations over time (e.g., in urine). However, testing and interpretation are time-consuming and inconvenient; as a result, phenotyping is seldom performed.

Below is a listing of the possible hepatic metabolic enzymes that may be part of a hepatic

function panel.

CYP2C19 metabolizes several important types of drugs, including proton-pump inhibitors,

diazepam, propranolol, imipramine, and amitriptyline. FDA cleared the test "based on results of a study

5   conducted by the manufacturers of hundreds of DNA samples as well as on a broad range of supporting

peer-reviewed literature." According to FDA labeling, "Information about CYP2D6 genotype may be

used as an aid to clinicians in determining therapeutic strategy and treatment doses for therapeutics that

are metabolized by the CYP2D6 product." Thus, a hepatic function panel employing the methods of the

invention, may be used to genotype patient or subject samples to assess the status of the cytochrome P450

10   enzyme system to then optimize therapeutic efficacy and safety.

CYP2D6 (cytochrome P450 2D6) is the best studied of the DMEs and acts on one-fourth of all

prescription drugs, including the selective serotonin reuptake inhibitors (SSRI), tricylic antidepressants

(TCA), beta-blockers such as Inderal and the Type 1A antiarrhythmics. Approximately 10% of the

population has a slow acting form of this enzyme and 7% a super-fast acting form. Thirty-five percent

15   are carriers of a non-functional 2D6 allele, especially elevating the risk of ADRs when these individuals

are taking multiple drugs. Drugs that CYP2D6 metabolizes include Prozac, Zoloft, Paxil, Effexor,

hydrocodone , amitriptyline, Claritin, cyclobenzaprine, Haldol, metoprolol, Rythmol, Tagamet,

tamoxifen, dextromethorphan, beta-blockers, antiarrhythmics, antidepressants, and morphine derivatives,

including many of the most prescribed drugs and the over-the-counter diphenylhydramine drugs (e.g.,

20   Allegra, Dytuss, and Tusstat). CYP2D6 is responsible for activating the pro-drug codeine into its active

form and the drug is therefore inactive in CYP2D6 slow metabolizers.

CYP2C9 (cytochrome P450 2C9) is the primary route of metabolism for Coumadin (warfarin).

Approximately 10% of the population are carriers of at least one allele for the slow-metabolizing form of

CYP2C9 and may be treatable with 50% of the dose at which normal metabolizers are treated. Other

25   drugs metabolized by CYP2C9 include Amaryl, isoniazid, ibuprofen, amitriptyline, Dilantin, Hyzaar,

THC (tetrahydrocannabinol), naproxen, and Viagra.

CYP2C19 (cytochrome P450 2C19) is associated with the metabolism of carisoprodol, diazepam,

Dilantin, and Prevacid.

CYP1A2 (cytochrome P450 1A2) is associated with the metabolism of amitriptyline, olanzapine,

30   haloperidol, duloxetine, propranolol, theophylline, caffeine, diazepam, chlordiazepoxide, estrogens,

tamoxifen, and cyclobenzaprine.

NAT2 (N-acetyltransferase 2) is a secondary drug metabolizing enzyme that acts on isoniazid,

procainamide, and Azulfidine. The frequency of the NAT2 "slow acetylator" in various worldwide

populations ranges from 10% to more than 90%.

35   DPD (Dihydropyrimidine dehydrogenase) is responsible for the metabolism of Fluorouracil (5-

FU), one of the most successful and widely used chemotherapy drugs.

UGT1A1 (UDP-glucuronosyltransferase) variations can lead to severe even fatal reactions to the first dost of Camptosar (irinotecan).

5HTT (Serotonin Transporter) helps determine whether people are likely to respond to SSRIs, a class of medications that includes citalopram, fluoxetine, paroxetine, and sertraline, among others, and often is prescribed for depression or anxiety.

Diagnostic genotyping tests for certain CYP450 enzymes are now available. Some tests are offered as in house laboratory-developed test services, which do not require U.S. Food and Drug Administration (FDA) approval but which must meet CLIA quality standards for high complexity testing. The AmpliChip® (Roche Molecular Systems, Inc.) is the only FDA-cleared test for CYP450 genotyping. The AmpliChip® is a microarray consisting of many DNA sequences complementary to 2 CYP450 genes and applied in microscopic quantities at ordered locations on a solid surface (chip). The AmpliChip® tests the DNA from a patient's white blood cells collected in a standard anticoagulated blood sample for 29 polymorphisms and mutations for the CYP2D6 gene and 2 polymorphisms for the CYP2C19 gene.

Therefore, the invention features a multiplexed analysis of a single blood sample (e.g., a single blood draw, or any other type of patient sample described herein) from a patient to determine a) liver enzymatic status, as well as b) the genotype of key metabolic enzymes to then be able to design pharmacotherapy regimes for optimal therapeutic care using the systems and methods of the invention.

The systems and methods of the invention can include one or more multi-well cartridges prepared with at least one whole blood sample from the patient; magnetic particles for detecting each of the analytes to be detected; analyte antibodies; multivalent binding agents; and/or dilution and wash buffers for use in a multiplexed assay as described above.

Nephrotoxicity

Renal toxicity is a common side effect of use of xenobiotics and early, rapid detection of early stages of nephrotoxicity may assist in medical decision making. Early reports of detection of renal toxicity suggest that increased mRNA expression of certain genes can be monitored. However, others have suggested that markers of renal toxicity can be detected in urine. These markers include: kim-1, lipocalin-2, neutrophil gelatinase-associated lipocalin (NGAL), timp-1, clusterin, osteopontin, vimentin, and heme oxygenase 1 (HO-1). More broadly, detection of DNA, heavy metal ions or BUN levels in urine can be useful clinical information. Thus, the methods and utlity of the instant invention also includes the ability to detect these markers of renal toxicity. Optionally, a hepatic function panel may also include one or two hallmark biomarkers of nephrotoxicity, or visa versa.

Non-Agglomeration-Based Assays and Methods

In some embodiments, the magnetic particles described herein may be utilized in an assay that does not feature particle agglomeration. For example, the magnetic particles may be used to capture or concentrate an analyte, e.g., by passing a liquid sample containing the analyte over magnetic particles that

include binding moieties specific for the analyte. Some advantages of this approach include a) no clusters need be formed (the clusters may be inherently unstable over a certain size, leading to increased CV's); b) no clustering may not require vortexing as flow shear forces may dislodge non-specific binding of magnetic particles, c) fluidic handling steps may be reduced, and d) miniaturization of the assay may favor these non-agglomerative methods. Broadly, two models for surface based detection include: (i) changes in T2 signal arising from the depletion of magnetic particles from a solution and (ii) changes in T2 signal arising from magnetic particle enrichment of a surface.

The magnetic particles derivatized with a binding moiety can be held in position by an external magnetic field while sample containing the corresponding analyte is circulated past the "trapped" magnetic particles allowing for capture and/or concentrate the analyte of interest. The particles may be pulled to the side or bottom of the assay vessel, or a magnetizable mesh or magnetizable metal foam with appropriate pore size can be present in the reaction vessel, creating very high local magnetic gradients. An advantage of having the mesh/metal foam in the reaction vessel is that the distance each magnetic particle needs to travel to be "trapped" or "captured" can be very short, improving assay kinetics.

Another non-agglomerative assay is to have surfaces derivitized with ligands complementary to the binding moiety present on the magnetic particle and using a capture/depletion/flow through format. Specific binding of magnetic particles to a surface depletes magnetic particles from the bulk particle suspension used in the assay, thus leading to a change in the T_2 value in the reaction volume interrogated by the MR reader. Pre-incubation of the particles with the sample containing analyte can reduce/inhibit the specific binding/capture/depletion of the magnetic particle by the derivitized surface in proportion to the concentration of analyte in the sample. One example of this type of assay approach has been demonstrated using PhyNexus affinity chromatography micropipette tips. The 200ul PhyTips contain a 20 μl volume of resin bed trapped between 2 frits. The resin bed consists of 200 μm cross-linked agarose beads derivitized with avidin, protein A, protein G, or an analyte. A programmable electronic pipettor can aspirate and dispense various volumes at various flow rates. The magnetic particles flow through the pores created by the packed agarose bead resin bed. By repeatedly passing the appropriate magnetic particle suspension over the trapped resin bed to allow for productive interactions to occur between, say, an avidin-derivatized agarose bead resin bed and biotin-derivatized magnetic particles, some of the magnetic particles will specifically bind to and be depleted from the particles suspension. By measuring the T_2 of the particle suspension before and after exposure to the agarose resin bed, the amount of particle depletion can be quantified.

Another non-agglomerative assay format is similar to that described above, but uses derivatized magnetizable metal foam to replace the resin bed. The advantage of the metal foam as the solid phase substrate is that when placed in a magnetic field, the metal foam generates very high local magnetic field gradients over very short distances which can attract the derivatized magnetic particles and bring them in contact with the complementary binding partner on the metal foam and improve the chances of a specific

productive interaction. By optimizing the pore size and surface area of the metal foam, the assay kinetics can be vastly improved because the particles need to travel much shorter distances to find a complementary surface to bind. The particle concentration in the flow-through reaction volume will be reduced inversely proportional to the analyte concentration in the sample and can be quantified using the MR reader. The metal foam can be nickel bearing directly bound his-tagged moieties, or can be nickel treated with aminosilane and covalently linkedbinding moieties. This process has been demonstrated using aminosilane-treated nickel metal foam with 400 μm pores decorated with anti-creatinine antibodies and shown to specifically bind creatinine-derivatized magnetic particles.

To prepare small circular pieces of nickel metal foam (NMF), NMF material is incubated with deionized water and then frozen. The frozen water in the NMF crevices support the foam so that it will not collapse or create differential edges. Next, a punch is used to create uniform-sized pieces of NMF; a hammer and punch (e.g., a circular tube having a circular cutting edge at one end) is used to cut out circular pieces, e.g., 2-3 mm in size, of the frozen foam. A wire is then used to poke out the pieces, which are dried in a glassware oven. To derivatize the NMF pieces and prepare them for use in the devices and methods described herein, the following steps are performed. First, NMF pieces are cleaned with 2M H_2SO_4 in a sonicator, and sulfuric acid solution is used to clean the NMF and to roughen the NMF surfaces in order to assist in subsequent attachment of the amino groups of aminosilane. The acid-washed NMF pieces are then rinsed with deionized water to remove any residual acid solution, and the NMF pieces are dried in a glassware oven. Next the NMF pieces are derivatized with aminosilane, and 70kD aminodextran is covalently attached. The aminodextran is then optionally crosslinked with gluteraldehyde. Specific antibodies, oligonucleotides, and analytes can then be covalently attached to the amino groups on the aminodextran using various chemistries, and the derivatized NMF pieces are incubated to block non-specific binding. Common blockers include but are not limited to BSA, non-fat dried milk, detergents, salmon sperm DNA, among others.

Further, there are examples of assays that would be aimed at detecting a physical property change in a liquid sample. As described in pending cases, PCT/US2009/062537 (published as WO2010/051362) and PCT/US2008/073346 (published as WO2009/026164), coagulation of blood can be determined by the instant methods described therein. Further, other physical properties may be detected such as solidification, changes in density and may have uses in determining curing of materials (plastic compositions), changes in food and food products with time, contamination of products found in nature, and monitoring certain biological fluids such as urine as a function of kidney function.

The magnetic particles utilized in the non-agglomerative methods described herein can have an average diameter of from 10 nm to 1200 nm (e.g., from 10 to 50, 50 to 150, 150 to 250, 200 to 350, 250 to 450, 300 to 500, 450 to 650, 500 to 700 nm, 700 to 850, 800 to 950, 900 to 1050, or from 1000 to 1200 nm).

Amplification and Detection of Nucleic Acids from Complex Samples

Systems and methods of the invention can include amplification based nucleic acid detection
assays conducted starting with complex samples (e.g., for diagnostic, forensic, and environmental
5   analyses).

Sample preparation must also remove or provide resistance for common PCR inhibitors found in
complex samples (e.g., body fluids, soil, or other complex milieu). Common inhibitors are listed in Table
5 (see also, Wilson, Appl. Environ. Microbiol., 63:3741 (1997)). Inhibitors typically act by either
prevention of cell lysis, degradation or sequestering a target nucleic acid, and/or inhibition of a
10   polymerase activity. The most commonly employed polymerase, Taq, is inhibited by the presence of
0.1% blood in a reaction. Very recently, mutant Taq polymerases have been engineered that are resistant
to common inhibitors (e.g., hemoglobin and/or humic acid) found in blood and soil (Kermekchiev et al.,
Nucl. Acid. Res., 37(5): e40, (2009)). Manufacturer recommendations indicate these mutations enable
direct amplification from up to 20% blood. Despite resistance afforded by the mutations, accurate real
15   time PCR detection is complicated due to fluorescence quenching observed in the presence of blood
sample (Kermekchiev et al., Nucl. Acid. Res., 37:e40 (2009)).

Table 5. PCR inhibitors and facilitators/methods for overcoming inhibition.

Substrate	Target	Inhibitor	Facilitator
feces	Escherichia coli	>10^3 bacterial cells	ion-exchange column
CSF	Treponema pallidum	Cellular debris causing nonspecific amplification	nested primers
whole blood	mammalian tissue	>4 μl of blood/100-ml reaction mix (hemoglobin)	1-2% blood per reaction
feces	Rotatvirus	unknown dilution	cellulose fiber
clinical specimens	Cytomegalovirus	unidentified components	glass bead extraction
human blood and tissue	human genes	DNA binding proteins	thermophilic protease from Thermus strain rt44A
mammalian tissue	Mammalian tissue genetics	thermal cycler variations	formamide
mammalian tissue	Mammalian tissue genetics	thermal cycler variations	DMSO, glycerol, PEG, organic solvents
clinical specimens	Treponema pallidum	unknown factors	Various substrate-specific physicochemical methods
forensic semen samples	Sperm	Genotyping errors; selective/total PCR inhibition by vaginal microorganisms	
feces	Salmonella enterica	various body fluids	immunomagnetic separation
feces	Various enteric viruses	unknown	size exclusion chromatography, physicochemical extraction
clinical specimens	Herpes simplex virus	endogenous inhibitors, random effects	repurification, coamplified positive control
feces	Escherichia coli	nonspecific inhibitors, urea, hemoglobin, heparin, phenol, SDS	additional primers and reaction cyclers, booster PCR

tissue culture	Cytomegalovirus HIV	glove powder	
suspensions, skin biopsies	Mycobacterium leprae	mercury-based fixatives, neutral buffered formaline	reduced fixation times, ethanol fixation
clinical specimens	Mycobacterium tuberculosis	unknown inhibitors in pus, tissue biopsies, sputum, pleural fluid	physicochemical extraction
mammalian tissue	mammalian tissue genetics	unknown contaminant of reverse transcriptase	additional DNA
formalin-fixed paraffin tissue	Hepatitus C virus	ribonucleotide vanadyl complexes	phenol/chloroform extraction
nasopharyngeal aspirates and swabs	Bordetella pertussis	unknown inhibitors	phenol/chloroform extraction
human mononuclear blood cells	HIV type I	detergents	mineral oil
bloodstain	human mitochondrial DNA	unidentified heme compound, hemin	BSA
blood	various	heparin	alternative polymerases and buffers, chelex, spermine, [Mg2+], glycerol, BSA, heparinase
sputa	Mycoplasma pneumonia	N-acetyl-L-cysteine, dithiothreitol, mucolytic agents -	
human tissue	HLA-DRB1 genotyping	pollen, glove powder,impure DNA, heparin, hemoglobin	
clinical specimens	Mycobacterium tuberculosis	unknown	competitive internal control
dental plaque	many	unknown	diatomaceous earth, guanidium isothiocyante, ethanol, acetone
ancient mammalian tissues	Cytochrome b gene	unknown	ammonium acetate, ethidium bromide

Polymerase chain reaction amplification of DNA or cDNA is a tried and trusted methodology; however, as discussed above, polymerases are inhibited by agents contained in crude samples, including but not limited to commonly used anticoagulants and hemoglobin. Recently mutant Taq polymerases have been engineered to harbor resistance to common inhibitors found in blood and soil. Currently available polymerases, e.g., HemoKlenTaq™ (New England BioLabs, Inc., Ipswich, MA) as well as OmniTaq™ and OmniKlenTaq™ (DNA Polymerase Technology, Inc., St. Louis, MO) are mutant (e.g., N-terminal truncation and/or point mutations) Taq polymerase that render them capable of amplifying DNA in the presence of up to 10%, 20% or 25% whole blood, depending on the product and reaction conditions (See, e.g., Kermekchiev et al. Nucl. Acids Res. 31:6139 (2003); and Kermekchiev et al., Nucl. Acid. Res., 37:e40 (2009); and see U.S. Patent No. 7,462,475). Additionally, Phusion® Blood Direct PCR Kits (Finnzymes Oy, Espoo, Finland), include a unique fusion DNA polymerase enzyme engineered to incorporate a double-stranded DNA binding domain, which allows amplification under conditions which are typically inhibitory to conventional polymerases such as Taq or Pfu, and allow for amplification of DNA in the presence of up to about 40% whole blood under certain reaction conditions.

See Wang et al., Nuc. Acids Res. 32:1197 (2004); and see U.S. Patent Nos. 5,352,778 and 5,500,363. Furthermore, Kapa Blood PCR Mixes (Kapa Biosystems, Woburn, MA), provide a genetically engineered DNA polymerase enzyme which allows for direct amplification of whole blood at up to about 20% of the reaction volume under certain reaction conditions. Despite these breakthroughs, direct optical detection

5   of generated amplicons is not possible with existing methods since fluorescence, absorbance, and other light based methods yield signals that are quenched by the presence of blood. See Kermekchiev et al., Nucl. Acid. Res., 37:e40 (2009).

We have found that complex samples such as whole blood can be directly amplified using about 5%, about 10%, about 20%, about 25%, about 30%, about 25%, about 40%, and about 45% or more

10   whole blood in amplification reactions, and that the resulting amplicons can be directly detected from amplification reaction using magnetic resonance (MR) relaxation measurements upon the addition of conjugated magnetic particles bound to oligonucleotides complementary to the target nucleic acid sequence. Alternatively, the magnetic particles can be added to the sample prior to amplification. Thus, provided are methods for the use of nucleic acid amplification in a complex dirty sample, hybridization of

15   the resulting amplicon to paramagnetic particles, followed by direct detection of hybridized magnetic particle conjugate and target amplicons using magnetic particle based detection systems. In particular embodiments, direct detection of hybridized magnetic particle conjugates and amplicons is via MR relaxation measurements (e.g., T_2, T_1, T1/T2 hybrid, T_2^*, etc). Further provided are methods which are kinetic, in order to quantify the original nucleic acid copy number within the sample (e.g., sampling and

20   nucleic acid detection at pre-defined cycle numbers, comparison of endogenous internal control nucleic acid, use of exogenous spiked homologous competitive control nucleic acid).

The terms "amplification" or "amplify" or derivatives thereof as used herein mean one or more methods known in the art for copying a target or template nucleic acid, thereby increasing the number of copies of a selected nucleic acid sequence. Amplification may be exponential or linear. A target or

25   template nucleic acid may be either DNA or RNA. The sequences amplified in this manner form an "amplified region" or "amplicon." Primer probes can be readily designed by those skilled in the art to target a specific template nucleic acid sequence. In certain preferred embodiments, resulting amplicons are short to allow for rapid cycling and generation of copies. The size of the amplicon can vary as needed to provide the ability to discriminate target nucleic acids from non-target nucleic acids. For example,

30   amplicons can be less than about 1,000 nucleotides in length. Desirably the amplicons are from 100 to 500 nucleotides in length (e.g., 100 to 200, 150 to 250, 300 to 400, 350 to 450, or 400 to 500 nucleotides in length).

While the exemplary methods described hereinafter relate to amplification using polymerase chain reaction ("PCR"), numerous other methods are known in the art for amplification of nucleic acids

35   (e.g., isothermal methods, rolling circle methods, etc.). Those skilled in the art will understand that these other methods may be used either in place of, or together with, PCR methods. See, e.g., Saiki, "Amplification of Genomic DNA" in PCR Protocols, Innis et al., Eds., Academic Press, San Diego,

Calif., pp 13-20 (1990); Wharam et al., Nucleic Acids Res. 29:E54 (2001); Hafner et al., Biotechniques, 30:852 (2001). Further amplification methods suitable for use with the present methods include, for example, polymerase chain reaction (PCR) method, reverse transcription PCR (RT-PCR), ligase chain reaction (LCR), transcription based amplification system (TAS), transcription mediated amplification

5   (TMA), nucleic acid sequence based amplification (NASBA) method, the strand displacement amplification (SDA) method, the loop mediated isothermal amplification (LAMP) method, the isothermal and chimeric primer-initiated amplification of nucleic acid (ICAN) method, and the smart amplification system (SMAP) method. These methods, as well as others are well known in the art and can be adapted for use in conjunction with provided methods of detection of amplified nucleic acid.

10   The PCR method is a technique for making many copies of a specific template DNA sequence. The PCR process is disclosed in U.S. Patent Nos. 4,683,195; 4,683,202; and 4,965,188, each of which is incorporated herein by reference. One set of primers complementary to a template DNA are designed, and a region flanked by the primers is amplified by DNA polymerase in a reaction including multiple amplification cycles. Each amplification cycle includes an initial denaturation, and up to 50 cycles of

15   annealing, strand elongation (or extension) and strand separation (denaturation). In each cycle of the reaction, the DNA sequence between the primers is copied. Primers can bind to the copied DNA as well as the original template sequence, so the total number of copies increases exponentially with time. PCR can be performed as according to Whelan, et al, Journal of Clinical Microbiology, 33:556(1995). Various modified PCR methods are available and well known in the art. Various modifications such as the "RT-

20   PCR" method, in which DNA is synthesized from RNA using a reverse transcriptase before performing PCR; and the "TaqMan PCR" method, in which only a specific allele is amplified and detected using a fluorescently labeled TaqMan probe, and Taq DNA polymerase, are known to those skilled in the art. RT-PCR and variations thereof have been described, for example, in U.S. Patent Nos. 5,804,383; 5,407,800; 5,322,770; and 5,310,652, and references described therein, which are hereby incorporated by

25   reference; and TaqMan PCR and related reagents for use in the method have been described, for example, in U.S .Patent Nos. 5,210,015; 5,876,930; 5,538,848; 6,030,787; and 6,258,569, which are hereby incorporated by reference.

        LCR is a method of DNA amplification similar to PCR, except that it uses four primers instead of two and uses the enzyme ligase to ligate or join two segments of DNA. Amplification can be performed

30   in a thermal cycler (e.g., LCx of Abbott Labs, North Chicago, IL). LCR can be performed for example, as according to Moore et al., Journal of Clinical Microbiology 36:1028 (1998). LCR methods and variations have been described, for example, in European Patent Application Publication No. EP0320308, and U.S. Patent No. 5,427,930, each of which is incorporated herein by reference.

        The TAS method is a method for specifically amplifying a target RNA in which a transcript is

35   obtained from a template RNA by a cDNA synthesis step and an RNA transcription step. In the cDNA synthesis step, a sequence recognized by a DNA-dependent RNA polymerase (i.e., a polymerase-binding sequence or PBS) is inserted into the cDNA copy downstream of the target or marker sequence to be

amplified using a two-domain oligonucleotide primer. In the second step, an RNA polymerase is used to synthesize multiple copies of RNA from the cDNA template. Amplification using TAS requires only a few cycles because DNA-dependent RNA transcription can result in 10-1000 copies for each copy of cDNA template. TAS can be performed according to Kwoh et al., PNAS 86:1173 (1989). The TAS

5   method has been described, for example, in International Patent Application Publication No. WO1988/010315, which is incorporated herein by reference.

Transcription mediated amplification (TMA) is a transcription-based isothermal amplification reaction that uses RNA transcription by RNA polymerase and DNA transcription by reverse transcriptase to produce an RNA amplicon from target nucleic acid. TMA methods are advantageous in that they can

10   produce 100 to 1000 copies of amplicon per amplification cycle, as opposed to PCR or LCR methods that produce only 2 copies per cycle. TMA has been described, for example, in U.S. Patent No. 5,399,491which is incorporated herein by reference. NASBA is a transcription-based method which for specifically amplifying a target RNA from either an RNA or DNA template. NASBA is a method used for the continuous amplification of nucleic acids in a single mixture at one temperature. A transcript is

15   obtained from a template RNA by a DNA-dependent RNA polymerase using a forward primer having a sequence identical to a target RNA and a reverse primer having a sequence complementary to the target RNA a on the 3' side and a promoter sequence that recognizes T7 RNA polymerase on the 5' side. A transcript is further synthesized using the obtained transcript as template. This method can be performed as according to Heim, et al., Nucleic Acids Res., 26:2250 (1998). The NASBA method has been

20   described in U.S. Patent No. 5,130,238, which is incorporated herein by reference.

The SDA method is an isothermal nucleic acid amplification method in which target DNA is amplified using a DNA strand substituted with a strand synthesized by a strand substitution type DNA polymerase lacking 5' - >3' exonuclease activity by a single stranded nick generated by a restriction enzyme as a template of the next replication. A primer containing a restriction site is annealed to

25   template, and then amplification primers are annealed to 5' adjacent sequences (forming a nick). Amplification is initiated at a fixed temperature. Newly synthesized DNA strands are nicked by a restriction enzyme and the polymerase amplification begins again, displacing the newly synthesized strands. SDA can be performed according to Walker, et al., PNAS, 89:392 (1992). SDA methods have been described in U.S. Patent Nos. 5,455,166 and 5,457,027, each of which are incorporated by reference.

30   The LAMP method is an isothermal amplification method in which a loop is always formed at the 3' end of a synthesized DNA, primers are annealed within the loop, and specific amplification of the target DNA is performed isothermally. LAMP can be performed according to Nagamine et al., Clinical Chemistry. 47:1742 (2001). LAMP methods have been described in U.S. Patent Nos. 6,410,278; 6,974,670; and 7,175,985, each of which are incorporated by reference.

35   The ICAN method is anisothermal amplification method in which specific amplification of a target DNA is performed isothermally by a strand substitution reaction, a template exchange reaction, and a nick introduction reaction, using a chimeric primer including RNA-DNA and DNA polymerase having

a strand substitution activity and RNase H. ICAN can be performed according to Mukai et al., J. Biochem. 142: 273(2007). The ICAN method has been described in U.S. Patent No. 6,951,722, which is incorporated herein by reference.

5   The SMAP (MITANI) method is a method in which a target nucleic acid is continuously synthesized under isothermal conditions using a primer set including two kinds of primers and DNA or RNA as a template. The first primer included in the primer set includes, in the 3' end region thereof, a sequence (Ac') hybridizable with a sequence (A) in the 3' end region of a target nucleic acid sequence as well as, on the 5' side of the above-mentioned sequence (Ac'), a sequence (B') hybridizable with a sequence (Bc) complementary to a sequence (B) existing on the 5' side of the above-mentioned sequence

10   (A) in the above-mentioned target nucleic acid sequence. The second primer includes, in the 3' end region thereof, a sequence (Cc') hybridizable with a sequence (C) in the 3' end region of a sequence complementary to the above-mentioned target nucleic acid sequence as well as a loopback sequence (D-Dc') including two nucleic acid sequences hybridizable with each other on an identical strand on the 5' side of the above-mentioned sequence (Cc'). SMAP can be performed according to Mitani et al., Nat.

15   Methods, 4(3): 257 (2007). SMAP methods have been described in U.S. Patent Application Publication Nos. 2006/0160084, 2007/0190531 and 2009/0042197, each of which is incorporated herein by reference.

The amplification reaction can be designed to produce a specific type of amplified product, such as nucleic acids that are double stranded; single stranded; double stranded with 3' or 5' overhangs; or double stranded with chemical ligands on the 5' and 3' ends. The amplified PCR product can be detected

20   by: (i) hybridization of the amplified product to magnetic particle bound complementary oligonucleotides, where two different oligonucleotides are used that hybridize to the amplified product such that the nucleic acid serves as an interparticle tether promoting particle agglomeration; (ii) hybridization mediated detection where the DNA of the amplified product must first be denatured; (iii) hybridization mediated detection where the particles hybridize to 5' and 3' overhangs of the amplified product; (iv) binding of the

25   particles to the chemical or biochemical ligands on the termini of the amplified product, such as streptavidin functionalized particles binding to biotin functionalized amplified product.

The systems and methods of the invention can be used to perform real time PCR and provide quantitative information about the amount of target nucleic acid present in a sample (see Figure 52 and Example 18). Methods for conducting quantitative real time PCR are provided in the literature (see for

30   example: RT-PCR Protocols. Methods in Molecular Biology, Vol. 193. Joe O'Connell, ed. Totowa, NJ: Humana Press, 2002, 378 pp. ISBN 0-89603-875-0.). Example 18 describes use of the methods of the invention for real time PCR analysis of a whole blood sample.

The systems and methods of the invention can be used to perform real time PCR directly in opaque samples, such as whole blood, using magnetic nanoparticles modified with capture probes and

35   magnetic separation. Using real-time PCR allows for the quantification of a target nucleic acid without opening the reaction tube after the PCR reaction has commenced.

In one approach, biotin or avidin labeled primers can be used to perform real-time PCR. These labels would have corresponding binding moieties on the magnetic particles that could have very fast binding times. This allows for a double stranded product to be generated and allows for much faster particle binding times, decreasing the overall turnaround time. The binding chemistry would be reversible, preventing the primers from remaining particle bound. In order to reverse the binding, the sample can be heated or the pH adjusted.

In another approach, the real-time PCR can be accomplished through the generation of duplex DNA with overhangs that can hybridize to the superparamagnetic particles. Additionally, LNA and/or fluorinated capture probes may speed up the hybridization times. An exemplary set of capture probes useful in this method is set forth in the table below:

Pan Candida F Uni-Tail	5'- CAT GAT CTG CTG CAG /iSp18/GG CAT GCC TGT TTG AGC GTC -3' (SEQ ID NO. 19)
Pan Candida R Uni-Tail	5'- GCA GAA CTC CAG ACC /iSp18/GC TTA TTG ATA TGC TTA AGT TCA GCG GGT -3' (SEQ ID NO. 20)
3'AM universal tail CP	5'- CTG CAG CAG ATC ATG TTT TTT TTT TTT /3AmMO/ -3' (SEQ ID NO. 21)
5'AM universal tail CP	5'- /5AmMC6/TT TTT TTT TTT TGG TCT GGA GTT CTG C -3'
Fluorinated 3'AM uni CP	5'- CTG /i2FC/AG /i2FC/AG /i2FA/TC /i2FA/TG TTT TTT TTT TTT /3AmMO/ -3' (SEQ ID NO. 22)
Fluorinated 5'AM uni CP	5'- /5AmMC12/TT TTT TTT TTT TGG T/i2FC/T G/i2FG/A G/i2FU/T CTG C -3' (SEQ ID NO. 23)

In still another approach, the particles are designed to have a hairpin that buries the binding site to the amplicon. Heating the particles to a higher melt temperature would expose the binding site of the hairpin to allow binding to the target.

In another approach, a probe that hybridizes to an amplicon is tethering two (or more) particles. The reaction would be conducted in the presence of a polymerase with 5' exonuclease activity, resulting in the cleavage of the inter-particle tether and a subsequent change in T2. The polymerase is selected to have exonuclease activity and compatibility with the matrix of choice (e.g. blood). In this approach, smaller particles (e.g., 30 nm CLIO) can be used to reduce steric hindrance of the hybridization to target or subsequent enzymatic digestion during polymerization (see, e.g., Heid et al Genome Research 1996 6: 986-994).

In another approach, two particle populations can be synthesized to bear complementary capture probes. In the absence of amplicon, the capture probes hybridize promoting particle clustering. Upon generation of amplicon, the amplicon can compete,hybridize, and displace the capture probes leadingto particle declustering. The method can be conducted in the presence or absence of nanoparticles. The particles free in solution will cluster and decluster due to the thermocycling (because, e.g., the Tm can be below 95°C). The Tm of the amplicon binding to one of the particle-immobilized capture probes can be designed such that that binding interaction is more favorable than the particle-to-particle binding interaction (by, e.g., engineering point mutations within the capture probes to thermodynamically

destabilize the duplexes). In this embodiment, the particle concentration can be kept at, e.g., low or high levels. Examples of probes and primers useful in such a system are set forth in the table below.

C. albicans ITS2 Reverse P	5'- CCG TCT TTC AAG CAA ACC CAA GTC G -3' (SEQ ID NO. 24)
C. albicans ITS2 Forward P	5'- TTT CTC CCT CAA ACC GCT GG -3' (SEQ ID NO. 25)

C.alb ITS2 mut 4 CP1	5'- /5AmMC12/TT TTT TTT TTT TGG TCT GGC GTA GAG CCA TAC G -3' (SEQ ID NO. 31)

5   Previous work showed that in some cases the presence of particles in the PCR reaction could inhibit PCR. For these inhibitory particles, it is envisioned that the particles could be pulled to the side of the tube (or other location within the container) to keep them out of solution during the PCR reaction. Methods can be used to release the particles back into suspension to allow them to hybridize to the PCR product and then pull them back out of solution.

10   In certain embodiments, the invention features the use of enzymes compatible with whole blood, e.g., NEB Hemoklentaq, DNAP Omniklentaq, Kapa Biosystems whole blood enzyme, Thermo-Fisher Finnzymes Phusion enzyme.

The invention also features quantitative asymmetric PCR. In any of the real-time PCR methods of the invention, the method can involve the following steps:

15

1. aliquoting whole blood into a prepared PCR mastermix containing superparamagnetic particles;

2. prior to the first PCR cycle, closing the tube until PCR cycling is completed;

3. loading the tube onto thermal cycler;

4. running "n" cycles of standard PCR thermal cycling;

20   5. conducting a T2 detection (the exact time duration and steps for this vary depending on the biochemical and particle design approach described below); and

6. repeating steps 4 and 5 until enough T2 readings have been taken for an accurate quantification of initial target concentration.

25   The above methods can be used with any of the following categories of detection of aggregation or disaggregation described herein, including:

| Name | Description |

Clustering-based detection and magnetic separation	• Particles >100 nm or magnetic-separation compatible. • Particles removed from solution during PCR • T2 goes up with amplicon generation • Agitation during step 5
Clustering-based detection with particles >100 nm	• Particles >100 nm • Particles do not inhibit PCR • T2 goes up with amplicon generation • Agitation during step 5
De-clustering-based detection and magnetic separation	• Particles >100 nm • Particles on the side of the tube during PCR • T2 goes down with amplicon generation • Agitation during step 5
De-clustering-based detection with particles >100 nm	• Particles >100 nm • Particles do not inhibit PCR • T2 goes down with amplicon generation • Agitation during step 5
Clustering-based detection with particles <100 nm	• Particles <100 nm (e.g., 30 nm particles) • T2 goes down with amplicon appearance (at least for initial cycles, T2 may subsequently increase as cluster size increases) • Has potential for much more rapid hybridization times • No agitation required to keep particles suspended • Particle concentration in nM range
De-clustering-based detection with particles <100 nm	• Particles <100 nm (e.g., 30 nm particles) • T2 goes up with amplicon appearance • T2 could decrease as the cluster size increase above 100nm • No agitation required to keep particles suspended • Has potential for most rapid detection times • Particle concentration in nM range

A variety of impurities and components of whole blood can be inhibitory to the polymerase and primer annealing. These inhibitors can lead to generation of false positives and low sensitivities. To reduce the generation of false positives and low sensitivities when amplifying and detecting nucleic acids in complex samples, it is desirable to utilize a thermal stable polymerase not inhibited by whole blood samples (see, e.g., U.S. Patent No. 7,462,475) and include one or more internal PCR assay controls (see Rosenstraus et al. J. Clin Microbiol. 36:191 (1998) and Hoofar et al., J. Clin. Microbiol. 42:1863 (2004)). For example, to assure that clinical specimens are successfully amplified and detected, the assay can include an internal control nucleic acid that contains primer binding regions identical to those of the target sequence. As shown in the examples, the target nucleic acid and internal control can be selected such that each has a unique probe binding region that differentiates the internal control from the target nucleic acid. The internal control is, optionally, employed in combination with a processing positive control, a processing negative control, and a reagent control for the safe and accurate determination and identification of an infecting organism in, e.g., a whole blood clinical sample. The internal control can be an inhibition control that is designed to co-amplify with the nucleic acid target being detected. Failure of the internal inhibition control to be amplified is evidence of a reagent failure or process error. Universal primers can be designed such that the target sequence and the internal control sequence are amplified in the same reaction tube. Thus, using this format, if the target DNA is amplified but the internal control is

not it is then assumed that the target DNA is present in a proportionally greater amount than the internal control and the positive result is valid as the internal control amplification is unnecessary. If, on the other hand, neither the internal control nor the target is amplified it is then assumed that inhibition of the PCR reaction has occurred and the test for that particular sample is not valid. The assays of the invention can

5   include one or more positive processing controls in which one or more target nucleic acids is included in the assay (e.g., each included with one or more cartridges) at 3× to 5× the limit of detection. The measured T2 for each of the positive processing controls must be above the pre-determined threshold indicating the presence of the target nucleic acid. The positive processing controls can detect all reagent failures in each step of the process (e.g., lysis, PCR, and T2 detection), and can be used for quality control

10   of the system. The assays of the invention can include one or more negative processing controls consisting of a solution free of target nucleic acid (e.g., buffer alone). The T2 measurements for the negative processing control should be below the threshold indicating a negative result while the T2 measured for the internal control is above the decision threshold indicating an internal control positive result. The purpose of the negative control is to detect carry-over contamination and/or reagent

15   contamination. The assays of the invention can include one or more reagent controls. The reagent control will detect reagent failures in the PCR stage of the reaction (i.e. incomplete transfer of master mix to the PCR tubes). The reagent controls can also detect gross failures in reagent transfer prior to T2 detection.

20   **Contamination control**

One of the major problems in the use of PCR as an analytical tool is the risk of having new reactions contaminated with old, amplified products. Potential sources of contamination include a) large numbers of target organisms in clinical specimens that may result in cross-contamination, b) plasmid clones derived from organisms that have been previously analyzed and that may be present in larger

25   numbers in the laboratory environment, and c) repeated amplification of the same target sequence leading to accumulation of amplification products in the laboratory environment. A common source of the accumulation of the PCR amplicon is aerosolization of the product. Typically, if uncontrolled aerosolization occurs, the amplicon will contaminate laboratory reagents, equipment, and ventilation systems. When this happens, all reactions will be positive, and it is not possible to distinguish between

30   amplified products from the contamination or a true, positive sample. In addition to taking precautions to avoid or control this carry-over of old products, it is necessary to include a blank reference reaction in every PCR experiment to check for carry-over. In order to be certain that all results are reliable, there must be no amplified products after the temperature cycling. A carry-over contamination will be visible on the agarose gel as faint bands. Furthermore, it is also very important to include a positive sample. If,

35   contrary to expectation, the sample is negative, none of the results can be considered as trustworthy. (see Aslanzadeh et al., Annals of Clin Lab Science, 34:389 (2004)).

It is conceivable that the reagents used to prepare the PCR may be contaminated. After the amplification a positive sample may contain 250 ng PCR product in 50 μl. This gives a total of 3.9 1011 copies of a 600 bp double-stranded product. One thousandth of a microliter of this reaction will contain approximately 8 million copies. If a very small and invisible aerosol is formed when the PCR vessel is

5   opened, there is a possibility that this aerosol can contain a very large number of amplified products. Furthermore, the microscopic droplets in an aerosol are able to float for a long time in the air, and if there is turbulence in the room, they can be carried a long way. Considering the fact that only one copy is enough to create a false positive reaction, it is obvious that great care must be taken to avoid this carry-over contamination.

10   To address the problem of contamination problem, one or more of the following protocols can be used:

(i) Replace all reagents and stock buffers with new chemicals and new water which have never been in contact with the areas of sample preparation and PCR analysis.

(ii) Physically divide the area of reagent mixing and sample preparation from the area of product

15   analysis (Kwok & Higuchi, Nature, 339:237 (1989)).

(iii) Sample preparation workstations can be cleaned (e.g., with 10% sodium hypochlorite solution, followed by removal of the bleach with ethanol). Oxidative breakdown of nucleic acids prevents reamplification of impurities in subsequent PCR reactions.

(iv) Sterilization of the amplification products ensures that subsequent diagnostic assays are not

20   compromised by carryover DNA, and must follow two generally accepted criteria: (a) the PCR needs to be exposed to the environment after there has been some form of modification of amplicon, and (b) the modification must not interfere with the detection method. For example, UV irradiation can effectively remove contaminating DNA (see Rys et al., J. Clin Microbiol. 3:2356 (1993); and Sarker et al., Nature, 343:27 (1990)), but the irradiation of the PCR reagents must take place before addition of polymerase,

25   primers, and template DNA. Furthermore, this approach may be inefficient because the large numbers of mononucleotides present in the reaction will absorb much of the UV light (See Frothingham et al., BioTechniques 13:208 (1992)). UV light sterilization of the amplification products uses the property of UV light to induce thymine dimmers and other covalent modifications of the DNA that render the contaminating DNA un-amplifiable. Alternatively, incorporation of dUTP into the amplified fragments

30   will also alter the composition of the product so that it is different from the template DNA composition (see Longo et al., Gene 93:125 (1990); and U.S. Patent Nos. 5,035,996; 7,687,247; and 5,418,149). The enzyme Uracil-N-Glycosylase (UNG) is added together with the normal PCR enzyme to the reaction mix. The UNG enzyme will cleave the uracil base from DNA strands before amplification, and leave all the old amplified products unable to act as templates for new amplification, but will not react on

35   unincorporated dUTP or new template. This will efficiently remove contaminating PCR products from the reaction after the PCR vessel has been closed, and thus no new contamination is possible. However, the use of dUTP in PCR reactions to prevent carry-over can cause problems when the products are used in

a later hybridization study, due to the low capability of uracil to act in hybridization (Carmody et al., Biotechniques 15:692 (1993)). dUTP is incorporated instead of dTTP. When a probe rich in T's is amplified with the substitution of dTTP for dUTP in the reaction mixture, a later hybridization signal with the probe may be eliminated. To avoid the decrease in hybridization signal the probe binding site should

5   be chosen with no more than 25% T's, and without stretches of poly-T. Furthermore, the PCR should contain equal concentrations of dUTP and dTTP and not only dUTP. In contrast to the decrease in hybridization signal is the increase in product amplification when using dUTP, especially when AT-rich target sequences are selected. This is probably because the incorporation of dUTP decreases re-annealing of formed PCR products which would prevent primers from annealing. If this approach is used to

10   increase the product yield, the primer binding sites should be selected with a low content of T's, since primer annealing also will be inhibited by dUTP incorporation (Carmody et al., Biotechniques 15:692 (1993)). Heat labile UDG isolated from BMTU 3346 is described in Schmidt et al. Biochemica 2:13 (1996) (see also U.S. Patent No. 6,187,575). A uracil-DNA glycosylase gene from Psychrobacter sp HJ147 was described in U.S. Patent No. 7,723,093. Lastly a cod uracil-DNA glycosylase was described

15   (U.S. Patent No. 7,037,703).

(v) DNase digestion after PCR can be used to reduce contamination. A heat labile DNase enzyme was identified that can be used to digest ds DNA to remove any contaminating DNA prior to the PCR amplification step of the target DNA. In this case, the ds DNA is digested, the sample is heated to inactivate the DNase, and the target sample and PCR reactants are added to the reaction tube to carry out

20   the target specific PCR. (see U.S. Patent No. 6,541,204).

(vi) Sterilization after PCR can be used to reduce contamination. Incorporation of a photochemical reagent (isopsoralen) into the product during amplification will create a difference in composition between the template DNA and the amplified PCR products (see Rys et al., J. Clin Microbiol. 3:2356 (1993)). Furocoumarin compounds, such as isopsoralen or psoralen, are a class of

25   planar tricylcic reagents that are known to intercalate between base pairs of nucleic acids (see U.S. Patent No. 5,532,145). Light treatment of the closed PCR vessel will render previously formed PCR products unable to act as templates for further amplification. The hybridization abilities of the product are not changed, but the detection capabilities on agarose gel can be decreased due to reduced binding of EtBr. Isopsoralen of 25 mg/ml was shown to be ineffective at preventing contamination, and at concentrations

30   up to 100mg/ml, isopsoralen may have an inhibitory effect on the PCR reaction itself (see U.S. Patent No. 5,221,608). Alternatively, primer hydrolysis can be used to sterilize a reaction after amplification. Primer hydrolysis of sterilization of amplification products relies on the uniquely synthesized chimeric primers that contain one or more ribose linkages at the 3' end. The generated amplification products containing those ribose residues are susceptible to alkaline hydrolysis at the site of the ribose molecule.

35   The method includes exposure to 1M NaOH and incubated for 30 minutes to hydrolyze the amplification products at the sites of the incorporated ribose. Thus, if there is carryover contamination, the old amplicon has lost its primer site due to the hydrolysis of the ribose molecules and the new amplicon will

have the primer binding sites. In another approach, addition of hydroxylamine hydrochloride to PCR reaction tubes after amplification sterilizes the reaction contents, and is especially effective for short (<100bp) and GC rich amplification products. The hydroxylamine preferentially reacts with oxygen atoms in the cytosine residues and creates covalent adducts that prevent base-pairing with guanine

5   residues in subsequent reactions. Thus, the modified amplification product are not recognized as amplification targets in subsequent PCR reactions.

(vii) Prevention of carry-over by changing the product composition from the template can reduce contamination. In one approach the DNA composition of the PCR product can be different from the natural template DNA composition. This altered composition is intended to make the PCR products

10   sensitive to treatment that will not alter the template DNA. The treatment of the closed PCR vessel just before amplification should make the contaminating PCR product unable to participate in the amplification. Here the modification would have to be innocuous to the detection method. The types of modifications that can be useful in distinguishing contaminant amplification product will be apparent, but include introduction of a ligand, cross-linking agent, enzyme recognition site, or other cleavable moiety

15   (See U.S. Patent Nos.5,427,929; 5,650,302; 5,876,976; and 6,037,152).

One or more of the methods described above can be used in conjunction with the methods of the invention to reduce the risk of contamination and false positives. Carry-over of old amplified PCR products can be a very serious risk in the nucleic acid analysis in the T2 Biosystems diagnostic platform. One way to prevent this contamination is to physically divide the PCR working areas. Alternatives to the

20   physical separation of the PCR reaction method include UV irradiation of PCR mix and incorporation of reagents into the newly formed PCR product can be used to alter it from the template.

Reaction Kinetics

The reaction of magnetic particles and specific analytes to form aggregates can be used to

25   produce a diagnostic signal in the assays of the invention. In many instances, incubation of the reaction mixture for a period of time is sufficient to form the aggregates. The methods, kits, cartridges, and devices of the invention can be configured to shorten the amount of time needed to capture a particular analyte, or produce aggregates of magnetic particles. While altering the overall concentration of magnetic particles would appear to be a simple and direct approach to increasing aggregation rates, this

30   approach is complicated by (i) nonspecific aggregation that can arise with high magnetic particle concentrations, and (ii) the need to produce an observable signal change (i.e., change in relaxation signal) in response to aggregation in the presence of a low concentration of analyte. Reaction kinetics can be improved, for example, by mechanically induced aggregation, by acoustically induced aggregation, by ultrasonically induced aggregation, by electrostatically induced aggregation, or by trapping the magnetic

35   particles in a portion of the liquid sample.

Mechanically induced aggregation

The kinetics of aggregation can be increased by passing the particle/analyte solution through a vessal in which there is a narrowing of the path of the fluid flow. The narrowing enhances particle-particle interactions.

Acoustically induced aggregation

The aggregation of magnetic particles can be accelerated by applying an acoustic standing wave to the sample (see Aboobaker et al., Journal of Enviromnental Engineering, 129:427 (2003) and U.S. Patent No. 4,523,682). For example, a flow chamber with two transducers at opposite ends can be used to generate an acoustic standing wave in the sample that causes the magnetic particles to migrate (or be segregated) in a manner that increases the rate of magnetic particle aggregation.

Ultrasonically induced aggregation

The aggregation of magnetic particles can be accelerated by applying an ultrasonic wave to the sample (see Masudo et al., Anal. Chem. 73:3467 (2001)). In the presence of a standing plane ultrasound wave particles can move to the node of the wave along the ultrasound force gradient. This approach can be used to provide a reliable method for assisting the agglomeration reaction.

Electrostatically induced aggregation

The aggregation of magnetic particles can be accelerated by electrostatic interactions. Electrostatic separation or movement of the magnetic particles utilizes inherent differences in friction charge characteristics, electric conductivity, and dielectric constants. Since the magnetic particles will behave differently under the application of an electrostatic field, movement and enhanced collisions can occur. Electrostatic force exertion on the particles can be proportional to the surface area available for surface charge, so the nanoparticles will typically move in the presence of the electrostatic field when coated with varying materials, such as dextran or other large molecular coatings, and whether or not the nanoparticle has bound to one of the binding moieties a analyte. The nanoparticles must first be charged and the charge could optionally be pulsed. See, for example, Sinyagin et al., J. Phys. Chern. B 110:7500 (2006); Kretschmer et al., Langmuir 20:11797 (2004); Bernard et al., Nanotechnology 18: 235202 (2007); and Costanzo et al., Lab Chip 2005 5:606 (2005).

Trapping

The magnetic particles derivatized with a binding moiety can be held in position by an external magnetic field while sample containing the corresponding analyte is circulated past the "trapped" magnetic particles allowing for capture and/or concentrate the analyte of interest. The capture and/or aggregation can be facilitated by exposure to a magnetic field (i.e., MAA or gMAA) as described herein.

Alternatively, the kinetics of magnetic particle aggregation can be increased by sequestering the magnetic particles in a compartment defined by a porous membrane, such as a tea bag, that permits flow

of analytes into and out of the compartment. The increase in the local concentration of magnetic particles can increase the reaction kinetics between magnetic particles and analytes, and the kinetics of aggregation. After mixing the solution and magnetic particles for a predetermined period of time, the magnetic particles are released from the compartment and the sample is measured.

5   In certain instances, the particles may be pulled to the side or bottom of the assay vessel, or a magnetizable mesh or magnetizable metal foam with appropriate pore size can be present in the reaction vessel, creating very high local magnetic gradients. The metal foam generates very high local magnetic field gradients over very short distances which can attract the derivatized magnetic particles and bring them in contact with the complementary binding partner on the metal foam and improve the chances of a

10   specific productive interaction. An advantage of having the mesh/metal foam in the reaction vessel is that the distance each magnetic particle needs to travel to be "trapped" or "captured" can be very short, improving assay kinetics. For example, to a reaction tube can be added a magnetizable mesh foam having pores of 100 to 1000 microns, a liquid sample, and magnetic particles for detecting an analyte in the liquid sample. The reaction tube is exposed to a magnetic field to magnetize the mesh. The magnetic

15   particles are then attracted to the magnetized mesh and become trapped within the pores of the mesh. The concentration of the magnetic particles within the mesh increases the reaction kinetics between the magnetic particles and the analyte diffusing into and out of the mesh (the reaction tube is optionally agitated to expedite the diffusion of analyte onto the trapped magnetic particles). The mesh is then demagnetized (e.g., by heating the mesh or exposing the mesh to an alternating magnetic field), thereby

20   permitting the release of magnetic particles complexed to analyte. Larger aggregates of magnetic particles can then be formed, completing the reaction.

        In an analogous approach, the kinetics of magnetic particle aggregation can be increased by centrifugally pulling the magnetic particles down to the bottom of the sample tube. The increase in the local concentration of magnetic particles can increase the aggregation kinetics. To facilitate separation by

25   centrifugation the particles are, desirably, greater than about 30 nm in diameter.

NMR Units

        The systems for carrying out the methods of the invention can include one or more NMR units. Figure 1A is a schematic diagram 100 of an NMR system for detection of a signal response of a liquid

30   sample to an appropriate RF pulse sequence. A bias magnet 102 establishes a bias magnetic field Bb 104 through a sample 106. The magnetic particles are in a liquid or lyophilized state in the cartridge prior to their introduction to a sample well (the term "well" as used herein includes any indentation, vessel, container, or support) 108 until introduction of the liquid sample 106 into the well 108, or the magnetic particles can be added to the sample 106 prior to introduction of the liquid sample into the well 108. An

35   RF coil 110 and RF oscillator 112 provides an RF excitation at the Larmor frequency which is a linear function of the bias magnetic field Bb. In one embodiment, the RF coil 110 is wrapped around the sample well 108. The excitation RF creates a nonequilibrium distribution in the spin of the water protons

(or free protons in a non-aqueous solvent). When the RF excitation is turned off, the protons "relax" to their original state and emit an RF signal that can be used to extract information about the presence and concentration of the analyte. The coil 110 acts as an RF antenna and detects a signal, which based on the applied RF pulse sequence, probes different properties of the material, for example a T_2 relaxation. The signal of interest for some cases of the technology is the spin-spin relaxation (generally 10-2000 milliseconds) and is called the T_2 relaxation. The RF signal from the coil 110 is amplified 114 and processed to determine the T_2 (decay time) response to the excitation in the bias field Bb. The well 108 may be a small capillary or other tube with nanoliters to microliters of the sample, including the analyte and an appropriately sized coil wound around it (see Figure 1B). The coil is typically wrapped around the sample and sized according to the sample volume. For example (and without limitation), for a sample having a volume of about 10 ml, a solenoid coil about 50 mm in length and 10 to 20 mm in diameter could be used; for a sample having a volume of about 40 µl, a solenoid coil about 6 to 7 mm in length and 3.5 to 4 mm in diameter could be used; and for a sample having a volume of about 0.1 nl a solenoid coil about 20 µm in length and about 10 µm in diameter could be used. Alternatively, the coil may be configured as shown in any of Figures 2A-2E about or in proximity to the well. An NMR system may also contain multiple RF coils for the detection of multiplexing purposes. In certain embodiments, the RF coil has a conical shape with the dimensions 6 mm×6 mm×2mm.

Figures 2A-2E illustrate exemplary micro NMR coil (RF coil) designs. Figure 2A shows a wound solenoid micro coil 200 about 100 µm in length, however one could envision a coil having 200µm, 500µm or up to 1000 µm in length. Figure 2B shows a "planar" coil 202 (the coil is not truly planar, since the coil has finite thickness) about 1000 µm in diameter. Figure 2C shows a MEMS solenoid coil 204 defining a volume of about 0.02 µL. Figure 2D shows a schematic of a MEMS Helmholz coil 206 configuration, and Figure 2E shows a schematic of a saddle coil 220 configuration.

A wound solenoid micro coil 200 used for traditional NMR detection is described in Seeber et al., "Design and testing of high sensitivity micro-receiver coil apparatus for nuclear magnetic resonance and imaging," Ohio State University, Columbus, Ohio. A planar micro coil 202 used for traditional NMR detection is described in Massin et al., "High Q factor RF planar microcoil for micro-scale NMR spectroscopy," Sensors and Actuators A 97-98, 280-288 (2002). A Helmholtz coil configuration 206 features a well 208 for holding a sample, a top Si layer 210, a bottom Si layer 212, and deposited metal coils 214. An example of a Helmholtz coil configuration 206 used for traditional NMR detection is described in Syms et al, "MEMS Helmholz Coils for Magnetic Resonance Spectroscopy," Journal of Micromechanics and Micromachining 15 (2005) S1-S9.

The NMR unit includes a magnet (i.e., a superconducting magnet, an electromagnet, or a permanent magnet). The magnet design can be open or partially closed, ranging from U- or C-shaped magnets, to magnets with three and four posts, to fully enclosed magnets with small openings for sample placement. The tradeoff is accessibility to the "sweet spot" of the magnet and mechanical stability (mechanical stability can be an issue where high field homogeneity is desired). For example, the NMR

unit can include one or more permanent magnets, cylindrically shaped and made from SmCo, NdFeB, or other low field permanent magnets that provide a magnetic field in the range of about 0.5 to about 1.5 T (i.e., suitable SmCo and NdFeB permanent magnets are available from Neomax, Osaka, Japan). For purposes of illustration and not limitation, such permanent magnets can be a dipole/box permanent

5   magnet (PM) assembly, or a hallbach design (See Demas et al., Concepts Magn Reson Part A 34A:48 (2009)). The NMR units can include, without limitation, a permanent magnet of about 0.5T strength with a field homogeneity of about 20-30 ppm and a sweet spot of 40 µL, centered. This field homogeneity allows a less expensive magnet to be used (less tine fine-tuning the assembly/shimming), in a system less prone to fluctuations (e.g. temperature drift, mechanical stability over time-practically any impact is much

10   too small to be seen), tolerating movement of ferromagnetic or conducting objects in the stray field (these have less of an impact, hence less shielding is needed), without compromising the assay measurements (relaxation measurements and correlation measurements do not require a highly homogeneous field).

The coil configuration may be chosen or adapted for specific implementation of the micro-NMR-MRS technology, since different coil configurations offer different performance characteristics. For

15   example, each of these coil geometries has a different performance and field alignment. The planar coil 202 has an RF field perpendicular to the plane of the coil. The solenoid coil 200 has an RF field down the axis of the coil, and the Helmholtz coil 206 has an RF field transverse to the two rectangular coils 214. The Helmholtz 206 and saddle coils 220 have transverse fields which would allow the placement of the permanent magnet bias field above and below the well. Helmholtz 206 and saddle coils 220 may be most

20   effective for the chip design, while the solenoid coil 200 may be most effective when the sample and MRS magnetic particles are held in a micro tube.

The micro-NMR devices may be fabricated by winding or printing the coils or by microelectromechanical system (MEMS) semiconductor fabrication techniques. For example, a wound or printed coil/sample well module may be about 100 µm in diameter, or as large as a centimeter or more. A

25   MEMS unit or chip (thusly named since it is fabricated in a semiconductor process as a die on a wafer) may have a coil that is from about 10 µm to about 1000 µm in characteristic dimension, for example. The wound or printed coil/sample well configuration is referenced herein as a module and the MEMS version is referenced herein as a chip. For example, the liquid sample 108 may be held in a tube (for example, a capillary, pipette, or micro tube) with the coil wound around it, or it may be held in wells on the chip with

30   the RF coil surrounding the well. Alternatively, the sample is positioned to flow through a tube, capillary, or cavity in the proximity to the RF coil.

The basic components of an NMR unit include electrical components, such as a tuned RF circuit within a magnetic field, including an MR sensor, receiver and transmitter electronics that could be including preamplifiers, amplifiers and protection circuits, data acquisitions components, pulse

35   programmer and pulse generator.

Systems containing NMR units with RF coils and micro wells containing magnetic particle sensors described herein may be designed for detection and/or concentration measurement of specific

analyte(s) of interest by development of a model for particle aggregation phenomena and by development of an RF-NMR signal chain model. For example, experiments can be conducted for analyte/magnetic particle systems of interest by characterizing the physics of particle aggregation, including, for example, the effects of affinities, relevant dimensions, and concentrations. Also, experiments can be conducted to

5   characterize the NMR signal(s) (T_2, T_1, T_2^*, T_{2rho}, T_{1rho} and/or other signal characteristics, such as T1/T2 hybrid signals and may also include but are not limited to diffusion, susceptibility, frequency) as functions of particle aggregation or depletion and magnetic particle characteristics. Signal characteristics specific to the MRS (magnetic resonance switch) phenomenon in a given system can be used to enhance detection sensitivity and/or otherwise improve performance.

10   The NMR system may include a chip with RF coil(s) and electronics micromachined thereon. For example, the chip may be surface micromachined, such that structures are built on top of a substrate. Where the structures are built on top of the substrate and not inside it, the properties of the substrate are not as important as in bulk micromachining, and expensive silicon wafers used in bulk micromachining can be replaced by less expensive materials such as glass or plastic. Alternative embodiments, however,

15   may include chips that are bulk micromachined. Surface micromachining generally starts with a wafer or other substrate and grows layers on top. These layers are selectively etched by photolithography and either a wet etch involving an acid or a dry etch involving an ionized gas, or plasma. Dry etching can combine chemical etching with physical etching, or ion bombardment of the material. Surface micromachining may involve as many layers as is needed.

20   In some cases, an inexpensive RF coil maybe integrated into a disposable cartridge and be a disposable component. The coil could be placed in a manner that allows electrical contact with circuitry on the fixed NMR setup, or the coupling could be made inductively to a circuit.

Where the relaxation measurement is T_2, accuracy and repeatability (precision) will be a function of temperature stability of the sample as relevant to the calibration, the stability of the assay, the signal-to-

25   noise ratio (S/N), the pulse sequence for refocusing (e.g., CPMG, BIRD, Tango, and the like), as well as signal processing factors, such as signal conditioning (e.g., amplification, rectification, and/or digitization of the echo signals), time/frequency domain transformation, and signal processing algorithms used. Signal-to-noise ratio is a function of the magnetic bias field (Bb), sample volume, filling factor, coil geometry, coil Q-factor, electronics bandwidth, amplifier noise, and temperature.

30   In order to understand the required precision of the T_2 measurement, one should look at a response curve of the assay at hand and correlate the desired precision of determining the analyte concentration and the precision of the measureable, e.g., T_2 for some cases. Then a proper error budget can be formed.

For example, to obtain a 10-fold improvement in the 0.02 ng/mL detection limit for Troponin

35   (10-fold increase in sensitivity), it would be necessary to discern a delta-T_2 less than about 5.6 milliseconds from a traditional (non-MRS-measured) T_2 of about 100 milliseconds. The minimum signal-to-noise ratio (S/N) would need to be about 20 to detect this difference.

The NMR units for use in the systems and methods of the invention can be those described in U.S. Patent No. 7,564,245, incorporated herein by reference.

The NMR units of the invention can include a small probehead for use in a portable magnetic resonance relaxometer as described in PCT Publication No. WO09/061481, incorporated herein by reference.

The systems of the invention can be implantable or partially implantable in a subject. For example, the NMR units of the invention can include implantable radiofrequency coils and optionally implantable magnets as described in PCT Publication Nos. WO09/085214 and WO08/057578, each of which is incorporated herein by reference.

The systems of the invention can include a polymeric sample container for reducing, partly or completely, the contribution of the NMR signal associated with the sample container to the nuclear magnetic resonance parameter of the liquid sample as described in PCT Publication No. WO09/045354, incorporated herein by reference.

The systems of the invention can include a disposable sample holder for use with the MR reader that is configured to permit a predetermined number of measurements (i.e., is designed for a limited number of uses). The disposable sample holder can include none, part, or all, of the elements of the RF detection coil (i.e., such that the MR reader lacks a detection coil). For example, the disposable sample holder can include a "read" coil for RF detection that is inductively coupled to a "pickup" coil present in the MR reader. When the sample container is inside the MR reader it is in close proximity to the pickup coil and can be used to measure NMR signal. Alternatively, the disposable sample holder includes an RF coil for RF detection that is electrically connected to the MR reader upon insertion of the sample container. Thus, when the sample container is inserted into the MR reader the appropriate electrical connection is established to allow for detection. The number of uses available to each disposable sample holder can be controlled by disabling a fusable link included either in the electrical circuit within the disposable sample holder, or between the disposable sample holder and the MR reader. After the disposable sample holder is used to detect an NMR relaxation in a sample, the instrument can be configure to apply excess current to the fusable link, causing the link to break and rendering the coil inoperable. Optionally, multiple fusable links could be used, working in parallel, each connecting to a pickup on the system, and each broken individually at each use until all are broken and the disposable sample holder rendered inoperable.

Cartridge Units

The systems for carrying out the methods of the invention can include one or more cartridge units to provide a convenient method for placing all of the assay reagents and consumables onto the system. For example, the system may be customized to perform a specific function, or adapted to perform more than one function, e.g., via changeable cartridge units containing arrays of micro wells with customized magnetic particles contained therein. The system can include a replaceable and/or interchangeable

cartridge containing an array of wells pre-loaded with magnetic particles, and designed for detection and/or concentration measurement of a particular analyte. Alternatively, the system may be usable with different cartridges, each designed for detection and/or concentration measurements of different analytes, or configured with separate cartridge modules for reagent and detection for a given assay. The cartridge

5   may be sized to facilitate insertion into and ejection from a housing for the preparation of a liquid sample which is transferred to other units in the system (i.e., a magnetic assisted agglomeration unit, or an NMR unit). The cartridge unit itself could potentially interface directly with manipulation stations as well as with the MR reader(s). The cartridge unit can be a modular cartridge having an inlet module that can be sterilized independent of the reagent module.

10   For handling biological samples, such as blood samples, there are numerous competing requirements for the cartridge design, including the need for sterility for the inlet module to prevent cross contamination and false positive test results, and the need to include reagents in the package which cannot be easily sterilized using standard terminal sterilization techniques like irradiation. An inlet module for sample aliquoting can be designed to interface with uncapped vacutainer tubes, and to aliquot two a

15   sample volume that can be used to perform, for example, a candida assay (see Figures 7D-7F). The vacutainer permits a partial or full fill. The inlet module has two hard plastic parts, that get ultrasonically welded together and foil sealed to form a network of channels to allow a flow path to form into the first well overflow to the second sample well. A soft vacutainer seal part is used to for a seal with the vacutainer, and includes a port for sample flow, and a venting port. To overcome the flow resistance once

20   the vacutainer is loaded and inverted, some hydrostatic pressure is needed. Every time sample is removed from a sample well, the well will get replenished by flow from the vacutainer.

A modular cartridge can provide a simple means for cross contamination control during certain assays, including but not limited to distribution of PCR products into multiple detection aliquots. In addition, a modular cartridge can be compatible with automated fluid dispensing, and provides a way to

25   hold reagents at very small volumes for long periods of time (in excess of a year). Finally, pre-dispensing these reagents allows concentration and volumetric accuracy to be set by the manufacturing process and provides for a point of care use instrument that is more convenient as it can require much less precise pipetting.

The modular cartridge of the invention is a cartridge that is separated into modules that can be

30   packaged and if necessary sterilized separately. They can also be handled and stored separately, if for example the reagent module requires refrigeration but the detection module does not. Figure 6 shows a representative cartridge with an inlet module, a reagent module and a detection module that are snapped together. In this embodiment, the inlet module would be packaged separately in a sterile package and the reagent and detection modules would be pre-assembled and packaged together.

35   During storage, the reagent module could be stored in a refrigerator while the inlet module could be stored in dry storage. This provides the additional advantage that only a very small amount of refrigerator or freezer space is required to store many assays. At time of use, the operator would retrieve

a detection module and open the package, potentially using sterile technique to prevent contamination with skin flora if required by the assay. The Vacutainer tube is then decapped and the inverted inlet module is placed onto the tube as shown in Figure 7A. This module has been designed to be easily moldable using single draw tooling as shown in Figures 7B and 7C and the top and bottom of the

5   cartridge are sealed with foil to prevent contamination and also to close the channels. Once the tube has been re-sealed using the inlet module, the assembly is turned right side up and snapped onto the remainder of the cartridge. The inlet section includes a well with an overflow that allows sample tubes with between 2 and 6ml of blood to be used and still provide a constant depth interface to the system automation. It accomplishes this by means of the overflow shown in Figure 8, where blood that

10   overflows the sampling well simply falls into the cartridge body, preventing contamination.

Figures 9A-9C show the means of storing precisely pipetted small volume reagents. The reagents are kept in pipette tips that are shown in Figure 9C. These are filled by manufacturing automation and then are placed into the cartridge to seal their tips in tight fitting wells which are shown in a cutaway view Figure 9B. Finally, foil seals are placed on the back of the tips to provide a complete water vapor proof

15   seal. It is also possible to seal the whole module with a seal that will be removed by the operator, either in place of or in addition to the aforementioned foils. This module also provides storage for empty reaction vessels and pipette tips for use by the instrument while the detection module provides storage for capped 200 μl PCR vials used by the instrument to make final measurements from.

Figures 10-13C show an alternative embodiment of the detection module of the cartridge which is

20   design to provide for contamination control during, for example, pipetting of post-PCR (polymerase chain reaction) products. This is required because the billion fold amplification produced by PCR presents a great risk of cross contamination and false positives. However, it is desirable to be able to aliquot this mixture safely, because low frequency analytes will have been amplified up and can be distributed for separate detection or identification. There are three ways in which this portion of the cartridge aids in

25   contamination control during this aliquoting operation.

First, the cartridge contains a recessed well to perform the transfer operations in as shown in Figures 10A and 10B. Second, the machine provides airflow through this well and down into the cartridge through holes in the bottom of the well, as shown in Figure 11. The depth of the well is such that a pipette tip will remain in the airflow and prevent any aerosol from escaping. Figure 12 depicts a

30   bottom view of the detection module, showing the bottom of the detection tubes and the two holes used to ensure airflow. An optional filter can be inserted here to capture any liquid aerosol and prevent it from entering the machine. This filter could also be a sheet of a hydrophobic material like Gore-tex that will allow air but not liquids to escape. Finally, there is a special seal cap on each 200ul tube to provide a make then break seal for each pipette tip as it enters the vessel, as shown in Figures 13A-13C. It is

35   contemplated that the pipette tip used for aliqouting be stored in this well at all, thus making it possible for the tip never to leave the controlled air flow region.

Alternatively, the modular cartridge is designed for a multiplexed assay. The challenge in multiplexing assays is combining multiple assays which have incompatible assay requirements (i.e., different incubation times and/or temperatures) on one cartridge. The cartridge format depicted in Figures 14A-14C allows for the combination of different assays with dramatically different assay requirements. The cartridge features two main components: (i) a reagent module (i.e., the reagent strip portion) that contains all of the individual reagents required for the full assay panel, and (ii) the detection module. The detection modules contain only the parts of the cartridge that carry through the incubation, and can carry single assays or several assays, as needed. The detection module depicted in Figure 14B includes two detection chambers for a single assay, the first detection chamber as the control and the second detection chamber for the sample. This cartridge format is expandable in that additional assays can be added by including reagents and an additional detection module.

The operation of the module begins when the user inserts the entire or a portion of the cartridge into the instrument. The instruments performs the assay actuation, aliquoting the assays into the separate detection chambers. These individual detection chambers are then disconnected from the reagent strip and from each other, and progress through the system separately. Because the reagent module is separated and discarded, the smallest possible sample unit travels through the instrument, conserving internal instrument space. By splitting up each assay into its own unit, different incubation times and temperatures are possible as each multiplexed assay is physically removed from the others and each sample is individually manipulated.

The cartridge units of the invention can include one or more populations of magnetic particles, either as a liquid suspension or dried magnetic particles which are reconstituted prior to use. For example, the cartridge units of the invention can include a compartment including from 1×10^6 to 1×10^{13} magnetic particles (e.g., from 1×10^6 to 1×10^8, 1×10^7 to 1×10^9, 1×10^8 to 1×10^{10}, 1×10^9 to 1×10^{11}, 1×10^{10} to 1×10^{12}, 1×10^{11} to 1×10^{13}, or from 1×10^7 to 5×10^8 magnetic particles) for assaying a single liquid sample.

MAA Units

The systems for carrying out the methods of the invention can include one or more magnetic assisted agglomeration (MAA) units to expedite agglomeration of the magnetic particles, allowing the assay reactions to reach completion (i.e., a stable reading) more quickly. The methods of the invention utilize functionalized magnetic particles to interact with analytes or multivalent binding agents (with multiple binding sites). Agglomeration of the magnetic particles alters the spin-spin relaxation rate of the sample when exposed to a magnetic field with a subsequent change in T_2 relaxation time.

For example, a field gradient can be used to sweep magnetic particles (MPs) through the liquid sample, allowing the magnetic particles to bind to either specific antibody (analyte-coated magnetic particles) or analyte (antibody-coated magnetic particles), and then concentrating the magnetic particles in a portion of the reaction chamber so as to facilitate particle-particle interactions that lead to specific,

ligand/analyte induced agglomeration. The magnetic particles can optionally be allowed to diffuse in the absence of a magnetic field, sonicated, vortexed, shaken, or subjected to ultrasonic mixing to break apart non-specific magnetic particle interactions and re-distribute the magnetic particles back into the liquid sample. The process can be repeated to promote further specific agglomeration. This cycling of

5   magnetic particles between being dispersed in the liquid sample and then concentrated at the side or bottom of the reaction vessel can be repeated as many times as necessary to maximize specific agglomeration, and consequently maximize the assay signal. The agglomeration state of the magnetic particles can be determined using an NMR relaxation measurement.

The MAA method of the invention can employ a gradient magnetic field in order to promote

10   rapid magnetic particle-particle interactions. In one example, analyte coated magnetic particles are added to a solution with a multimeric-analyte specific ligand and placed in a gradient magnetic field. The magnetic field causes particles to concentrate on the side or bottom of a reaction vessel (highest magnetic field strength) resulting in enhanced particle-particle interaction and subsequent aggregation. Aggregation is measured by observing a change in, for example, T_2 signal. Improvements of 10 to 1000

15   percent signal change (e.g., from 10 to 30%, from 20% to 50%, from 40% to 80%, from 50% to 200%, from 100% to 500%, or from 500% to 1000% signal change) can be observed.

Traditional homogenous MAA takes advantage of dipole-dipole forces for assisting particle-particle interactions while particle dipoles are aligned with the magnetic field of the hMAA unit throughout the liquid sample. In contrast, gradient MAA rapidly concentrates magnetic particles to a

20   locus, thereby greatly facilitating particle-particle interactions.

The cycling MAA approach described herein can accelerate the kinetics of magnetic particle-analyte clustering by (i) reducing the spatial entropy of the binding interaction step by maintaining local concentration of the magnetic particles, (ii) introducing localized mixing by magnet mediated transportation of the pellet from position to position, (iii) reducing shearing of the specific-bound clusters

25   by reducing the need for more energetic dispersion methods, such as vortexing, and/or (iv) changing the magnetic field direction, and thereby causing a local dispersion and re-aggregation of magnetically clustered particles as they re-align their dipoles with the new magnetic field direction, and allowing the locally dispersed magnetic particles to form specific binding interactions involving the target analyte.

In one example, magnet assemblies producing a magnetic field gradient are placed in two

30   positions relative to the assay tube, one to the side of the tube and one at the bottom of the tube (side-bottom configuration). Alternatively, the second magnet position can be located on a different side of the tube (side-side configuration). The tube then is moved to ensure exposure to one magnet followed by exposure to the other magnet (see Figure 15). This has also been observed to produce a similar enhancement in clustering.

35   An alternate methodology is to rotate the liquid sample within a gradient magnetic field (or to rotate the magnetic field gradient about the sample) to simultaneously effect a re-orientation of particles within the pellet (relative to the remainder of the liquid sample) and to sweep the pellet through the liquid

sample. The rate of rotation can be slow to allow the pellet of magnetic particles to largely remain held in proximity to the gradient magnet (rather than moving in concert with the solvent and analytes in liquid sample). For example, the rotation is typically slower than 0.0333 Hz (e.g., from 0.000833 Hz to 0.0333 Hz, from 0.00166 Hz to 0.0333 Hz, or from 0.00333 Hz to 0.0333 Hz), such that the particles are retained

5   adjacent to the magnetic field source, while the remaining contents in the tube are rotated.

A single gradient magnet can be used, while the sample can be moved around the magnet (or use the same location close to the magnet and alternate with a position removed from the field of the single magnet. The magnet could be moved to the proximity or away from the sample.

The sample can be placed between magnets of the same field orientation for a "field averaging"

10   effect in alternating fashion, in order to simplify the fabrication of a gMAA system (i.e., eliminate the need to carefully select magnets that generate same field profiles). For example a plurality of such magnets could be placed in a circular setup, and samples rotated via a carousel setup, from the first magnet to a null (small magnetic field exposure) to the second magnet etc. The rotary gMAA device can include a fixed baseplate to which an electric motor is attached, with a number of magnets mounted

15   around it in a circular pattern. The magnets are spaced such that there is minimal magnetic interference between positions. A carousel capable of holding sample vials is attached to the motor shaft such that it rotates with the motor, exposing the samples to different magnetic field orientations from one position to the next. Any combination of side-oriented magnets, bottom-oriented magnets and positions with very low residual field (null) can be used. See Figure 56A.

20   In another example, a homogenous field is used to expedite the agglomeration of magnetic particles in an assay of the invention. We have observed that hMAA is not as effective as exposure to field gradients in terms of concentrating particles and sweeping them through the sample, for timescales relevant to applications. However hMAA has advantages over the field gradient assisted agglomeration method. Using hMAA the magnetic particles are not enticed to move towards a specific location in the

25   tube (see Figure 16), minimizing non-specific trapping of particles within specific cluster fragments. Agitation after hMAA appears to minimize the non-specific binding. The hMAA treatment appears to enhance analyte induced clustering by increasing the collision frequency (a possible result of decreasing the particle's position and rotational entropies due to localization in an ordered state). The magnetic particles can subsequently be sonicated, vortexed, shaken (i.e., energy additions) to break apart any non-

30   specific particle interactions and re-distribute the particles back into the sample. Additional mixing or gentle agitation during this process would potentially further increase the analyte-specific binding events for enhancement of the overall assay signal. The agglomeration/clustering state of the magnetic particles can be determined by monitoring changes in an NMR relaxation rate. It is also possible to rotate the liquid sample within a homogenous magnetic field (or to rotate a homogenous magnetic field about the

35   sample) to expedite the aggregation of magnetic particles in a liquid sample.

We have observed that longer MAA times leads to increased changes in T_2, presumably from an increased fraction of clustered particles. We have found that cycled magnetic separation and

resuspension leads to increased changes in T_2 and increased clustering. All of these observations point towards a system that must be driven to a steady state or completion (e.g., maximally clustered).

The systems of the invention can include one or more MAA units. For example, the MAA unit can be one or more magnets configured to apply a gradient magnetic field in a first direction relative to the liquid sample, and, after repositioning the sample chamber, apply a gradient magnetic field in a second direction relative to the liquid sample (see Figure 17). Alternatively, the MAA unit can be an array of magnets configured to apply a gradient magnetic field to, e.g., the side of a liquid sample, and, after repositioning the sample chamber, to, e.g., the bottom of the liquid sample (see Figures 18A-18C). The systems of the invention can include an MAA unit configured to apply a homogenous magnetic field to one or more liquid samples (see Figures 19A and 19B).

Agitation Units

The systems for carrying out the methods of the invention can include one or more agitation units to break apart non-specific magnetic particle interactions and re-distribute the magnetic particles back into the liquid sample, or to simply agitate the sample tube to completely mix the assay reagents. For example, the agitation units can include a sonication, vortexing, shaking, or ultrasound station for mixing one or more liquid samples. Mixing could be achieved by aspiration dispensing or other fluid motion (e.g., flow within a channel). Also, mixing could be provided by a vibrating pipette or a pipette that moves from side to side within the sample tube.

The agitation unit can be vortexer or a compact vortexer each of which can be designed to provide a stable motion for the desired sample mixing.

The vortexer includes the following components: (i) a sample support, (ii) a main plate, (iii) four linkages, (iv) linear rail and carriage system (x2), (v) a support for driveshaft and rails, (vi) coupling and driveshaft, (vii) a mounting plate, and (viii) a drive motor (see Figure 20).

The compact vortexer includes the following components: (i) a sample support, (ii) a main plate, (iii) two linkages, (iv) linear rail and carriage system (x1), (v) a support for linear rail, (vi) support for driveshaft, (vii) coupling and driveshaft, (viii) a mounting plate, and (ix) a drive motor (see Figure 21).

The basic principle of motion for a vortexer is as follows: the driveshaft including one axis coaxial to the motor shaft, and a second that is offset and parallel to the motor shaft. When the motor shaft is attached to the driveshaft (typically through a helical coupling) and rotated, the offset axis of the driveshaft is driven in an orbital path. The typical offset is ¼" to produce a vortex in a single 0.2 mL sample tube, but this can be easily modified to effectively mix different sample volumes in other tube geometries.

Alternatively, the vortexer can be of the type utilizing a planetary belt drive (see Figures 23A-23C). Figure 23A is an overall view showing the vortexer configured for 1 large tube. Figure 23B is a section view showing 2 tube holders for small tubes. Figure 23C is an overall view of vortexer showing 4 tubes and a close-up of planetary belt drive mechanism.

The drive motor is typically a servo or stepper with an encoder. These motors have an "index" mark that allows the motor to find a specific point in its rotation. These index marks are used to home the system, and ensure that the sample can be returned to a known position after mixing. Knowing the exact position of the sample in the vortex station allows theses vortexers to be easily accessed by robotic

5   actuators and thus integrated into an automated system. In lieu of index marks, sensing devices external could be employed (see Figure 22A). These could be mechanical, magnetic, optical or other sensor that is capable of resolving the sample's position at any point along the system's path or at a fixed "home" position. In order to access a vortexers or centrifuge via a robotic sample holder/positioned, the system can include using an index mark or external switch to "home" the system to a set position after running,

10   using a sensor which tracks the sample motion at all times, so that wherever the system stops the robot knows the position, and using a "find" method that includes finding a sample after running that would employ a vision system that tracks the sample. The guide mechanism is depicted in Figure 22B. The main plate is connected to the offset axis of the drive shaft and is free to rotate. The plate follows the orbital path around and dictated by the motor shaft. One end of a linkage is connected to the main plate,

15   and is free to rotate. Therefore in this way, the connected linkage is then connected to the orbital rotation of the drive shaft. The other end of the linkage is connected to a carriage of the linear rail system and is free to rotate. Thus this end of the linkage follows the linear path of the rail. Having two linkages connected to both the carriage and main plate in this way prevents the main plate from rotating around its own center. In the vortexer, two linkages are used on two sides of the main plate (4 in total) to balance

20   and stabilize the entire system.

The two vortexers differ because of their use and design requirements. The compact version is designed to occupy less space, and requires less durability than this version because it is run at a lower speed, as limited by its smaller motor. For these reasons only two linkages are used to connect to a single linear rail system in the compact vortexer. This version needs to be capable of higher speeds, and a

25   nearly continuous utilization due to the large throughput capability of this system. For these reasons a second carriage and set of linkages is added to balance the system, and increase its durability.

Systems

The systems for carrying out the methods of the invention can include one or more NMR units,

30   MAA units, cartridge units, and agitation units. Such systems may further include other components for carrying out an automated assay of the invention, such as a PCR unit for the detection of oligonucleotides; a centrifuge, a robotic arm for delivery an liquid sample from unit to unit within the system; one or more incubation units; a fluid transfer unit (i.e., pipetting device) for combining assay reagents and a biological sample to form the liquid sample; a computer with a programmable processor

35   for storing data, processing data, and for controlling the activation and deactivation of the various units according to a one or more preset protocols; and a cartridge insertion system for delivering pre-filled

cartridges to the system, optionally with instructions to the computer identifying the reagents and protocol to be used in conjunction with the cartridge. See Figure 42.

The systems of the invention can provide an effective means for high throughput and real-time detection of analytes present in a bodily fluid from a subject. The detection methods may be used in a

5   wide variety of circumstances including, without limitation, identification and/or quantification of analytes that are associated with specific biological processes, physiological conditions, disorders or stages of disorders. As such, the systems have a broad spectrum of utility in, for example, drug screening, disease diagnosis, phylogenetic classification, parental and forensic identification, disease onset and recurrence, individual response to treatment versus population bases, and monitoring of therapy. The

10   subject devices and systems are also particularly useful for advancing preclinical and clinical stage of development of therapeutics, improving patient compliance, monitoring ADRs associated with a prescribed drug, developing individualized medicine, outsourcing blood testing from the central laboratory to the home or on a prescription basis, and monitoring therapeutic agents following regulatory approval. The devices and systems can provide a flexible system for personalized medicine. The system

15   of the invention can be changed or interchanged along with a protocol or instructions to a programmable processor of the system to perform a wide variety of assays as described herein. The systems of the invention offer many advantages of a laboratory setting contained in a desk-top or smaller size automated instrument.

The systems of the invention can be used to simultaneously assay analytes that are present in the

20   same liquid sample over a wide concentration range, and can be used to monitor the rate of change of an analyte concentration and/or or concentration of PD or PK markers over a period of time in a single subject, or used for performing trend analysis on the concentration, or markers of PD, or PK, whether they are concentrations of drugs or their metabolites. For example, if glucose were the analyte of interest, the concentration of glucose in a sample at a given time as well as the rate of change of the glucose

25   concentration over a given period of time could be highly useful in predicting and avoiding, for example, hypoglycemic events. Thus, the data generated with the use of the subject fluidic devices and systems can be utilized for performing a trend analysis on the concentration of an analyte in a subject.

For example, a patient may be provided with a plurality of cartridge units to be used for detecting a variety of analytes at predetermined times. A subject may, for example, use different cartridge units on

30   different days of the week. In some embodiments the software on the system is designed to recognize an identifier on the cartridge instructing the system computer to run a particular protocol for running the assay and/or processing the data. The protocols on the system can be updated through an external interface, such as an USB drive or an Ethernet connection, or in some embodiments the entire protocol can be recorded in the barcode attached to the cartridge. The protocol can be optimized as needed by

35   prompting the user for various inputs (i.e., for changing the dilution of the sample, the amount of reagent provided to the liquid sample, altering an incubation time or MAA time, or altering the NMR relaxation collection parameters).

A multiplexed assay can be performed using a variety of system designs. For example, a multiplexed assay can performed using any of the following configurations: (i) a spatially-based detection array can be used to direct magnetic particles to a particular region of a tube (i.e., without aggregation) and immobilize the particles in different locations according to the particular analyte being detected. The immobilized particles are detected by monitoring their local effect on the relaxation effect at the site of immobilization. The particles can be spatially separated by gravimetric separation in flow (i.e., larger particles settling faster along with a slow flow perpendicular to gravity to provide spatial separation based on particle size with different magnetic particle size populations being labeled with different targets). Alternatively, of capture probes can be used to locate magnetic particles in a particular region of a tube (i.e., without aggregation) and immobilize the particles in different locations (i.e., on a functionalized surface, foam, or gel). Optionally, the array is flow through system with multiple coils and magnets, each coil being a separate detector that has the appropriate particles immobilized within it, and the presence of the analyte detected with signal changes arising from clustering in the presence of the analyte. Optionally, once the particles are spatially separated, each individual analyte in the multiplexed assay can be detected by sliding a coil across the sample to read out the now spatially separated particles. (ii) A microfluidic tube where the sample is physically split amongst many branches and a separate signal is detected in each branch, each branch configured for detection of a separate analyte in the multiplexed assay. (iii) An array of 96 wells (or less or more) where each well has its own coil and magnet, and each well is configured for detection of a separate analyte in the multiplexed assay. (iv) A sipper or flow through device with multiple independently addressable coils inside one magnet or inside multiple mini magnets that can be used for sequential readings, each reading being a separate reaction for detection of a separate analyte in the multiplexed assay. (v) A sipper or flow through device with multiple independently addressable wells on a plate inside one magnet or inside multiple mini magnets that can be used for sequential readings using a single sided coil that can be traversed along the plate, each reading being a separate reaction for detection of a separate analyte in the multiplexed assay. (vi) A tube containing two compartments read simultaneously, resulting in one relaxation curve which is then fit using bi-exponential fitting to produce the separate readings for the multiplexed array. (vii) A microfluidics system where each droplet of liquid is moved around individually, to produce readings for the multiplexed array. (viii) Sequential measurements using magnetic separation and resuspension requires novel binding probes or the ability to turn them on and off. This method would be used for nucleic acid analytes in which turn on/off mechanism is based mostly on melting temperature (at higher temperatutres hairpin loops relax, denaturation of double strand binding), and hybridization will occur at different temperatures. (ix) Individual capillaries, each equipped with dried particles within them, allow for small volume rapid multiplexing of one small aliquot. The dried particles are spatially separated, and this spatial separation permits the MR Reader to read each capillary tube independently. (x) Binding moieties conjugated to nanoparticles are placed in a gel or other viscous material forming a region and analyte specific viscous solution. The gel or viscous solution enhances spatial separation of more than one

analyte in the starting sample because after the sample is allowed to interact with the gel, the target analyte can readily diffuse through the gel and specifically bind to a conjugated moiety on the gel or viscous solution held nanoparticle. The clustering or aggregation of the specific analyte, optionally enhanced via one of the described magnetic assisted agglomeration methods, and detection of analyte

5   specific clusters can be performed by using a specific location NMR reader. In this way a spatial array of nanoparticles, and can be designed, for example, as a 2d array. (xi) Magnetic particles can be spotted and dried into multiple locations in a tube and then each location measured separately. For example, one type of particle can be bound to a surface and a second particle suspended in solution, both of which hybridize to the analyte to be detected. Clusters can be formed at the surface where hybridization

10   reactions occur, each surface being separately detectable. (xii) A spotted array of nucleic acids can be created within a sample tube, each configured to hybridize to a first portion of an array of target nucleic acids. Magnetic particles can be designed with probes to hybridize to a second portion of the target nucleic acid. Each location can be measured separately. Alternatively, any generic beacon or detection method could be used to produce output from the nucleic acid array. (xiii) An array of magnetic particles

15   for detecting an array of targets can be included in a single sample, each configured (e.g., by size, or relaxation properties) to provide a distinct NMR relaxation signature with aggregate formation. For example, each of the particles can be selected to produce distinct T2 relaxation times (e.g., one set of particles covers 10-200ms, a second set from 250 -500 a third set from 550-1100, and so on). Each can be measured as a separate band of relaxation rates. (xiv) For detection of analytes of various size or

20   magnetic particles, or aggregates of various size, a single sample with multiple analytes and magnetic particles can undergo separation in the presence of a magnetic or electric field (i.e., electrophoretic separation of magnetic particles coated with analytes), the separate magnetic particles and/or aggregates reaching the site of a detector at different times, accordingly. (xv) The detection tube could be separated into two (or more) chambers that each contain a different nanoparticle for detection. The tube could be

25   read using the reader and through fitting a multiple exponential curve such as $A*exp(T2\_1) + B*exp(T2\_2)$, the response of each analyte could be determined by looking at the relative size of the constants A and B and T2_1 and T2_2. (xvi) Gradient magnetic fields can be shimmed to form narrow fields. Shim pulses or other RF based Shimming within a specific field can be performed to pulse and receive signals within a specific region. In this way one could envision a stratification of the Rf pulse

30   within a shim and specific resonance signals could be received from the specific shim. While this method relies on shimming the gradient magnetic field, multiplexing would include then, to rely on one of the other methods described to get different nanaoparticles and the clusters to reside in these different shims. Thus there would be two dimensions, one provided by magnetic field shims and a second dimension provided by varying nanoparticle binding to more than one analyte. Nanoparticles having two distinct

35   NMR relaxation signals upon clustering with an analyte may be employed in a multiplexed assay. In this methods, the observation that small particles (30-200nm) cause a deccrease in T2 with clustering whereaslarge particles (>800nm) cause an increase with clustering. The reaction assay is designed as a

competitive reaction, so that with the addition of the target it changes the equilibrium relaxation signal. For example, if the T2 relaxation time is shorter, clusters forming of analyte with small particles are forming. If on the other hand, the T2 relaxation becomes longer, clusters of analyte with larger particles are forming. It's probably useful to change the density/viscosity of the solution with additives such as

5   trehalose or glucose or glycerol to make sure the big particles stay in solution. One nanoparticle having binding moieties to a specific analyte for whose T2 signal is decreased on clustering may be combined with a second nanaoparticle having a second binding moiety to a second analyte for whose T2 signal is increased on clustering. In the case for which the sample is suspected to have both analytes and the clustering reaction may cancel each other out (the increased clustering cancels the decreased clustering),

10   one could envision an ordering of the analysis, i.e. addition of competitive binding agents to detect a competitive binding and thus T2 signal that would be related to the presence/absence of the analyte of interest in the sample. Alternatively, if the increased clustering cancels the decreased clustering in this multiplexing format, one could envision use of different relaxation pulse sequences or relaxation determinants to identify the presence/absence or concentration of analyte in the sample. (xvii)

15   Precipitation measurement of particles. In this method, multiple types of particles designed to capture different target sequences of nucleic acid are designed So that the particle size is small enough that the particles bound with analyte remain suspended in solution. Sequential addition of an "initiator" sequence that is complementary to a nucleic acid sequence conjugatged to a second set of particles (a larger particle, not necessarily having magnetic properties) and contains a complementary sequence to the

20   captured target DNA sequence. After hybridization, clusters will form if the target DNA sequence is present, e.g. the magnetic nanoparticle conjugated with probe anneals to one specific sequence on the target analyte and the other particle binds to another sequence on the target nucleic acid sequence. These clusters will be big enough to precipitate (this step may require a centrifugation step). In the same reaction, and simultaneously, one could design an additional magnetic particle, second particle set to

25   anneal with a second nucleic acid sequence for which formation of the magnetic nanparticle-analyte-second particle clusters do not precipitate. In this way sequential addition of particles can result in differential signaling. (xvii) One possible different detection technique includes phase separated signals, which would stem from differing RF coil pulse sequences that are optimized for the conjugated nanoparticle-analyte interaction. Optimally, this could be achieved with multiple coils in an array that

30   would optimize the ability of the different RF pulses and relaxation signal detection to be mapped and differentiated to ascertain the presence/absence of more than one analyte. Multiplexing may also employ the unique characteristic of the nanoparticle-analyte clustering reaction and subsequent detection of water solvent in the sample, the ability of the clusters to form various "pockets" and these coordinated clusters to have varying porosity. For example, linkers having varying length or conformational structures can be

35   employed to conjugate the binding moiety to the magnetic nanoparticle. In this way, more than one type of cluster formed in the presence of an analyte could be designed having the ability of differing solvent water flow, and thus relaxation signal differences, through the aggregated nanoparticle-analyte-

nanoparticle formation. In this way, two or more linker/binding moiety designs would then allow for detection of more than one analyte in the same sample. (xviii) The methods of the invention can include a fluorinated oil/aqueous mixture for capturing particles in an emulsion. In this design one hydrophobic capture particle set and an aqueous capture set are used, the hydrophic capture particle set is designed to

5   bind and aggregate more readily in an hydrophobic environment, whereas the aqueous capture particle set is designed to bind and aggregate in an aqueous environment. Introduction of an analyte containing sample having specific analytes that will bind to either the hydrophic or aqueous particle, and subsequent mixing in the detection tube having both hydrophobic and aqueous solvents, binding and clustering would then result in a physical separation of analytes to either the aqueous or hydrophobic phase. The relaxation

10   signal could be detected in either solution phase. In the event that the analytes and nanoparticles designed in this manner are physically found in an emulsion created by the mixing of the hydrophic/aqueous phases, relaxation curves would be distinguishable in the emulsion phase. The detection tube may have a capsular design to enhance the ability to move the capsules through an MR detector to read out the signal. Further, additional use of a fluorescent tag to read out probe identity may be employed, i.e. in the case of

15   two different analytes in the same aqueous or hydrophic phase, the addition of a fluorescent tag can assist determination of the identify of the analyte. This method is amenable in samples for which limited isolation or purification of the target analyte away from the other material in the sample because the described resonance signals are independent of sample quality. Further, the addition of the flurorescent tag can be added in much higher concentrations that usually added in typical fluorescent studies because

20   these tags will never interfere with the relaxation measurements. In this method, oligonucleotide capture probes that are conjugated to the magnetic nanoparticles are designed so that specific restriction endonuclease sites are located within the annealed section. After hybridization with the sample forming nanoparticle-analyte clusters, a relaxation measurement then provides a base signal. Introduction of a specific restriction endonuclease to the detection tube and incubation will result in a specific reduction of

25   the nanoparticle/analtye cluster after restriction digestion has occured. After a subsequent relaxation measurement, the pattern of signal and restriction enzyme digestion, one can deduce the target. (xix) In a combined method, a magnetic nanoparticle is conjugated with two separate and distinct binding moieties, i.e. an oligonucleotide and an antibody. This nanoparticle when incubated with a sample having both types of analytes in the sample will form nanoparticle-analyte complexes, and a baseline T2 relaxation

30   signal will be detectable. Subsequent addition of a known concentration of one of the analytes can be added to reduce the clustering formed by that specific analyte from the sample. After known analyte addition a subsequent T2 relaxation signal is detected and the presence/absence of the sample analyte can be surmised. Further, a second analyte can be added to compete with the analyte in the sample to form clusters. Again, after a subsequent T2 relaxation signal detection the presence/absence of the second

35   sample analyte can be surmised. This can be repeated.

Broadly a multiplexed assay employing the methods of this invention can be designed so that the use of one non-superparamagnetic nanoparticle to generate clusters with analyte from a sample, will

reduce the overall Fe2+ in assay detection vessel and will extend the dynamic range so that multiple reactions can be measured in the same detection vessel.

Multiplexing nucleic acid detection can make use of differeing hybridization qualities of the conjugated magnetic nanoparticle and the target nucleic acid analyte. For example, capture probes conjugated to magnetic nanoparticles can be designed so that annealing the magnetic nanoparticle to the target nucleic acid sequence is different for more than one nucleic acid target sequence. Factors for the design of these different probe-target sequences include G-C content (time to form hybrids), varying salt concentration, hybridization temperatures, and/or combinations of these factors. This method then would entail allowing various nucleic acid conjugated magnetic nanoparticles to interact with a sample suspected of having more than one target nucleic acid analyte. Relaxation times detected after various treatments, i.e. heating, addition of salt, hybridization timing, would allow for the abilty to surmise which suspected nucleic acid sequence is present or absent in the sample.

Use complimentary amplicons to block one reaction and allow serial hybridizations. In this method, universal amplification primers are used to amplify more than one specific nucleic acid sequence in the stargin sample, forming an amplicon pool. Specific oligonucloetide conjugated to magnetic nanoparticles are added to the sample and a relaxation measurement is taken. The sample is then exposed to a temperature to melt the oligonucleotide-analyte interaction and addition of a oligonucleotide that is not attached to a magnetic nanoparticle is added to compete away any analyte binding to the magnetic nanoparticle. A second magnetic nanoparticle having a second oligonucleotide conjugated to it is then added to form clusters with a second specific target nucleic acid analyte. Alternatively, the method could have a step prior to the addition of the second magnetic nanoparticle that would effectively sequester the first magnetic nanoparticle from the reaction vessel, i.e. exposing the reaction vessel to a magnetic field to move the particles to an area that would not be available to the second, or subsequent reaction.

Each of the multiplexing methods above can employ a step of freezing the sample to slow diffusion and clustering time and thus alter the measurement of the relaxation time. Slowing the diffusion and clustering of the method may enhance the ability to separate and detect more than one relaxation timeEach of the multiplexing methods above can make use of sequential addition of conjugated nanoparticles followed by relaxation detection after each addition. After each sequential addition, the subsequent relaxation baseline becomes the new baseline from the last addition and can be used to assist in correlating the relaxation time with presence/absence of the analyte or analyte concentration in the sample.

Hidden capture probes. In this method of multiplexing, oligonulceotides conjugated to the magntic nanoparticles are designed so that secondary structure or a complementary probe on the surface of the particle hides or covers the sequence for hybridization initially in the reaction vessel. These hidden hybridization sequences are then exposed or revealed in the sample vessel spatially or temporally during the assay. For example, as mentioned above, hybridization can be affected by salt, temperature and time to hybridize. Thus, in one form of this method, secondary or complementary structures on the

oligonucleotide probe conjugated to the magnetic nanaoparticle can be reduced or relaxed to then expose or reveal the sequence to hybridize to the target nucleic acid sample. Further, secondary structures could be reduced or relaxed using a chemical compound, e.g. DMSO. Another method to selectively reveal or expose a sequence for hybridization of the oligonucleotide conjugated nanoparticle with the target analyte

5   is to design stem-loop structures having a site for a restriction endonuclease; subsequent digestion with a restriction endonuclease would relax the stem-loop structure and allow for hybridization to occur. Alternatively, a chemical cut of the stem-loop structure, releasing one end could make the sequence free to then hybridize to the target nucleic acid sequence.

Where the multiplexed array is configured to detect a target nucleic acid, the assay can include a

10   multiplexed PCR to generate different amplicons and then serially detect the different reactions.

The multiplexed assay optionally includes a logical array in which the targets are set up by binary search to reduce the number of assays required (e.g., gram positive or negative leads to different species based tests that only would be conducted for one group or the other).

The systems of the invention can run a variety of assays, regardless of the analyte being detected

15   from a bodily fluid sample. A protocol dependent on the identity of the cartridge unit being used can be stored on the system computer. In some embodiments, the cartridge unit has an identifier (ID) that is detected or read by the system computer, or a bar code (1D or 2D) on a card that then supplies assay specific or patient or subject specific information needed to be tracked or accessed with the analysis information (e.g., calibration curves, protocols, previous analyte concentrations or levels). Where

20   desired, the cartridge unit identifier is used to select a protocol stored on the system computer, or to identify the location of various assay reagents in the cartridge unit. The protocol to be run on the system may include instructions to the controller of the system to perform the protocol, including but not limited to a particular assay to be run and a detection method to be performed. Once the assay is performed by the system, data indicative of an analyte in the biological sample is generated and communicated to a

25   communications assembly, where it can either be transmitted to the external device for processing, including without limitation, calculation of the analyte concentration in the sample, or processed by the system computer and the result presented on a display readout.

For example, the identifier may be a bar code identifier with a series of black and white lines, which can be read by a bar code reader (or another type of detector) upon insertion of the cartridge unit.

30   Other identifiers could be used, such as a series of alphanumerical values, colors, raised bumps, RFID, or any other identifier which can be located on a cartridge unit and be detected or read by the system computer. The detector may also be an LED that emits light which can interact with an identifier which reflects light and is measured by the system computer to determine the identity of a particular cartridge unit. In some embodiments, the system includes a storage or memory device with the cartridge unit or the

35   detector for transmitting information to the system computer.

Thus, the systems of the invention can include an operating program to carry out different assays, and cartridges encoded to: (i) report to the operating program which pre-programmed assay was being

employed; (ii) report to the operating program the configuration of the cartridges; (iii) inform the operating system the order of steps for carrying out the assay; (iv) inform the system which pre-programmed routine to employ; (v) prompt input from the user with respect to certain assay variables; (vi) record a patient identification number (the patient identification number can also be included on the

5   Vacutainer holding the blood sample); (vii) record certain cartridge information (i.e., lot #, calibration data, assays on the cartridge, analytic data range, expiration date, storage requirements, acceptable sample specifics); or (viii) report to the operating program assay upgrades or revisions (i.e., so that newer versions of the assay would occur on cartridge upgrades only and not to the larger, more costly system).

The systems of the invention can include one or more fluid transfer units configured to adhere to

10   a robotic arm (see Figures 43A-43C). The fluid transfer unit can be a pipette, such as an air-displacement, liquid backed, or syringe pipette. For example, a fluid transfer unit can further include a motor in communication with a programmable processor of the system computer and the motor can move the plurality of heads based on a protocol from the programmable processor. Thus, the programmable processor of a system can include instructions or commands and can operate a fluid transfer unit

15   according to the instructions to transfer liquid samples by either withdrawing (for drawing liquid in) or extending (for expelling liquid) a piston into a closed air space. Both the volume of air moved and the speed of movement can be precisely controlled, for example, by the programmable processor. Mixing of samples (or reagents) with diluents (or other reagents) can be achieved by aspirating components to be mixed into a common tube and then repeatedly aspirating a significant fraction of the combined liquid

20   volume up and down into a tip. Dissolution of reagents dried into a tube can be done is similar fashion.

A system can include one or more incubation units for heating the liquid sample and/or for control of the assay temperature. Heat can be used in the incubation step of an assay reaction to promote the reaction and shorten the duration necessary for the incubation step. A system can include a heating block configured to receive a liquid sample for a predetermined time at a predetermined temperature. The

25   heating block can be configured to receive a plurality of samples.

The system temperature can be carefully regulated. For example, the system includes a casing kept at a predetermined temperature (i.e., 37 °C) using stirred temperature controlled air. Waste heat from each of the units will exceed what can be passively dissipated by simple enclosure by conduction and convection to air. To eliminate waste heat, the system can include two compartments separated by an

30   insulated floor. The upper compartment includes those portions of the components needed for the manipulation and measurement of the liquid samples, while the lower compartment includes the heat generating elements of the individual units (e.g., the motor for the centrifuge, the motors for the agitation units, the electronics for each of the separate units, and the heating blocks for the incubation units). The lower floor is then vented and forced air cooling is used to carry heat away from the system. See Figures

35   44A and 44B.

The MR unit may require more closely controlled temperature (e.g., ± 0.1 °C), and so may optionally include a separate casing into which air heated at a predetermined temperature is blown. The

casing can include an opening through which the liquid sample is inserted and removed, and out of which the heated air is allowed to escape. See Figures 45A and 45B. Other temperature control approaches may also be utilized.

The following examples are put forth so as to provide those of ordinary skill in the art with a complete disclosure and description of how the devices, systems, and methods described herein are performed, made, and evaluated, and are intended to be purely exemplary of the invention and are not intended to limit the scope of what the inventors regard as their invention.

Example 1. Preparation of coated particles.

Briefly, 1mg of substantially monodisperse carboxylated magnetic particles were washed and resuspended in 100 µl of activation buffer, 10mM MES. 30 µl of 10mg/ml 10kDa amino-dextran (Invitrogen) was added to activation buffer and incubated on a rotator for 5 minutes at room temp. For coupling of the carboxyl groups to amines on the dextran, 30 µl of 10mg/ml 1-Ethyl-3-[3-dimethylaminopropyl]carbodiimide Hydrochloride (EDC) was added and incubated on rotator for 2 hours at room temperature. Particles were washed away from free dextran 3× in 1 ml of PBS using magnetic separation, then resuspended in 1 ml of PBS. 100 µl of a 100mM solution of Sulfo-NHS-biotin (Invitrogen) was used to decorate the amino groups on the dextran surface with biotin. After 30 minutes of incubation, particles were washed 3× in 1 ml activation buffer. Next, a protein block of 100 µl of 0.5 mg/ml of bovine serum albumin (BSA) (Sigma) and 30 µl of 10mg/ml EDC was introduced and incubated overnight (Sigma). Prepared particles were washed 3× in 1 ml PBS and resuspended to the desired concentration.

Prepared particles synthesized with this protocol have been shown to give similar results in T_2 assays for detection of analyte, whether samples include buffer or 20% lysed blood (see Figure 37). Variations of the preparations wherein pre-biotinylated amino dextran was conjugated directly to particles in one step have also resulted in similar performance in T_2 assays in both blood and buffer samples.

Example 2. Assessment of particles prepared with and without a protein block.

Briefly, biotin decorated amino-dextran magnetic particles prepared according to the method described in Example 1 were assayed in PBS and in 20% lysed blood samples in an anti-biotin titration T_2 assay.

The assay was performed with the following procedure. 50 µL of matrix, either PBS or 20% Lysed blood sample, 50 µL of varying concentrations of Anti-biotin antibody, and 50 µL of 1.0 µg/ml secondary antibody were added to a 5 mm NMR Tube. 150 µL of 0.02 mM Fe particles were then added to each tube (i.e., 2.7×10^8 particles per tube). The samples were then vortexed for 4 seconds and incubated in a 37 °C heat block for 2 minutes. Each sample was then revortexed for 4 seconds, and incubated for an additional minute in the 37 °C heat block. Following incubation, each sample was placed into a Bruker Minispec for 10 minutes, under a magnetic field. After 10 minutes, the sample was

removed from the magnet, vortexed for 4 seconds, and incubated in 37 °C heat block for 5 minutes. After 5 minutes, each sample was revortexed and incubated in a 37 °C heat block for an additional 1 minute. T_2 values were taken using the Bruker Minispec program with the following parameters:

5
Scans: 1
Gain: 75
Tau: 0.25
Echo Train: 3500
Total Echo Train: 4500
10
Dummy Echos: 2

Δ T_2 values were calculated: $T_2 - (T_2)_0$, and results are depicted in Figure 37.

Particles synthesized with a protein block, AXN4, gave nearly equal performance in blood and

15   buffer (Figure 37). The graph depicted in Figure 38 compares particles prepared with (open circle) and without (filled circle) a protein blocking step. We have thus found the protein block may be needed to achieve similar functionality in blood matrices.

Additional protein blocks including but not limited to fish skin gelatin have also been successful. Particles were prepared according to the method described above, with the exception that in lieu of using

20   BSA as the protein block, fish skin gelatin(FSG) was substituted. The graph depicted in Figure 39 shows results of a T_2 assay (as described above) using antibody titration for particles blocked with BSA and compared to FSG. The data indicates that there is little or no difference between the two protein blocking methods (see Figure 39). However, BSA has proven to be a more reliable block.

25   Example 3. Determination of amount of dextran coating.

Attempts to increase dextran coating density on particles have been found to reduce functionality of prepared particles in blood. The preparation of particles described in Example 1 above that demonstrated nearly equivalent buffer/blood performance used a 10× excess of dextran base upon a space filling model to determine amount of dextran to include in coating experiments. In an attempt to

30   functionalize particles with a higher fidelity, increasing the dextran coating to a 1000-10000× excess of dextran in coating experiments generated particles having a thicker dextran coating which yielded a reduced response in blood as compared to buffer. We conclude that a moderate density of dextran with a protein block may be desirable to produce a particle coating that functions well in T_2 assays in the presence of blood sample (see Figures 40A and 40B).

35

Example 4. Detection of a small molecule analyte in whole blood samples.

Materials and Methods:

Jackson Immuno Research Labs Mouse Anti-Biotin Monoclonal Antibody (200-002-211)
Jackson Immuno Research Labs Sheep Anti-Mouse (515-005-071)
40
Tween 20
Bovine Serum Albumin (Sigma Product #: B4287-256)

1×PBS Tablets (Sigma P4417)
PEG FITC Biotin Analyte
100 mM Tris HCl in dH₂0
0.1% Tween®
EDTA Whole blood lysed 1:5 with 1X Trax buffer
Superparamagnetic, iron oxide, COOH-coated particles

Equipment:

Bruker Minispec
Variable Speed Vortexer (VWR)
5 mm NMR Tubes
37°C Heat block with custom made NMR Tube slots

Buffer/Analyte Preparation: 0.1% BSA, 0.1% Tween® in 1× PBS: A 10% Tween® 20 solution by weight was prepared. Briefly, Tween® in 1X PBS was prepared. 500 mL of 0.2% Tween® solution was prepared by adding 10 mL of 10% Tween® to 490 mL of 1X PBS. A 2% solution of BSA was prepared in 1× PBS solution by weight. A 0.2% solution of BSA solution was prepared by adding 50 mL of 2% BSA in PBS to 450 mL of 1× PBS. Dilutions were combined to make a final volume of 1 L and a final buffer concentration of 0.1% BSA, 0.1% Tween® in 1× PBS.

PEG-FITC-Biotin Analyte: 100 μl of a 0.5 mM solution was prepared from 1mM Tris HCl. 40 μl of PEG FITC biotin was mixed with 40 μl of 0.5 mM Tris HCl, and incubated for 15 minutes at room temperature. After 15 minutes, 70 μl of PEG-FITC-Biotin in 0.5 mM Tris HCl was added to 630 μl of 0.1% Tween® to make a 100 μM stock solution. Stock solution was vigorously mixed by vortexing. 200 μl of 100 μM solution was added to 900 μl of 0.1% Tween® to make 20,000 nM analyte. 10 fold dilutions were prepared down to 0.02 nM

Procedure:

25 μl of appropriate analyte and 50 μl of 1:5 Lysed blood matrix were pipetted directly into a 5 mm NMR tube. Samples were vortexed for 4 seconds. 25 μl of primary Anti-biotin antibody (0.18 μg/ml diluted in 0.1% Tween 20, 0.1% BSA, 1×PBS) was added, followed by a 37°C incubation for 15 minutes. After 15 minutes, 50 μl of 3.0 μg/ml Secondary Anti-Mouse antibody (diluted in 0.1% Tween, 0.1% BSA, 1×PBS) and 150 μl of 0.02 mM Fe particles (2.7×10^8 particles per tube) were added to the NMR Tube. The sample was then vortexed for 4 seconds and incubated for 5 minutes at 37°C. The sample was placed in a Bruker Minispec for 10 minutes, under magnetic field. After 10 minutes, the sample was removed from the magnet and incubated for an additional 5 minutes. The sample was again vortexed for 4 seconds and incubated for an additional 1 minute. T_2 values were taken using the Bruker Minispec program with the following parameters:

Scans: 1
Gain: 75
Tau: 0.25
Echo Train: 3500
Total Echo Train: 4500
Dummy Echos: 2

Example 5: Synthesis of antibody decorated particles.

Amino dextran coated magnetic particles prepared as described in Example 1 can be further functionalized with antibodies via an SMCC-SATA linkage (SMCC = succinimidyl 4-[N-maleimidomethyl]cyclohexane-1-carboxylate; SATA = N-succinimidyl-S-acetylthioacetate). The carboxylated magnetic particles are first conjugated to 10kDa amino dextran via EDC chemistry as described above. The dextran coated particles are further modified with an excess of sulfo-SMCC to provide a maleimide functional group. Antibodies are modified with a SATA linker, which primarily binds to the amines on the antibody. The SATA linkage is controlled to minimize over-functionalization of the antibody which may lead to cross-linking of the particles or reduced affinity of the antibody. After deacetylation, the SATA linker exposes a thiol functional group which can be used to directly attach to the malemide functionalized particles forming a thioether bond. The number of antibodies conjugated to each particle can be measured using a BCA protein assay (Pierce). Linkers that provide similar functionality to SATA have been used successfully, such as SPDP (N-Succinimidyl 3-[2-pyridyldithio]-propionate).

Antibody coated magnetic particles can also be prepared using the chemistries described above, but with direct covalent linkage to the base carboxylated particle. In some instances it may necessary to add additional coating to the particle surface, such as dextran, or a blocking agent. Similar chemistries can be used with alternate coatings to the amino dextran, such as PEG or BSA.

Example 6. Creatinine assay.

Briefly, the assay includes the following: a target sample is incubated in the presence of a magnetic particle that has been decorated with creatinine, which is linked to the surface of the magnetic particles. The creatinine decorated magnetic particles are designed to aggregate in the presence of the creatinine antibody. Each of the creatinine decorated magnetic particles and creatinine antibody is added to the liquid sample containing creatinine, which competes with the magnetic particles for the creatinine antibody. Thus, the binding of the creatinine to the antibody blocks agglomeration of the magnetic particles, and low levels of creatinine are marked by the formation of agglomerates. These agglomerates alter the spin-spin relaxation rates of sample when exposed to a magnetic field and the change in the T_2 relaxation times (measuring a change in the magnetic resonance signal from the surrounding water molecules) can be directly correlated to presence and/or concentration of the analyte in the target sample.

Creatinine antibody

In establishing an antibody generation program for creatinine, a modified creatinine molecule was devised (COOH-creatinine) and conjugated to transferrin for immunization in BALB-C and AJ mice.
COOH-creatinine

Thirty four stable antibody producing clones were generated. These clones arose from either

BALB-C (spleen cells) (n=17) or AJ mice (n=17). The two genetically different mouse lines were

5   selected for the known genetic differences in their immune systems. Criteria and a selection process were

developed for screening and identification of an optimal monoclonal antibody for use in the assay. The

antibody selection process included screening for binding to BSA-creatinine by ELISA, antibody

affinity/sensitivity/specificity by ELISA competitive assays using free creatinine and potential

interferents, determination of the ability of the antibody to be conjugated to the magnetic particle and

10   functionality in a T_2 magnetic relaxation switch assay.

Using the established antibody selection criteria outlined above, seven monoclonal antibodies

were identified and selected as potential candidates in the assay.

Creatinine-coated magnetic particles

15   Substantially monodisperse carboxylated magnetic particles were washed and resuspended in 100

μl of coupling buffer (50 mM MES, pH = 4.75). Sulfo-NHS (55 μmol in 200 μl MES buffer) was added

and the mixture vortexed. To the mixture was added EDC (33.5 μmol in 200 μl MES buffer). The

solution was briefly vortexed and placed on an end over end mixer for 1 hour at room temperature,

allowed to settle, and the supernatant removed. To the resulting solids was added 1 mL of 1% BSA in

20   PBS, and again the mixture was vortexed and placed on an end over end mixer for 15-18 hours at room

temperature. The particles were allowed to settle and the supernatant removed.

The BSA-coated particles were suspended in 0.5 mL PBS-0.01%T20 (10 mM phosphate buffer,

pH = 7.4, 150 mM NaCl, with 0.01% Tween® 20). Unreacted carboxyl groups were subjected to

Methyl-PEG4-amine (20 μl of 10% v/v in DMSO) as a blocking agent. The mixture was vortexed and

25   placed on an end over end mixer for 8 hours at room temperature. The resulting BSA-coated particles

were repeatedly washed with 0.5 mL PBS-0.01%T20.

COOH-creatinine (66 μmol), EDC (140 μmol), and NHS (260 μmol) were combined with 300 μl

of dry DMSO to form a slurry, which cleared as the reaction reached completion. BSA-coated particles

were suspended in 0.5 mL PBS-0.01%T20 (pH = 8), followed by the addition of the activated COOH-

30   creatinine solution. The resulting mixture was vortexed and placed on an end over end mixer for 4 hours

at room temperature. The resulting particles were washed 3× each with sonication using 1:15 and 1:30

DMSO: PBS-0.01%T20 (vol/vol). The particles were then washed 3× each with sonication using PBS-

0.01%T20. The particles were resuspended in PBS-0.1%T20 (pH = 8) and 2 mg of NHS-PEG 2K in 200 µl PBS-0.01%T20 was added. The mixture was placed on an end over end mixer for 12-20 hours at room temperature. The particles were then washed 3× each with sonication using PBS-0.01%T20 to produce creatinine-conjugated magnetic particles with sequential BSA, creatinine coating, PEG cap and block.

5   The creatinine coated particles were resuspended in assay buffer (100 mM glycine (pH = 9.0), 150 mM NaCl, 1% BSA, 0.05% ProClin®, and 0.05% Tween®).

The creatinine assay protocol was performed using creatinine conjugated particles and soluble creatinine antibody with detection using the T_2 signal was generated/completed. The creatinine competitive assay architecture is depicted in Figure 24.

10   Solutions of magnetic particles, antibody, and liquid sample were, where indicated, subject to dilution with an assay buffer that included 100mM Tris pH 7.0, 800mM NaCl, 1% BSA, 0.1% Tween®, and 0.05% ProClin®.

The creatinine-coated magnetic particles were diluted to 0.4 mM Fe (5.48×10^9 particles/ml) in assay buffer, vortexed thoroughly, and allowed to equilibrate for 24 hours at 4-8 °C.

15   The anti-creatinine mouse monoclonal antibody (described above) was employed as a multivalent binding agent for the creatinine-conjugated magnetic particles. The antibody was diluted to a concentration of 0.8 µg/ml in assay buffer and vortexed thoroughly.

Samples and calibrators were diluted 1 part sample to 3 parts assay buffer. The upper assay range is ca. 4 mg/dL creatinine. For samples with expected creatinine levels > 4 mg/dL an additional sample

20   dilution was performed using 1 part initial diluted sample to 4 parts assay buffer.

The pre-diluted sample, assay buffer, magnetic particle, and antibody solutions were each vortexed. 10 µL of each solution added to a tube, and the tube was vortexed for 5 seconds.

The tube was then subjected to 12 minutes of gMAA, incubated for 5 minutes at 37 °C, placed in the MR Reader (T_2 MR, Reader with 2200 Fluke Temperature Controller, with NDxlient software

25   0.9.14.1/ hardware Version 0.4.13 Build 2, Firmware Version 0.4.13 Build 0) to measure the T_2 relaxation rate of the sample, and the T_2 relaxation rate of the sample was compared to a standard curve (see Figure 25A) to determine the concentration of creatinine in the liquid sample.

Performance of modified creatinine antibodies

30   Different creatinine antibodies were tested in the assay to ascertain the effect of the antibody on agglomeration. We observed that the performance of the creatinine antibodies varied in their performance characteristics when combined with creatinine-coated magnetic particles (see Figure 25B). SDS-PAGE gel analysis of the two preparations revealed significantly enhanced aggregation in preparation 1, believed to arise from an increase in the creatinine binding valency for this antibody, which

35   is aggregated due to its purification process. For comparison, we multimerized another creatinine monoclonal antibody (14HO3) by biotinylating the antibody and multimerizing the antibody in the presence of streptavidin. The monomeric, biotinylated monomeric, and multimerized forms were then

tested with creatinine-coated magnetic particles to assess the effect of increased valency on T_2 time. The results are depicted in Figure 25C, showing the multimerized antibody forms clusters at much lower concentrations that the non-multimerized antibodies. This valency enhancement for particle clustering has also been observed using IgM antibodies.

5

Example 7. Creatinine antibody-coated magnetic particle.

Using an alternative assay architecture, the assay includes the following: a target sample is incubated in the presence of (i) a magnetic particle that has been decorated with creatinine antibody; and (ii) a multivalent binding agent including multiple creatinine conjugates. The magnetic particles are

10   designed to aggregate in the presence of the multivalent binding agent, but aggregation is inhibited by competition with creatinine in the liquid sample. Thus, the binding of the creatinine to the antibody-coated particle blocks agglomeration of the magnetic particles in the presence of the multivalent binding agent, and low levels of creatinine are marked by the formation of agglomerates. These agglomerates alter the spin-spin relaxation rates of sample when exposed to a magnetic field and the change in the T_2

15   relaxation times (measuring a change in the magnetic resonance signal from the surrounding water molecules) can be directly correlated to presence and/or concentration of the analyte in the target sample.

Substantially monodisperse carboxylated magnetic particles were washed and resuspended in 300 μl of coupling buffer (50 mM MES, pH = 4.75), and sulfo-NHS (46 μmol) EDC (25 μmol) were added to the particles. The solution was briefly vortexed and placed on an end over end mixer for 1 hour at room

20   temperature. The activated particles were washed with mL PBS-0.01%T20, and resuspended in 1 mL of 10% w/v solution of amine-PEG-amine in PBS-0.01%T20. The mixture was vortexed and placed on an end over end mixer for 2 hours at room temperature, and then washed 3× with PBS-0.01%T20.

BSA can be substituted for amine-PEG-amine as an alternate chemistry. The BSA-coated magnetic particles were prepared as described in example 6, in the section describing creatinine coated

25   magnetic particles.

The particles were resuspended in 260 μl PBS-0.01%T20 and reacted with 198 μl sulfo SMCC (5 mg/mL in PBS-0.01%T20). The solution was briefly vortexed and placed on an end over end mixer for 1 hour at room temperature, and then washed 3× with PBS-0.01%T20 with 10 mM EDTA to produce SMCC-coated particles.

30   SATA-labeled antibody was prepared by combining SATA (30 nmol in DMSO) with antibody (2 nmol in PBS, pH = 7.4). The solution was placed on an end over end mixer for 1 hour at room temperature. Blocked sulfhydryl groups on SATA-labeled antibody were deprotected by treatment with deacetylation buffer (0.5M hydroxylamine hydrochloride in pH 7.4, 10mM phosphate, 150 mM sodium chloride, 10mM EDTA) for 1 hour and purified through a desalting column using PBS containing 10mM

35   EDTA prior to use.

As an alternate to SATA, SPDP-labeled antibody can be used. SPDP-labeled antibody was prepared by adding SPDP (10mmol in DMSO) with antibody (2nmol in PBS, pH 7.4). The solution was

incubated for 1 hour at room temperature and purified through a desalting column. The disulfide linkage of SPDP on the SPDP-labeled antibody was cleaved in a reaction with 5mM mercaptoethyamine and incubated for 10 minutes at ambient temperature. The disulfide bond-cleaved SPDP-labeled antibody was purified through a desalting column prior to use.

5   The SMCC-functionalized particles with PEG- or BSA-coating and deacetylated SATA-modified antibody were combined and placed on an end over end mixer for overnight at room temperature, washed 3× with PBS-0.05% Tween® 80, and resuspended in PBS-0.01%T20 with 10 mM EDTA. A blocking agent (m-PEG-SH 2K) was added, the solution was placed on an end over end mixer for 2 hours, washed 2× with PBS-0.05% Tween® 80, and resuspended in PBS-0.05% Tween® 80, 1% BSA, and 0.05%

10   ProClin® to produce antibody-coated magnetic particles.

The SMCC-functionalized BSA-coated particles and disulfide-bind cleaved SPDP-labeled antibody were combined and placed on an end over end mixer for 2 hours at room temperature, washed 2 times with PBS-0.01% Tween® 20, 10 mM EDTA, and resuspended in PBS, 0.01% T20, and 10mM EDTA. A blocking agent, m-PEG-SH 2K (1μmole), was added, and the solution was placed on an end

15   over end mixer for 2 hours. A second blocking agent, n-ethyl maleimide (5μmole), was added. The particles were mixed for 15 minutes, washed twice with PBS-0.01% Tween® 20, and resuspended in pH 9, 100mM Tris, 0.05% Tween® 80, 1% BSA, and 0.05% ProClin® to produce antibody coated magnetic particles.

The procedure outlined above can be used with creatinine antibodies, or the creatinine antibodies

20   can be coupled directly to the surface of the carboxylated magnetic particles via EDC coupling.

Creatinine multivalent binding agents

COOH-creatinine was conjugated to 3 amino-dextran compounds (Invitrogen; MW 10k, 40k, and 70kwith 6.5, 12, and 24 amino groups per molecule of dextran respectively) and BSA via EDC coupling.

25   The resulting BSA-creatinine and amino-dextran-creatinine multivalent binding agents can be used in the competitive inhibition assay described above. Degrees of substitution between 2-30 creatinines per dextran moiety were achieved. An example creatinine inhibition curve is shown in Figure 33. The binding agent used is a 40kDa dextran with ~10creatinines per dextran molecule.

30   Example 8. Preparation of tacrolimus multivalent binding agents.

Tacrolimus conjugates were prepared using dextran and BSA. FK-506 was subjected to the olefin metathesis reaction using Grubbs second generation catalyst in the presence of 4-vinylbenzoic acid as depicted below in Scheme 1. The crude product mixture was purified by normal phase silica gel chromatography.

35

Scheme 1
Dextran conjugates

Dextran-tacrolimus conjugates were prepared using three different molecular weight amino-dextrans, each with a different amino group substitution.

2.78 mL of EDC solution (40 mg/mL EDC hydrochloride) and 2.78 mL of sulfo-NHS solution (64 mg/mL sulfo-NHS) were combined with stirring. To this mixture was added 0.96 mL of tacrolimus-acid derivative (C21) solution (28.8 mg/mL in DMSO) and the contents stirred for 30 minutes at room temperature to form the activated tacrolimus-acid derivative (activated Tac solution 4.6 mM). The activated tacrolimus was used immediately.

Various amino-dextran polymers were dissolved in 100 mM sodium phosphate buffer (pH 8.0) to make a 9.5 mg/mL stock solution.

Activated Tac solution was added drop-wise with stirring at room temperature to the stock solution of amino-dextran in the ratios tabulated below. Each reaction was stirred vigorously for at least 2 hours.

Table 6

Reaction	Amino Dextran m.w.	Ratio of Amine:Tac	Amino Dextran (µL)	Volume Tac (µL)	Estimated Tac:Dextran molar ratio
1	70K	1:0.2	1000	70.8	Not tested
2	70K	1:0.4	1000	141.6	Not tested
3	70K	1:0.8	1000	283.2	4.1
4	70K	1:1.6	1000	566.4	Not tested
5	70K	1:3.2	1000	1132.8	Not tested
6	70K	1:5	1000	1770	15.8
7	10K	1:0.8	1000	283	1.0
8	10K	1:5	1000	1766	2.2
9	40K	1:0.8	1000	287	2.0
10	40K	1:5	1000	1793	8.2

The resulting Tac-dextran conjugates were purified using a 5-step serial dialysis of each reaction product (1st – 15% (v/v) aqueous DMSO; 2nd – 10% (v/v) aqueous methanol; 3rd to 5th – high purity water; at least 2 hours for each step; using a 3,500 MWCO dialysis membrane for the 10K MW amino-dextran and a 7K MWCO dialysis membrane for the 40K and 70K amino-dextran).

Following purification, each of the samples was lyophilized and the dry weight determined. The multivalent binding agents were reconstituted prior to use.

After reconstitution, the tacrolimus substitution ratios were estimated based upon the absorbance at 254nm.

5   Experiments were performed to determine which size dextran provided the most optimal agglomerative performance. Briefly, 10 μL of 10% MeOH, 1% BSA in PBS pH 6.3 buffer, 20 μL of Dextran Tac agglomerator, 10K, 40K, 70K, at varying concentrations, and 10 μL of Anti-Tacrolimus coated magnetic particles at 0.2 mM Fe was added to a 200 μL PCR Tube (2.7×10^9 particles per tube). The sample was vortexed using a plate mixer at 2000 rpm for 2 minutes, preheated for 15 minutes at 37

10   °C in an incubation station, exposed to a side and bottom magnet for 1 minute each, repeated for 6 cycles, vortexed again for 2 minutes at 2000 rpm, incubated for 5 minutes in 37 °C incubator containing PCR tube designed heat block, and the T_2 was read on the MR Reader. Data indicates that increased molecular weight/varied substitution ratios of dextran Tac can result in the improved T_2 signal (see Figure 34). In addition, higher substitution also resulted in improved response (see Figure 35).

15

BSA conjugates

BSA-tacrolimus conjugates were prepared with varying degrees of tacrolimus substitution.

34.5 μL of NHS solution (66.664 mg/mL in acetonitrile) and 552 μL of EDC (6.481 mg/mL in 50mM MES pH 4.7) were combined with stirring. 515.2 μL of this EDC NHS mixture was added drop-

20   wise to 220.8 μL of tacrolimus-acid derivative (C21) solution (33.33mg/mL in acetonitrile) and the contents stirred for 1 hour at room temperature to form the activated tacrolimus-acid derivative. The activated tacrolimus was used immediately.

BSA was dissolved in phosphate buffered saline and acetonitrile to form a solution containing 5mg/mL BSA in 40% acetonitrile.

25   Activated Tac solution was added drop-wise with stirring at room temperature to the BSA solution in the ratios tabulated below. Each reaction was stirred vigorously for at least 2 hours.

Table 7

Reaction	Ratio of Tac:BSA	BSA (μL)	Volume Tac (μL)
1	5:1	1000	35
2	10:1	1000	70
3	20:1	1000	140
4	30:1	1000	210
5	50:1	1000	350

The resulting Tac-BSA conjugates were purified using a PD10 size exclusion column pre-

30   equilibrated with 40% acetonitrile. The eluent was collected in 1 mL fractions and monitored for absorbance at 280nm to identify fractions containing BSA.

The BSA-containing fractions were combined and the acetonitrile removed under vacuum.

Tac-BSA conjugates were evaluated for clustering ability by performing a titration similar to that used for the dextran-tacrolimus conjugates. As observed, clustering performance differs with Tac substitution ratio (see Figure 36).

Example 9.   Tacrolimus competitive assay protocol (antibody on particle architecture).

A tacrolimus assay was developed using anti-tacrolimus antibody conjugated particles and BSA-tacrolimus multivalent binding agent with detection using an MR Reader (see Example 6). This assay was designed for testing whole blood samples that have been extracted to release tacrolimus from the red blood cells and binding proteins (the extraction of hydrophobic analyte from a sample can be achieved, for example, using the methodology described in U.S. Patent No. 5,135,875). The tacrolimus competitive assay architecture is depicted in Figure 28.

Solutions of magnetic particles and multivalent binding agent were, where indicated, subject to dilution with an assay buffer that included 100 mM Glycine pH 9, 0.05% Tween® 80, 1% BSA, 150 mM NaCl, 0.1% CHAPS.

A base particle with COOH functionality was modified by sequential aminated coating (PEG or BSA), antibody covalent attachment, PEG cap and PEG/protein block (as described in the examples above). The antibody-coated magnetic particles were diluted to 0.4 mM Fe (5.48×10^9 particles/ml) in assay buffer, and vortexed thoroughly.

The multivalent binding agent was formed from COOH-modified tacrolimus covalently conjugated to BSA (as described in Example 8). The multivalent binding agent was diluted to 0.02 µg/ml in assay buffer, and vortexed thoroughly.

The extracted sample solution (10 µL) and the magnetic particle solution (10 µL) were combined and vortexed for five seconds and incubated at 37 °C for 15 minutes. To this mixture was added 20 µL of the multivalent binding agent and the resulting mixture vortexed for five seconds and incubated at 37 °C for 5 minutes.

Several samples were prepared as described above. All samples were placed into the gMAA unit for 1 minute. All samples were then placed into a tray removed from the magnetic field. Each sample was vortexed for at least five seconds and returned to the tray. All samples were again placed into the gMAA unit for 1 minute, followed by vortexing. This process was repeated twelve times for each sample.

The sample was incubated for 5 minutes at 37 °C, placed in the MR Reader (see Example 6) to measure the T_2 relaxation rate of the sample, and the T_2 relaxation rate of the sample was compared to a standard curve (see Figure 29) to determine the concentration of tracrolimus in the liquid sample.

Tacrolimus antibody

Several antibody development programs were pursued to create a high-affinity tacrolimus antibody including traditional mouse monoclonal models, in vitro phage display strategies, and rabbit

models. C21 derivatives of tacrolimus were used as the haptens for the immunogen and screening conjugates used in these programs. A set of criteria was developed for screening and identification of an optimal antibody for use in the assay. The criteria include the ability to bind tacrolimus-protein conjugates, the inhibition of that binding in the presence of nanomolar levels of free tacrolimus, all while

5   exhibiting little or no affinity for the metabolites of tacrolimus (depicted below).

Using the established antibody selection criteria outlined above, several monoclonal antibodies, polyclonal antibodies, and Fab fragments have been identified and selected as potential candidates in a tacrolimus assay.

10
Example 10. Side-side gradient magnetic assisted agglomeration (gMAA).

An evaluation of alternative methods of gMAA was performed using the creatinine immunoassay described in Example 6 with sample containing no analyte to compete with the particle-antibody specific

15   agglomeration.

Several identical samples were prepared as described in Example 6. All samples were placed into the gMAA unit for 1 minute. All samples were then placed into a tray removed from the magnetic field. Each sample was vortexed for at least five seconds and returned to the tray. All samples were again placed into the gMAA unit for 1 minute. This process was repeated twelve times for each sample, to

20   obtain replicate measurements.

After the last gMAA cycle, the sample was vortexed for 5 seconds, incubated for 5 minutes at 37 °C, and placed in the MR Reader to measure the T_2 relaxation rate of the sample.

The specific aggregation achieved with various methods of gMAA are depicted in Figure 26, wherein (i) "control" is gMAA (magnet exposure + vortex, repeat) in which the relative position of the

25   sample and the magnetic field direction are unchanged with each cycle; (ii) "twist is gMAA (magnet

exposure + rotation within magnet, repeat) with rotating tube ca. 90° relative to the gradient magnet with each cycle; (iii) "180 turn" is gMAA (magnet exposure + remove tube from magnet, rotate, place back in magnet, repeat) with rotating tube ca. 180° relative to the gradient magnet with each cycle; and (iv) "remove 5 s" is = removal of tube from magnet, 5 sec rest (no rotation), repeat.

5   In the pulsed (cycled) magnetic assisted agglomeration of the invention, the liquid sample is exposed to magnetic fields from different directions in an alternating fashion. As shown in Figure 26, the rate at which a steady state degree of agglomeration, and stable T_2 reading, is achieved is expedited by cycling between the two or more positions over a series of gMAA treatments.

10   Example 11. Side-bottom gradient magnetic assisted agglomeration (gMAA).
         An evaluation of "side-bottom" gMAA was performed using the creatinine basic immunoassay described in Example 6. For this evaluation, creatinine antibody was diluted to 1 μg/ml and serum calibrators were diluted 1:5 prior to the assay. 10 μl of diluted calibrator, 10 μL of particle reagent and 20 μL of antibody reagent were pipetted into the reaction well. The tube was preheated to 37C for 5

15   minutes and then processed through gMAA with a 60 sec exposure in the side magnet, followed by 60 sec in the bottom magnet. This was completed for 6 total cycles or 12 minutes total. A final mix using a vortex for 60 sec was performed prior to the reading operation.
         A standard curve for the competitive creatinine creatinine assay with alternating side-bottom gMAA is shown in Figure 27 demonstrating good response with the side-bottom gMAA configuration.

20
         Example 12. Effect of varying the gMAA dwell time and temperature.
         An evaluation of gMAA dwell time and temperature on assisted agglomeration was performed.
         The following conditions were tested to determine the most optimal temperature and dwell time for T_2 performance: Alterations – 6, 12, 24, 48; for each number of alterations the following dwell time was evaluated: 30, 60, 120 seconds. A fixed magnet time of 6 minutes with the following dwell times

25   was also evaluated: 30, 60, 120 seconds. Samples were prepared by adding 20 μL of varied concentrations of Protein A (a target protein) and 20 μL Anti-Protein A antibody coated magnetic particles at 0.08 mM Fe to a PCR Tube (1.2×10^9 particles per tube). Samples were placed into a 32 position tray, vortexed in a plate shaker for 2 minutes at 2000 rpm and incubated in a 37 °C incubation

30   station for 15 minutes. Samples were then exposed to the aforementioned dwell and alteration conditions between alternating magnetic fields. Following gMAA treatment, samples were vortexed manually for 5 minutes, incubated in a 37 °C heat block compatible with PCR Tubes, and the T_2 was read using the MR Reader (see Example 6). Data in Figures 30A and 30B show that T_2 response is directly proportional to temperature and dwell time. Therefore, increased temperature and dwell time/total time results in

35   improved T_2 response.

Example 13. Effect of varying the number of gMAA cycles.

An evaluation of varying the number of gMAA cycles was performed using the system and procedure of Example 12.

The following conditions were tested for effect on T_2 performance: cycles – 3, 6, 12, 24; for each cycle the following dwell time were evaluated: 30, 60, 120 seconds. A cycle consists of dwell in the side, followed by bottom. 6 cycles = 12 total alterations. Samples were prepared as described in Example 12. As shown in Figure 31, the degree of aggregation is directly proportional to number of gMAA cycles. It was also found that when magnet exposure time reaches or exceeds 24 minutes, there is an increase in non-specific aggregation that cannot be dispersed with vortex (not shown here).

Example 14. Candida assay.

In the assay used for Candida, two pools of magnetic particles are used for detection of each Candida species. In the first pool, a species specific Candida capture oligonucleotide probe is conjugated to the magnetic particles. In the second pool, an additional species-specific capture oligonucleotide probe is conjugated to the magnetic particles. Upon hybridization, the two particles will hybridize to two distinct species-specific sequences within the sense strand of the target nucleic acid, separated by approximately 10 to 100 nucleotides. (Alternatively, the two capture oligonucleotides can be conjugated to a single pool of particles, resulting in individual particles having specificity for both the first and second regions). The oligonucleotide-decorated magnetic particles are designed to aggregate in the presence of nucleic acid molecules from a particular species of Candida. Thus, unlike the inhibition assays used for creatinine and tacrolimus, the Candida assay features an increase in agglomeration in the presence of the target Candida nucleic acid molecules. The hybridization-mediated agglomerative assay architecture is depicted in Figure 32.

Carboxylated magnetic particles are used in the Candida assays. Magnetic particles were conjugated to oligonucleotide capture probes to create oligonucleotide-particle conjugates. For each target amplicon, two populations of oligonucleotide-particle conjugates were prepared. Oligonucleotide-particle conjugates were prepared using standard EDC chemistry between aminated oligonucleotides and carboxylated particles, or, optionally, by coupling biotin-TEG modified oligonucleotides to streptavidin particles. Coupling reactions were typically performed at a particle concentration of 1% solids.

Post-conjugation, functional oligonucleotide densities were measured by hybridizing Cy5-labeled complements to the particles, washing the particles three times to remove non-hybridized oligo; and eluting by heating to 95 °C for 5 minutes. The amount of Cy5 labeled oligonucleotide was quantified via fluorescence spectroscopy.

The coupling reactions were performed at 37 °C overnight with continuous mixing using a rocker or roller. The resulting particle conjugates were washed twice with 1x reaction volume of Millipore water; twice with 1x reaction volume of 0.1 M Imidazole (pH 6.0) at 37 °C for 5 minutes; three times with 1x reaction volume of 0.1 M sodium bicarbonate at 37 °C for 5 minutes; then twice with 1x reaction

volume of 0.1 M sodium bicarbonate at 65 °C for 30 minutes. The resulting particle conjugates were stored at 1 % solids in TE (pH 8), 0.1% Tween®20).

The panel of Candida species detected includes C. albicans, C. glabrata, C. krusei, C. tropicalis, and C. parapsilosis. The sequences are amplified using universal primers recognizing highly conserved
5   sequence within the genus Candida. The capture oligonucleotides were designed to recognize and hybridize to species-specific regions within the amplicon.

An aliquot of a blood sample was first subjected to lysis as follows:

(i) A whole blood sample was mixed with an excess (1.25×, 1.5×, or 2×) volume of ammonium chloride hypotonic lysis solution. Addition of lysis solution disrupts all RBCs, but does not disrupt
10   WBC, yeast, or bacteria cells. The cellular matter was centrifuged at 9000 rpm for 5 minutes and lysate was removed. Intact cells were reconstituted with 100 μl TE (tris EDTA, pH = 8) to a final volume of about 100 μl; and

(ii) To the approximately 100 μl sample, 120 mg of 0.5 mm beads were added. The sample was agitated for 3 minutes at about 3K rpm, thereby forming a lysate.
15   An aliquot of ca. 50 μl of lysate was then subjected to PCR amplification by addition of the lysate to a PCR master mix including nucleotides; buffer (5mM (NH₄)SO₄ 3.5 mM MgCl₂, 6% glycerol, 60mM Tricine, pH = 8.7 at 25 °C; primers (forward primer in 4× excess (300mM forward; 0.75mM reverse) to allow for asymmetric single strand production in the final product); and thermostable polymerase (HemoKlenTaq (New England Biolabs)). After an initial incubation at 95 °C for 3 minutes, the mixture
20   is subjected to PCR cycles: 62°C annealing; 68°C elongation; 95°C- for 40 cycles. Note: there is a 6°C difference in the annealing and elongation temperatures; the annealing and elongation may be combined into a single step to reduce the total amplification turn-around time.

The PCR amplicon, now ready for detection, is combined with two populations of particles in a sandwich assay.
25   The PCR primers and capture probes which can be used in the Candida assay are provided below in Table 8.

1.   NitInd is 5' 5-Nitroindole, a base that is capable of annealing with any of the four DNA bases.

2.   Note that oligo Ts are added as spacers

5   Optionally, the assay is carried out in the presence of a control sequence, along with magnetic particles decorated with probes for confirming the presence of the control sequence.

Example 15. Non-agglomerative methods.

This process has been demonstrated using aminosilane-treated nickel metal foam with 400 μm

10   pores decorated with anti-creatinine antibodies and shown to specifically bind creatinine-detivatized magnetic particles. A 1cm square piece of nickel metal foam (Recemat RCM-Ni-4753.016) was washed by incubating at room temperature for 1 hr in 2M HCL, rinsed thoroughly in deionized water, and dried at 100 °C for 2 hours. The nickel foam was then treated with 2% 3-aminopropyltriethoxysilane in acetone at room temp overnight. The nickel metal foam was then washed extensively with deionized water and

15   dried for 2 hours at 100 °C. The aminosilane-treated nickel metal foam was treated with 2% gluteraldehyde in water for 2 hours at room temp and washed extensively with deionized water. Next, the metal foam was exposed to 100μg/ml of anti-creatinine antibody (14H03) (see Example 6) in PBS overnight, washed extensively with PBS, and treated with Surmodics Stabilguard to stabilize and block non-specific binding. Two mm square pieces of the derivatized metal foam were cut using a fresh razor

20   blade being careful not to damage the foam structure. A piece of the derivatized metal foam was place into a PCR tube in 20 μl assay buffer(100 mM glycine (pH = 9.0), 150 mM NaCl, 1% BSA, 0.05%

ProClin®, and 0.05% Tween®). Twenty microliters of control particles (that should not bind to the metal
foam ABX1-11) at 0.2mMFe were added to the tube to bring the final volume to 40ul and final particle
concentration to 0.1mM Fe ($1 \times 10^6 - 1 \times 10^8$ particles/tube). A separate PCR tube with the exact particle
and buffer, without the metal foam was also prepared. The PCR tube containing the derivatized metal

5   foam and control particles was placed in a gMAA fixture (side pull 6 position) for one minute and
removed touched with a hand demagnetizer, and placed back into the gMAA fixture for another minute,
removed touched with a hand demagnetizer and placed back into the gMAA fixture for another minute
and vortexed (three 1 minute magnetic exposures). Thirty µl of sample was removed from both PCR
tubes, heated to 37 °C in a grant block heater for 5 minutes and the T_2 read using the MR Reader (see

10   Example 6). The T_2 from the sample with no foam read 39.2, and the samples from the PCR tube
containing the foam read 45.1, demonstrating a low level of particle depletion due to NSB. The
derivatized metal foam was de-magnetized, vortexed and rinsed in assay buffer. It was placed in a new
PCR tube with 20 µl of assay buffer and 20 µl of AACr2-3-4 particles derivatized with creatinine with a
final particle concentration of 0.1mMFe. A duplicate PCR tube without the derivatized metal foam was

15   also set up as in the control experiment. The PCR tube with the metal foam was cycled twice through the
gMAA device exactly as the control experiment (3 one minute exposures with demag after each exposure,
and final vortex). Thirtly µl samples from both tubes were removed and heated to 37 °C for 5 minutes
and then read on the MR reader. The sample from the PCR tube with the derivatized metal foam read
41.5, and the sample from the PCR tube with the metal foam derivatized with the anti-creatinine antibody

20   read 324.2, thus demonstrating specific binding/depletion of the appropriate creatinine-derivatized
magnetic particles from the aqueous volume read by the MR reader.

         Example 16. Detection of single nucleotide polymorphisms.
         There are numerous methods by which T_2 measurements could detect single nucleotide

25   polymorphisms.
         The simplest application would involve discrimination of mismatches via a thermophilic DNA
ligase (Tth ligase). This assay would require lysis of the sample material followed by DNA shearing.
Adaptors could be ligated onto the sheared DNA if a universal amplification of the genomic DNA was
needed. The SNP would be detected by engineering superparamagnetic particle bound capture probes

30   which flank the SNP such that the 5' end of the 3' aminated capture probe would be perfectly
complementary to one particular SNP allele and subsequent treatment with Tth ligase would result in the
ligation of the two particle-bound capture probes. Ligation would therefore lock the particles into an
agglomerated state. Repeated melt, hybridization cycles will result in signal amplification in cases where
genomic DNA amplification is not desired because of the amplification bias risk. The same 5'aminated

35   capture probe could be utilized in all case while the 3' aminated probe could be generated to yield 4
distinct pools (an A, G, C, or T) at the extreme 5' end. Detection would require splitting of the sample
into the 4 pools to determine which nucleotide(s) were present at the polymorphic site within that

particular individual. For example a strong T_2 switch in the G detection tube only would indicate the individual were homozygous for G at that particular sequence location , while a switch at G and A would indicate the individual is a heterozygote for G and A at that particular SNP site. The advantage of this method is Tth polymerase has been demonstrated to have superior discrimination capability even

5   discriminating G-T mismatches (a particular permissive mismatch and also the most common) 1:200 fold against the correct complement. While ligase detection reactions as well as oligonucleotide ligase assays have been employed in the past to define nucleotide sequences at known polymorphic sites, all required amplification either before or after ligation; in this particular example the signal could be amplified via a ligation induced increase in the size of the resulting agglomerated particle complex and thereby increases

10   in the measured relaxation times (T_2).

A modification to this procedure could include hybridization of a particle bound capture probe flanking the hybridization of a biotinylated probe. When a perfectly complementary duplex is formed via hybridization of the particle bound probe, the ligase would covalently bind the biotin probe to the magnetic particle. Again repeated rounds of heat denaturation followed by annealing and ligation should

15   yield a high proportion of long biotinylated oligos on the magnetic particle surface. A wash to remove any free probe would be conducted followed by the addition of a second streptavidin labeled superparamagnetic particle. Agglomeration would ensue only if the biotinylated probes were ligated onto the surface of first particle.

A hybridization discrimination approach could as well be employed. In this example, aminated

20   oligonucleotide complements adjacent to known SNPs would be generated. These aminated oligonucleotides would be used to derivatize the surface of a 96-well plate with 1 SNP detection reaction conducted per well. Genomic DNA would then be sheared, ligated to adaptors, and asymmetrically amplified. This amplified genomic DNA would then be applied to the array as well as a short biotinylated SNP detecting probe. The amplified genomic DNA would hybridize to the well-bound

25   capture probe and the SNP detecting probe would then bind to the tethered genomic DNA. Washing would be conducted to remove free SNP-detecting probe. A streptavidin (SA) magnetic particle would then be added to each well. Washing again would be required to remove free-SA particles. T_2 detection could be conducted directly within the wells by added biotinylated superparamagnetic particles to yield surface tethered agglomerated particles, or the SA magnetic particles could be eluted from each well on

30   the array and incubated in detection reactions with biotinylated magnetic particles.

Lastly a primer extension reaction could be coupled to T_2 detection to discriminate which nucleotide is present at a polymorphic site. In this assay, a pool of dideoxynucleotides would be employed with one nucleotide per pool possessing a biotin (i.e., ddA, ddT, ddbiotin-C, and/or ddG). A superparamagnetic particle bearing a capture probe whose last base upon hybridization lies adjacent to a

35   SNP would be employed.

The sheared genomic DNA would be split and incubated in four separate primer extension reactions. An exo- DNA polymerase would then catalyze the addition of a dideoxy complementary to the

nucleotide present in the SNP. Again this reaction could be cycled if a thermophilic polymerase is employed to ensure that most of the capture probes on the particle will be extended. A magnetic separation followed by a wash of the particles would be conducted followed by incubation with streptavidin superparamagnetic particles. Clustering would ensue proportional to the extent of

5   biotinylated capture probe on the surface of the first particle. If two of the dideoxypools generated a gain in T_2 (i.e., facilitate particle agglomeration), the patient would be a heterozygote. If only one pool yielded and increase in T_2, the patient would be a homozygote.

A final method to detect SNPs employs allele-specific PCR primers, in which the 3' end of the primer encompasses the SNP. Since stringent amplification conditions are employed, if the target

10   sequence is not perfectly complementary to the primer, PCR amplification will be compromised with little or no product generated. In general, multiple forward primers would be designed (one perfectly complementary to each allele) along with a single reverse primer. The amplicon would be detected using two or more capture probe bound superparamagnetic particles to induce hybridization based agglomeration reactions. One advantage of this approach is that it leverages some of the work already

15   conducted at T_2 on PCR within crude samples, and would merely entail primers designed to encompass known SNPs. A disadvantage in this approach is that it cannot determine de novo SNP locations.

An additional method which can be used is simply relying on the discrimination capabilities of particle-particle cross-linking due to hybridization to a short nucleic acid target. Mismatches in base pairs for oligonucleotides have been shown to dramatically shift the agglomeration state of particles, and the

20   measured T_2 signal, due to reduced hybridization efficiencies from the presence of a single base mismatch.

Example 17. Diagnostic Candida Panel.

Testing was performed over the course of 45 days. C. albicans and C. krusei reference strains as

25   well as C. albicans clinical isolates were cultivated and maintained for the duration of the study.

Materials:

C. albicans and C. krusei nanoparticles: Two particle populations were generated for each species, the particles bearing covalently conjugated to oligos complementary to species-specific sequences within the ITS2 region (see Example 14). The particles were stored at 4-8 °C in TE (pH 8),

30   0.1% Tween and were diluted to 0.097 mM Fe in DNA hybridization buffer immediately before use.

Candida strains: Panels were performed using C. albicans reference strain MYA 2876 (GenBank FN652297.1), C. krusei reference strain 24210 (GenBank AY939808.1), and C. albicans clinical isolates. The five C. albicans isolates used were cultivated on YPD at room temperature. Single colonies were selected, washed 3 times with PBS, and then quantified via hemocytometer for preparation of whole

35   blood spikes. The samples were stored as frozen glycerol stocks as -80 °C.

Human whole blood: Whole blood was collected from healthy donors and treated with K₂EDTA and spiked with washed serially diluted Candida cells at concentrations spanning 1E5 to 5 cells/mL. Cell spikes prepared in fresh blood were stored at -20°C.

Erythrocyte Lysis buffer: A hypotonic lysis buffer containing 10mM potassium bicarbonate, 155 mM ammonium chloride, and 0.1 mM EDTA was filter sterilized and stored at room temperature prior to use. Alternatively an erythrocyte lysis agent can be used, such as a non-ionic detergent (e.g., a mixture of Triton-X 100 and igepal, or Brij-58).

PCR master mix: A master mix containing buffer, nucleotides, primers, and enzyme was prepared (20 μL 5× reaction buffer, 22 μL water, 2 μL 10 mM dNTP, 3 μL 10 μM forward primer, 3 μL 2.5 μM reverse primer, 10 μL HemoKlenTaq, and 40 μL bead beaten lysate) and stored at room temperature.

Particle hybridization master mix: A master mix consisting of nanoparticle conjugates, salts, surfactant, and formamide was prepared (78 μL formamide, 78 μL 20× SSC, 88.3 μL 1×TE + 0.1%Tween, 7.5 μL CP 1 - 3', and 8.2 μL CP 3 - 5') immediately before use.

Glass beads (0.5 mm), used in mechanical lysis of Candida, were washed in acid and autoclaved and stored at room temperature prior to use.

PCR protocol:

A general scheme of the workflow for detection of a pathogen (e.g., Candida) in a whole blood sample is shown in Figure 47. The protocol was as follows: (i) human whole blood spiked samples were allowed to warm to room temperature (~30 minutes); (ii) 1 mL of erythrocyte lysis buffer was aliquotted into each tube; (iii) each tube was centrifuged at 9000 g for 5 minutes and the lysed blood discarded; (iv) 100 μL of 0.2 micron filtered TE was aliquotted into each tube; (v) 120 mg of acid washed glass beads were added to each tube; (vi) each tube was vortexed for 3 minutes at maximum speed (~3000 rpm); (vii) 50 μL of lysed sample was aliquotted into a tube containing PCR master mix (viii) cycle PCR reactions as follows: (initial denaturation: 95 °C, 3 minutes; 30–40 cycles at 95 °C, 20 seconds; 30–40 cycles at 62 °C, 30 seconds; 30–40 cycles at 68 °C, 20 seconds; final extension: 68 °C, 10 minutes; final soak: 4°C); (ix) each of the samples was briefly centrifuged after thermocycling to form pellet clotted blood; (x) 5 μL of particle master mix was aliquotted into the tube for every 10 μL of amplified sample; (xi) the resulting mixture was well mixed and the sample denatured at 95 °C for 3 minutes; (xii) the sample was hybridized at 60 °C for 1 hour with gentle agitation; (xiii) the sample was then diluted to 150 uL with particle dilution buffer, and equilibrated to 37°C in a heat block for 1 minute; and (xiv) the T₂ of the sample was measured using a T₂ MR reader.

Test Results

Repeatability of Candida albicans detection in human whole blood: To determine the repeatability of the T₂ measurement on C. albicans infected human whole blood, we conducted an eight day study in which the same donor spiked and amplified sample was hybridized to the superparamagnetic particles (n=3) each day and the resulting T₂ values were recorded.

The within run precision is shown in Figure 46A and in general is tight with the CV's of all measurands less than 12%. The repeatability observed over the course of eight days is shown in Figure 46B with the CVs less than 10% across the range of Candida concentrations and 6% for the negative control. Importantly, a two population two-tailed Student's T-test was applied to determine if the difference in means between the mock Candida infected blood at 10 cells/mL and the healthy donor blood was significant. The results are summarized in Table 9.

Table 9. The difference in means between 10cells/mL infected blood and negative control is significant (p value <0.0001)

P value	< 0.0001
Are means signif. different? (P < 0.05)	Yes
One- or two-tailed P value?	Two-tailed
t, df	t=40.69 df=23
Number of pairs	24
Mean of differences	287.7
95% confidence interval	273.0 to 302.3
R square	0.9863

Influence of sample matrix on Candida albicans and Candida krusei detection and reproducibility: Healthy blood from 6 donors was spiked with a range of C. albicans or C. krusei cells (1E5 cells/mL to 0 cells/mL). From the Candida albicans spiked blood, sixteen independent experiments were conducted. Each experiment consisted of PCR amplification of the 1E5 to 0 cells/mL spiked blood with each amplification reaction subjected to three replicate T_2 detection experiments; thus for C. albicans a total of 48 T_2 values were recorded at each tested concentration (see Figure 48A). At the lowest test concentration (10 cells/mL), we failed to detect Candida albicans 37% of the time (6 out of 16 experiments); however at 100 cells/mL Candida albicans was detected 100% of the time. This suggests the LOD for C. albicans is above 10 cells/mL but below 100 cells/mL. More concentrations will be tested between the 10 CFU to 100 cells/mL to better define the LOD; however we do not expect to observe any major matrix effects on assay performance. This is evidenced by the CVs of the T_2 measurements which are as follows: 12.6% at 1E5 cells/mL in 6 donor bloods, 13.7% at 1E4 cells/mL, 15% at 1E3 cells/mL, 18% at 1E2 cells/mL, and 6% at 0 cells/mL. This suggests the assay can robustly detect at C. albicans concentrations greater than or equal to 100 cells/mL with no major inhibition of performance introduced through the donor blood samples.

The same experiment was conducted using a reference strain of C. krusei. In this case 7 independent experiments were conducted as the remaining spiked blood was reserved for blood culture analysis. We did not detect at 10 cells/mL in any of the experimental runs but detected at 100 cells/mL for all experimental runs. This suggests the LOD between 10 and 100 cells/mL. Again a titration of cell concentrations between 100 and 10 cells/mL will need to be conducted to better define the LOD. The

CV's of the measurements across the range of concentrations was: 10.5% at 1E5, 9% at 1E4, 12% at 1E3, 20% at 1E2, 6.4% at 10, and 5.2% at 0 cells/mL. The results are shown in Figure 48B.

Preliminary determination of limit of detection: Five Candida albicans clinical isolates were spiked into 6 different donor blood samples at concentrations of 1E4, 1E3, 5E2, 1E2, 50, 10, 5, and 0 cells/mL. Each isolate was spiked into a minimum of two different donor blood samples. Amplification reactions were detected via T_2 measurement with the results plotted in Figure 49. It is important to note that no data was removed for cause within this study. We did not detect C. albicans 50% of the time at 5 cells/mL or 10 cells/mL; however at 50 cells/mL C. albicans was detected 95% of the time. These data were generated using different clinical isolates; each isolate contains a different number of rDNA repeats and the number of these repeats can vary as much as 4-fold from strain to strain (i.e. ~50 units to 200 units). Since the input target copy numbers will vary slightly from strain to strain and certainly from species to species, there will be subtle differences in the absolute T_2 values observed at very low cell numbers (i.e. 10 cells/mL). Based on our very preliminary study, the data suggests a cut-off of 10 cells/mL; however this determination cannot be made in the absence of final formulations of reagents as well as the instrument/cartridge. It does suggest that defining the C5-C95 interval will be difficult because at 10 cells/mL each reaction contains only 4 cells. Titrating at cell numbers lower than this becomes challenging with this input volume of blood. Using the Poisson distribution to calculate the number of reactions that would contain 0 cells at 10 cells/mL indicates only 2% of the reactions would not contain cells; however at 5 cells/mL, 13% of the reactions will contain no Candida cells, and at 2 cells/mL, ~37% of the reactions would not contain Candida cells. To increase the assay's sensitivity to 95% at 10 cells/mL, we could increase the amount of lysate added to the PCR reactions from 40 μL to 50 μL and increase the amount of patient blood from 400 μL to 800 μL/reaction.

Preliminary determination of sensitivity/specificity: Initially, quantification of input Candida colony forming units was conducted using a hemocytometer; however in this case the operator counted budding daughter cells as separate cells. As our data is reported in colony forming units/mL and not cells/mL, buds should not be quantified. Because of this error, fewer cells/mL of Candida are present at the various spike concentrations and our sensitivity at 10 cells/mL was only 90%, while our specificity was 100%. At 25 cells/mL or greater we observe 100% sensitivity and 100% specificity. In all cases, blood culture vials inoculated with Candida cells were blood culture positive by day 8. It should be noted that the default setting for blood culture is incubation for 5 days; however we needed to extend this incubation time as many of our inoculums required >5 days incubation. As an example, Table 10A shows the time from inoculation to culture positive recorded for four different C. albicans clinical isolates inoculated into blood culture.

The results of T_2 measurements conducted on 800 μL aliquots from these spiked whole blood samples is shown in Table 10B. In all cases we were able to detect at 25 cells/mL, or greater, however we were unable to detect clinical isolate C3 at 12 cells/mL. It is important to note the CFU's were quantified via hemocytometer and not Coulter counter for this particular method compare experiment. In

total 51 blood culture bottles were inoculated with hemocytomer quantified Candida albicans clinical isolates and 35 negative blood culture vials were included in the experiment. The results for inoculums greater than 25 cells/mL are shown in the contingency table in Table 11.

Table 10A. Time to blood culture positive results for 4 different Candida albicans clinical isolates.

C. albicans isolate	100 CFU/mL	25 CFU/mL	12 CFU/mL	0.0	0.0
C1	161 hrs+/-12	161 hrs +/-12	161 hrs +/-12	192 hrs	192 hrs
C2	40 hrs +/- 12	65 hrs +/- 12	47.5 hrs	192 hrs	192 hrs
C3	69.5 hrs	161 hrs +/-12	161 hrs +/-12	192 hrs	192 hrs
C4	40 hrs +/- 12	43 hrs	47.5 hrs	192 hrs	192 hrs

*Note: all blood culture negative vials were negative and discarded at t= 8 days

Table 10B. T_2 values obtained following PCR amplification and T2 detection on the pre-culture in vitro spiked blood samples shown above (assay time ~3 hrs).

C. albicans isolate	100 CFU/mL	25 CFU/mL	12 CFU/mL	0.0	0.0
C1	739.0	409.0	632.5	112.7	112.8
C2	983.2	1014.5	997.6	117.4	114.8
C3	912.7	510.5	113.3	116.2	112.0
C4	807.6	741.2	665.2	119.1	115.9

T2 values (in msec) are the mean n=3 with CV's less than 10% for replicate measurements

Table 11. Contingency Table used to calculate sensitivity/specificity at > 25 cells/mL C. albicans.

Positive	51(true positive)	0 (false positive)	51 (TP+FP)
Negative	0 (false negative)	35 (true negative)	35 (FN+TN)
Total	51 (TP+FN)	35 (FP+TN)	86 (N)

Estimated Sensitivity= 100x[TP/(TP+FN)]= 100% (95% confidence interval= 93 to 100%)

Estimated Specificity= 100x[TN/(FP+TN]= 100% (95% confidence interval= 90 to 100%)

Standardization of CFU quantification has improved our assay sensitivity and reproducibility. Preliminary results from 27 blood culture bottles are shown in Table 12. These preliminary results indicate we have 100% sensitivity and specificity at 10 cells/mL or greater. We have additionally begun method comparisons using C. krusei. Preliminary results (from 36 vials) are shown in Table 13. The results indicate we have a sensitivity/specificity of 88%/100% at 10 cells/mL or greater and 100%sensitivity/100% specificity at 33 cells/mL or greater for Candida krusei. Another important change which was instituted prior to the new blood culture agreement comparisons was the employment of a multi-probe particle. In this case the T_2 clustering reactions for C. albicans detection were conducted using albicans/parapsilosis/tropicalis multi-functional particles while C. krusei was detected using the glabrata/krusei multi-functional particles.

Table 12. Contingency Table used to calculate sensitivity/specificity at > 10 cells/mL C. albicans.

Positive	18 (true positive)	0 (false positive)	18 (TP+FP)
Negative	0 (false negative)	6 (true negative)	6 (FN+TN)
Total	18 (TP+FN)	6 (FP+TN)	24 (N)

Estimated Sensitivity= 100x[TP/(TP+FN)]= 100% (95% confidence interval= 81.4 to 100%)

Estimated Specificity= 100x[TN/(FP+TN]= 100% (95% confidence interval= 54 to 100%)

Table 13. Contingency Table used to calculate sensitivity/specificity at > 10 cells/mL Candida
krusei.

Positive	24 (true positive)	0 (false positive)	24 (TP+FP)
Negative	3 (false negative)	9 (true negative)	12 (FN+TN)
Total	27 (TP+FN)	9(FP+TN)	36 (N)

Estimated Sensitivity= 100x[TP/(TP+FN)]=   89% (95% confidence interval= 71 to 98%)

Estimated Specificity= 100x[TN/(FP+TN]= 100% (95% confidence interval= 66 to 100%)

Preliminary assessment of clinical accuracy: Clinical accuracy is defined as the ability to discriminate between two or more clinical states, for example Candidemia versus no Candidemia. Receiver Operator Characteristic (ROC) plots describe the test's performance graphically illustrating the relationship between sensitivity (true positive fraction) and specificity (true negative fraction). The clinical accuracy (sensitivity/specificity pairs) is displayed for the entire spectrum of decision levels. Using the data generated from the 10 cells/mL and 50 cells/mL clinical isolate spiked whole blood samples, two ROC plots were generated and are shown in Figures 50A and 50B. The area under the curve is often used to quantify the diagnostic accuracy; in this case our ability to discriminate between a Candidemic patient with an infection of 10 cells/mL or 50 cells/mL versus a patient with no Candidemia. At 10 cells/mL the area under the curve is 0.72 which means that if the T_2 assay was run on a randomly chosen person with Candidemia at a level of infection of 10 cells/mL, there is an 72% chance their T_2 value would be higher than a person with no Candidemia. The clinical accuracy of the test is much higher at 50 cells/mL with the area under the curve at 0.98. Again indicating that in a person with Candidemia at this level of infection, the T_2 assay would give a value higher than a sample from a patient without Candidemia 98% of the time. This is excellent clinical accuracy for infection levels of 50 cells/mL. ROC plots were not prepared for the 100 cells/mL samples or higher as the area would be translating to 100% clinical diagnostic accuracy. Final clinical accuracy is determined from real patient samples on the clinical platform.

Assay turnaround time: The primary assay steps with estimated times are: (i) hypotonic lysis/centrifugation / bead beating (8 min); (ii) PCR (120 min.); (iii) hybridization of amplicon to particles (30 min.); (iv) hMAA (10 min.); and (v) transfer and read (10 sec.). The processing time for the assay is estimated at ~ 178 minutes (~3 hrs), excluding reagent and equipment preparation. This is the workflow used for qualification; however we have demonstrated that the following modified work-flow with shorter

PCR and hybridization steps does yield the same detection sensitivity (see Figure 51) (albeit with a reduction in the amount of amplicon generated for some Candida species (i.e., glabrata) and hence a smaller delta T_2 between diseased and normal): (i) hypotonic lysis/centrifugation / bead beating (8 min.); (ii) PCR (70 min.); (iii) hybridization of amplicon to particles (30 min.); (iv) hMAA (10 min.); and (v)
5   transfer and read (10 sec.). This modified flow generates a TAT of 133 minutes or 2 hours and 13 minutes (and this is without migration to a faster thermocycler).

Conclusions

This testing demonstrates a current T_2 based molecular diagnostic assay for Candidemia with the following metrics: (i) detection of Candida albicans within whole blood at a range spanning 5–1E5
10   cells/mL (5-log); (ii) detection of Candida krusei within whole blood at a range spanning 10 cells/mL to 1E5 cells/mL; (iii) sensitivity/specificity of 100%/100% at > 25 cells/mL; (iv) diagnostic accuracy of greater than 98% for concentrations > 50 cells/mL; (v) assay compatibility with whole blood (no major matrix effects observed using twelve different donor blood samples); (vi) repeatability of T_2 measurements (less than 12% within the same day and less than 13% across eight days); and (vii) reduced
15   total assay turnaround time to 2 hours 3 minutes.

We have tested higher input volumes of human blood and found that efficient hypotonic lysis is achievable with these larger blood volumes; further it has increased the reproducibility of detection at 10 cells/mL.

Contamination was observed within 2 samples of the 50 titrations. To reduce contamination
20   issues, the PCR steps may be separated from the detection steps. Further, chemical/biochemical methods may be used to render the amplicons unamplifiable. For example, uracils may be incorporated into the PCR product, and a pre-PCR incubation may be conducted with uracil N glycosylase.

The advantages of the systems and methods of the invention include the ability to assay whole blood samples without separating proteins and non-target nucleic acids from the sample. Because no
25   losses in target nucleic acids are incurred through DNA purification (e.g., running Qiagen column after lysis and prior to amplification results in >10× loss in sensitivity; and use of whole blood interferes with optical detection methods at concentrations above 1%), sample-to-sample variability and biases (which can be introduced by DNA purification) are minimized and sensitivity is maximized.

Over 10% of septic shock patients are carriers of Candida; this is the third most prevalent
30   pathogen after S. aureus & E. coli, and there is an approximately 50% mortality rate for septic shock patients infected with Candida. Candida is the fourth leading cause of hospital acquired infections. Rapid identification of these patients is critical to selecting proper treatment regimens.

Example 18. Viral assay.
35   CMV genomic DNA was spiked into CMV-free healthy donor blood samples, 40 µL of this spiked blood was aliquoted into a 100 µL total volume PCR reaction. Amplification was conducted using a whole blood compatible thermophilic DNA polymerase (T2 Biosystems, Lexington, MA) and

- 161 -

exemplary universal primers that were designed as follows: 24 mer end—C6 linker—CMV specific sequence, the exact sequences were as follows:

5'-CAT GAT CTG CTG GAG TCT GAC GTT A-3'   (SEQ ID NO. 11, universal tail probe #1)

5'-GCA GAT CTC CTC AAT GCG GCG-3'   (SEQ ID NO. 12, universal tail probe #2)

5   5'-CGT GCC ACC GCA GAT AGT AAG-3'   (SEQ ID NO. 13, CMV US8 forward primer)

5'-GAA TAC AGA CAC TTA GAG CTC GGG-3'   (SEQ ID NO. 14, CMV US8 reverse primer)

The primers were designed such that the capture probes (i.e., the nucleic acid decorating the magnetic particle) would anneal to the 10mer region (10mers are different on either 5' or 3' end). The final primer concentration in the reaction tube was 300 nM and PCR master mix which included 5mM

10      $(NH_4)_2SO_4$, 3.5 mM $MgCl_2$, 6% glycerol, 60 mM Tricine (pH 8.7)). Five separate sample reaction tubes were set up. Cycle PCR reactions followed an initial denaturation of 95 °C for 3 minutes, and each cycle consisted of 95 °C, 20 seconds; 55 °C, 30 seconds; and 68 °C, 20 seconds. At 30, 33, 36, 39, and 42 cycles reaction tubes were removed and maintained at 4 °C. Once all samples were ready, 5 µL of particle master mix (6×SSC, 30% formamide, 0.1% Tween) was aliquoted into the tube for every 10 µL

15   of amplified sample; the resulting mixture was well mixed and the sample denatured at 95 °C for 3 minutes; the sample was hybridized at 45 °C for 1 hour with gentle agitation; the sample was then diluted to 150 µL with particle dilution buffer (PBS, 0.1% Tween, 0.1% BSA), placed into a temperature controlled hMAA magnet for 10 minutes, and equilibrated to 37 °C in a heat block for 1 minute; and the T_2 relaxation time for each of the five separate samples was measured using a T_2 MR reader (see Figure

20   52).

The primers were designed to allow the magnetic particles decorated with capture probes to anneal to the 10mer region (10mers are different on either 5' or 3' end), providing particles with a universal architecture for aggregation with specific amplification primers.

The results provided in Figure 52 show that the methods and systems of the invention can be used

25   to perform real time PCR and provide quantitative information about the amount of target nucleic acid present in a whole blood sample.

Example 19. Real-time PCR

Previous results showed that when particles were present in the PCR reaction the amplicon

30   production was inhibited. We hypothesize that moving the particles to the side of the reaction tube during the thermocycling will allow production of amplicon. A simple magnetic separator/PCR block insert (Figure 53) was designed to keep nanoparticles on the side walls during PCR reaction, thus minimizing interference and particle exposure to the PCR reaction components. Upon removal of the magnetic field, particles can be completely resuspended into the reaction mixture.

35   In one experiment, we tested the rate at which particles could be sequestered to the side of the tube and returned to solution. In this experiment, 100 µL of the *C. albicans* (3' and 5') particle mix in 1x

TE (~150 msec unclustered T2 baseline) went three times through clustering/unclustering process at 95°C. This was followed by the following protocol

    1. vortex, incubate at 37°C for 1 min, measure T2;

    2. heat at 95°C for 5 min on the magnetic PCR insert;

5   3. incubate at 37°C for 1 min, measure T2;

    4. vortex 15 sec, incubate at 37°C for 1 min, measure T2; and

    5. go to step 2.

The results of this experiment are shown in Table 14 below.

10

Table 14

cycle #	1	2	3	4				
tube 1	147.1	150.8	154.9	140.9	T2 unclustered			
	2198.6	1965.6	2161.4		T2 clustered at 95 'C			
% T2 incr.	1494.2	1303.5	1395.1				avrg. %	1397.6
tube 2	143.5	147.4	150.4	144.2	T2 unclustered			
	2240.7	2141.3	2086.5		T2 clustered at 95 'C			
% T2 incr.	1561.4	1452.9	1386.9				avrg. %	1467.1

As shown in Table 14, fully reversible nanoparticle clustering was demonstrated at 95°C when using the tested magnetic separator. Particles are stable at 95°C for at least 3 clustering/unclustering

15   cycles.

We next tested PCR efficiency in the presence of nanoparticles in reaction solution. PCR was performed under two conditions: (1) nanoparticles are fully dispersed in solution; and (2) nanoparticles are concentrated on the PCR test tube side walls using magnetic insert.

Three PCR reactions (with nanoparticles concentrated on the test tube wall; fully dispersed in

20   solution; and no nanoparticles) were set up using *C. albicans* genomic DNA as a starting material. Successful target DNA amplification was validated using gel electrophoresis. Capture-probe decorated Seramag particles were used.

Asymmetric (4:1) PCR reactions were setup using pre-made PCR mix and 100 copies of genomic *C. albicans* DNA as a starting material. *C. albicans* capture particle mix (3' and 5') in 1x TE was added

25   to reactions (1) and (3) (baseline ~150msec). Control reaction (2) did not have nanoparticles added (Figure 54).

No difference was observed in PCR product formation when nanoparticles were present in solution (dispersed in solution or concentrated on test tube side walls via magnetic field) during PCR. Therefore, nanoparticles modified with capture probes do not interfere with PCR. Comparable amounts

30   of product were generated in the reactions with and without nanoparticles present in solution as

evidenced by gel electrophoresis. Also, magnetic concentration of nanoparticles on test tube side walls during PCR process does not have an effect on the PCR.

Example 20. Internal Controls for C. Albicans.

5   A variety of impurities and components of whole blood can be inhibitory to the polymerase and primer annealing. These inhibitors can lead to generation of false positives and low sensitivities. To assure that clinical specimens are successfully amplified and detected, the assay can include an internal control nucleic acid that contains primer binding regions identical to those of the target sequence. The target nucleic acid and internal control are selected such that each has a unique probe binding region that

10   differentiates the internal control from the target nucleic acid. The internal control can be an inhibition control that is designed to co-amplify with the nucleic acid target being detected. Failure of the internal inhibition control to be amplified is evidence of a reagent failure or process error. Universal primers can be designed such that the target sequence and the internal control sequence are amplified in the same reaction tube. Thus, using this format, if the target DNA is amplified but the internal control is not it is

15   then assumed that the target DNA is present in a proportionally greater amount than the internal control and the positive result is valid as the internal control amplification is unnecessary. If, on the other hand, neither the internal control nor the target is amplified it is then assumed that inhibition of the PCR reaction has occurred and the test for that particular sample is not valid.

           The already amplified and detected Candida albicans sequence was examined for use in

20   generating an internal control. The universal primer sequences were removed from the 5' and 3' ends. The residual internal sequence was subjected to a random sequence generator and a random sequence was generated. The universal primer sequences were replaced at the ends and the full internal control sequence was cloned into pCR2.1-TOPO and was sequence verified.

           In designing these internal controls, the following criteria and features for use in diagnostic PCR

25   assays were employed: 1) the target and internal control DNA share the same primers; 2) the internal control and target DNA are easily distinguishable (i.e. different capture probes); 3) the amplification efficiencies of the target and internal control have been tested and are acceptable; 4) the source of the internal control is a plasmid DNA carrying the cloned internal control sequence; 5) the internal control is detected by sequence dependent hybridization; 6) the internal control plasmid is highly purified; 7) the

30   concentration of the internal control is determined by titration; 8) the internal control plasmid is added to the PCR mix to ensure equal distribution to all of the PCR tubes; 9) it has been determined the amount of internal control in the assay reaction tubes is 100-1000 copies/ reaction and this concentration has been determined to be the lowest amount that still elicits a signal via amplification. See Hoofar et al., J. Clin. Microbiol. 42:1863 (2004).

35   The internal inhibition control for the Candida assay was designed to co-amplify with the Pan Candida PCR primers and contain a unique intervening sequence of similar length and base composition as the Candida species. The intervening sequence was developed by applying a sequence randomizing

algorithm to the C. ablicans amplicon sequence. Four randomized sequences were then thermodynamically and bioinformatically characterized. A nucleotide megaBLAST search was conducted for each sequence using both the human genomic + transcript database as well as the nr database. No significant alignments were identified with the four query sequences in either database.

5   Each sequence was then subjected to UNAfold analysis to determine the extent of secondary structure present at the hybridization concentration of monovalent cation (600 mM) at a temperature of 60 degrees C. Two sequences were excluded at this point due to the presence of extensive stems under these hybridization conditions. Two were further characterized to determine if capture probes could be designed complementary to the 5' and 3' ends of the strand amplified in excess that would be devoid of

10   poly-G tracts, and have low probabilities of forming homo and heterodimers. One sequence met all the criteria and was ordered as a PAGE purified synthetic oligonucleotide and its respective complement from IDT Technologies (Coralville, IA). The sequence of the internal control that will be amplified in excess is:

          5- GGC ATG CCT GTT TGA GCG TCC TGC ATC ATA CTG AAA TAG ATC CTT CGA

15   CAA CCT CGG TAC ACT GGG AAC AAG GCC TCA AAC ATT GAT GCT CGA CTA CAC GTA
       GGG CAATGC GTC TTG CTA GAA GCG AAA TCT GTG GCT TGC TAG TGC AAG CTG GTC
       GGC GTA TTA TTC CAA CCC GCT GAA CTT AAG CAT ATC AAT AAG CA-3 (SEQ ID NO. 15)
          The annealed complementary sequence is:

          5- GCT TAT TGA TAT GCT TAA GTT CAG CGG GTT GGA ATA ATA CGC CGA CCA

20   GCT TGC ACT AGC AAG CCA CAG ATT TCG CTT CTA GCA AGA CGC ATT GCC CTA CGT
       GTA GTC GAG CAT CAA TGT TTG AGG CCT TGT TCC CAGTGT ACC GAG GTT GTC GAA
       GGATCT ATT TCA GTA TGA TGC AGG ACG CTC AAA CAG GCATGC CA -3 (SEQ ID NO. 16)
          5 uM of the annealed duplex in 2× SSC was sent to SeqWright for subcloning and sequencing. The annealed duplexes contain 3' adenosine overhangs to facilitate cloning into a TA cloning vector.

25   This construct was cloned into pCR2.1-TOPO. Upon transformation, 5 clones were selected and sequenced to confirm the presence of the correct insert. Upon verification of the correct cloned insert, the mini-prepped plasmid DNA should be digested with *EcoRV* and *HindIII* and the insert subcloned into pBR322. From this transformation, 5 transformants were selected and the insert verified via sequencing. Two E. coli hosts bearing the pBR322-IC were frozen in 30% glycerol + LB amp. A plasmid maxi-prep

30   was conducted using the Qiagen and yieldied ~1 mg of purified plasmid DNA.

          Capture probes were designed to hybridize nested to the Pan Candida PCR primer sequences. A 3' aminated capture probe with a T-9 linker was designed to complementary to the 5' end of the strand amplified in excess. A 5' aminated capture probe with a C12 T-9 linker was designed complementary to the 3' end of the strand amplifed in excess. These sequences are shown below:

35   GGT TGT CGA AGG ATC TAT TTC AGT ATG ATG CAG-TTT TTT TTT-3'Amino (SEQ ID NO. 17)

5'Amino-C12-TTT TTT TTT- TGG AAT AAT ACG CCG ACC AGC TTG CAC TA (SEQ ID NO. 18)

The predicted melting temperatures (Allawi, 1997) were 75 and 78 °C, respectively.

5   Example 21. Rotary gMAA.

Three prototype rotary gMAA configurations were designed, built and tested with comparison to the conventional plate based gMAA (see Figure 56A). The three configurations included varying magnetic field exposures – side-bottom; side-null and bottom-null. The plate based gMAA used for comparison is the standard side-bottom. Assay functional performance (non-specific binding and 10   clustering) was evaluated using the Creatinine agglomerative assay system. Particles derivatized with creatinine antibody were mixed with 1:5 diluted serum and creatinine dextran agglomerator. The agglomerator was tested at 6 concentrations to provide a titration curve. Each concentration level was tested in triplicate. The T2 of samples with no agglomerator was measured before and after gMAA to assess non-specific binding. gMAA was performed at room temperature for a total of 12 minutes with 1 15   minute dwells at the magnet stations.

With respect to non-specific binding, all rotary configurations yielded acceptable results (<10% difference) and were comparable to the conventional plate gMAA.

With respect to aggregate formation, all rotary gMAA devices produced aggregation. The rotary side-bottom configuration provided the highest T2 signal at a given agglomerator concentration, followed 20   by the comparison side-bottom plate configuration. Rotary side-null provides equivalent signal to the plate side-bottom; and the bottom-null produces the lowest signal (see Figure 56B).

Example 22. Candida assay and clinical data.

A rapid, accurate, and reproducible molecular diagnostic test was developed for the detection of 25   five *Candida* species directly within human whole blood with a limit of detection (LOD) of 10 cells/mL and a time to result of less than 2 hours. The assay's clinical performance was determined using 32 blinded clinical specimens and in this study we observed 100% positive and 100% negative agreement with blood culture while accurately identifying the causative *Candida* species within 100% of the candidemic patient samples. We further applied the assay to blood specimens drawn from *Candida* 30   positive patients and observed a decrease in *Candida* detection concordant with the time course of antifungal treatment. This diagnostic method is rapid, amenable to automation, and offers clinicians the opportunity to detect multiple human pathogens within complex biological specimens.

Magnetic Resonance Relaxometer

35   A compact magnetic resonance (MR) system was designed and constructed for precise T2 relaxation measurements in order to perform the intended assay under the described conditions. This system was held at 37°C via temperature control and contains a samarium cobalt permanent magnet of

approximately 0.5 T, corresponding to a proton frequency of operation of 22-24 MHz. All standard MR components: radio frequency probe, low-noise pre-amplifier and transmitter electronics, spectrometer board, as well as the temperature control hardware are packaged in the system. The system uses standard AC power input and connects to an external computer via Ethernet. A user friendly graphical user

5   interface allows users to set experimental parameters.

The system has been designed to accept samples in standard 0.2 ml PCR tubes. The electronics as well as the coil were optimized to improve the measurement precision of the applicable sample volumes, allowing us to achieve single-scan run to run CVs in T2 of less than 0.1 %. Instrument to instrument variability is under 2% with minimal tolerance requirements on the system components and

10   without calibration.

Nanoparticle Sensor Conjugation and Characterization

800 nm carboxylated iron oxide superparamagnetic particles, consisting of numerous iron oxide nanocrystals embedded in a polymer matrix including a total particle diameter of 800 nm (see Demas et

15   al., New J. Phys. 13:1 (2011)), were conjugated to aminated DNA oligonucleotides using standard carbodiimide chemistry. DNA-derivatized nanoparticles were stored at 4°C in 1× Tris-EDTA (pH 8), 0.1% Tween-20. Iron concentration of nanoparticle conjugates were measured by dissolving the particle with 6M HCl followed by addition of hydroxylamine hydrochloride and 1,10 O-phenanthroline and subsequent spectrophotometric detection as described in Owen et al., J Immunol Methods, 73:41 (1984).

20   Oligonucleotide derivatized particles are then subjected to a functional performance test by conducting hybridization induced agglomeration reactions using diluted synthetic oligonucleotide targets identical in sequence to the fungal ITS2 sequences from the five different *Candida* species within a sodium phosphate hybridization buffer 4×SSPE (600 mM NaCl, 40 mM sodium phosphate, 4mM EDTA). Reversibility of the agglomeration reaction was confirmed by subjecting agglomerated reactions to a 95°C heat

25   denaturation step, conducting a T2 measurement, and repeat hybridization at 60°C followed by a second T2 measurement.

PCR primer and nanoparticle capture probe design

Universal Pan Candida PCR primers were designed complementary to 5.8S and 26S rRNA

30   sequences that amplify the intervening transcribed spacer 2 (ITS2) region of the Candida genome. A pair of oligonucleotide capture probes was designed complementary to nested sequences at the 5' and 3' end respectively of the asymmetrically amplified PCR product. The capture probe that hybridizes to the 5' end of the amplicon was 3' aminated while the capture probe that hybridizes to the 3' end of the amplicon was 5' aminated. A poly-T linker (n=9 to 24) is added between the amino group and the first nucleotide

35   base of the capture probe sequence. HPLC purified PCR primers and capture probes were procured from IDT Technologies (Coralville, IA).

Inhibition Control Design

A PCR inhibition control was designed to co-amplify with the Candida species and monitor factors within the whole blood specimens that inhibit PCR amplification. A synthetic template was designed to contain 30 nucleotide flanking sequences identical in sequence to the 5.8S and 26S regions of

5   the Candida rRNA operon. The internal sequence within this template consists of a randomly scrambled C. albicans amplicon. Capture probes were designed complementary to the strand amplified in excess within the asymmetric Candida PCR reactions. Synthetic oligonucleotide ultramers were procured from IDT (Coralville, IA) identical in sequence to the inhibition control. The oligonucleotides were annealed at a concentration of 5 μM in 2×SSC and cloned into HindII/EcoRV digested pBR322 (NEB, Ipswich,

10   MA) using standard methods. Transformation was conducted via electroporation of 1 μL of the ligation reaction into electrocompetant E. coli K12 cells and the transformants were plated onto Luria Bertani (LB) agar plates containing 100 μg/mL ampicillin. Two ampicillin resistant colonies were selected and cultivated in 2 mL LB ampicillin media. Plasmid mini-preps were conducted followed by restriction enzyme mapping to confirm the clones contained the correct insert. Sanger dideoxy sequencing was then

15   conducted (SeqWright, Houston,TX) to confirm successful cloning of the control and DNA maxi-preps were conducted on correct insert bearing clones. Titrations of the inhibition control in the presence of increasing concentrations of all 5 species of Candida were conducted to determine the lowest concentration of inhibition control that could be reproducibly detected. Confirmation of the function of the inhibition control was demonstrated by conducting PCR reactions in the presence of titrations of

20   known PCR interferents (SDS, heparin, ethanol) and demonstrating that amplification of the control was inhibited.

Candida cultivation and in-vitro spiked sample preparation

MYA-2876, ATCC 2001, ATCC 24210, ATCC 66029, and ATCC 22019 were the C. albicans,

25   C. glabrata, C. krusei, C. tropicalis, and C. parapsilosis laboratory reference strains (ATCC, Manassas, VA) used to prepare the in-vitro spiked whole blood specimens. Yeasts were cultivated on yeast peptone dextrose agar plates (YPD) and incubated at 25 °C. Single colonies were selected and suspended in phosphate buffered saline (PBS). The species were verified via ITS2 sequencing at Accugenix (Newark, Delaware). The cells were then subjected to a low speed centrifugation (3000 g for 2 minutes) and

30   washed three times with fresh PBS. An aliquot of the PBS washed cells was then diluted in ISOTON II diluent (Beckman Coulter, Brea, CA) within a 20 mL Accuvette and cells were quantified on a Multisizer 4 Coulter Counter (Beckman Coulter, Brea, CA) following the manufacturers instruction. Cells were then serially diluted to concentrations ranging from 500 to 5 cells/100 μL PBS buffer. Fresh human healthy donor blood drawn by sterile collection in K2EDTA vacutainer tubes (BD Diagnostics, Franklin Lakes,

35   NJ) was obtained from ProMedX. Typically five milliliters of human blood was spiked with 100 μL of quantified Candida cells. Whole blood spiked samples are then used immediately in the assay.

- 168 -

Whole Blood PCR

Erythrocyte lysis was conducted within 1 mL of the whole blood sample using previously described methods (see Bramley et al., Biochimica et Biophysica Acta (BBA) - Biomembranes, 241:752 (1971) and Wessels JM, Biochim Biophys Acta., 2:178 (1973)), a low speed centrifugation is then

5   conducted and the supernatant was removed and discarded. One hundred uL of Tris EDTA (TE) buffer pH 8.0 containing 1500 copies of the inhibition control was then added to the harvested pellets and the suspension was subjected to mechanical lysis (see Garver et al., Appl. Microbiol. , 1959. 7:318 (1959); Hamilton et al., Appl. Microbiol., 10: 577 (1962); and Ranhand, J.M., Appl. Microbiol., 28:66 (1974)). Fifty µL of lysate was then added to 50 µL of an asymmetric PCR master mix containing a

10   deoxynucleotides, PCR primers and a whole blood compatible thermophilic DNA polymerase (T2 Biosystems, Lexington, MA). Thermocycling was conducted using the following cycle parameters: heat denaturation at 95°C for 5 minutes, 40 cycles consisting of a 30 second 95°C heat denaturation step, a 20 second 62°C annealing step, and a 30 second 68°C elongation step, and a final extension at 68°C for 10 minutes.

15

Hybridization induced agglomeration assays

Fifteen microliters of the resulting amplification reaction was aliquoted into 0.2 mL thin walled PCR tubes and incubated within a sodium phosphate hybridization buffer (4×SSPE) with pairs of oligonucleotide derivatized nanoparticles at a final iron concentration of 0.2 mM iron per reaction.

20   Hybridization reactions were incubated for 3 minutes at 95°C followed by 30 minutes incubation at 60°C within a shaking incubator set at an agitation speed of 1000 rpm (Vortemp, LabNet International). Hybridized samples are then placed in a 37°C heating block to equilibrate the temperature to that of the MR reader for 3 minutes. Each sample is then subjected to a 5 second vortexing step (3000 rpm) and inserted into the MR reader for T2 measurement.

25

Candida Patient sample collection protocol.

Blood specimen discards that had been drawn in K2EDTA vacutainers (BD) on the same day as specimens drawn for blood culture (T=0) were obtained from the clinical hematology laboratory at the Massachusetts General Hospital (MGH) or Houston University Hospital. Specimens were collected and

30   catalogued from patients having blood culture positive results. Samples were stored within the original vacutainer at -80°C and the blinded specimen collection was shipped overnight on dry ice to T2 Biosystems. Clinical sample collection protocols were reviewed by the appropriate Human Research Committees.

35   Statistical analyses

For each species, the limit of detection was determined with the use of probit modeling. For each species, the 90% level of detection and 95% fiducial intervals were calculated. Each raw T2 signal was

transformed as T2_msec over the assay's background. SAS v. 9.1.3 (Cary, NC) was used in the statistical calculations for the analyses for limit of detection, agreement of spiked specimens with culture, sensitivity and specificity in clinical specimens, and serial assays to measure Candida clearance.

5   Agreement of T2 MR detection of Candida with blood culture

The current gold standard for *Candida* diagnosis is blood culture. *In vitro* spiked healthy donor whole blood specimens were prepared using laboratory reference strains for *C. albicans* and *C. krusei* and clinical isolates of *C. albicans* at concentrations of 0, 33, and 100 cells/mL. Pediatric BACTEC blood culture vials (BACTEC Peds Plus/F vials, Beckton Dickenson) were inoculated with an aliquot of the *in-*

10   *vitro* spiked specimens evaluated by T2MR. Blood culture vials inoculated with *Candida* cells were blood culture positive by day 8 in all cases. In total, 133 blood culture bottles were inoculated with 90 *Candida* spiked blood samples (inoculum of 33 cells/mL) or 43 negative blood samples. Ninety eight percent positive agreement and 100% negative agreement was observed between T2MR and blood culture.

15

Clinical Specimen Data

K2 EDTA whole blood patient specimens were obtained to test the clinical performance of the T2MR *Candida* assay. The patients presented with symptoms of septicemia and blood was drawn for culture. Blood sample retains were stored at 4°C in the hematology lab and selected for T2MR if the

20   outcome was blood culture positive for *Candida*, blood culture positive for bacteremia, or blood culture negative to better represent the spectrum of samples that would be run on the platform. Fourteen of the samples were from candidemic patients, eight were from bacteremic patients, and ten were from blood-culture negative patients. Figure 57 shows the measured T2 values for all 32 patient samples. A single PCR reaction was conducted using 1 mL of each specimen. 750 copies of the internal inhibition control

25   were added to each PCR reaction. Among *Candida* negative samples the average internal control (IC) signal was 279 ms with a CV across the 18 *Candida* negative specimens of 25%. In no cases was the IC signal below the decision threshold (128 ms, 5 standard deviations added to the mean T2 measured in Candida negative detection reactions) suggesting that all negatives were true negatives and no inhibitory substances were present with the whole blood samples. The detection reactions were multiplexed based

30   on IDSA guidelines, such that three results were reported as follows: *C. albicans* or *C tropicalis* positive; *C.krusei* or *C. glabrata* positive; and *C. parapsilosis* positive. The average T2 measured in the *Candida* negative specimens is 114 ms, the CV for these measurements was 2.4%, and the decision threshold (calculated by addition of five times the standard deviation measured in the Candida negative detection reactions plus the mean T2 measured in Candida negative specimens) was 128 ms. In specimens positive

35   for *Candida*, the IC signal was suppressed due to competition for the amplification reagents. In instances of high *C. albicans*, some cross-reactivity was observed for detection with the *C. parapsilosis* particles (e.g. patient sample #3) however this signal is not significantly above the cut-off (20 ms) and does not

lead to a difference in antifungal therapy as both *C. albicans* and *C. parapsilosis* are susceptible to fluconazole.

T2MR successfully identified fourteen samples of *C. albicans*, *C. parapsilosis*, or *C. krusei* which were confirmed positive by blood culture followed by the Vitek 2 biochemical card. Furthermore, the

5 detection was specific for *Candida* spp. as bacteremic patient samples with *Escherichia coli*, *Enterococcus sp.*, *Staphylococcus aureus*, *Klebsiella pneumoniae*, coagulase negative *Staphylococcus*, or alpha hemolytic *Streptococcus* remained negative.

Serially drawn samples were tested from two patients who exhibited symptoms suggestive of candidemia, such as persistent fever after receiving antibiotics to demonstrate the assay's utility in

10 monitoring Candida clearance. Blood draws for T2MR occurred the same day as blood draws for blood culture. Surveillance cultures were then drawn over a course of nine days for Patient A and over a course of five days for Patient B. Figure 3 shows the results obtained with the T2MR method for both patients. Patient A had blood drawn for culture (t=0), was diagnosed with candidemia and administered intravenous micafungin (*C. glabrata*) the following day via blood culture (t=1). Whole blood specimens

15 were tested with T2MR at t=0 days, t=3 days, t=7 days, t=8 days, t= 9 days. The T2MR values obtained were 320 ms at t=0, 467 ms at t=3, 284 ms at t=7, 245 ms at t=8, and 117 ms (below cut-off) for t=9. Subsequent blood culture draws on day 3 and day 8 took 24 and 48 hours to culture positive, respectively. A series of serially drawn specimens were obtained from Patient B. *C. albicans* was correctly detected with T2MR on day 0 (T2 = 426 ms). Blood culture came up positive on day 2 with subsequent *C.*

20 *albicans* identification. One day after the patient was administered micafungin, a sharp decrease in *C. albicans* T2MR was evident (T2= 169 ms) and three or more days after antifungal treatment was initiated no detectable *C. albicans* was observed. All tests were completed in a total processing time of two hours, using a fast block PCR thermocycler and three step thermocycling procedure that was not optimized for speed.

25

Conclusions

We have developed and validated a whole blood T2MR *Candida* assay capable of detecting five clinically important species of *Candida* that leverages the advantages of non-optical detection to eliminate analyte purification, thus enabling enable more rapid turn-around times and more reproducible results.

30 Asymmetric PCR was used to specifically amplify the ITS2 region of the *Candida* genome directly in whole blood to achieve clinically relevant detection sensitivities. A T2 detection method was developed in which two pools of oligonucleotide derivatized nanoparticles hybridize to each end of the single stranded amplicon. The amplicons thus serve as interparticle tethers and induce nanoparticle agglomeration which yields a measurable and reproducible change in the spin-spin relaxometry (T2) of

35 the protons in water molecules. We further constructed and implemented an internal inhibition control to monitor for PCR inhibitors that may be present in the patient samples.

The assay was evaluated using reference strains and clinical isolates quantified by Coulter Counter and spiked into healthy donor whole blood. Assay repeatability was measured using *C. albicans* spiked blood (same sample, same operator, same instrument) over the course of 10 days and we observe CV's less than 12.8% (n=30) over the entire dynamic response range (0 to 1E5 cells/mL). The analytical

5   sensitivity and limit of detection of ≤10 cells/mL were measured for *C. albicans*, *C. tropicalis*, *C. krusei*, and *C. parapsilosis* and >10 cells/mL with 92.5% detected at 10 cells/mL for *C. glabrata*. Although not proven, a possible cause of the higher LoD observed in *C. glabrata* may be that the rDNA operon copy number is reduced in *C. glabrata* as compared to the other queried *Candida* spp since it is known that *C. glabrata* exists in nature as a haploid while the other Candida species are diploids. Agreement with the

10   gold standard for *Candida* diagnosis was high with 98% positive and 100% negative agreement observed for 133 *in vitro* spiked *C. albicans* and *C. krusei* samples. It should be noted that the time to result was 2 hours for the T2 *Candida* test while the time to blood culture positivity was typically 2 days for *C. albicans* and ~1 day (18-24 hours) for *Candida krusei*.

The 32 clinical specimens are similar to blood culture results. The measured T2 was above a cut-

15   off established at five standard deviations of the T2 values measured in the *Candida* negative specimens added to their mean. In this case the threshold was 128 ms (n=54). In no cases did we observe inhibition of the PCR reaction, as the internal control was detected within all 32 reactions with a reduced IC signal observed in *Candida* positive patients and a CV of 25% (mean T2 of 279 ms) across the *Candida* negative specimens (n=18). The assay is highly specific for *Candida* detection as no cross-reactivity was

20   observed with any of the bacteremic specimens (n=8). *Candida* positive specimens were accurately identified, the causative *Candida* spp. was accurately identified, and all within a time to answer of 2 hours.

The potential for this assay to provide a rapid detection of *Candida* clearance after administration of antifungal therapy was also demonstrated. Two sets of patient samples were drawn and subjected to

25   T2MR (Figure 3). Moderate to high T2 signals for *C. glabrata* were observed in patient A at day 0 and day 3 with antifungal agents administered at day 1. A decrease in *C. glabrata* signal was observed over subsequent days with none detectable after eight days of anti-fungal treatment. A strong *C. albicans* signal was measured for patient B at day 0, and a sharp decline (delta T2 of 306 ms) in T2 signal was observed one day after antifungal administration with none detectable after two days of anti-fungal

30   treatment. Although preliminary, this data suggests the test could be used to monitor treatment effectiveness and *Candida* clearance in a real-time fashion.

In conclusion, we have developed a sensitive and specific test for the diagnosis of candidemia caused by the five most commonly encountered *Candida* species. Early clinical results were encouraging and show that rapid diagnosis and species identification is achievable and could not only facilitate early

35   treatment with the appropriate antifungal but also provide a means to monitor *Candida* clearance. We anticipate that this nanoparticle-based T2MR method can be broadly applied to infectious disease diagnoses in a variety of specimen types and pathogens.

Example 23. Tacrolimus assay utilizing Fab.

The tacrolimus assay is a homogeneous competitive immunoassay performed using an EDTA whole blood sample extracted to release tacrolimus from the red blood cells and binding proteins. A key component of the assay is a high affinity tacrolimus antibody, a reliable extraction method, and improvement of the buffer systems selected to promote specific aggregation and minimize non-specific aggregation. This version of the assay utilizes a recombinant monovalent Fab with high affinity for tacrolimus.

The tacrolimus assay was assessed using whole blood calibrators, commercial whole blood controls, spiked samples and patient samples.

Assay reagents included: (a) 244 nm particle conjugated with sequential BSA, and monovalent Fab antibody and blocked with mPEG-thiol + NEM (particle is diluted to 0.2 mM Fe in assay buffer); (b) C22 modified tacrolimus conjugated to BSA at tacrolimus to BSA input ratio of 10:1 (diluted to 600 ng/ml in assay buffer); (c) assay buffer of 100 mM Glycine pH 9.0, 1% BSA, 0.05% Tween 80, 150 mM NaCl, and 0.05% Proclin; and (d) extraction reagent of 70% MeOH, 60 mM $ZnSO4$ in $dH20$.

Whole blood calibrators were prepared using 1 mg/ml Sigma FK506 Stock in 100% MeOH. EDTA whole blood was spiked at varying levels with the tacrolimus solution. The spiked blood was incubated at 37 °C with gentle mixing and then stored overnight at 4°C prior to aliquoting and freezing. Target levels were 0, 1, 2, 5, 10, 20, 50, 100, and 250 ng/ml of tacrolimus. The calibrators were provided to an external lab for value assignment by the Architect Tacrolimus assay. The samples were assayed by mass spectroscopy. Results show a correlation of 0.9998 for theoretical versus actual value assignment

Quality controls consisted of 3 levels of UTAK Immunosuppressant Matrix Controls. Patient samples were obtained from transplant patients on tacrolimus therapy.

The testing protocol was as follows:

(i) Allow all samples, calibrators, QC and reagents to equilibrate to room temperature, mix by gentle inversion.

(ii) Pipette 200 µL of sample, calibrator, or QC material into a 1.5 mL microfuge tube. Add 200 uL of extraction reagent and vortex for 30 secs. Allow the sample to incubate for 2 minutes at room temperature, and centrifuge for 5 minutes at 10,000 rpm. Transfer the clean supernatant to a clean tube and prepare a 2.5× dilution using assay buffer.

(iii) pipette 10 µL of the diluted extract and 10 µL of diluted particle into the reaction tube, vortex mix and incubate for 15 minutes at 37 °C. Pipette 20 µL of BSA-tac conjugate into the reaction tube, vortex mix and incubate for 15 minutes at 37 °C. Perform gMAA for 6 cycles (12 min.). Vortex mix, incubate for 5 minutes at 37 °C and read in the T2 reader at 37 °C.

Calibrators were tested in triplicate for each test run (6 total runs). Individual run data were fit with a 5PL model using GraphPad Prism 5 for Windows, version 5.02, GraphPad Software, San Diego California USA. The 0 calibrator was entered as 0.01 ng/ml and used in the curve model. The resulting

calibration curves (Run Calibration) were used to back-calculate the tacrolimus concentration for all calibrators, whole blood spikes, QC and patient samples contained in the run.

In addition, a Master Calibration curve was obtained by fitting data across the entire 3-day study (n=18) for each calibrator. All samples were back-calculated using the Master Curve and the resulting

5   tacrolimus levels compared to those obtained using the Run Calibration.

A reproducibility panel consisting of 13 members (9 calibrators, 3 controls and 1 spiked whole blood sample) was tested in triplicate for 3 days with 2 runs per day for a total of 18 replicates. Calibrators were stored at -80 °C while the controls and whole blood spike were stored at 4-8 °C for the duration of the study.

10   Sample concentrations were predicted using the run calibration curve, as well as the master curve in GraphPrism. Within-run, within-day, day-to-day and total precision were calculated by ANOVA using MiniTab15.

Data predicted using the Run Calibration method showed total imprecision < 25%CV across a tacrolimus concentration range from ~ 3 – 210 ng/ml.

15   Analytical sensitivity was calculated by the 2SD method. The standard deviation of 18 replicates of the 0 calibrator was determined. The tacrolimus level at the maximum T2 (top asymptote of the curve fit) – 2SD was then calculated and the concentration predicted using the Master Calibration Curve. Analytical sensitivity is 0.8 ng/ml.

During tacrolimus antibody development and screening, antibody specificity was evaluated

20   against five tacrolimus metabolites. ELISA inhibition was performed with each of the 5 metabolites and compared to free tacrolimus for five affinity matured clones and seven clones with additional affinity maturation by cross-cloning. Data for two of the cross-clones and a state-of-the-art murine monoclonal RUO antibody are shown below. The only cross-reactivity observed was slight reactivity to the 15-O-desmethyl metabolite.

25   A summary of the tacrolimus assay performance is tabulated below.

Requirement	Results
Reportable range:	~ 3.5 – 200 ng/ml based on calibrator %CV<30% and 90 – 110% recovery. ~ 2 to >200 ng/ml based on calibrator %CV<30% and 85 – 115% recovery.
Analytical Sensitivity (2SD):	0.8 ng/ml
Precision:	@ 2.8 ng/ml: 22% CV @ 6.9 ng/ml: 14% CV @ 14.6 ng/ml: 4% CV
Time to result:	56 minutes
Specimen type:	Whole Blood
Pre-treatment:	Solvent-based extraction process demonstrated using functionality planned on instrument
Sample volume:	200 μL

Example 24. Preparation of nanoparticles for detection of nucleic acid analytes.

Preparation of single probe particles: 800 nm carboxylated iron oxide superparamagnetic particles, consisting of numerous iron oxide nanocrystals embedded in a polymer matrix including a total particle diameter of 800 nm (see Demas et al., New J. Phys. 13:1 (2011)) were washed using a magnetic rack prior to use. The magnetic particles were resusupended in 66 µL of nuclease-free water, 20 µL of 250 mM MES buffer pH 6, and 4 µL of aminated probe (obtained from IDT), at 1 mM concentration per mg of particle to be prepared. A 3' aminated probe particle and a 5' aminated probe particle were prepared (e.g., the probe for C. parapsilosis). The probe was added to the particle and the suspension was vortexed using a vortexer equipped with a foam holder to hold the tube. The vortexer was set to a speed that keeps the particles well-suspended without any splashing. N-ethyl-N'-(3-dimethylaminopropyl) carbodiimide hydrochloride (EDC) was then dissolved in water and immediately added to the vortexing particle-probe mixture. The tube was then closed and incubated with rotation in an incubator at 37 °C for 2 hours. The tube was then placed in a magnetic rack and the reaction fluid was removed. The particles were washed with a series of washes (125 µL/mg particle) as follows: water, water, 0.1M imidazole, pH 6.0 with a 5 minute incubation with rotation at 37 °C, water, 0.1 M sodium bicarbonate, pH 8.0 with a 5 minute incubation with rotation at 37 °C water. The particles were then subjected to a 1 hour heat-stress at 60-65 °C in 0.1M sodium bicarbonate pH 8.0 with rotation. After the heat-stress, the bicarbonate was removed by placing the tube in a magnetic rack. The particles were then resuspended in the storage buffer (Tris-EDTA, 0.1% tween 20) and vortexed. The storage buffer was removed and a final 100 µl of storage buffer was added to the particle preparation. The particles were stored at 2-8 °C, qualified using an iron test to determine the iron concentration of the particles, and tested against target nucleic acid (e.g., C. paraplsilosis ITS2 oligo titration). In the Candida assay, the particles are diluted in 8× SSPE supplemented with 0.09% sodium azide as a preservative.

Preparation of dual probe particles: For the preparation of a dual probe particle, the procedure is the same as above, except that equal volumes of a second probe (e.g., 3' aminated C. albicans) and the first probe (e.g., 3'aminated C. tropicalis) were mixed prior to addition to the magnetic particles. Similarly, equal volumes of the 5'aminated probes were mixed prior to addition to the magnetic particles.

Example 25. Candida assay improvements.

The limit of detection for the Candida assay of Example 22 was improved by washing the pellet. 2.0 mL of whole blood was combined with 100 µL of TRAX erythrocyte lysis buffer (i.e., a mixture of nonyl phenoxy-polyethoxylethanol (NP-40) and 4-octylphenol polyethoxylate (Triton-X100)) and incubated for about 5 minutes. The sample was centrifuged for 5 minutes at 6000g and the resulting supernatant was removed and discarded. To wash the pellet, the pellet was mixed with 200 µL of Tris EDTA (TE) buffer pH 8.0 and subjected to vortexing. The sample was again centrifuged for 5 minutes at 6000g and the resulting supernatant was removed and discarded. Following the wash step the pellet was

mixed with 100 µL TE buffer and subjected to bead beating (e.g., such as with 0.5 mm glass beads, 0.1 mm silica beads, 0.7 mm silica beads, or a mixture of differently sized beads) with vigorous agitation. The sample was again centrifuged. Fifty µL of the resulting lysate was then added to 50 µL of an asymmetric PCR master mix containing a deoxynucleotides, PCR primers and a whole blood compatible thermophilic DNA polymerase (T2 Biosystems, Lexington, MA). Thermocycling and hybridization induced agglomeration assays were conducted as described in Example 22 to produce T2 values characteristic of the presence of Candida in the blood sample. The assay can produce (i) a coefficient of variation in the T2 value of less than 20% on Candida positive samples; (ii) at least 95% correct detection at less than or equal to 5 cells/mL in samples spiked into 50 individual healthy patient blood samples; (iii) at least 95% correct detection less than or equal to 5 cells/mL in samples spiked into 50 indiviudal unhealthy patient blood samples; and/or (iv) greater than or equal to 80% correct detection in clinically positive patient samples (i.e., Candida positive by another technique, such as by cell culture) starting with 2mL of blood.

This application claims priority to U.S. Application Serial No. 12/910,594, filed October 22, 2010, and claims benefit of U.S. Provisional Patent Application No. 61/414,141, filed November 16, 2010, U.S. Provisional Patent Application No. 61/418,465, filed December 1, 2010, and U.S. Provisional Patent Application No. 61/497,374, filed June 15, 2011, each of which is incorporated herein by reference.

Other Embodiments

All publications, patents, and patent applications mentioned in this specification are herein incorporated by reference to the same extent as if each independent publication or patent application was specifically and individually indicated to be incorporated by reference.

While the invention has been described in connection with specific embodiments thereof, it will be understood that it is capable of further modifications and this application is intended to cover any variations, uses, or adaptations of the invention following, in general, the principles of the invention and including such departures from the present disclosure that come within known or customary practice within the art to which the invention pertains and may be applied to the essential features hereinbefore set forth, and follows in the scope of the claims.

Other embodiments are within the claims.

What is claimed is:

Claims

1. A method for detecting the presence of an analyte in a liquid sample, the method comprising:

(a) contacting a solution with magnetic particles to produce a liquid sample comprising from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the liquid sample, wherein the magnetic particles have a mean diameter of from 150 nm to 699 nm, a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} mM^{-1}s^{-1}, and binding moieties on their surface, the binding moieties operative to alter aggregation of the magnetic particles in the presence of the analyte or a multivalent binding agent;

(b) placing the liquid sample in a device, the device comprising a support defining a well holding the liquid sample comprising the magnetic particles, the multivalent binding agent, and the analyte, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using one or more magnets and an RF pulse sequence;

(c) exposing the sample to a bias magnetic field and an RF pulse sequence;

(d) following step (c), measuring the signal; and

(e) on the basis of the result of step (d), detecting the analyte.

2. A method for detecting the presence of an analyte in a liquid sample, the method comprising:

(a) contacting a solution with magnetic particles to produce a liquid sample comprising from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the liquid sample, wherein the magnetic particles have a mean diameter of from 700 nm to 1200 nm, a T_2 relaxivity per particle of from 1×10^9 to 1×10^{12} mM^{-1}s^{-1}, and have binding moieties on their surface, the binding moieties operative to alter an aggregation of the magnetic particles in the presence of the analyte;

(b) placing the liquid sample in a device, the device comprising a support defining a well holding the liquid sample comprising the magnetic particles, the multivalent binding agent, and the analyte, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using one or more magnets and an RF pulse sequence;

(c) exposing the sample to a bias magnetic field and an RF pulse sequence;

(d) following step (c), measuring the signal; and

(e) on the basis of the result of step (d), detecting the presence or concentration of an analyte.

3. The method of claim 1 or 2, wherein the magnetic particles are substantially monodisperse.

4. The method of claim 1 or 2, wherein the magnetic particles exhibit nonspecific reversibility in the absence of the analyte and multivalent binding agent.

5. The method of claim 4, wherein the magnetic particles further comprise a surface decorated with a blocking agent selected from albumin, fish skin gelatin, gamma globulin, lysozyme, casein, peptidase, and an amine-bearing moiety.

6. The method of claim 5, wherein the blocking agent is an amine-bearing moiety selected from amino polyethyleneglycol, glycine, ethylenediamine, or amino dextran.

7. The method of claim 1 or 2, wherein the liquid sample further comprises a buffer, from 0.1% to 3% (w/w) albumin and from 0.01% to 0.5% nonionic surfactant, or a combination thereof.

8. The method of claim 1 or 2, wherein the magnetic particles comprise a surface decorated with 40 µg to 100 µg of one or more proteins per milligram of the magnetic particles.

9. The method of claim 1 or 2, wherein the liquid sample comprises a multivalent binding agent bearing a plurality of analytes conjugated to a polymeric scaffold.

10. The method of claim 1 or 2, wherein the analyte is creatinine and the liquid sample comprises a multivalent binding agent bearing a plurality of creatinine conjugates.

11. The method of claim 10, wherein the magnetic particles comprise a surface decorated with creatinine antibodies.

12. The method of claim 1 or 2, wherein the analyte is tacrolimus and the liquid sample comprises a multivalent binding agent bearing a plurality of tacrolimus conjugates.

13. The method of claim 12, wherein the magnetic particles comprise a surface decorated with tacrolimus antibodies.

14. The method of claim 1 or 2, wherein step (d) comprises measuring the T_2 relaxation response of the liquid sample, and wherein increasing agglomeration in the liquid sample produces an increase in the observed T_2 relaxation rate of the sample.

15. The method of claim 1 or 2, wherein the analyte is a target nucleic acid.

16. The method of claim 15, wherein said target nucleic acid is extracted from a leukocyte.

17. The method of claim 15, wherein said target nucleic acid is extracted from a pathogen.

18. A method for detecting the presence of a pathogen in a whole blood sample, the method comprising:

(a) providing a whole blood sample from a subject;

(b) mixing the whole blood sample with an erythrocyte lysis agent to produce disrupted red blood cells;

(c) following step (b), centrifuging the sample to form a supernatant and a pellet, discarding some or all of the supernatant, and resuspending the pellet to form an extract, optionally washing the pellet prior to resuspending the pellet and optionally repeating step (c);

(d) lysing cells of the extract to form a lysate;

(e) placing the lysate of step (d) in a detection tube and amplifying a target nucleic acid in the lysate to form an amplified lysate solution comprising the target nucleic acid, wherein the target nucleic acid is characteristic of the pathogen to be detected;

(f) following step (e), adding to the detection tube from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the amplified lysate solution, wherein the magnetic particles have a mean diameter of from 700 nm to 1200 nm and binding moieties on their surface, the binding moieties operative to alter aggregation of the magnetic particles in the presence of the target nucleic acid or a multivalent binding agent;

(g) placing the detection tube in a device, the device comprising a support defining a well for holding the detection tube comprising the magnetic particles and the target nucleic acid, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using one or more magnets and an RF pulse sequence;

(h) exposing the sample to a bias magnetic field and an RF pulse sequence;

(i) following step (h), measuring the signal from the detection tube; and

(j) on the basis of the result of step (i), detecting the pathogen.

19. The method of claim 18, wherein steps (a) through (i) are completed within 3 hours.

20. The method of claim 18, wherein step (i) is carried out without any prior purification of the amplified lysate solution.

21. A method for detecting the presence of a target nucleic acid in a whole blood sample, the method comprising:

(a) providing one or more cells from a whole blood sample from a subject;

(b) lysing said cells to form a lysate;

(c) amplifying a target nucleic acid in the lysate to form an amplified lysate solution comprising the target nucleic acid;

(d) following step (c), adding to a detection tube the amplified lysate solution and from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the amplified lysate solution, wherein the magnetic particles have a mean diameter of from 700 nm to 1200 nm and binding moieties on their surface, the binding moieties operative to alter aggregation of the magnetic particles in the presence of the target nucleic acid or a multivalent binding agent;

(e) placing the detection tube in a device, the device comprising a support defining a well for holding the detection tube comprising the magnetic particles and the target nucleic acid, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using one or more magnets and an RF pulse sequence;

(f) exposing the sample to a bias magnetic field and an RF pulse sequence;

(h) following step (f), measuring the signal from the detection tube; and

(i) on the basis of the result of step (h), detecting the target nucleic acid.

22. The method of claim 21, wherein said target nucleic acid is purified prior to step (d).

23. A method for detecting the presence of a target nucleic acid in a whole blood sample, the method comprising:

(a) providing an extract produced by lysing the red blood cells in a whole blood sample from a subject, centrifuging the sample to form a supernatant and a pellet, discarding some or all of the supernatant, and resuspending the pellet to form an extract, optionally washing the pellet prior to resuspending the pellet and optionally repeating the centrifuging, discarding, and resuspending steps;

(b) lysing cells in the extract to form a lysate;

(c) placing the lysate of step (b) in a detection tube and amplifying nucleic acids therein to form an amplified lysate solution comprising from 40% (w/w) to 95% (w/w) the target nucleic acid and from 5% (w/w) to 60% (w/w) nontarget nucleic acid;

(d) following step (c), adding to the detection tube from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the amplified lysate solution, wherein the magnetic particles have a mean diameter of from 700 nm to 1200 nm and binding moieties on their surface, the binding moieties operative to alter aggregation of the magnetic particles in the presence of the target nucleic acid or a multivalent binding agent;

(e) placing the detection tube in a device, the device comprising a support defining a well for holding the detection tube comprising the magnetic particles and the target nucleic acid, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using one or more magnets and an RF pulse sequence;

(f) exposing the sample to a bias magnetic field and an RF pulse sequence;

(g) following step (f), measuring the signal from the detection tube; and

(h) on the basis of the result of step (g), detecting the target nucleic acid, wherein step (g) is carried out without any prior purification of the amplified lysate solution.

24. The method of claim 18, 21, or 23, wherein step (b) comprises combining the extract with beads to form a mixture and agitating the mixture to form a lysate.

25. The method of 18-24, wherein said magnetic particles comprise one or more populations having a first probe and a second probe conjugated to their surface, the first probe operative to bind to a first segment of the target nucleic acid and the second probe operative to bind to a second segment of the target nucleic acid, wherein the magnetic particles form aggregates in the presence of the target nucleic acid.

26. The method of 18-24, wherein said magnetic particles comprise a first population having a first binding moiety on their surface and a second population having a second binding moiety on their surface, and said multivalent binding moiety comprising a first probe and a second probe, the first probe operative to bind to said first binding moiety and the second probe operative to bind to a second binding moiety, the binding moieties and multivalent binding moiety operative to alter an aggregation of the magnetic particles in the presence of the target nucleic acid.

27. A method for detecting the presence of a Candida species in a liquid sample, the method comprising:

(a) lysing the Candida cells in the liquid sample;

(b) amplifying a nucleic acid to be detected in the presence of a forward primer and a reverse primer, each of which is universal to multiple Candida species to form a solution comprising a Candida amplicon;

(c) contacting the solution with magnetic particles to produce a liquid sample comprising from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the liquid sample, wherein the magnetic particles have a mean diameter of from 700 nm to 1200 nm, a T_2 relaxivity per particle of from 1×10^9 to 1×10^{12} mM^{-1}s^{-1}, and binding moieties on their surface, the binding moieties operative to alter aggregation of the magnetic particles in the presence of the Candida amplicon or a multivalent binding agent;

(d) placing the liquid sample in a device, the device comprising a support defining a well for holding the liquid sample comprising the magnetic particles and the Candida amplicon, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using one or more magnets and an RF pulse sequence;

(e) exposing the sample to a bias magnetic field and an RF pulse sequence;

(f) following step (e), measuring the signal; and

(g) on the basis of the result of step (f), determining whether the Candida species was present in the sample.

28. The method of claim 27, wherein the forward primer comprises the oligonucleotide sequence 5'-GGC ATG CCT GTT TGA GCG TC-3'.

29. The method of claim 27, wherein the reverse primer comprises the oligonucleotide sequence 5'-GCT TAT TGA TAT GCT TAA GTT CAG CGG GT-3'.

30. The method of claim 27, wherein the Candida species is Candida albicans, and wherein the first probe comprises the oligonucleotide sequence:
5'-ACC CAG CGG TTT GAG GGA GAA AC-3',
and the second probe comprises the oligonucleotide sequence:
5'-AAA GTT TGA AGA TAT ACG TGG TGG ACG TTA-3'.

31. The method of claim 27, wherein the Candida species is Candida krusei, and wherein the first probe and the second probe comprise an oligonucleotide sequence selected from:
5'-CGC ACG CGC AAG ATG GAA ACG-3',
5'-AAG TTC AGC GGG TAT TCC TAC CT-3', and
5'-AGC TTT TTG TTG TCT CGC AAC ACT CGC-3'.

32. The method of claim 27, wherein the Candida species is Candida glabrata, and wherein the first probe comprises the oligonucleotide sequence:
5'-CTA CCA AAC ACA ATG TGT TTG AGA AG-3',
and the second probe comprises the oligonucleotide sequence:
5'-CCT GAT TTG AGG TCA AAC TTA AAG ACG TCT G-3'.

33. The method of claim 27, wherein the Candida species is Candida parapsilosis or Candida tropicalis, and wherein the first probe and the second probe comprise an oligonucleotide sequence selected from:
5'-AGT CCT ACC TGA TTT GAG GTCNitIndAA-3',
5'-CCG NitIndGG GTT TGA GGG AGA AAT-3',
5'-AAA GTT ATG AAATAA ATT GTG GTG GCC ACT AGC-3',
5'-ACC CGG GGGTTT GAG GGA GAA A-3',
5'-AGT CCT ACC TGA TTT GAG GTC GAA-3', and
5'-CCG AGG GTT TGA GGG AGA AAT-3'.

34. The method of any of claims 27-33, wherein steps (a) through (h) are completed within 3 hours.

35. The method of any of claims 27-33, wherein the magnetic particles comprise two populations, a first population bearing the first probe on its surface, and the second population bearing the second probe on its surface.

36. The method of any of claims 27-33, wherein said magnetic particles comprise one or more populations having a first probe and a second probe conjugated to their surface, the first probe operative to bind to a first segment of the Candida amplicon and the second probe operative to bind to a second segment of the Candida amplicon, wherein the magnetic particles form aggregates in the presence of the Candida amplicon.

37. The method of any of claims 27-33, wherein said magnetic particles comprise a first population having a first binding moiety on their surface and a second population having a second binding moiety on their surface, and said multivalent binding moiety comprising a first probe and a second probe, the first probe operative to bind to said first binding moiety and the second probe operative to bind to a second binding moiety, the binding moieties and multivalent binding moiety operative to alter an aggregation of the magnetic particles in the presence of the Candida amplicon.

38. A method for detecting the presence of a pathogen in a whole blood sample, the method comprising:
(a) providing from 0.05 to 4.0mL of the whole blood sample from a subject;
(b) placing an aliquot of the sample of step (a) in a container and amplifying a target nucleic acid in the sample to form an amplified solution comprising the target nucleic acid, wherein the target nucleic acid is characteristic of the pathogen to be detected;
(c) placing the amplified liquid sample in a detecting device; and
(d) on the basis of the result of step (c), detecting the pathogen,
wherein the pathogen is selected from bacteria and fungi, and wherein the method is capable of detecting a pathogen concentration of 10 cells/mL in the whole blood sample.

39. The method of claim 38, wherein the detecting device detects the pathogen via an optical, fluorescent, mass, density, magnetic, chromatographic, and/or electrochemical measurement of the amplified liquid sample.

40. The method of claim 38, wherein steps (a) through (d) are completed within 3 hours.

41. The method of claim 38, wherein step (b) or (c) is carried out without any prior purification of the amplified solution.

42. The method of claim 38, wherein the liquid sample of step (c) comprises whole blood proteins and non-target oligonucleotides.

43. The method of claim 38, wherein the pathogen is selected from bacteria and fungi.

44. A method for detecting the presence of a pathogen in a whole blood sample, the method comprising:

(a) providing a whole blood sample from a subject;

(b) mixing from 0.05 to 4.0 mL of the whole blood sample with an erythrocyte lysis agent to produce disrupted red blood cells;

(c) following step (b), centrifuging the sample to form a supernatant and a pellet, discarding some or all of the supernatant, and resuspending the pellet to form an extract, optionally washing the pellet prior to resuspending the pellet and optionally repeating step (c);

(d) lysing cells of the extract to form a lysate;

(e) placing the lysate of step (d) in a container and amplifying a target nucleic acid in the lysate to form an amplified lysate solution comprising the target nucleic acid, wherein the target nucleic acid is characteristic of the pathogen to be detected;

(f) following step (e), mixing the amplified lysate solution with from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the amplified lysate solution to form a liquid sample, wherein the magnetic particles have a mean diameter of from 150 nm to 1200 nm, a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} mM^{-1}s^{-1}, and binding moieties on their surface, the binding moieties operative to alter aggregation of the magnetic particles in the presence of the target nucleic acid or a multivalent binding agent;

(g) placing the liquid sample in a device, the device comprising a support defining a well for holding the detection tube comprising the magnetic particles and the target nucleic acid, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using one or more magnets and an RF pulse sequence;

(h) exposing the sample to a bias magnetic field and an RF pulse sequence;

(i) following step (h), measuring the signal from the liquid sample; and

(j) on the basis of the result of step (i), detecting the pathogen,

wherein the pathogen is selected from bacteria and fungi, and wherein the method is capable of detecting a pathogen concentration of 10 cells/mL in the whole blood sample.

45. The method of claim 44, wherein steps (a) through (i) are completed within 3 hours.

46. The method of claim 44, wherein step (i) is carried out without any prior purification of the amplified lysate solution.

47. The method of claim 44, wherein the liquid sample of step (i) comprises whole blood proteins and non-target oligonucleotides.

48. The method of claim 44, wherein the pathogen is selected from bacteria and fungi.

49. The method of claim 44, wherein the method is capable of measuring a pathogen concentration of 10 cells/mL in the whole blood sample with a coefficient of variation of less than 15%.

50. A method for detecting the presence of a virus in a whole blood sample, the method comprising:

(a) providing a plasma sample from a subject;

(b) mixing from 0.05 to 4.0 mL of the plasma sample with a lysis agent to produce a mixture comprising disrupted viruses;

(c) placing the mixture (b) in a container and amplifying a target nucleic acid in the filtrate to form an amplified filtrate solution comprising the target nucleic acid, wherein the target nucleic acid is characteristic of the virus to be detected;

(d) following step (c), mixing the amplified filtrate solution with from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the amplified filtrate solution to form a liquid sample, wherein the magnetic particles have a mean diameter of from 150 nm to 1200 nm, a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} $mM^{-1}s^{-1}$, and binding moieties on their surface, the binding moieties operative to alter aggregation of the magnetic particles in the presence of the target nucleic acid or a multivalent binding agent;

(e) placing the liquid sample in a device, the device comprising a support defining a well for holding the detection tube comprising the magnetic particles and the target nucleic acid, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using one or more magnets and an RF pulse sequence;

(f) exposing the liquid sample to a bias magnetic field and an RF pulse sequence;

(g) following step (f), measuring the signal from the liquid sample; and

(h) on the basis of the result of step (g), detecting the virus,
wherein the method is capable of detecting fewer than 100 virus copies in the whole blood sample.

51. The method of claim 50, wherein steps (a) through (g) are completed within 3 hours.

52. The method of any of 44-51, wherein said magnetic particles comprise one or more populations having a first probe and a second probe conjugated to their surface, the first probe operative

to bind to a first segment of the target nucleic acid and the second probe operative to bind to a second segment of the target nucleic acid, wherein the magnetic particles form aggregates in the presence of the target nucleic acid.

53. The method of any of 44-51, wherein said magnetic particles comprise a first population having a first binding moiety on their surface and a second population having a second binding moiety on their surface, and said multivalent binding moiety comprising a first probe and a second probe, the first probe operative to bind to said first binding moiety and the second probe operative to bind to a second binding moiety, the binding moieties and multivalent binding moiety operative to alter an aggregation of the magnetic particles in the presence of the target nucleic acid.

54. A method of quantifying a target nucleic acid molecule in a sample, said method comprising amplifying the target nucleic acid molecule in an amplification reaction mixture in a detection tube resulting in the production of amplicons corresponding to the target nucleic acid molecule, wherein said amplification reaction mixture comprises

(1)   a target nucleic acid molecule;

(2)   biotin labeled amplification primers specific for said target nucleic acid molecule;

(3)   avidin labeled superparamagnetic particles; and

wherein said amplification is performed in a device, the device comprising a support defining a well for holding the detection tube comprising the superparamagnetic particles and the target nucleic acid molecule, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the sample to a bias magnetic field created using one or more magnets and an RF pulse sequence; and said amplification comprising the following steps:

(a)   performing one or more cycles of amplification;

(b)   exposing said amplification reaction mixture to conditions permitting the aggregation or disaggregation of said avidin labeled superparamagnetic particles,

(c)   exposing the sample to a bias magnetic field and an RF pulse sequence;

(d)   following step (c), measuring the signal from the detection tube;

(e)   repeating steps (a)-(d) until a desired amount of amplification is obtained; and

(f)   on the basis of the result of step (d), quantifying the amplicons present at the corresponding cycle of amplification;

wherein the initial quantity of target nucleic acid molecule in said sample is determined based on the quantity of amplicons determined at each cycle of said amplification.

55. A method of quantifying a target nucleic acid molecule in a sample, said method comprising amplifying the target nucleic acid molecule in an amplification reaction mixture in a detection tube

resulting in the production of amplicons corresponding to the target nucleic acid molecule, wherein said amplification reaction mixture comprises:

(1)   a target nucleic acid molecule;

(2)   amplification primers comprising a 5' overhang, wherein said amplification primers are specific for said target nucleic acid molecule; and

(3)   oligonucleotide labeled superparamagnetic particles, wherein the oligonucleotide label is substantially complementary to said 5' overhang of said amplification primers; and

wherein said amplification is performed in a device, the device comprising a support defining a well for holding the detection tube comprising the superparamagnetic particles and the target nucleic acid molecule, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the sample to a bias magnetic field created using one or more magnets and an RF pulse sequence; and said amplification comprising the following steps:

(a)   performing one or more cycles of amplification;

(b)   exposing said amplification reaction mixture to conditions permitting the hybridization of said oligonucleotide labeled superparamagnetic particles with said 5' overhang;

(c)   exposing the sample to a bias magnetic field and an RF pulse sequence;

(d)   following step (c), measuring the signal from the detection tube;

(e)   repeating steps (a)-(d) until a desired amount of amplification is obtained; and

(f)   on the basis of the result of step (d), quantifying the amplicons present at the corresponding cycle of amplification;

wherein the initial quantity of target nucleic acid molecule in said sample is determined based on the quantity of amplicons determined at each cycle of said amplification.

56. A method of quantifying a target nucleic acid molecule in a sample, said method comprising amplifying the target nucleic acid molecule in an amplification reaction mixture in a detection tube resulting in the production of amplicons corresponding to the target nucleic acid molecule, wherein said amplification reaction mixture comprises:

(1)   a target nucleic acid molecule;

(2)   amplification primers specific for said target nucleic acid molecule; and

(3)   oligonucleotide labeled superparamagnetic particles, wherein said oligonucleotide label contains a hairpin structure and a portion of said hairpin structure is substantially complementary to a portion of the nucleic acid sequence of said amplicons; and

wherein said amplification is performed in a device, the device comprising a support defining a well for holding the detection tube comprising the superparamagnetic particles and the target nucleic acid molecule, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the sample to a bias magnetic field created using one or more magnets and an RF pulse sequence; and said amplification comprising the following steps:

(a)   performing one or more cycles of amplification;

(b)   exposing said amplification reaction mixture to conditions permitting the hybridization of said portion of said hairpin structure of (3) with said amplicons;

(c)   exposing the sample to a bias magnetic field and an RF pulse sequence;

(d)   following step (c), measuring the signal from the detection tube;

(e)   repeating steps (a)-(d) until a desired amount of amplification is obtained; and

(f)   on the basis of the result of step (d), quantifying the amplicons present at the corresponding cycle of amplification;

wherein the initial quantity of target nucleic acid molecule in said sample is determined based on the quantity of amplicons determined at each cycle of said amplification.

57. A method of quantifying a target nucleic acid molecule in a sample, said method comprising amplifying the target nucleic acid molecule using PCR in an amplification reaction mixture in a detection tube resulting in the production of amplicons corresponding to the target nucleic acid molecule, wherein said amplification reaction mixture comprises:

(1)   a target nucleic acid molecule;

(2)   a polymerase with 5′exonuclease activity;

(3)   amplification primers specific for said target nucleic acid molecule; and

(4)   oligonucleotide tethered superparamagnetic particles, wherein said oligonucleotide tether connects at least two superparamagnetic particles and said oligonucleotide tether is substantially complementary to a portion of the nucleic acid sequence of said amplicons; and

wherein said amplification is performed in a device, the device comprising a support defining a well for holding the detection tube comprising the superparamagnetic particles and the target nucleic acid molecule, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the sample to a bias magnetic field created using one or more magnets and an RF pulse sequence; and said amplification comprising the following steps:

(a)   performing one or more cycles of PCR under conditions permitting the hybridization of said oligonucleotide tether to an amplicon during the extension phase of said PCR, wherein during the extension phase of said PCR, the 5′ exonuclease activity of said polymerase untethers said at least two superparamagnetic particles permitting a decrease in superparamagnetic particle aggregation;

(b)   exposing the sample to a bias magnetic field and an RF pulse sequence;

(c)   following step (b), measuring the signal from the detection tube;

(d)   repeating steps (a)-(c) until said PCR is complete; and

(e)   on the basis of the result of step (c), quantifying the amplicons present at the corresponding cycle of PCR;

wherein the initial quantity of target nucleic acid molecule in said sample is determined based on the quantity of amplicons determined at each cycle of said PCR.

58. A method of quantifying a target nucleic acid molecule in a sample, said method comprising amplifying the target nucleic acid molecule in an amplification reaction mixture in a detection tube resulting in the production of amplicons corresponding to the target nucleic acid molecule, wherein said amplification reaction mixture comprises:

(1)   a target nucleic acid molecule;

(2)   amplification primers specific for said target nucleic acid molecule; and

(3)   superparamagnetic particles labeled with a plurality of oligonucleotides, wherein a first group of said plurality of oligonucleotides are substantially complementary to a portion of the nucleic acid sequence of said amplicons and substantially complementary to a second group of said plurality of oligonucleotides, wherein said first group of said plurality of oligonucleotides has a lesser hybridization affinity for said second group of said plurality of oligonucleotides than for said amplicons; and

wherein said amplification is performed in a device, the device comprising a support defining a well for holding the detection tube comprising the superparamagnetic particles and the target nucleic acid molecule, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the sample to a bias magnetic field created using one or more magnets and an RF pulse sequence; and said amplification comprising the following steps:

(a)   performing one or more cycles of amplification;

(b)   exposing said amplification reaction mixture to conditions permitting the preferential hybridization of said first group of said plurality of oligonucleotides with said amplicons thereby permitting disaggregation of said superparamagnetic particles;

(c)   exposing the sample to a bias magnetic field and an RF pulse sequence;

(d)   following step (c), measuring the signal from the detection tube;

(e)   repeating steps (a)-(d) until a desired amount of amplification is obtained; and

(f)   on the basis of the result of step (d); quantifying the amplicons present at the corresponding cycle of amplification;

wherein the initial quantity of target nucleic acid molecule in said sample is determined based on the quantity of amplicons determined at each cycle of said amplification.

59. A method of quantifying a target nucleic acid molecule in a sample, said method comprising amplifying the target nucleic acid molecule in an amplification reaction mixture in a detection tube resulting in the production of amplicons corresponding to the target nucleic acid molecule, wherein said amplification reaction mixture comprises:

(1)   a target nucleic acid molecule;

(2)   amplification primers specific for said target nucleic acid molecule; and

(3)   superparamagnetic particles;

wherein said amplification is performed in a device, the device comprising a support defining a well for holding the detection tube comprising the superparamagnetic particles and the target nucleic acid molecule, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the sample to a bias magnetic field created using one or more magnets and an RF pulse sequence; and said amplification comprising the following steps:

(a)   performing one or more cycles of amplification;

(b)   exposing said amplification reaction mixture to conditions permitting the aggregation or disaggregation of said superparamagnetic particles;

(c)   exposing the sample to a bias magnetic field and an RF pulse sequence;

(d)   following step (c), measuring the signal from the detection tube;

(e)   repeating steps (a)-(d) until a desired amount of amplification is obtained; and

(f)   on the basis of the result of step (d), quantifying the amplicons present at the corresponding cycle of amplification;

wherein the initial quantity of target nucleic acid molecule in said sample is determined based on the quantity of amplicons determined at each cycle of said amplification.

60.   The methods of any one of claims 54-59, wherein said detection tube remains sealed throughout the amplification reaction.

61.   The methods of any one of claims 54-60, further comprising applying a magnetic field to said detection tube following said measuring the signal from the detection tube, resulting in the sequestration of said superparamagnetic particles to the side of the detection tube, and releasing said magnetic field subsequent to the completion of one or more additional cycles of amplification.

62.   The methods of any one of claims 54-60, wherein said superparamagnetic particles are greater than 100 nm in diameter.

63.   The methods of any one of claims 54-60, wherein said superparamagnetic particles are less than 100 nm in diameter.

64.   The methods of claim 63, wherein said superparamagnetic particles have a diameter of 30 nm.

65.   The methods of any of claims 54-64, wherein said sample does not comprise isolated nucleic acid molecules prior to step (a).

66. The method of claim 65, wherein said sample is a whole blood sample.

67. The method of any one of claims 54-64, wherein said target nucleic acid molecule has not been isolated in said sample prior to step (a).

68. A method of monitoring one or more analytes in a liquid sample derived from a patient for the diagnosis, management, or treatment of a medical condition in a patient, the method comprising:

(a) combining with the liquid sample from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the liquid sample, wherein the magnetic particles have a mean diameter of from 150 nm to 1200 nm and a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} mM^{-1}s^{-1}, and wherein the magnetic particles have binding moieties on their surfaces, the binding moieties operative to alter the specific aggregation of the magnetic particles in the presence of the one or more analytes or a multivalent binding agent;

(b) placing the liquid sample in a device, the device comprising a support defining a well for holding the liquid sample comprising the magnetic particles and the one or more analytes, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using one or more magnets and an RF pulse sequence;

(c) exposing the sample to the bias magnetic field and the RF pulse sequence;

(d) following step (c), measuring the signal;

(e) on the basis of the result of step (d), monitoring the one or more analytes; and

(f) using the result of step (e) to diagnose, manage, or treat the medical condition.

69. The method of claim 68, wherein the one or more analytes comprise creatinine.

70. The method of claim 68, wherein the patient is immunocompromised, and the one or more analytes comprise an analyte selected from pathogen-associated analytes, antibiotic agents, antifungal agents, and antiviral agents.

71. The method of claim 70, wherein the one or more analytes comprise Candida spp., tacrolimus, fluconazole, and creatinine.

72. The method of claim 68, wherein the patient has cancer, and the one or more analytes are selected from anticancer agents, and genetic markers present in a cancer cell.

73. The method of claim 68, wherein the patient has, or is at risk of, an infection, and the one or more analytes comprise an analyte selected from pathogen-associated analytes, antibiotic agents, antifungal agents, and antiviral agents.

74. The method of claim 68, wherein the patient has an immunoinflammatory condition, and the one or more analytes comprise an analyte selected from antiinflammatory agents and TNF-alpha.

75. The method of claim 68, wherein the patient has heart disease, and the one or more analytes comprise a cardiac marker.

76. The method of claim 68, wherein the method is used to monitor the liver function of the patient, and wherein the one or more analytes are selected from albumin, aspartate transaminase, alanine transaminase, alkaline phosphatase, gamma glutamyl transpeptidase, bilirubin, alpha fetoprotein, lactase dehydrogenase, mitochondrial antibodies, and cytochrome P450.

77. The method of claim 76, wherein the one or more analytes comprise cytochrome P450 polymorphisms, and the ability of the patient to metabolize a drug is evaluated.

78. The method of claim 77, wherein the patient is identified as a poor metabolizer, a normal metabolizer, an intermediate metabolizer, or an ultra rapid metabolizer.

79. The method of claim 68, wherein the patient has HIV/AIDS, and the one or more analytes comprise CD3, viral load, and AZT.

80. The method of claim 68, wherein the method is used to determine an appropriate dose of a therapeutic agent in a patient, the method further comprising:

(i) administering the therapeutic agent to the patient;

(ii) following step (i), obtaining a sample comprising the therapeutic agent or metabolite thereof from the patient;

(iii) contacting the sample with the magnetic particles and exposing the sample to the bias magnetic field and the RF pulse sequence and detecting a signal produced by the sample; and

(iv) on the basis of the result of step (iii), determining the concentration of the therapeutic agent or metabolite thereof.

81. The method of claim 80, wherein the therapeutic agent is an anticancer agent, antibiotic agent, or antifungal agent.

82. The method of claim 68 or 80, wherein the monitoring is intermittent.

83. The method of claim 68 or 80, wherein the monitoring is continuous.

84. A method of diagnosing sepsis in a subject, the method comprising

(a) obtaining a liquid sample derived from the blood of a patient;

(b) preparing a first assay sample by combining with a portion of the liquid sample from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the liquid sample, wherein the magnetic particles have a mean diameter of from 150 nm to 1200 nm and a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} mM^{-1}s^{-1}, and wherein the magnetic particles have binding moieties on their surfaces, the binding moieties operative to alter the specific aggregation of the magnetic particles in the presence of one or more pathogen-associated analytes or a multivalent binding agent;

(c) preparing a second assay sample by combining with a portion of the liquid sample from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the liquid sample, wherein the magnetic particles have a mean diameter of from 150 nm to 1200 nm and a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} mM^{-1}s^{-1}, and wherein the magnetic particles have binding moieties on their surfaces, the binding moieties operative to alter the specific aggregation of the magnetic particles in the presence of one or more analytes characteristic of sepsis selected from GRO-alpha, High mobility group-box 1 protein (HMBG-1), IL-1 receptor, IL-1 receptor antagonist, IL-1b, IL-2, IL-4, IL-6, IL-8, IL-10, IL-12, IL-13, IL-18, macrophage inflammatory protein (MIP-1), macrophage migration inhibitory factor (MIF), osteopontin, RANTES (regulated on activation, normal T-cell expressed and secreted; or CCL5), TNF-α, C-reactive protein (CRP), CD64, monocyte chemotactic protein 1 (MCP-1), adenosine deaminase binding protein (ABP-26), inducible nitric oxide synthetase (iNOS), lipopolysaccharide binding protein, and procalcitonin;

(d) placing each assay sample in a device, the device comprising a support defining a well for holding the liquid sample comprising the magnetic particles and the one or more analytes, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using one or more magnets and an RF pulse sequence;

(e) exposing each assay sample to the bias magnetic field and the RF pulse sequence;

(f) following step (e), measuring the signal produced by the first assay sample and the signal produced by the second assay sample;

(g) on the basis of the result of step (f), monitoring the one or more analytes of the first assay sample and monitoring the one or more analytes of the second assay sample; and

(h) using the results of step (g) to diagnose the subject.

85. The method of claim 84, wherein the one or more pathogen-associated analytes of the first assay sample are derived from a pathogen associated with sepsis selected from Acinetobacter baumannii, Aspergillus fumigatis, Bacteroides fragilis, B. fragilis, blaSHV, Burkholderia cepacia, Campylobacter jejuni/coli, Candida guilliermondii, C. albicans, C. glabrata, C. krusei, C. Lusitaniae, C. parapsilosis, C. tropicalis, Clostridium pefringens, Coagulase negative Staph, Enterobacter aeraogenes, E. cloacae,

Enterobacteriaceae, Enterococcus faecalis, E. faecium, Escherichia coli, Haemophilus influenzae, Kingella Kingae, Klebsiella oxytoca, K. pneumoniae, Listeria monocytogenes, Mec A gene (MRSA), Morganella morgana, Neisseria meningitidis, Neisseria spp. non-meningitidis, Prevotella buccae, P. intermedia, P. melaninogenica, Propionibacterium acnes, Proteus mirabilis, P. vulgaris, Pseudomonas aeruginosa, Salmonella enterica, Serratia marcescens, Staphylococcus aureus, S. haemolyticus, S. maltophilia, S. saprophyticus, Stenotrophomonas maltophilia, S. maltophilia, Streptococcus agalactie, S. bovis, S. dysgalactie, S. mitis, S. mutans, S. pneumoniae, S. pyogenes, and S. sanguinis.

86. The method of claim 84, wherein the one or more pathogen-associated analytes of the first assay sample are derived from treatment resistant strains of bacteria.

87. The method of claim 86, wherein the one or more pathogen-associated analytes are derived from penicillin-resistant, methicillin-resistant, quinolone-resistant, macrolide-resistant, and/or vancomycin-resistant bacterial strains.

88. The method of claim 87, wherein the one or more pathogen-associated analytes are derived from methicillin resistant Staphylococcus aureus or vancomycin-resistant enterococci.

89. The method of any of claims 84-88, wherein the one or more analytes of the second assay sample are selected from GRO-alpha, High mobility group-box 1 protein (HMBG-1), IL-1 receptor, IL-1 receptor antagonist, IL-1b, IL-2, IL-4, IL-6, IL-8, IL-10, IL-12, IL-13, IL-18, macrophage inflammatory protein (MIP-1), macrophage migration inhibitory factor (MIF), osteopontin, RANTES (regulated on activation, normal T-cell expressed and secreted; or CCL5), TNF-α, C-reactive protein (CRP), CD64, and monocyte chemotactic protein 1 (MCP-1).

90. The method of claim 84, wherein the method further comprises preparing a third assay sample to monitor the concentration of an antiviral agent, antibiotic agent, or antifungal agent circulating in the blood stream of the subject.

91. The method of claim 84, wherein the patient is immunocompromised.

92. A method of monitoring one or more analytes in a liquid sample derived from a patient for the diagnosis, management, or treatment of sepsis or SIRS in a patient, the method comprising:

(a) combining with the liquid sample from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the liquid sample, wherein the magnetic particles have a mean diameter of from 150 nm to 1200 nm and a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} mM^{-1}s^{-1}, and wherein the magnetic particles have binding

moieties on their surfaces, the binding moieties operative to alter the specific aggregation of the magnetic particles in the presence of the one or more analytes or a multivalent binding agent;

(b) placing the liquid sample in a device, the device comprising a support defining a well for holding the liquid sample comprising the magnetic particles and the one or more analytes, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using one or more magnets and an RF pulse sequence;

(c) exposing the sample to the bias magnetic field and the RF pulse sequence;

(d) following step (c), measuring the signal;

(e) on the basis of the result of step (d), monitoring the one or more analytes; and

(f) using the result of step (e) to diagnose, manage, or treat the sepsis or SIRS.

93. The method of claim 92, comprising (i) monitoring a pathogen-associated analyte, and (ii) monitoring a second analyte characteristic of sepsis selected from GRO-alpha, High mobility group-box 1 protein (HMBG-1), IL-1 receptor, IL-1 receptor antagonist, IL-1b, IL-2, IL-4, IL-6, IL-8, IL-10, IL-12, IL-13, IL-18, macrophage inflammatory protein (MIP-1), macrophage migration inhibitory factor (MIF), osteopontin, RANTES (regulated on activation, normal T-cell expressed and secreted; or CCL5), TNF-α, C-reactive protein (CRP), CD64, monocyte chemotactic protein 1 (MCP-1), adenosine deaminase binding protein (ABP-26), inducible nitric oxide synthetase (iNOS), lipopolysaccharide binding protein, and procalcitonin.

94. The method of claim 93, wherein the a pathogen-associated analyte is derived from a pathogen associated with sepsis selected from Acinetobacter baumannii, Aspergillus fumigatis, Bacteroides fragilis, B. fragilis, blaSHV, Burkholderia cepacia, Campylobacter jejuni/coli, Candida guilliermondii, C. albicans, C. glabrata, C. krusei, C. Lusitaniae, C. parapsilosis, C. tropicalis, Clostridium pefringens, Coagulase negative Staph, Enterobacter aeraogenes, E. cloacae, Enterobacteriaceae, Enterococcus faecalis, E. faecium, Escherichia coli, Haemophilus influenzae, Kingella Kingae, Klebsiella oxytoca, K. pneumoniae, Listeria monocytogenes, Mec A gene (MRSA), Morganella morgana, Neisseria meningitidis, Neisseria spp. non-meningitidis, Prevotella buccae, P. intermedia, P. melaninogenica, Propionibacterium acnes, Proteus mirabilis, P. vulgaris, Pseudomonas aeruginosa, Salmonella enterica, Serratia marcescens, Staphylococcus aureus, S. haemolyticus, S. maltophilia, S. saprophyticus, Stenotrophomonas maltophilia, S. maltophilia, Streptococcus agalactie, S. bovis, S. dysgalactie, S. mitis, S. mutans, S. pneumoniae, S. pyogenes, and S. sanguinis.

95. The method of claim 93, wherein the pathogen-associated analyte is derived from a treatment resistant strain of bacteria.

96. The method of claim 95, wherein the pathogen-associated analyte is derived from penicillin-resistant, methicillin-resistant, quinolone-resistant, macrolide-resistant, and/or vancomycin-resistant bacterial strains.

97. The method of claim 96, wherein the pathogen-associated analyte is derived from a methicillin resistant Staphylococcus aureus or vancomycin-resistant enterococci.

98. The method of any of claims 108-97, wherein the second analytes is selected from GRO-alpha, High mobility group-box 1 protein (HMBG-1), IL-1 receptor, IL-1 receptor antagonist, IL-1b, IL-2, IL-4, IL-6, IL-8, IL-10, IL-12, IL-13, IL-18, macrophage inflammatory protein (MIP-1), macrophage migration inhibitory factor (MIF), osteopontin, RANTES (regulated on activation, normal T-cell expressed and secreted; or CCL5), TNF-α, C-reactive protein (CRP), CD64, monocyte chemotactic protein 1 (MCP-1).

99. The method of claim 93, wherein the method further comprises monitoring the concentration of an antiviral agent, antibiotic agent, or antifungal agent circulating in the blood stream of the subject.

100. The method of claim 92, wherein the patient is immunocompromised.

101. A method for assisting the specific agglomeration of magnetic particles in a liquid sample, the method comprising:

(i) providing a liquid sample comprising one or more analytes and the magnetic particles, wherein the magnetic particles have binding moieties on their surfaces, the binding moieties operative to alter the specific aggregation of the magnetic particles in the presence of the one or more analytes or a multivalent binding agent;

(ii) exposing the liquid sample to a magnetic field;

(iii) removing the liquid sample from the magnetic field; and

(iv) repeating step (ii).

102. A method for assisting the specific agglomeration of magnetic particles in a liquid sample, the method comprising:

(i) providing a liquid sample comprising one or more analytes and the magnetic particles, wherein the magnetic particles have binding moieties on their surfaces, the binding moieties operative to alter the specific aggregation of the magnetic particles in the presence of the one or more analytes or a multivalent binding agent;

(ii) applying a magnetic field gradient to the liquid sample for a time sufficient to cause concentration of the magnetic particles in a first portion of the liquid sample, the magnetic field gradient being aligned in a first direction relative to the liquid sample;

(iii) following step (ii), applying a magnetic field to the liquid sample for a time sufficient to cause concentration of the magnetic particles in a second portion of the liquid sample, the magnetic field being aligned in a second direction relative to the liquid sample; and

(iv) optionally repeating steps (ii) and (iii).

103. The method of claim 102, wherein the angle between the first direction and the second direction relative to the liquid sample is between 0° and 180°.

104. The system of claim 103, wherein the angle between the first direction and the second direction relative to the liquid sample is 90°.

105. A method for assisting the specific agglomeration of magnetic particles in a liquid sample, the method comprising:

(i) providing a liquid sample comprising one or more analytes and the magnetic particles, wherein the magnetic particles have binding moieties on their surfaces, the binding moieties operative to alter the specific aggregation of the magnetic particles in the presence of the one or more analytes or a multivalent binding agent;

(ii) applying a magnetic field gradient to the liquid sample for a time sufficient to cause concentration of the magnetic particles in a first portion of the liquid sample;

(iii) following step (ii), agitating the liquid sample; and

(iv) repeating step (ii).

106. The method of claim 105, wherein step (iii) comprises vortexing the liquid sample.

107. A method for assisting the specific agglomeration of magnetic particles in a liquid sample, the method comprising:

(i) providing a liquid sample comprising one or more analytes and the magnetic particles, wherein the magnetic particles have binding moieties on their surfaces, the binding moieties operative to alter the specific aggregation of the magnetic particles in the presence of the one or more analytes or a multivalent binding agent; and

(ii) exposing the liquid sample to a gradient magnetic field and rotating the gradient magnetic field about the sample, or rotating the sample within the gradient magnetic field.

108. The method of claim 107, further comprising:

(iii) following step (ii), agitating the liquid sample; and

(iv) repeating step (ii).

109.   The method of any of claims 101, 102, 105, or 108, wherein step (ii) is repeated from 1 to 100 times.

110.   The method of any of claims 102, 105, or 107, wherein the one or more magnets providing the magnetic field gradient within the liquid sample have a maximum field strength of from 0.01T to 10T and wherein the gradient magnetic field varies from 0.1mT/mm to 10T/mm across the liquid sample.

111.   The method of any of claims 101-110, wherein step (ii) comprises applying the magnetic field gradient to the liquid sample for a period of from 1 second to 5 minutes.

112.   The method of any of claims 101-110, wherein the liquid sample comprises from 1×10^5 to 1×10^{15} of the one or more analytes per milliliter of the liquid sample.

113.   The method of claim 112, wherein the liquid sample comprises from 1×10^7 to 1×10^{11} of the one or more analytes per milliliter of the liquid sample.

114.   The method of any of claims 101-110, wherein the liquid sample comprises from 1×10^6 to 1×10^{13} of the magnetic particles per milliliter of the liquid sample.

115.   The method of any of claims 101-110, wherein the magnetic particles have a T_2 relaxivity per particle of from 1×10^4 to 1×10^{12} mM^{-1}s^{-1}.

116.   The method of any of claims 101-110, wherein the magnetic particles have an average diameter of from 150 nm to 1200 nm.

117.   The method of claim 116, wherein the magnetic particles are substantially monodisperse.

118.   The method of any of claims 101-110, wherein the magnetic particles in the liquid sample exhibit nonspecific reversibility in the absence of the one or more analytes and multivalent binding agent.

119.   The method of claim 118, wherein the magnetic particles further comprise a surface decorated with a blocking agent selected from albumin, fish skin gelatin, gamma globulin, lysozyme, casein, peptidase, and an amine-bearing moiety.

120. The method of claim 119, wherein the blocking agent is an amine-bearing moiety selected from amino polyethyleneglycol, glycine, ethylenediamine, or amino dextran.

121. The method of any of claims 101-110, wherein the liquid sample further comprises a buffer, from 0.1% to 3% (w/w) albumin and from 0.01% to 0.5% nonionic surfactant, or a combination thereof.

122. The method of any of claims 101-110, wherein the magnetic particles comprise a surface decorated with 40 μg to 100 μg of one or more proteins per milligram of the magnetic particles.

123. A system for the detection of one or more analytes, the system comprising:

(a) a first unit comprising (a1) a permanent magnet defining a magnetic field; (a2) a support defining a well for holding a liquid sample comprising magnetic particles and the one or more analytes and having an RF coil disposed about the well, the RF coil configured to detect a signal by exposing the liquid sample to a bias homogenous magnetic field created using the permanent magnet and an RF pulse sequence; and (a3) one or more electrical elements in communication with the RF coil, the electrical elements configured to amplify, rectify, transmit, and/or digitize the signal; and

(b) one or more second units comprising (b1) a permanent magnet adjacent a first sample position for holding a liquid sample and configured to apply a first gradient magnetic field to the liquid sample.

124. The system of claim 123, wherein the one or more second units further comprises a second permanent magnet adjacent a second sample position for holding a liquid sample and configured to apply a second gradient magnetic field to the liquid sample, the second magnetic field aligned to apply a gradient magnetic field to the sample from a direction different from the direction of the first field gradient, and a means for moving a liquid sample from the first sample position to the second sample position.

125. The system of claim 123, wherein the one or more second units is incapable of measuring an NMR relaxation rate.

126. The system of claim 124, wherein the angle between the first direction and the second direction relative to the liquid sample is between 0° and 180°.

127. The system of claim 126, wherein the angle between the first direction and the second direction relative to the liquid sample is 90°.

128. The system of claim 125, further comprising a sample holder for holding the liquid sample and configured to move the liquid sample from the first position to the second position.

129. The system of claim 125, comprising an array of the one or more second units for assisting the agglomeration of an array of samples simultaneously.

130. The system of claim 129, wherein said array is configured to rotate one or more liquid from a first position in which a magnetic field is applied to the side of a sample to a second position in which a magnetic field is applied to the bottom of a sample.

131. The system of claim 124, further comprising: (c) a third unit comprising a removable cartridge sized to facilitate insertion into and removal from the system and having a compartment comprising one or more populations of magnetic particles having binding moieties on their surfaces, wherein the binding moieties are operative to alter an aggregation of the magnetic particles in the presence of the one or more analytes.

132. The system of claim 131, wherein the removable cartridge is a modular cartridge comprising (i) a reagent module for holding one or more assay reagents; and (ii) a detection module comprising a detection chamber for holding a liquid sample comprising magnetic particles and one or more analytes,

wherein the reagent module and the detection module can be assembled into the modular cartridge prior to use, and wherein the detection chamber is removable from the modular cartridge.

133. The system of claim 132, wherein the modular cartridge further comprises an inlet module, wherein the inlet module, the reagent module, and the detection module can be assembled into the modular cartridge prior to use, and wherein the inlet module is sterilizable.

134. The system of claim 131, wherein the system further comprises a system computer with processor for implementing an assay protocol and storing assay data, and wherein the removable cartridge further comprises (i) a readable label indicating the analyte to be detected, (ii) a readable label indicating the assay protocol to be implemented, (iii) a readable label indicating a patient identification number, (iv) a readable label indicating the position of assay reagents contained in the cartridge, or (v) a readable label comprising instructions for the programmable processor.

135. A system for the detection of one or more analytes, the system comprising:

(a) a first unit comprising (a1) a permanent magnet defining a magnetic field; (a2) a support defining a well for holding a liquid sample comprising magnetic particles and the one or more analytes and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using the permanent magnet and an RF pulse

sequence; and (a3) one or more electrical elements in communication with the RF coil, the electrical elements configured to amplify, rectify, transmit, and/or digitize the signal; and

(b) a second unit comprising a removable cartridge sized to facilitate insertion into and removal from the system, wherein the removable cartridge is a modular cartridge comprising (i) a reagent module for holding one or more assay reagents; and (ii) a detection module comprising a detection chamber for holding a liquid sample comprising the magnetic particles and the one or more analytes,

wherein the reagent module and the detection module can be assembled into the modular cartridge prior to use, and wherein the detection chamber is removable from the modular cartridge.

136. The system of claim 135, wherein the modular cartridge further comprises an inlet module, wherein the inlet module, the reagent module, and the detection module can be assembled into the modular cartridge prior to use, and wherein the inlet module is sterilizable.

137. The system of claim 135, wherein the system further comprises a system computer with processor for implementing an assay protocol and storing assay data, and wherein the removable cartridge further comprises (i) a readable label indicating the analyte to be detected, (ii) a readable label indicating the assay protocol to be implemented, (iii) a readable label indicating a patient identification number, (iv) a readable label indicating the position of assay reagents contained in the cartridge, or (v) a readable label comprising instructions for the programmable processor.

138. An agitation unit for the automated mixing of a liquid sample in a sample chamber, comprising a motor for providing a rotational driving force to a motor shaft coupled to a drive shaft, the driveshaft having a first end coupled to the motor shaft and a second end coupled to a plate bearing a sample holder for holding the sample chamber, the draft shaft including a first axis coaxial to the motor shaft, and a second axis that is offset and parallel to the motor shaft, such that the second axis of the driveshaft, the plate, and the sample holder are driven in an orbital path, wherein the motor comprises an index mark, and/or other position sensing means such as an optical, magnetic or resitive position encoder, for positioning the sample chamber in a predetermined position following the mixing or a sensor which tracks the sample's position throughout its path.

139. A system for the detection of one or more analytes, the system comprising:

(a) a first unit comprising (a1) a permanent magnet defining a magnetic field; (a2) a support defining a well for holding a liquid sample comprising magnetic particles and the one or more analytes and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using the permanent magnet and an RF pulse sequence; and (a3) one or more electrical elements in communication with the RF coil, the electrical elements configured to amplify, rectify, transmit, and/or digitize the signal; and

(b) a second unit for the automated mixing of a liquid sample in a sample chamber, comprising a motor for providing a rotational driving force to a motor shaft coupled to a drive shaft, the driveshaft having a first end coupled to the motor shaft and a second end coupled to a plate bearing a sample holder for holding the sample chamber, the draft shaft including a first axis coaxial to the motor shaft, and a second axis that is offset and parallel to the motor shaft, such that the second axis of the driveshaft, the plate, and the sample holder are driven in an orbital path, wherein the motor comprises an index mark, and/or other position sensing means such as an optical, magnetic or resitive position encoder, for positioning the sample chamber in a predetermined position following the mixing or a sensor which tracks the sample's position throughout its path.

140. The system of claim 139, further comprising a robotic arm for placing the sample chamber in, and removing the sample chamber from, the agitation unit.

141. A system for the detection of one or more analytes, the system comprising:

(a) a first unit comprising (a1) a permanent magnet defining a magnetic field; (a2) a support defining a well for holding a liquid sample comprising magnetic particles and the one or more analytes and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using the permanent magnet and an RF pulse sequence; and (a3) one or more electrical elements in communication with the RF coil, the electrical elements configured to amplify, rectify, transmit, and/or digitize the signal; and

(b) a centrifuge comprising a motor for providing a rotational driving force to a drive shaft, the drive shaft having a first end coupled to the motor and a second end coupled to a centrifuge rotor bearing a sample holder for holding the sample chamber, wherein the motor comprises an index mark, and/or other position sensing means such as an optical, magnetic or resitive position encoder, for positioning the sample chamber in a predetermined position following the centrifuging of the sample or a sensor which tracks the sample's position throughout its path.

142. A system for the detection of one or more analytes, the system comprising:

(a) a disposable sample holder defining a well for holding a liquid sample and having an RF coil contained within the disposable sample holder and disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using the permanent magnet and an RF pulse sequence, wherein the disposable sample holder comprises one or more fusable links; and

(b) an MR reader comprising (b1) a permanent magnet defining a magnetic field; (b2) an RF pulse sequence and detection coil; (b3) one or more electrical elements in communication with the RF coil, the electrical elements configured to amplify, rectify, transmit, and/or digitize the signal; and (b4) one or more electrical elements in communication with the fusable link and configured to apply excess

current to the fusable link, causing the link to break and rendering the coil inoperable following a predetermined working lifetime.

143. The system of claim 142, wherein the electrical element in communication with the RF coil is inductively coupled to the RF coil.

144. A system for the detection of creatinine, tacrolimus, and Candida, the system comprising:

(a) a first unit comprising (a1) a permanent magnet defining a magnetic field; (a2) a support defining a well for holding a liquid sample comprising magnetic particles and the creatinine, tacrolimus, and Candida and having an RF coil disposed about the well, the RF coil configured to detect signal produced by exposing the liquid sample to a bias magnetic field created using the permanent magnet and an RF pulse sequence; and (a3) an electrical element in communication with the RF coil, the electrical element configured to amplify, rectify, transmit, and/or digitize the signal; and

(b) a second unit comprising a removable cartridge sized to facilitate insertion into and removal from the system, wherein the removable cartridge is a modular cartridge comprising (i) a plurality of reagent modules for holding one or more assay reagents; and (ii) a plurality of detection module comprising a detection chamber for holding a liquid sample comprising the magnetic particles and the creatinine, tacrolimus, and Candida,

wherein the plurality of reagent modules comprises (i) a first population of magnetic particles having a mean diameter of from 150 nm to 699 nm, a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} $mM^{-1}s^{-1}$, and creatinine antibodies conjugated to their surface; (ii) a multivalent binding agent bearing a plurality of creatinine conjugates designed to form aggregates with the first population of magnetic particles in the absence of creatinine; (iii) a second population of magnetic particles having a mean diameter of from 150 nm to 699 nm, a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} $mM^{-1}s^{-1}$, and tacrolimus antibodies conjugated to their surface; (iv) a multivalent binding agent bearing a plurality of tacrolimus conjugates designed to form aggregates with the second population of magnetic particles in the absence of tacrolimus; (v) a third population of magnetic particles have a mean diameter of from 700 nm to 1200 nm, a T_2 relaxivity per particle of from 1×10^9 to 1×10^{12} $mM^{-1}s^{-1}$, and having a first probe and a second probe conjugated to their surface selected to form aggregates in the presence of a Candida nucleic acid, the first probe operative to bind to a first segment of the Candida nucleic acid and the second probe operative to bind to a second segment of the Candida nucleic acid.

145. A method for measuring the concentration of creatinine in a liquid sample, the method comprising:

(a) contacting a solution with (i) magnetic particles to produce a liquid sample comprising from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the liquid sample, wherein the magnetic particles have a mean diameter of from 150 nm to 1200 nm, a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} $mM^{-1}s^{-1}$,

and creatinine antibodies conjugated to their surface, and (ii) a multivalent binding agent bearing a plurality of creatinine conjugates designed to form aggregates with the magnetic particles in the absence of creatinine;

(b) placing the liquid sample in a device, the device comprising a support defining a well for holding the liquid sample comprising the magnetic particles, the multivalent binding agent, and the creatinine, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using one or more magnets and an RF pulse sequence;

(c) exposing the sample to a bias magnetic field and an RF pulse sequence;

(d) following step (c), measuring the signal; and

(e) on the basis of the result of step (d), determining the concentration of creatinine in the liquid sample.

146. A multivalent binding agent comprising two or more creatinine moieties covalently linked to a scaffold.

147. The multivalent binding agent of claim 146, wherein the multivalent binding agent is a compound of formula (I):
$$(A)_n\text{-}(B),$$

wherein (A) is

(B) is a polymeric scaffold covalently attached to each (A), m is an integer from 2 to 10, and n is an integer from 2 to 50.

148. A multivalent binding agent comprising two or more tacrolimus moieties covalently linked to a scaffold.

149. The multivalent binding agent of claim 148, wherein the multivalent binding agent is a compound of formula (II):
$$(A)_n\text{-}(B),$$

wherein (A) is
(B) is a polymeric scaffold covalently attached to each (A), and

n is an integer from 2 to 50.

150. A solution comprising from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the solution, wherein the magnetic particles have a mean diameter of from 150 nm to 600 nm, a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} mM^{-1}s^{-1}, and a surface bearing creatinine conjugate (A), wherein (A) is selected from:
and m is an integer from 2 to 10.

151. A solution comprising from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the solution, wherein the magnetic particles have a mean diameter of from 150 nm to 600 nm, a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} mM^{-1}s^{-1}, and a surface bearing antibodies having affinity for the creatinine conjugate:
wherein (B) is a polymeric scaffold.

152. A method for measuring the concentration of tacrolimus in a liquid sample, the method comprising:

(a) contacting a solution with (i) magnetic particles to produce a liquid sample comprising from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the liquid sample, wherein the magnetic particles have a mean diameter of from 150 nm to 1200 nm, a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} $mM^{-1}s^{-1}$, and tacrolimus antibodies conjugated to their surface, and (ii) a multivalent binding agent bearing a plurality of tacrolimus conjugates designed to form aggregates with the magnetic particles in the absence of tacrolimus;

(b) placing the liquid sample in a device, the device comprising a support defining a well for holding the liquid sample comprising the magnetic particles, the multivalent binding agent, and the tacrolimus, and having an RF coil disposed about the well, the RF coil configured to detect a signal produced by exposing the liquid sample to a bias magnetic field created using one or more magnets and an RF pulse sequence;

(c) exposing the sample to a bias magnetic field and an RF pulse sequence;

(d) following step (c), measuring the signal; and

(e) on the basis of the result of step (d), determining the concentration of tacrolimus in the liquid sample.

153. A solution comprising from 1×10^6 to 1×10^{13} magnetic particles per milliliter of the solution, wherein the magnetic particles have a mean diameter of from 150 nm to 600 nm, a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} $mM^{-1}s^{-1}$, and a surface bearing antibodies having affinity for the tacrolimus conjugate:
wherein (B) is a polymeric scaffold.

154. The solution of any of claims 150-153, wherein the magnetic particles are substantially monodisperse.

155. The solution of any of claims 150-153, wherein the magnetic particles exhibit nonspecific reversibility in plasma.

156. The solution of any of claims 150-153, wherein the magnetic particles further comprise a surface decorated with a blocking agent selected from albumin, fish skin gelatin, gamma globulin, lysozyme, casein, peptidase, and an amine-bearing moiety.

157. The method of claim 156, wherein the blocking agent is an amine-bearing moiety selected from amino polyethyleneglycol, glycine, ethylenediamine, or amino dextran.

158. The solution of any of claims 150-153, wherein the solution further comprises a buffer, from 0.1% to 3% (w/w) albumin and from 0.01% to 0.5% nonionic surfactant, or a combination thereof.

159. The solution of any of claims 150-153, wherein the magnetic particles comprise a surface decorated with 40 μg to 100 μg of one or more proteins per milligram of the magnetic particles.

160. A removable cartridge sized to facilitate insertion into and removal from a system of the invention, wherein the removable cartridge comprises one or more chambers for holding a plurality of reagent modules for holding one or more assay reagents, wherein the reagent modules include (i) a chamber for holding from 1×10^6 to 1×10^{13} magnetic particles having a mean diameter of from 100 nm to 699 nm, a T_2 relaxivity per particle of from 1×10^8 to 1×10^{12} mM^{-1}s^{-1}, and binding moieties on their surfaces, the binding moieties operative to alter the specific aggregation of the magnetic particles in the presence of the one or more analytes or a multivalent binding agent; and (ii) a chamber for holding a buffer.

161. A removable cartridge sized to facilitate insertion into and removal from a system of the invention, wherein the removable cartridge comprises one or more chambers for holding a plurality of reagent modules for holding one or more assay reagents, wherein the reagent modules include (i) a chamber for holding from 1×10^6 to 1×10^{13} magnetic particles having a mean diameter of from 700 nm to 1200 nm, a T_2 relaxivity per particle of from 1×10^9 to 1×10^{12} mM^{-1}s^{-1}, and oligonucleotide binding moieties on their surfaces, the oligonucleotide binding moieties operative to alter the specific aggregation of the magnetic particles in the presence of the one or more analytes; and (ii) a chamber for holding a buffer.

162. The removable cartridge of claim 160 or 161, wherein magnetic particles and buffer are together in a single chamber withing the cartridge.

163. The removable cartridge of claim 160 or 161, wherein said buffer includes from 0.1% to 3% (w/w) albumin, from 0.01% to 0.5% nonionic surfactant, a lysis agent, or a combination thereof

164. The removable cartridge of claim 160 or 161, further comprising a chamber comprising beads for lysing cells.

165. The removable cartridge of claim 160 or 161, further comprising a chamber comprising a polymerase.

166. The removable cartridge of claim 160 or 161, further comprising a chamber comprising a primer.
