(54) Title: 1,4-DIHYDROPYRIDINE-FUSED HETEROCYCLES,
PROCESS FOR PREPARING THE SAME, USE AND COM-
POSITIONS CONTAINING THEM

(57) Abstract: 1,4-Dihydropyridine-fused heterocycles,
process for preparing the same, use and compositions
containing them. The invention is about substituted
dihydropyridine-fused heterocycles useful for the
treatment of cancer disease, especially for preventing
cancerous cells to divide. These compounds act as
inhibitors of Aurora A and/or B kinases. Formula (I).
1.4-D)HYDROPYRIDINE-FUSED HETEROCYCLES, PROCESS FOR PREPARING THE SAME, USE AND COMPOSITIONS CONTAINING THEM

The present invention relates in particular to novel chemical compounds, particularly novel substituted dihydropyridine-fused heterocycles, to the compositions containing them and to their use as medicinal products. More particularly, the invention relates to specific partially saturated pyrrole or pyrazole fused 5-oxo-hexahydronaphtyridines or 5-oxo-hexahydroquinolines, exhibiting anticancer activity via modulation of the activity of proteins, in particular of kinases.

To date, most of the commercial compounds used in chemotherapy are cytotoxic agents, which poses considerable problems of side effects and of tolerance in patients. These effects may be limited in so far as the medicinal products used act selectively on cancer cells, with exclusion of healthy cells. One of the solutions for limiting the adverse effects of chemotherapy may therefore consist in using medicinal products which act on metabolic pathways or elements constituting these pathways, expressed mainly in cancer cells, and which would be expressed very little or not at all in healthy cells.

Protein kinases are a family of enzymes which catalyze the phosphorylation of hydroxyl groups of specific protein residues such as tyrosine, serine or threonine residues. Such phosphorylations can widely modify the function of proteins; thus, protein kinases play an important role in regulating a large variety of cell processes, including in particular metabolism, cell proliferation, cell differentiation, cell migration or cell survival. Among the various cellular functions in which the activity of a protein kinase is involved, certain processes represent attractive targets for treating cancer-related diseases and also other diseases.

Thus, one of the objects of the present invention is to provide compositions having anticancer activity, acting in particular with respect to kinases. Among the kinases for which modulation of the activity is sought, Aurora A and B are preferred. The use of Aurora kinase inhibitors as anticancer agents has recently been reviewed in "aurora kinase inhibitors as anticancer agents, N. Keen and S. Taylor, Nature Reviews 2004, 4, 927-936.

Many proteins involved in chromosome segregation and spindle assembly have been identified in yeast and drosophila. Disorganization of these
proteins leads to non-segregation of chromosomes and to monopolar or disorganized spindles. Among these proteins, some kinases, including Aurora and IpH, which originate respectively from drosophila and \textit{S. cerevisiae}, are necessary for chromosome segregation and separation of the centrosome. A human analogue of yeast IpH has recently been cloned and characterized by various laboratories. This kinase, called Aurora2, Aurora A, STK15 or BTAK, belongs to the serine/threonine kinase family. Bischoff et al. have shown that Aurora2 is oncogenic and is amplified in human colorectal cancers (EMBO J, 1998, 17, 3052-3065). Examples of this have also been shown in cancers involving epithelial tumours, such as breast cancer.

It is worth mentioning that one of the advantages of the current invention is to provide quite selective compounds. Indeed, these compounds mostly avoid inhibiting kinases involved in cellular transcription, which may result in severe side effects and/or higher toxicity towards quiescent cells. As a result, the compounds according to the invention mostly avoid inhibiting CDK7 and/or CDK9 kinases, or at least the inhibition ratio is in favour of an Aurora kinase.

\[
R_2-\text{CHO}
\]

A/ General procedure for the preparation of N-substituted tricyclic dihydropyridines
The tricyclic compound I in solution in dichloromethane (DCM) is treated by with 2 equivalents of benzyloxycarbonyl chloride, 2 equivalents of diisopropylethylamine (DIEA) and a catalytic amount of A-dimethylaminopyridine (DMAP) at room temperature for 24 hours. The reaction mixture is poured into a 10% solution of potassium hydrogenosulfate and extracted with DCM. The organic phase is washed with water, dried over magnesium sulfate (MgSO₄) and concentrated under vacuum. The crude products are purified on silica gel to give the Cbz-protected derivative III.

The Boc protection is removed by treating compound III with a mixture of trifluoroacetic acid (TFA) and DCM (50/50) at room temperature for 1 hour. After evaporation of the solvent, the crude product is purified on silica gel to give IV.

Acyl derivatives of general formula V are prepared in 2 steps. The compounds of formula IV are first acylated by various acyl chlorides in DCM using DIEA and a catalytic amount of DMAP. The reaction mixture is stirred overnight at room temperature and poured into water. The mixture is extracted with DCM. The organic phase is washed with water, dried over MgSO₄ and concentrated under vacuum. The compounds V are purified using preparative HPLC.

Alkyl derivatives of general formula VI are prepared from compounds IV using the corresponding epoxides in ethanol. The solution is either heated at reflux temperature for 2 hours or irradiated with microwaves at 110°C for 10 minutes. The mixture is poured in water and extracted with DCM. The DCM solution is washed with water, dried over MgSO₄ and concentrated. The resulting product is hydrogenated with Pd/C under hydrogen atmosphere. After filtration on Celite® and evaporation, the crude product is purified using preparative liquid chromatography coupled to mass spectrometry (LC/MS).

Acyl derivatives of general formula VII are prepared by direct acylation of I with acyl chlorides as described for III or with acid anhydrides in DCM using DIEA for 2 hours at room temperature. The mixture is poured in 10% potassium hydrogenosulfate solution and extracted with DCM. The organic solution is washed with water, dried over MgSO₄ and concentrated. The crude product is treated directly with a solution of TFA/DCM (50/50) for 1 hour.
at room temperature. The crude products are purified using preparative LC/MS to give VII.

Alkyl derivatives of general formula VIII are obtained by treating in a microwave apparatus at 150°C compound I with the corresponding epoxide in N,N-dimethylformamide (DMF). The intermediate is purified using preparative HPLC. The resulting derivative is deprotected with a TFA/DCM solution (50/50). The crude product is purified by preparative LC/MS.

The organic extracts are combined, dried on MgSO4 and concentrated. When needed the crude products are purified via column chromatography on silica gel or via recrystallization to yield compounds of formula XIX.

**Experimental Part**

**Methods**:

Analytical LC/MS method A: Analytical LC/MS analyses were conducted using Shimadzu LC-10AD HPLC pumps; a Gilson 215 well plate autosampler; a Shimadzu SPD-10A UV detector; the mass spectrometer was a PE Sciex API 100LC instrument model on a YMC basic S5 column eluted with a gradient of acetonitrile (ACN) containing 0.1% TFA in water at a flow rate of 0.1mi/min, gradient details are
given for each example. Compounds eluting off the column are detected by electrospray ionisation mass spectrometry (EIMS).

**Analytical LC/MS method B:**

Analysis is conducted on Waters model ZQ mass spectrometer working in positive and negative ion electrospray mode (mass range = 100-1200 amu) fitted on a Agilent HP1100 HPLC instrument. Separation is done on a Waters Xbridge C18 column (3x50 mm, 2.5 μm particle diameter) maintained at a temperature of 60°C and eluted by a gradient of acetonitrile in water containing 0.1% (v/v) formic acid at a flow rate of 1.1 ml/min. The gradient has the following shape: 5 to 100% acetonitrile in 5 minutes, maintain 100% acetonitrile for 0.5 minute, then back to 5% acetonitrile in 1 minute. Total run time is 7 minutes. In addition to mass spectrometry, UV diode array detection is performed at wavelengths = 210 to 400 nM and evaporative light scattering is carried out using a Sedere Sedex 85 instrument.

**Analytical LC/MS method C:**

Analysis is conducted on Waters model ZQ mass spectrometer working in positive and negative ion electrospray mode (mass range = 100-1200 amu) fitted on a Waters Acquity UPLC Instrument. Separation is done on a Waters UPLC BeH C18 column (2.1x50 mm, 1.7 μm particle diameter) maintained at a temperature of 55°C and eluted by a gradient of acetonitrile in water containing 0.1% (v/v) formic acid at a flow rate of 1.2 ml/min. The gradient has the following shape: 5 to 100% acetonitrile in 3 minutes, then back to 5% acetonitrile in 1 minute. Total run time is 4.5 minutes. In addition to mass spectrometry, UV diode array detection is performed at wavelengths = 210 to 400 nM.

**Preparative LC/MS method A:**

Preparative LC/MS separation were carried out on Waters HPLC instruments: 515 HPLC Pump; 2525 Binary Gradient Module; 2487 DAD (Dual Absorbance Detector); 2767 sample Manager connected with a Micromass mass spectrometer. Products were separated on a YMC Combi Prep Pro C18
column eluted with a gradient acetonitrile containing 0.1% TFA in water containing 0.1% TFA of flow rate 32 ml/min. For each separation gradient programation is adapted on the basis of an analytical LC/MS chromatogram of the sample.

Preparative LC/MS method B:

Compounds are purified by LC/MS using a Waters FractionLynx system composed of a Waters model 600 gradient pump, a Waters model 515 regeneration pump, a Waters Reagent Manager make-up pump, a Waters model 2700 autoinjector, two Rheodyne model LabPro switches, a Waters model 996 photodiode array detector, a Waters model ZMD mass spectrometer and a Gilson model 204 fraction collector. The instrument is controlled by a Waters FractionLynx software. At the output of the separating column the flow is split to the 1/1000 ratio using a LC Packing AccuRate splitter; 1/1000 of the flow is mixed with methanol (0.5 ml/min. flow rate) and sent to the detectors, this flow is split again: ¾ of the flow is sent to the photodiode array detector and ¼ to the mass spectrometer; the rest of the output of the column (999/1000) is sent to the fraction collector where flow was directed normally to waste unless expected mass signal is detected by the FractionLynx software. The FractionLynx software is supplied with molecular formulas of expected compounds and trigger the collection of compounds when mass signal corresponding to [M+H]^+ and [M+Na]^+ are detected. In certain cases (depending on analytical LC/MS result, when [M+2H]^++ is detected as an intense ion) the FractionLynx software is additionally supplied with calculated half molecular weight (MW/2), in these conditions collection is also triggered when mass signal corresponding to [M+2H]^++ and [M+Na+H]^++ are detected. Compounds are collected in tarred glass tubes. After collection, solvent is evaporated in a Jouan model RC 10.10 centrifuge evaporator and the weight of compound is determined by weighing of the tubes after solvent evaporation. Column and gradient details are given for each example in the following part.

Nitroaniline intermediate preparation:
4-amino-3-nitrophenol (2 g, 13 mmol) is treated with tert-butyl dimethylchlorosilane (2.94 g, 19.5 mmol) in dichloromethane (20 ml) in the presence of triethylamine (2.7 ml, 19.5 mmol) for 16 hours at room temperature. The reaction mixture is washed with water, dried over MgSO₄ and concentrated under reduced pressure to yield 1.9 g of 5-(ferf-butyl-dimethyl-silanyloxy)-2-nitro-aniiine as an orange powder. Yield=55%.

Ortfrø-phenylenediamine intermediate preparation:
A solution of 5-(ferf-butyl-dimethyl-silanyloxy)-2-nitro-aniline (1.9 g, 7.08 mmol) in methanol (40 ml) is introduced in a hydrogenation vessel with 10% palladium on carbon catalyst (0.226 g). The reaction mixture is heated at 80°C for 3 hours under an hydrogen atmosphere (P=1 bar). The reaction mixture is then filtered on Celite® and concentrated under reduced pressure.
The residue is dissolved in 10 ml of ethyl acetate and filtered through a silica gel plug (40 ml) that is washed with 600 ml of ethyl acetate. The organic filtrates are concentrated under vacuum to yield 2.55 g of 4-(ferf-butyl-dimethyl-silanyloxy)-or/70-phenylenediamine used without further purification in the following step. Analytical LC/MS (method B): retention time=3.12 min., m/z=239.15 (positive ion mode).

2-Mercaptobenzimidazole intermediate preparation: 1,1'-Thiocarboxyldiimidazole (1.87 g, 10.5 mmol) is added by portions to a solution of 4-(fe/f-butyl-dimethyl-silanyloxy)-or_/?o-phenylenediamine (2.5 g, 10.5 mmol) in 25 ml of tetrahydrofuran and the mixture is stirred at room temperature for 16 hours. The reaction mixture is then concentrated under reduced pressure, dissolved in 300 ml of ethyl acetate and washed with water (2x 100 ml). The organic phase is then dried over MgS04, filtered and concentrated. The residue is triturated in diisopropylether and pentane and dried under vacuum to yield 2.07 g of 2-mercapto-5-(ferf-butyl-dimethyl-silanyloxy)-benzimidazole. Yield=70%. Analytical LC/MS (method B): retention time=4.79 min, m/z=281.36 (positive ion mode).

Aldehyde intermediate preparation: A solution of 2-mercapto-5-(te/ t-butyl-dimethyl-silanyloxy)-benzimidazole (2.07 g, 7.38 mmol) in tetrahydrofuran (15 ml) is added dropwise to a mixture of sodium hydride (60% dispersion in mineral oil, 0.472 g, 11.8 mmol) and tetrahydrofuran (5 ml) at 0°C. The mixture is stirred at room temperature for 3 hours. A solution of 5-nitro-2-furaldehyde (1.04 g, 7.38 mmol) in tetrahydrofuran (10 ml) is then added dropwise over a 15 minute period and the mixture is stirred for 16 hours at room temperature. Water (10 ml) is then added and the reaction mixture is concentrated under reduced pressure. The residue is dissolved in a minimal volume of ethyl acetate and is filtered through a silica gel plug (20 ml) that is eluted with 500 ml of ethyl acetate. The organic filtrates are concentrated under reduced pressure and are purified on a silicagel column (120 g) eluted with a mixture of cyclohexane and ethyl acetate (7/3, v/v) to yield 1.4 g of 5-

A product of the invention may be useful for inhibiting the in vitro activity of an Aurora A and/or B kinase.

**Experimental protocols regarding the biochemical tests**

**Auroral and 2 (Respectively, Aurora B and A)**

The inhibitory effect of compounds with respect to the Auroral and 2 kinases is determined with a radioactivity scintillation assay using nickel chelate.

The kinase activity of Aurora is measured by the phosphorylation of NuMA-histidine substrate in the presence of radiolabeled ATP ([³³P] ATP) using 96 well Flash plates where the nickel-chelate is linked to the surface of the microplate. The amount of ³³P incorporated to the substrate NuMA is proportional to the aurora activity.

**Proteins:**

The protein production has been made in the protein production group of Sanofi-Aventis.

- **Aurora-A:** the full length recombinant protein including an N-terminal poly-histidine tail has been expressed in E. coli and purified to 82%.
Aurora-B: the full length protein (His tagged in N-terminal) has been co-expressed in SF9 cells with the C3 fragment of INCEP protein fused to GST protein. The complex has been purified using the N-terminal poly-histidine tail to 50% homogeneity.

NuMA, (a nuclear protein which binds to the mitotic system): fragment of 424 amino acids (position 1687-2101) has been expressed in E. coli (tagged on the N-terminal end with a poly-histidine tail for use as a the substrate for both Aurora enzymes.

Protocol:
The Flash plates used are nickel-chelate 96 well plates (Perkin Elmer, model SMP107).

The products to be evaluated are incubated in a 100 µl reaction volume per well in the presence of 10 nM of Aurora-B or Aurora-A, 500nM of NuMA substrate in the following buffer: 50 mM of NaCl, 5 mM MgCl2, (Aurora-B) or 10 mM MgCl2 (Aurora-A) and 1mM of DTT at 37°C.

80 µL of enzyme/substrate incubation buffer is distributed in each well, followed by 10 µL of solution of compound to be measured with various concentrations. The reaction is started by adding 1 µM of ATP (final concentration) containing 0.2 μCi of [33P] ATP (10 µL). After 30 minutes of incubation the reaction is stopped by removal of the reaction mixture and each well is washed twice with 300 µl of buffer Tris/HCl. The radioactivity is measured in each well using a Packard Top count scintillation counter instrument.

The enzymatic activity is expressed as counts per minute obtained in 30 minutes after subtraction of the background noise (reaction medium without enzyme). The measurement is expressed as percentage of inhibition of Aurora activity versus the control. To generate IC50 values, compounds of the invention are tested at different concentration and the percentage of inhibition are plotted as function of compound concentration, IC50s are calculated using the Xlfit 4 curve fitting software.
