Title: COATING COMPOSITION COMPRISING AUTOXIDISABLE COMPONENT

Abstract: An aqueous solution coating composition comprising an autoxidisable polyvinyl polymer having ≥ 20% of fatty acid residue by weight of polymer; Tg from -60 to +15°C; acid value of 15 to 75 mg KOH/g, Mw from 2500 to 100000 g/mol; polydispersity ≤ 30, said composition having ≤ 25% co-solvent by weight of solids, >30% solids by weight of composition; said composition when in the form of a coating having a telegraphing value defined as the difference in gloss at a 20° angle of between a film cast on rough PVC and a film cast on smooth PVC of 10 gloss units.
COATING COMPOSITION COMPRISING AUTOXI DISABLE COMPONENT

The present invention relates to certain coating compositions that comprise an autoxidisable component and processes for making such compositions. Coatings of the invention show reduced telegraphing of surface irregularities after the composition has been applied to a surface.

There is a general need when applying a decorative or protective coating to a substrate to obtain a smooth surface without visible irregularities. The degree to which an underlying surface can be visually ascertained through a coating is often described as telegraphing (i.e. giving a clumsily obvious hint or premature indication of something to come). It has been found that irregularities on substrates (such as wood), which contribute to the roughness, are often telegraphed through conventional dry coatings.

Thicker coating materials are often used to reduce telegraphing because they are sufficiently able to level out any unevenness in the surface. Thus the underlying surface roughness of the substrate shows through to a reduced extent into the final coating which appears visually smooth. However, thicker coatings are disadvantageous because they may need to be applied in several layers, increasing the cost. Also slower through-drying, wrinkling and sagging can occur when using thicker layers.

Organic solvents have been used to reduce telegraphing. However with a continuing concern about the use of organic solvents there has been a long felt need for an aqueous coating composition with comparable properties to those achievable using compositions based on organic solvents.

A coating should also dry sufficiently quickly to avoid the adherence of dust and to ensure that the coating quickly becomes water resistant (e.g. in case of outdoor applications), blocking resistant and tack-free.

Aqueous compositions such as water dilutable autoxidisable esters (also known as water dilutable unsaturated alkyds or alkyd emulsions) have also been used to address the issue of telegraphing. However these systems have many well known problems.

Water dilutable alkyds may also suffer from backbone hydrolysis. This may lead to changes in the performance over time which is undesirable. Traditional alkyd emulsions are discussed in "Water borne and solvent based alkyds
and their end user applications" by N. Tuck, volume VI, Wiley/Sita Series in Surface Coatings technology; (ISBN 471985910) published in 2000.

Another common problem of traditional alkyd emulsions is their tendency to produce cissing (also known as crawling) when applied as an overcoat. Cissing is when a coating refuses to form a continuous film, recedes from the surface, collects in beads and leaves the surface partially exposed thus reducing the appearance of the painted object.

Yet another disadvantage of traditional alkyd systems, especially those containing a relatively high percentage of unsaturated fatty acid residues, is their pronounced tendency to yellow (in light or dark) over time.

Current coatings lack some or all of the above mentioned performance characteristics, so coatings which exhibit reduced telegraphing with a combination of: minimal hydrolysis of the backbone of the alkyd, low yellowing over time and/or reduced cissing are desired.

Prior aqueous coatings have not been widely accepted in many markets as alternatives to solvent based coatings. For example solvent based alkyds are still preferred in the decorative market, where very low telegraphing is required as these coatings are often applied by brush. It is also desired that aqueous compositions are not milky or opaque but clear or transparent.

It is also generally known that polyester based alkyds (PE alkyds) typically have a broad molecular weight distribution and thus comprise a significant amount of material having a low molecular weight, which dries more slowly and therefore means the coating remains tacky for a longer period (i.e. has long tack free times). The presence of material of lower molecular weight cannot be avoided for many reasons. For example both glycerol (with three fatty acids - triglycerides) and pentaerythritol (with four fatty acids) are common raw materials used to prepare PE alkyds. To address the issues raised by the presence of the low molecular weight fraction, PE alkyds may be prepared in a highly branched form to obtain a high molecular weight fraction that dries more quickly. However the resultant branched PE alkyds have a significantly increased viscosity and reduced flow (compared to less branched equivalents) and thus must be diluted with more organic solvent before they can be used. This is undesirable as for example it increases the amount of volatile organic compounds (VOC) and adversely affects the flow of the composition.

It is known that autoxidisable vinyl polymers may be prepared by a radical polymerisation of vinyl monomers in the presence of a fatty acid derivative.
However the resultant polymers have a broad molecular weight distribution, and these polymers require higher amounts of solvent to make a coating, which generally also contains high levels of free monomer. Without wishing to be bound by theory it is believed that unsaturated fatty acids retard radical polymerisation and graft onto the vinyl polymer resulting in more material of higher molecular weight and a broader molecular weight distribution.

WO 2002-033012 (= EP 1328594) (Avecia) discloses an aqueous coating composition based on a crosslinkable water-dispersable vinyl oligomer and optionally a dispersed polymer. The oligomers described in this application have a low amount of fatty acid (< 40% by weight). As shown by the comparative data herein these oligomers are designed for a different purpose (improved open time) and produce coatings which, within a few days, lack satisfactory body (in the tests as defined herein), do not produce satisfactory tack free times and become unusable after one day.

US 5089342, EP 0370299 and EP 031 6732 (all Bayer) disclose an aqueous, air drying coating composition containing a water-soluble, air-drying polyacrylate with a molecular weight of more than 1000 g/mole and 5-40wt% of chemically incorporated fatty acids and 50-100 milli-equivalents per 100 grams of solid of chemically incorporated quaternary ammonium moieties. This reference describes systems that are cationic, teaching away from using anionic systems (e.g. see col. 1, line 53) and teaches use of styrenic monomers as part of the vinyl monomers which is not ideal as it can cause yellowing in the final product.

US 5096959 (Valspar) discloses water based alkyd resins that are modified to provided increased hydrolytic stability by reacting them with a polybasic acid composition containing one or more cycloaliphatic polybasic acids.

WO 2007-147559 (DSM) describes air drying fatty acid functional hyperbranched resins. The resins are water soluble, due to a relatively high OH content and a low fatty acid level. This is less desirable due to the effect it has on water resistance and rate of cure and therefore on final properties.

We have now found ways to overcome the above mentioned disadvantages, especially when combinations of more then one of the problems need to be overcome in one coating system.

It is an object of the invention to solve some or all or the problems identified herein. A preferred object of the invention provides a method of improving the appearance of coated substrates, the substrates containing visual irregularities. In a
more preferred object of the invention the method can be used with a wide variety of coating compositions.

The applicant has found that certain vinyl polymers prepared by radical polymerisation of certain vinyl / acrylic monomers may comprise significantly less low molecular weight fraction (like the aforementioned triglycerides) avoiding the need to use significant amounts of high molecular weight material, for example to improve drying. The applicant has also surprisingly found that certain vinyl polymers (with specific molecular weight, PDi and Tg values), that are prepared by radical polymerisation of epoxy functional vinyl monomers with other vinyl monomers, and then reacted with certain unsaturated fatty acids may overcome some or all of the above identified problems with prior art vinyl polymers.

According to the present invention there is provided an aqueous coating composition that comprises an autoxidisable polymer that comprises plurality of vinyl groups where:

I) said autoxidisable polyvinyl polymer has:
   i) fatty acid residue in an amount greater than or equal to 20% by weight of said autoxidisable polyvinyl polymer
   ii) a glass transition temperature (Tg) from -60°C to +20°C;
   iii) an acid value from 5 to 75, optionally from 15 to 75 mg KOH/g;
   iv) a weight average molecular weight (Mw) from 2500 to 100000 g/mol;

II) said composition has:
   a) a co-solvent content less that 25% by weight of solids;
   b) a solids content greater than or equal to 30% by the total weight of said composition; and

III) said composition when in the form of the film has a telegraphing value of less than 10 gloss units,

where the telegraphing value is the difference between an initial smooth gloss value minus an initial rough gloss value of the film, where

the initial smooth gloss value is the gloss when the film is cast on smooth PVC ($R_g = 1\mu m \pm 0.25\mu m$);

the initial rough gloss value is the gloss when the film is cast on rough PVC ($R_g = 25$ microns [\mu m] $\pm 5\mu m$); and

where each film has a dry film thickness of 52\mu m $\pm 6\mu m$; and each initial gloss value is measured at a 20° angle, one day (24 hours) after the film has been cast.
As used herein PVC means a polyvinylchloride substrate used as described in the test methods herein.

Dry film thickness herein is measured after 24 hours of drying, under standard conditions. As used herein, unless the context indicates otherwise, the term 'standard conditions' denotes a relative humidity of 50% ±5%, an air flow less than or equal to 0.1 m/s; and an 'ambient temperature' which herein denotes 23°C ±2°.

The telegraphing values herein will be positive numbers. In general the greater the reduction in telegraphing, the smaller will be the telegraphing value.

The term "comprising" as used herein means that the list that immediately follows is non-exhaustive and may or may not include any other additional suitable items, for example one or more further feature(s), component(s), ingredient(s) and/or substituent(s) as appropriate. "Substantially comprising" as used herein means a component or list of component(s) is present in a given material in an amount greater than or equal to about 90%, preferably ≥95%, more preferably ≥98% by weight of the total amount of the given material. The term "consisting of" as used herein mean that the list that follows is exhaustive and does not include additional items.

For all upper and lower boundaries of any parameters given herein, the boundary value is included in each range for each parameter. All combinations of minimum and maximum values of the parameters described herein may be used to define the parameter ranges for various embodiments and preferences of the invention.

It will be understood that the total sum of any quantities expressed herein as percentages cannot (allowing for rounding errors) exceed 100%. For example the sum of all components of which the composition of the invention (or part(s) thereof) comprises may, when expressed as a weight (or other) percentage of the composition (or the same part(s) thereof), total 100% allowing for rounding errors. However where a list of components is non-exhaustive the sum of the percentage for each of such components may be less than 100% to allow a certain percentage for additional amount(s) of any additional component(s) that may not be explicitly described herein.

As used herein the terms oligomer and polymer both refer to macromolecules which comprises a plurality of units derived, actually or conceptually, from molecules of lower molecular mass. These terms may also be used adjectivally to describe a part or the whole of a macromolecule. Often the term oligomer may be used more specifically to refer to macromolecules of intermediate relative molecular mass, where the oligomer properties vary significantly with the removal of one or a few units.
Polymer may be used both generally to refer to any macromolecule and also more specifically to refer to macromolecules of high relative molecular mass where usually addition or removal of one or a few units has a negligible effect on the molecular properties (although this may not be always be the case for example where polymers have certain properties that are critically dependent on fine details of the molecular structure). It will be understood that the molecular mass boundary between an oligomer and a polymer (in its specific rather than general meaning) may vary according to the specific macromolecule and/or applications of interest and so they may be significant overlap where the same macromolecules may be considered both a oligomer and a polymer. Therefore, unless the context herein clearly indicates otherwise, the terms oligomer and polymer are used herein interchangeably.

Preferably the coating compositions of the invention are non-adhesive compositions. As used herein the term 'non-adhesive composition' denotes any composition that does not remain substantially tacky after drying under standard conditions for a length of time which would be commercially acceptable. Preferred non-adhesive compositions are those which have a tack-free time of less than 16 hours, more preferably < 10 hours, most preferably < 6 hours. Tack free time may conveniently be measured as described herein.

Compositions of the invention may be aqueous solutions or emulsions where the continuous phase is aqueous, although aqueous solutions are preferred.

Preferred compositions of the invention produce coatings that have a telegraphing value (as defined herein) of less than 7 gloss units, more preferably less than 4.5 gloss units.

Preferably the initial rough gloss should not deteriorate significantly over time. This can be measured as a 'gloss decay' defined as the initial rough gloss minus a rough gloss measured at a later specified time. For example "gloss decay ('n' days)" is calculated as the initial rough gloss (measured 1 day after film formation) minus the rough gloss measured 'n' days after film formation (i.e. in this case n is always >1). Preferably the gloss decay is measured 4 days, more preferably 7 days and most preferably 14 days after film formation. Preferred values of gloss decay (for example after each of the periods given above) are less than 10 gloss units, more preferably less than 7 gloss units, most preferably less than 5 gloss units.

Without wishing to be bound by any theory it is believed that the vinyl polymers of the invention have a comb like structure allowing excellent control of
molecular weight distribution to give a relatively narrow distribution resulting in good flow, reduced telegraphing and fast drying. Conventional vinyl polymers are typically highly branched and used under conditions which are close to those which cause the polymer to gel. In contrast the vinyl polymers of the invention are hydrolytically stable as their backbone is more resistant to hydrolysis. These properties are especially important for decorative paints which may stay on the shelf for a long time.

Polymers of the invention have a narrow molecular weight distribution (which may be measured as a polydispersity, PDI) and a relatively low weight average molecular weight (Mw) and therefore an improved Mw / PDI balance. As these polymers have less material of low molecular weight, they produce coating compositions that dry fast, for example have short dust and/or tack free times. Compositions of the invention have other advantages. They may be prepared with lower viscosities due to the reduced amount of high molecular weight material and for example in solvent borne systems, less solvent is needed to achieve a certain viscosity and in aqueous systems lower viscosity can reduce telegraphing. Alternatively compositions with a similar solvent content to the prior art can be produced with a higher overall molecular weight. Compositions of the invention can also be prepared with a high solids content.

Preferably the autoxidisable polyvinyl polymer will crosslink at ambient temperature. Crosslinking by autoxidation means the crosslinking results from an oxidation occurring in the presence of air, usually involving a free radical mechanism and is preferably metal-catalysed resulting in covalent bonds. Suitable autoxidation is provided by for example fatty acid residues comprising unsaturated bonds, allyl functional residues and/or β(beta)-keto ester groups preferably by fatty acid residues comprising unsaturated bonds.

As used herein ‘fatty acid residue’ (or FA residue), means fatty acids, simple derivatives thereof (such as esters (e.g. C₁₄alkyl esters), salts, soaps, oils, fats and/or waxes) and mixtures thereof. As used herein ‘fatty acid’ means any predominately unbranched, non-cyclic (preferably substantially linear) aliphatic carboxylic acid that substantially comprises, preferably consists of an aliphatic hydrocarbon chain and at least one carboxy group, preferably a single terminal carboxyl group (i.e. located at the end of the chain). Fatty acids may comprise a limited number of other substituents such as hydroxyl and may be saturated, mono-unsaturated or poly-unsaturated.

The fatty acid residue may be obtained from one or more natural
and/or artificial source. Natural sources include animal sources and/or plant sources. Animal sources may comprise animal fat, butter fat, fish oil, lard, liver fats, sperm whale oil and/or tallow oil and waxes. Examples of waxes are beeswax, candelila and/or montan. Plant sources may comprise waxes and/or oils such as vegetable oils and/or non-vegetable oils. Examples of plant oils are: bitter gourd, borage, calendula, canola, castor, china wood, coconut, conifer seed, corn, cottonseed, dehydrated castor, flaxseed, grape seed, *Jacaranda mimosifolia* seed, linseed, olive, palm, palm kernel, peanut, pomegranate seed, rapeseed, safflower, snake gourd, soya(bean), sunflower, tung, and/or wheat germ. Artificial sources include synthetic waxes (such as micro crystalline and/or paraffin wax), distilling tall oil (a by-product of processing pine wood) and/or synthesis (for example by chemical and/or biochemical methods). Fatty acid residues having conjugated double bonds may be obtained by catalytic isomerisation of natural fatty acids and/or dehydrated castor oil. Conjugated oils are preferably obtained by dehydration of castor oil. Fatty acid residues may be obtained and/or obtainable from a plurality of the above sources and/or other sources not listed herein.

Preferred fatty acid residues may comprise fatty acid(s) having from 4 to 36, more preferably from 8 to 26, most preferably from 10 to 24, especially 12 to 22 carbon atoms. Generally fatty acids obtained from natural sources have an even number of carbon atoms due to their method of biosynthesis, however fatty acids with an odd number of carbon atoms may also be useful in the present invention. Fatty acid residues may comprise fatty acids with one or more carboxylic acid groups, for example dimer or trimer fatty acids. However preferred fatty acids are mono functional, more preferably C_{12-24} mono functional carboxylic acids, most preferably C_{12-22} linear mono functional terminal carboxylic acids.

As long as oxidative drying of the polymer is not impaired the fatty acid residue may comprise one or more saturated fatty acids and/or oils, however at least some unsaturated fatty acid(s) is needed for auto-oxidation to occur. In general the more unsaturation present the more rapid the autooxidative drying.

An iodine number may be used to indicate the amount of unsaturation contained in fatty acids where a higher the iodine number indicates more unsaturated double bonds are present. Preferably the fatty acid residue used herein has an average iodine value greater than or equal to 50, more preferably ≥ 80 and most preferably ≥ 100 g I₂/100 g fatty acid. Preferably the fatty acid residue used herein has an average iodine value less than or equal to 200, more preferably ≤ 180 and most preferably ≤ 150 g I₂/100 g fatty acid. The iodine value may be measured conventionally or
preferably as described in the test methods herein.

For the purpose of determining the amount of fatty acid residue used to obtain the polyvinyl polymer of the invention, it is convenient to calculate the weight of the fatty acid reactant by including the carbonyl group, but excluding the hydroxyl group of the terminal acid group of the fatty acid molecule.

Preferably the minimum amount of fatty acid residues in the autoxidisable vinyl polymer is greater than or equal to 28%, more preferably ≥ 38% and most preferably ≥ 43% by weight of the polymer.

Preferably the maximum amount of fatty acid residue in the autoxidisable vinyl polymer is less than or equal to 70%, more preferably £65% and most preferably ≤ 55% by weight of the polymer.

Preferably the fatty acid residue comprises C_{10-30} fatty acids, more preferably C_{8-20} fatty acids, in an amount greater than or equal to 80% by weight of the fatty acid residue. More preferably the fatty acid residue substantially comprises, most preferably consists of C_{10-30} fatty acids, especially C_{16-20} fatty acids.

If the fatty acid residue comprises saturated fatty acids they may be present in an amount less than or equal to 40%, more preferably ≤ 20% and most preferably from 3% to 18% by weight of the fatty acid residue.

Preferred polyvinyl polymers are those in which the autoxidisable groups are mainly derived from fatty acid residue. More preferably the fatty acid residue mainly comprises, most preferably substantially comprises unsaturated fatty acids. Useful unsaturated fatty acids have two or more double bonds, more usefully are conjugated fatty acids.

An embodiment of the invention provides polyvinyl polymers with autoxidisable groups mainly derived from unsaturated fatty acids having two or more double bonds, preferably conjugated fatty acids. More preferably at least 60% by weight of the total amount of unsaturated fatty acids are those fatty acids that contain at least two unsaturated groups.

The autoxidisable polyvinyl polymer may be obtained from a mixture of conjugated and non-conjugated unsaturated fatty acids. Preferably the autoxidisable polymer is obtained and/or obtainable from a mixture of unsaturated fatty acids that comprises 20% to 70% of conjugated and 80% to 30% of non-conjugated fatty acids by weight of the total amount of unsaturated fatty acids.

A known problem with many autoxidisable coating compositions is that the resultant coatings have a tendency to yellow, in particular where the
autoxidisable groups are derived from polyunsaturated fatty acids (e.g. those described herein). This may be unacceptable depending on the desired color of the resultant coating.

Therefore in another embodiment of the invention to reduce yellowing, preferred autoxidisable vinyl oligomers are those where the unsaturated fatty residue comprises low amounts of highly polyunsaturated fatty acids. For example vinyl polymers that are more resistant to yellowing may be obtained and/or obtainable from fatty acid residues that comprise by weight of total fatty acid no more than 10%, more preferably <7%, most preferably <4% and especially <2% of fatty acids with three or more double bonds. Examples of fatty acids that include three or more double bonds are given herein.

Preferred compositions of the invention have an initial yellowness value of less than or equal to 10, more preferably ≤ 7 and most preferably ≤ 4, when measured using the test method described herein. Preferred compositions show only a small increase in yellowness (Δb value) after being held in darkness for 3 weeks at 52 °C, more preferably Δb is less than or equal to 10, still more preferably is ≤ 7, most preferably ≤ 5 and especially ≤ 3.

In yet another embodiment of the invention (e.g. where yellowing is not a concern) preferred autoxidisable vinyl oligomers are those where the unsaturated fatty residue comprises higher amounts of highly polyunsaturated fatty acids (such as fatty acids with three or more double bonds) as this can improve the speed of autoxidative drying.

Preferably the unsaturated fatty acid is covalently bound to the vinyl oligomer in a one step process, either though the use of a fatty acid functional vinyl monomer or through a reaction of the fatty acid with the vinyl oligomer.

It is preferred that glycidyl esters of unsaturated fatty acids are not used in the preparation of the autoxidisable vinyl oligomer as the synthesis of these glycidyl esters requires toxic raw materials like epichlorohydrine which will also give chlorine containing waste material which is undesirable. A glycidyl ester of an unsaturated fatty acid is an epoxy functional fatty acid material (usually with a number average molecular weight (M_n) below 400) where the acid group has been reacted to obtain a glycidyl end group.

Optionally the fatty acid residue may also comprise one or more alkynyl group(s) and/or one or more (non carboxy) hydroxyl group(s).

Non limiting examples of some common fatty acids that may be used
in the present invention are listed below as their systematic (IUPAC) names with their trivial name(s) in square parentheses where known. It will be appreciated that in practice most fatty acid residues (especially those obtained from natural sources) will comprise a mixture of many of these acids as well as other acids not specifically listed herein.

Saturated fatty acids may be selected from:
butanoic [butyric] acid (C_4H_8O_2), pentanoic [valeric] acid (C_5H_10O_2), hexanoic [caproic] acid (C_6H_{12}O_2), heptanoic [enanthic] acid (C_7H_{14}O_2), octanoic [caprylic] acid (C_8H_{16}O_2), nonanoic [pelargonic] acid (C_9H_{18}O_2), decanoic [capric] acid (C_{10}H_{20}O_2), dodecanoic [lauric] acid (C_{12}H_{24}O_2), tetradecanoic [myristic] acid (C_{14}H_{28}O_2), hexadecanoic [palmitic] acid (C_{16}H_{32}O_2), heptadecanoic [margaric] also daturic acid (C_{17}H_{34}O_2), octadecanoic [stearic] acid (C_{18}H_{36}O_2), eicosanoic [arachidic] acid (C_{20}H_{40}O_2), docosanoic [behenic] acid (C_{22}H_{44}O_2), tetracosanoic [lignoceric] acid (C_{24}H_{48}O_2), hexacosanoic [cerotic] acid (C_{26}H_{52}O_2), heptacosanoic [carbocecic] acid (C_{27}H_{54}O_2), octacosanoic [montanic] acid (C_{28}H_{56}O_2), triacontanoic [melissic] acid (C_{30}H_{60}O_2), dotriacontanoic [lacceroic] acid (C_{32}H_{64}O_2), tritriacontanoic [ceromelissic] also psyllic acid (C_{33}H_{66}O_2), tetratriacontanoic [geddic] acid (C_{34}H_{68}O_2) and/or pentatriacontanoic [ceroplastic] acid (C_{35}H_{70}O_2).

Mono-unsaturated fatty acids may be selected from:
(Z)-decan-4-enolic [obtusilic] acid (C_{10}H_{18}O_2), (Z)-decan-9-enolic [caproleic] acid (C_{10}H_{18}O_2), (Z)-undecan-10-enolic [undecylenic also 10-hendecenoic] acid (C_{11}H_{20}O_2), (Z)-dodecan-4-enolic [linderic] acid (C_{12}H_{22}O_2), (Z)-dodecan-5-enolic [lauroleic] acid (C_{12}H_{22}O_2), (Z)-tetradecan-4-enolic [tsuzuic] acid (C_{14}H_{26}O_2), (Z)-tetradecan-5-enolic [physyteric] acid (C_{14}H_{26}O_2), (Z)-tetradecan-9-enolic [myristoleic] acid (C_{14}H_{26}O_2), (Z)-hexadan-3-enolic [sapienic] acid (C_{16}H_{30}O_2), (Z)-hexadan-9-enolic [palmitoleic] acid (C_{16}H_{30}O_2), (Z)-octadecan-3-enolic [petroselinic] acid (C_{18}H_{34}O_2), (E)-octadecan-9-enolic [elaidic] acid (C_{18}H_{34}O_2), (Z)-octadecan-9-enolic [oleic] acid (C_{18}H_{34}O_2), (Z)-octadecan-1-enoic [vaccenic also asclepic] acid (C_{18}H_{34}O_2), (Z)-eicosan-9-enolic [gadoleic] acid (C_{20}H_{38}O_2), (Z)-eicosan-1-enoic [gondoic] acid (C_{20}H_{38}O_2), (Z)-docosan-1-enoic [cetoleic] acid (C_{22}H_{42}O_2), (Z)-docosan-13-enoic [erucic] acid (C_{22}H_{42}O_2) and/or (Z)-tetracosan-15-enoic [nervonic] acid (C_{24}H_{48}O_2).

Di-unsaturated fatty acids may be selected from:
(5Z,9Z)-hexadec-5,9-dienolic acid (C_{16}H_{28}O_2),
(5Z,9Z)-octadec-5,9-dienolic [taxoleic] acid (C_{18}H_{32}O_2),
(9Z,12Z)-octadeca-9,12-dienonic [linoleic] acid (C_{18}H_{32}O_2).
(9Z,15Z)-octadeca-9,15-dienoic acid \((\text{C}_8\text{H}_{32}\text{O}_2)\) and/or
(7Z,1 1Z)-eicosa-7,1 1-dienoic [dihomotaxoleic] acid \((\text{C}_{20}\text{H}_{36}\text{O}_2)\).

Tri-unsaturated fatty acids may be selected from:

(5Z,9Z,12Z)-heptadeca-5,9,12-trienoic acid \((\text{C}_7\text{H}_{30}\text{O}_2)\).

(3Z,9Z,12Z)-octadeca-3,9,12-trienoic acid \((\text{C}_8\text{H}_{30}\text{O}_2)\).

(5Z,9Z,12Z)-octadeca-5,9,12-trienoic acid [pinolenic] \((\text{C}_8\text{H}_{30}\text{O}_2)\).

(6Z,9Z,12Z)-octadeca-6,9,12-trienoic acid [\(\gamma\) (gamma)-linolenic acid also GLA] \((\text{C}_8\text{H}_{30}\text{O}_2)\). (8E,10E,12Z)-octadeca-8,10,12-trienoic acid [calendic] \((\text{C}_8\text{H}_{30}\text{O}_2)\).

(8Z,10E,12Z)-octadeca-8,10,12-trienoic acid [Oacaric] \((\text{C}_8\text{H}_{30}\text{O}_2)\).

(9E,1 1E,13E)-octadeca-9, 11,13-tetraenoic acid [\(\beta\) (beta)-eleostearic also \(\beta\)-oleostearic] \((\text{C}_8\text{H}_{30}\text{O}_2)\). (9E,1 1E,13Z)-octadeca-9, 11,13-tetraenoic acid [catalpic] \((\text{C}_8\text{H}_{30}\text{O}_2)\).

(9Z,1 1E,13E)-octadeca-9, 11,13-tetraenoic acid [\(\alpha\) (alpha)-eleostearic also \(\alpha\)-oleostearic] \((\text{C}_8\text{H}_{30}\text{O}_2)\) (where \(\alpha\)-oleostearic acid comprises >65% of the fatty acids of tung oil),

(9Z,1 1E,13Z)-octadeca-9, 11,13-tetraenoic acid [punivic also trichosanic] \((\text{C}_8\text{H}_{30}\text{O}_2)\).

(9Z,11E,15Z)-octadeca-9, 11,13-tetraenoic acid [rumelenic] \((\text{C}_8\text{H}_{30}\text{O}_2)\).

(9Z,13E,15Z)-octadeca-9, 11,13,15-tetraenoic acid \((\text{C}_8\text{H}_{30}\text{O}_2)\).

(9Z,12Z,15Z)-octadeca-9, 12,15-tetraenoic acid [\(\alpha\) (alpha)-linolenic acid also ALA] \((\text{C}_8\text{H}_{30}\text{O}_2)\). (5Z,8Z,1 1Z)-eicosa-5,8,11 1-trienoic acid [dihomo-\(\gamma\) (gamma)-linolenic acid] \((\text{C}_{20}\text{H}_{34}\text{O}_2)\).

(8Z,11Z,14Z)-eicosa-8, 11,14-tetraenoic acid [Mead] \((\text{C}_{20}\text{H}_{34}\text{O}_2)\).

Tetra-unsaturated fatty acids may be selected from:

(6Z,8Z,10Z,12Z)-hexadeca-6,8,10,15-tetraenoic acid \((\text{C}_6\text{H}_{24}\text{O}_2)\).

(6Z,8Z,10Z,12Z)-octadeca-6,8,10,12-tetraenoic acid \((\text{C}_8\text{H}_{28}\text{O}_2)\).

(6Z,9Z,12Z,15Z)-octadeca-6,9,12,15-tetraenoic acid [stearidonic] \((\text{C}_8\text{H}_{28}\text{O}_2)\).

(9Z,11E,13E,15Z)-octadeca-9, 11,13,15-tetraenoic acid [\(\alpha\) (alpha)-parinaric] \((\text{C}_8\text{H}_{28}\text{O}_2)\).

(9Z,11Z,13Z,15Z)-octadeca-9, 11,13,15-tetraenoic acid [\(\beta\) (beta)-parinaric] \((\text{C}_8\text{H}_{28}\text{O}_2)\).

(5Z,8Z,1 1Z,14Z)-eicosa-5,8,11 1,14-tetraenoic acid [arachidonic acid also AA] \((\text{C}_{20}\text{H}_{34}\text{O}_2)\).

(6Z,8Z,10Z,12Z)-eicosa-6,8,10,12-tetraenoic acid \((\text{C}_{20}\text{H}_{34}\text{O}_2)\).

(8Z,1 1Z,14Z,11Z)-eicosa-8, 11,14,17-tetraenoic acid \((\text{C}_{20}\text{H}_{34}\text{O}_2)\).

(6Z,8Z,10Z,12Z)-docosa-6,8,10,12-tetraenoic acid \((\text{C}_{22}\text{H}_{36}\text{O}_2)\) and/or

(7Z,10Z,13Z,16Z)-docosa-7, 10,13,16-tetraenoic acid \((\text{C}_{22}\text{H}_{36}\text{O}_2)\).

Penta-unsaturated fatty acids may be selected from:

(x,6Z,8Z,10Z,12Z)-hexadeca-x,6,8, 10,12-pentaenoic acid(s) \((\text{C}_6\text{H}_{22}\text{O}_2)\) where x denotes a fifth double bond optionally in a position which does not conjugate with the other four conjugated ethylenic double bonds,
(x',6Z,8Z,10Z,12Z)-eicosa-x',6,8,10,12-pentaenoic acid(s) \( \text{C}_{20}\text{H}_{30}\text{O}_{2} \) where \( x' \) denotes a fifth double bond optionally in a position which does not conjugate with the other four ethylenic double bonds,

(5E,7E,9E,14Z,17Z)-eicosa-5,8,11,14,17-pentaenoic acid \( \text{C}_{20}\text{H}_{30}\text{O}_{2} \).

(5Z,7E,9E,14Z,17Z)-eicosa-5,8,1,14,17-pentaenoic acid \( \text{C}_{20}\text{H}_{30}\text{O}_{2} \).

(5Z,8Z,11Z,14Z,17Z)-eicosa-5,8,11,14,17-pentaenoic acid [EPA] \( \text{C}_{20}\text{H}_{30}\text{O}_{2} \).

(7Z,10Z,13Z,16Z,19Z)-docosa-4,7,10,13,16-pentaenoic [clupanodonic] acid \( \text{C}_{22}\text{H}_{34}\text{O}_{2} \).

(4Z,7Z,10Z,13Z,16Z)-docosa-4,7,10,13,16-pentaenoic [osbond] acid \( \text{C}_{22}\text{H}_{34}\text{O}_{2} \) and/or (7Z,10Z,13Z,16Z,19Z)-docosa-7,10,13,16,19-pentaenoic acid [DPA] \( \text{C}_{22}\text{H}_{34}\text{O}_{2} \).

Hexa-unsaturated fatty acids may be selected from:

\( (x'',6Z,8Z,10Z,12Z)\)-eicosa-x'',6,8,10,12-hexaenoic acid(s) \( \text{C}_{20}\text{H}_{28}\text{O}_{2} \) where \( x'' \) and \( y'' \) denote fifth and sixth double bonds optionally in positions which do not conjugate with the other four conjugated ethylenic double bonds,

(4Z,7Z,10Z,13Z,16Z,19Z)-docosa-4,7,10,13,16,19-hexaenoic acid [DHA] \( \text{C}_{22}\text{H}_{32}\text{O}_{2} \) and/or (6Z,9Z,12Z,15Z,18Z,21Z)-tetracosa-6,9,12,15,18,21-hexaenoic [nisinic] acid \( \text{C}_{22}\text{H}_{36}\text{O}_{2} \).

Hepta-unsaturated fatty acids may be selected from:

\( (w'',x'',y'',6Z,8Z,10Z,12Z)\)-eicosa-\( w'',x'',y'',6,8,10,12\)-heptaenoic acid(s) \( \text{C}_{22}\text{H}_{30}\text{O}_{2} \) where \( w'' \), \( x'' \) and \( y'' \) denote fifth, sixth and seventh double bonds optionally in positions which do not conjugate with the other four conjugated ethylenic double bonds, and/or (4Z,7Z,9Z,11Z,13Z,16Z,19Z)-docosa-4,7,9,11,13,16,19-heptaenoic [stellaeheptaenoic] acid \( \text{C}_{22}\text{H}_{30}\text{O}_{2} \).

Alkynyl-functional fatty acids may be selected from:

(9Z)-octadeca-9-en-12-ynoic [crepenynic] acid \( \text{C}_{18}\text{H}_{30}\text{O}_{2} \).

Hydroxy-functional fatty acids may be selected from:

12-hydroxy-(9Z)-octadeca-9-enolic [ricinoleic] acid \( \text{C}_{18}\text{H}_{34}\text{O}_{3} \).

Optionally autoxidation is used in combination with other crosslinking mechanisms as are known in the art. In an embodiment, metal ion crosslinking may be used in combination with the autoxidation mechanism, e.g. by use of coordinative driers as is well known by those skilled in the art. Other crosslinking mechanisms known in the art that may also be used in combination with autoxidation include the reaction of alkoxyisilane functional groups, Schiff base crosslinking, epoxy groups reacting with amino, carboxylic acid or mercapto groups, the reaction of amine or mercapto groups with ethylenically unsaturated groups such as fumarate and acryloyl
groups, the reaction of masked epoxy groups with amino or mercapto groups, the
reaction of isothiocyanates with amines, alcohols or hydrazines, the reaction of amines
(for example ethylene diamine or multifunctional amine terminated polyalkylene oxides)
with β-diketo (for example acetoacetoxy or acetoamide) groups to form enamines.

The autoxidisable vinyl polymer may contain bound hydrophilic
water-dispersing groups. Suitable hydrophilic groups are well known in the art, and can
be ionic water-dispersing groups or non-ionic water-dispersing groups. Preferred
non-ionic water-dispersing groups are polyalkylene oxide groups, more preferably
polyethylene oxide groups. A small segment of the polyethylene oxide group can be
replaced by a propylene oxide segment and/or butylene oxide segment, however the
polyethylene oxide group should still contain ethylene oxide (EO) as a major
component. When the water-dispersible group is polyethylene oxide, the preferred EO
chain length is ≥ 4, more preferably ≥ 8 and most preferably ≥ 15 EO units. Preferably if
the autoxidisable vinyl polymer contains polyalkylene oxide groups, the vinyl polymer
has a polyalkylene oxide (optionally EO) content which is at least ≥ 0%, more
preferably ≥ 2%, most preferably ≥ 3.5 % and especially ≥ 5% and/or is no more than
< 50%, more preferably ≤ 30%, most preferably ≤ 15% and especially ≤ 9% by weight
of the autoxidisable vinyl polymer. Preferably the polyalkylene oxide (optionally EO)
group has a M_w from 175 to 5000 g/mol, more preferably from 350 to 2200 g/mol, most
preferably from 660 to 2200 g/mol.

Preferred ionic water-dispersing groups are anionic water-dispersing
groups, especially carboxylic, phosphate, phosphonate and/or sulphonic acid groups.
Most preferred are carboxylic, phosphate and/or phosphonate groups. The anionic
water-dispersing groups are preferably fully or partially in the form of a salt. Conversion
to the salt form is optionally effected by neutralisation of the autoxidisable polymer with
a base, preferably during the preparation of the autoxidisable polymer and/or during the
preparation of the composition of the present invention. The anionic dispersing groups
may in some cases be provided by the use of a monomer having an already
neutralised acid group in the autoxidisable polymer synthesis so that subsequent
neutralisation is unnecessary. If anionic water-dispersing groups are used in
combination with a non-ionic water-dispersing group, neutralisation may not be
required.

If the anionic water-dispersing groups are neutralised, the base used
to neutralise the groups is preferably, an amine or an inorganic base. Suitable amines
include tertiary amines, for example triethyl amine or N,N-dimethylethanolamine.
Suitable inorganic bases include alkali hydroxides and carbonates, for example lithium hydroxide, sodium hydroxide, or potassium hydroxide. Generally a base is used which gives the required counter ion desired for the composition. For example, preferred counter ions include tertiary amines or Li⁺, Na⁺, K⁺, NH₄⁺ and substituted ammonium salts (for example a quaternary ammonium hydroxide +N(CH₃)₄OH⁺).

Cationic water dispersible groups can also be used, but are less preferred. Examples include pyridine groups, imidazole groups and or quaternary ammonium groups which may be neutralised or permanently ionised. Due to the influence that neutralisation agents have on yellowing, tertiary amines and/or LiOH, NaOH and KOH are especially preferred.

The autoxidisable polyvinyl polymer preferably has an acid value (AV, also referred to as an acid number [AN]) greater than or equal to 20, more preferably ≥ 25 mg KOH/g. The autoxidisable polymer preferably has an acid value of less than or equal to 65, more preferably ≤ 60 mg KOH/g.

The autoxidisable polyvinyl polymer, if carboxylic acid functional, preferably conforms to the following relationship (where ND denotes the degree to which the acid groups of the polymer are neutralised):

ND x AV > 22, more preferably > 27 and most preferably > 33 mg KOH/g.
ND x AV ≤ 65, more preferably ≤ 60 and most preferably < 45 mg KOH/g.

ND is a dimensionless fraction from 0 to 1 that indicates of the amount of neutralizing agent present in the polymer. For example if 80% of the acid groups on the polymer are neutralised, then the ND value is 0.8. AV is reported in units of mg KOH/g so the product ND x AV has units of mg KOH/g.

The autoxidisable polyvinyl polymer preferably has an hydroxyl number of ≤ 60 mg KOH/g, more preferably ≤ 40 mg KOH/g, more preferably ≤ 25 mg KOH/g.

Preferably the aqueous coating composition has a pH > 5.1, more preferably > 6.5. Preferably the composition has a pH < 9.2, more preferably < 8.4 and especially < 7.6.

The aqueous coating composition preferably comprises ≥ 30%, more preferably ≥ 35% and especially ≥40% by weight of the autoxidisable polymer of the invention. The aqueous coating composition preferably comprises ≤ 60%, more preferably ≤ 55%, and most preferably ≤ 50% by weight of the autoxidisable polymer of the invention.

The drying process of the aqueous coating composition can be
divided into stages for example the period of time necessary to achieve dust-free, 
tack-free coatings using the tests described herein.

Preferably the dust free time is ≤ 4 hours, more preferably ≤ 2 hours 
and most preferably ≤ 50 minutes.

Preferably the tack-free time is ≤ 16 hours, more preferably ≤ 8 hours 
and most preferably ≤ 5 hours.

Preferably the weight average (M_w) of the autoxidisable vinyl polymer 
is at least ≥ 3500, more preferably ≥ 5000, most preferably ≥ 7000, and/or is no more 
than ≤ 40000 more preferably ≤ 25000, most preferably ≤ 15000 g/mol. M_w is measured 
by GPC using polystyrene standards as described herein.

Preferably the significant part of any crosslinking reaction takes place 
only after the aqueous coating composition has been applied to a substrate. This 
avoids any excessive increase in molecular weight in the early stages of drying (and a 
consequent viscosity increase in the coating).

The molecular weight distribution (MWD) of the polyvinyl polymer has 
an influence on the viscosity of the composition and hence an influence on the 
telegraphing. MWD is conventionally described by a polydispersity index (PDI) defined 
as the weight average molecular weight (M_w) divided by the number average molecular 
weight (M_n) and is dimensionless. It has been found that a lower PDI often results in 
lower viscosity for a crosslinkable autoxidisable polymer of given M_w. Preferably the 
autoxidisable vinyl polymer has a PDI which is no more than ≤ 20, more preferably ≤ 16 
and more preferably ≤ 12 and/or is at least ≥ 2.5.

Preferably the weight average particle size of the autoxidisable vinyl 
polymer dispersed in an aqueous coating composition is no more than ≤ 120 nm, more 
preferably ≤ 90 nm, most preferably ≤ 50 nm. Preferably at least 80% of the particles 
have a weight average particle size ≤ 120 nm, more preferably ≤ 80 nm, most 
preferably ≤ 50 nm.

Weight average particle size can be measured by any suitable 
method such as that described in the test methods herein.

The glass transition temperature (T_g) (as measured by DSC of a solid 
material) of the autoxidisable vinyl oligomer may vary within a wide range and 
preferably is at least ≥ -60°C, more preferably ≥ -50°C, still more preferably ≥ -40°C. 
most preferably ≥ -35°C and especially ≥ -30°C and/or preferably is no more than 
< +15°C, more preferably <+10°C , most preferably <+5°C and especially <0°C.
Conveniently the $T_g$ of the autoxidisable polyvinyl polymer is $-10^\circ C$.

If the $T_g$ cannot be measured by DSC because the first derivative of the DSC curve does not show any identifiable maximum, an alternative method for determining the $T_g$ is by calculating the $T_g$ using the following equation that relates viscosity of the pure vinyl oligomer to its $T_g$ (which is derived from the Williams-Landau-Ferry [WLF] equation):

$$\ln(\eta) = 27.6 - \frac{[40.2 \times (T-T_g)]}{[51.6+(T-T_g)]}$$

where:

$\ln(\eta) = \text{Natural logarithm of the viscosity of the pure oligomer expressed in Pa.s}$

(measured at ambient temperature using a shear rate from 0.005 and 1 s$^{-1}$)

$T = 23^\circ C \pm 1^\circ C$ (i.e. ambient temperature is used to measure the viscosity of the pure oligomer) and

$T_g = \text{glass temperature expressed in } ^\circ C$.

Functional groups (such as fatty acid residue or water-dispersing groups) may be introduced into the autoxidisable polyvinyl polymer using two general methods: i) by using monomers carrying the functional group in the polymerisation process to form autoxidisable polyvinyl polymer carrying the functional group; or ii) using monomers bearing selected reactive groups where monomer is subsequently reacted with a compound carrying the functional group and also a reactive group of the type which will react with the selected reactive groups on the monomer to provide attachment of the functional group to the autoxidisable polyvinyl polymer via covalent bonding.

The polyvinyl autoxidisable polymer, may be prepared from free radically polymerisable olefinically unsaturated monomer(s), and can contain polymerised units of a wide range of such monomers, especially those commonly used to make binders for the coatings industry. By a vinyl polymer herein is meant a homo- or co-polymer derived from addition polymerisation, using a free radical initiated process which may be carried out in an aqueous or non-aqueous medium, of one or more olefinically unsaturated monomers. Therefore by a vinyl monomer is meant an olefinically unsaturated monomer.

Examples of vinyl monomers which may be used to form a vinyl polymer include but are not limited to 1,3-butadiene, isoprene, styrene, $\alpha$-methyl styrene, divinyl benzene, acrylonitrile, methacrylonitrile, vinyl halides such as vinyl chloride, vinylidene halides such as vinylidene chloride, vinyl ethers, vinyl esters such as vinyl acetate, vinyl propionate, vinyl laurate, and vinyl esters of versatic acid such as
Veova 9 and Veova 10 (Veova is a trademark of Shell), heterocyclic vinyl compounds, alkyl esters of mono-olefinically unsaturated dicarboxylic acids (such as di-n-butyl maleate and di-n-butyl fumarate) and, in particular, esters of acrylic acid and methacrylic acid of Formula 1

\[ \text{CH}_2=\text{CR}^1-\text{COOR}^2 \]

where \( R^1 \) is H or methyl and \( R^2 \) is optionally substituted \( C_{i-2}\)alkyl (preferably \( C_{i-8}\)alkyl) or optionally substituted \( C_{3-20}\)cycloalkyl (preferably \( C_{8-20}\)cycloalkyl), examples of which are methyl acrylate, methyl methacrylate, ethyl acrylate, ethyl methacrylate, n-butyl acrylate, n-butyl methacrylate, 2-ethylhexyl acrylate, 2-ethylhexyl methacrylate, isopropyl acrylate, isopropyl methacrylate, n-propyl acrylate, n-propyl methacrylate, and hydroxyalkyl (meth)acrylates such as hydroxyethyl acrylate, hydroxyethyl methacrylate, 2-hydroxypropyl methacrylate, 2-hydroxypropyl acrylate, 4-hydroxybutyl acrylate, 4-hydroxybutyl methacrylate and their modified analogues like Tone M-100 (Tone is a trademark of Union Carbide Corporation).

Ethlenically unsaturated monocarboxylic, sulphonic and/or dicarboxylic acids, such as acrylic acid, methacrylic acid, \( \beta \)-carboxy ethyl acrylate, fumaric acid and/or itaconic acid may be used. Ethlenically unsaturated monomers such as (meth)acrylamide and/or methoxypolyethyleneoxide (meth)acrylate may also be used.

The vinyl monomer may optionally contain functional groups to contribute to the crosslinking of the vinyl polymer(s) in the coating. Examples of such groups include maleic, epoxy, fumaric, acetoacetoxy, \( \beta \)-diketone, unsaturated fatty acid, acryloyl, methacryloyl, styrenic, (meth)allyl groups, mercapto groups, keto or aldehyde groups (such as methylvinylketone [MEK], diacetoneacrylamide and (meth)acrolein).

Preferred vinyl polymers have a backbone made from a monomer system comprising at least 40% of one or more monomers of Formula I by weight of the polymer. Such a preferred backbone for the vinyl polymer is defined herein as an (meth)acrylic polymer. A particularly preferred autoxidisable vinyl polymer is an autoxidisable acrylic polymer (i.e. based predominantly on at least one ester of acrylic and/or methacrylic acid). More preferably, the monomer system for the vinyl backbone comprises at least 50%, most preferably at least 60% of such monomers by weight of polymer. The other monomer(s) in such acrylic autoxidisable vinyl polymers (where used) may include one or more of the other vinyl monomers mentioned above, and/or
may include monomer(s) different to such other monomers.

Particularly preferred monomers include butyl acrylate (all isomers), butyl methacrylate (all isomers), methyl methacrylate, ethyl hexyl methacrylate, esters of (meth)acrylic acid, acrylonitrile, vinyl acetate and styrene. Alternatively vinyl functional monomers with an autoxidisable moiety can be used, such as the reaction product of GMA and fatty acid and/or that monomer available commercially from Servo Condea under the trade name SerAD FX521.

In a preferred embodiment a polyvinyl polymer is prepared, which is subsequently reacted to obtain an autoxidisable polymer of the invention.

Monomers "G" which are useful for grafting the fatty acid onto the vinyl polymer to give fatty acid residues include hydroxylalkyl(meth)acrylates, such as hydroxyethyl(meth)acrylate, hydroxypropyl(meth)acrylate and ToneM-100 and preferred are epoxy functional vinyl monomers like glycidyl(meth)acrylate or 3,4-epoxy-cyclohexylmethyl-acrylate. Preferably, the fatty acid is grafted to the vinyl polymer by a condensation reaction or by a ring opening reaction.

In a preferred embodiment 30 to 70% of monomer G by weight of the monomers is used, before functionalisation to obtain an autoxidisable polymer of the invention. Preferably the vinyl polymer comprising monomer G is then reacted with fatty acid, where typically between 0.4 and 1.0 equivalent of fatty acid is reacted with the graftable groups present on the vinyl polymer. For this purpose, it is considered that a hydroxyl graftable group can react once with a fatty acid, whereas a epoxy graftable group can react twice, due to the additionally formed hydroxyl group on ring opening.

Preferably the autoxidisable polyvinyl polymer comprises < 1% by weight of chlorine containing monomers.

Preferably the autoxidisable polyvinyl polymer comprises < 40% by weight of styrenic monomers.

The autoxidisable polyvinyl polymer is preferably prepared by free radical polymerisation, although in some circumstances anionic polymerisation may be used. The free radical polymerisation can be performed by techniques known in the art, for example as emulsion polymerisation, solution polymerisation, suspension polymerisation or bulk polymerisation.

A free-radical polymerisation of vinyl monomer(s) to form an autoxidisable polyvinyl polymer or precursor autoxidisable polyvinyl polymer will require the use of a free-radical-yielding initiator(s) to initiate the vinyl polymerisation. Suitable free-radical-yielding initiators include inorganic peroxides such as K, Na or ammonium.
persulphate, hydrogen peroxide, alkyl hydroperoxides such as t-butyl hydroperoxide and cumene hydroperoxide; dialkyl peroxides such as di-t-butyl peroxide and the like; mixtures may also be used. The peroxy compounds are in some cases advantageously used in combination with suitable reducing agents (redox systems) such as Na or K pyrosulphite or bisulphite, and iso-ascorbid acid.

It may be desirable to control the molecular weight by addition of a chain transfer agent to the free radical polymerisation process. Conventional chain transfer agents may be utilised and include mercaptans, sulphides, disulphides and halocarbons. In particular however the technique known as catalytic chain transfer polymerisation (CCTP) may be used to provide low molecular weights. In this case a free radical polymerisation is carried out using a free radical forming initiator and a catalytic amount of a selected transition metal complex acting as a catalytic chain transfer agent (CCTA), and in particular a selected cobalt chelate complex. Such a technique has been described for example in N.S. Enikolopyan et al, J.Polym.Chem.Ed., Vol 19, 879 (1981), US 4526945, US 4680354, EP-A-0196783, EP-A-0199436, EP-A-0788518 and WO-A-87/03605.

The use of catalytic chain transfer agents provide 4 important benefits:

a) very low concentrations of catalytic chain transfer agent (typically 1 to 1000ppm by weight of vinyl monomer used) are required to attain the preferred low molecular weight oligomer and do not have the odour often associated with conventional chain transfer agents;

b) an autoxidisable vinyl polymer prepared by CCTP contains a terminal unsaturated group on many, if not every vinyl oligomer molecule. This terminal unsaturation can participate in autooxidation reactions for example in fatty acid crosslinking systems. Thus the autoxidisable vinyl polymer of the present invention could have autoxidisable crosslinker groups comprising the unsaturated groups from fatty acids as well as terminal unsaturated groups resulting from CCTP.

c) CCTP allows the preparation of an autoxidisable vinyl polymer which has a narrower PDI than is achievable by the use of conventional chain transfer agents for low Mw autoxidisable polymer.

d) Especially when epoxy functional monomers are used, CCTP has the benefit compared to e.g. chain transfer agents with mercaptan groups, that the CCTA does not react with the epoxy groups.
The solids content of the aqueous coating composition of the invention may be at least preferably ≥ 35% and more preferably ≥ 38% and/or may be no more than preferably ≤ 72%, more preferably ≤ 65% and most preferably ≤ 63% by weight of the composition.

The autoxidisable polyvinyl polymer may be dispersed in water using techniques well known in the art. The crosslinkable autoxidisable polyvinyl polymer normally does not require the use of an external surfactant when being dispersed into water because it contains polymer bound dispersing groups. Surfactants may be utilised in order to assist in the dispersion of the autoxidisable polymer in water.

Suitable surfactants include but are not limited to conventional anionic, cationic and/or non-ionic surfactants such as Na, K and NH₄ salts of dialkylsulphosuccinat.es, Na, K and NH₄ salts of sulphated oils, Na, K and NH₄ salts of alkyl sulphonic acids, Na, K and NH₄ alkyl sulphates, alkali metal salts of sulphonic acids; fatty alcohols, ethoxylated fatty acids and/or fatty amides, and Na, K and NH₄ salts of fatty acids such as Na stearate and Na oleate. Other anionic surfactants include alkyl or (alk)aryl groups linked to sulphonic acid groups, sulphuric acid half ester groups (linked in turn to polyglycol ether groups), phosphonic acid groups, phosphoric acid analogues and phosphates or carboxylic acid groups. Cationic surfactants include alkyl or (alk)aryl groups linked to quaternary ammonium salt groups. Non-ionic surfactants include polyglycol ether compounds and polyethylene oxide compounds. The surfactants may also be polymeric surfactants which are also described as wetting agents.

The amount of total surfactants used in aqueous compositions of the invention is preferably at least ≥ 0.1 %, more preferably ≥ 1 %, and/or is preferably no more than ≤ 7 %, more preferably ≤ 4 % and most preferably ≤ 2 % by weight of the autoxidisable polyvinyl polymer. Preferably a mixture of anionic and non-ionic surfactants are used.

If the aqueous composition comprising anionic surfactant, the anionic surfactant may comprise ethylene oxide (EO) groups in an amount which is preferably no more than ≤ 90%, more preferably ≤ 70%; most preferably ≤ 55% and/or is preferably at least ≥ 10% and/or ≥ 20% EO groups by weight of the surfactant. Preferred anionic surfactants comprise sulphate, sulphonate, phosphate and/or phosphonate groups, more preferably phosphate and/or phosphonate groups.

Optionally to reduce the effect of cissing the composition comprises surfactant in an amount of no more than preferably ≤ 5%, more preferably ≤ 3%, most preferably ≤ 1.5% by weight of polyvinyl polymer solids.
Dispersants (such as dispersing compounds and/or dispersing resin) which preferably are autoxidisable (such as W-3000 available from Perstorp or as described in EP 1 870442) could also be employed instead of or combined with more conventional surfactants. Optionally where used the dispersant (such as a dispersing resin) is present in amount of at least preferably ≥ 0.1%, more preferably ≥ 3% and most preferably ≥ 5% and/or no more than preferably ≤ 30%, more preferably ≤ 20% and most preferably ≤ 12% by weight of solid resin.

The aqueous coating composition of the invention is particularly useful as or for providing the principle component of coating formulations (i.e. composition intended for application to a substrate without further treatment or additions thereto) such as protective or decorative coating compositions (for example paint, lacquer or varnish) wherein an initially prepared composition optionally may be further diluted with water and/or organic solvents, and/or combined with further ingredients or may be in more concentrated form by optional evaporation of water and/or organic components of the liquid medium of an initially prepared composition.

An organic solvent may optionally be added before, during and/or after the polymerisation process for making the autoxidisable polymer and the aqueous coating composition to control the viscosity. Examples of solvents include water-miscible solvents such as propylene glycol based solvents, especially propylene glycol mono methyl ether and dipropylene glycol mono methyl ether and glycol ethers such as butyl diglycol. Optionally no organic solvents are added.

A co-solvent, as is well known in the coating art, is an organic solvent employed in an aqueous composition to ameliorate the drying characteristics thereof, and in particular to lower its minimum film forming temperature. The co-solvent may be solvent incorporated or used during preparation of the autoxidisable polymer or may have been added during formulation of aqueous solution coating composition.

Preferably the aqueous coating composition has a co-solvent content ≤ 15%, more preferably ≤ 10%, most preferably ≤ 6%, and especially ≤ 5% by weight of solids.

Preferably the aqueous coating composition has a co-solvent content ≥ 0%, more preferably ≥ 2% and most preferably ≥ 3.5% by weight of solids.

An advantage of the current invention is that co-solvent can, as is often required for environmental and safety reasons, be present at a very low concentrations because of the plasticising nature of the autoxidisable polymer.

In general, aromatic or heterocyclic nitrogen-containing ligands
(except pyridine) or aromatic and aliphatic primary and secondary (di)amines were found to prolong the drying time to a considerable extent (as reported in Coordination Chemistry Reviews 249 (2005) 1709-1728). An example includes heterocyclic nitrogen-containing solvents such as N-methylpyrrolidone (NMP) and N-ethylpyrrolidone.

Preferably the aqueous coating composition comprises NMP in an amount of no more than $\leq 13\%$, more preferably $\leq 10\%$, most preferably $\leq 5\%$ and especially $\leq 0.5\%$ by weight of polymer solids.

Preferably the aqueous coating composition comprises only a small amount of nitrogen containing molecules with an evaporation rate $< 0.1$, more preferably $< 0.05$ (as calculated below), the molecules being aromatic, heterocyclic or aliphatic primary and secondary di-amines where the weight % of nitrogen is $\geq 5\%$ and more preferably $\geq 10\%$.

Preferably such nitrogen containing molecules are present in the aqueous coating composition in an amount $\leq 13\%$, more preferably $\leq 8\%$, most preferably $\leq 5\%$ and especially $\leq 0.5\%$ by weight of polymer solids.

Values for evaporation rates were published by Texaco Chemical Company in a bulletin Solvent Data; Solvent Properties (1990). These values are relative to the evaporation rate of n-butylacetate for which the evaporation rate is defined as 1.00. Determination of evaporation rates of solvents not listed in this bulletin is as described in ASTM D3539.

In an embodiment of the present invention there is provided an aqueous coating composition comprising:

i) 35 to 50% of an autoxidisable polyvinyl polymer by weight of the composition;

ii) 0 to 20%, more preferably 0 to 15%, most preferably 0 to 10%, especially 1 to 5% of co-solvent by weight of the composition; and

iii) 35 to 65% of water by weight of the composition;

where i) + ii) + iii) = 100%.

It is preferred to have $< 16\text{ wt}\%$ on oligomer solids of a co-solvent with an evaporation rate between 0.05 and 0.005.

Preferably when the aqueous composition is formulated as paint, the composition comprises 2% to 10%, more preferably 3% to 9% of solvent by weight of the total paint composition. Preferably at least 50%, more preferably $\geq 80\%$, most preferably $\geq 95\%$ by weight of the total solvent are solvent(s) having an evaporation rate (as defined herein) higher than 0.012, more preferably from 0.018 to 0.25, most
preferably lower than 0.21.

The aqueous coating composition of the invention may be applied to a variety of substrates including wood, board, metals, stone, concrete, glass, cloth, leather, paper, plastics, foam and the like, by any conventional method including brushing, dipping, flow coating, spraying, and the like. They are, however, particularly useful for providing coatings on wood and board substrates. The aqueous carrier medium is removed by natural drying or accelerated drying (by applying heat) to form a coating. Accordingly in a further embodiment of the invention there is provided a coating obtainable from an aqueous coating composition of the present invention.

The aqueous coating composition of the invention may contain other conventional ingredients including pigments, dyes, emulsifiers, surfactants, plasticisers, thickeners, heat stabilisers, levelling agents, anti-cratering agents, fillers, sedimentation inhibitors, UV absorbers, antioxidants, dispersants, reactive diluents, waxes, neutralising agents, adhesion promoters, defoamers, co-solvents, wetting agents and the like introduced at any stage of the production process or subsequently. It is possible to include fire retardants like antimony oxide in the dispersions to enhance the fire retardant properties.

Preferred reactive diluents (which may or may not be the autoxidisable) may also have one or more of the following properties:

- \( M_n > 1000 \text{ g/mol}, \) more preferably \( > 1500 \text{ g/mol} \) and most preferably \( > 2000 \text{ g/mol}; \)
- \( M_n < 5000 \text{ g/mol}, \) more preferably \( < 4000 \text{ g/mol} \) and especially \( < 3500 \text{ g/mol}; \) and/or optionally (e.g. where the reactive diluent is autoxidisable) from 60 to 90 wt%, more preferably 75 to 90%, most preferably 80 to 90% of fatty acid residues with an iodine value from 50 to 175, more preferably from 80 to 150 g I\(_2\) / 100 g by weight of sample.

If desired the aqueous dispersion of the invention can be used in combination with other polymer dispersions or solutions which are not according to the invention.

Compositions of the invention may comprise additional polymer dispersions or solutions not according to the invention preferably in an amount < 35 %, more preferably < 20 %, most preferably < 10% and especially < 4% by weight of total polymer solids. Mixtures of polymers according to the invention can be used as well, where examples include mixtures based on autoxidisable vinyl, polyester and/or polyamide polymers.

In particular, the aqueous coating compositions of the invention and formulations containing them advantageously include a drier salt(s). Drier salts are well
known to the art for further improving curing in unsaturated film-forming substances. Generally speaking, drier salts are metallic soaps, that is salts of metals and long chain carboxylic acids. It is thought that the metallic ions effect the curing action in the film coating and the fatty acid components confer compatibility in the coating medium.

Examples of drier metals are cobalt, manganese, zirconium, lead, neodymium, lanthanum and calcium. The level of drier salt(s) in the composition is typically that to provide an amount of metal(s) within the range of from 0.01 to 0.5% by weight based on the weight of autoxidisable polymer.

Drier salts are conventionally supplied as solutions in solvents for use in solvent-borne alkyd systems. They may, however, be used quite satisfactorily in aqueous coating compositions since they can normally be dispersed in such systems fairly easily. The drier salt(s) may be incorporated into the aqueous coating composition at any convenient stage. For example the drier salt(s) may be added prior to dispersion into water. Drier accelerators may be added to the drier salts. Suitable drier accelerators include 2,2'-bipyridyl and 1,10-phenanthroline.

Preferably the aqueous coating composition is a one component system, meaning that preferably no additional crosslinking agents, like for instance polyaziridines, polycarbodiimides or polyisocyanates or melamines are added to the aqueous coating composition, prior to the application of the coating to a substrate.

Preferably the aqueous coating composition is free from photoinitiators and is cured without the use of radiation curing equipment.

Another embodiment of the invention provides an aqueous (preferably solution) coating composition as described herein (i.e. capable of forming coating films having a telegraphing value as defined herein of less than 10 gloss units) where the autoxidisable polyvinyl polymer has:

i) fatty acid residue in an amount greater than or equal to 25% by weight of said autoxidisable polyvinyl polymer;

ii) a glass transition temperature (T<sub>g</sub>) from -40°C to +10°C;

iii) an acid value from 5 to 50 mg KOH/g;

iv) a weight average molecular weight (M<sub>w</sub>) from 6000 to 40000 g / mol; and

v) a polydispersity (PDI) less than or equal to 20; and

where the composition has a co-solvent content < 6% by weight of solids.

In a further embodiment of the present invention there is provided an aqueous coating composition comprising:

i) 15% to 40%, more preferably 20% to 35 wt% of TiO<sub>2</sub>;
ii) 15% to 40%, more preferably 20% to 35% of polymer solids;
Ni) 0% to 10%, more preferably 0% to 7%, most preferably 0% to 5% and
   especially 1% to 2.5% of co-solvent by weight of solids;
iv) 0.1% to 3% of thickener;

v) 0% to 5% dispersing agent;
vi) 25% to 70% water;
where all percentages are by weight of the composition and
i) + ii) + iii) + iv) + v) + vi) = 100%.

Preferably when the aqueous coating composition is formulated as a
paint, the composition comprises 2 to 10% of co-solvent by weight of paint solids,
preferably 3 to 9% of co-solvent, of which at least 50%, preferably at least 80% and
most preferably at least 95% by weight has an evaporation rate higher than 0.012,
more preferably higher than 0.018 and an evaporation rate lower than 0.25 and more
preferably lower than 0.21 (when compared to butyl acetate = 1.0).

If vinyl monomers are used, preferably less than 10% and more
preferred less than 5% of the autoxidisable polymer solids by weight should consist of
vinyl polymer material which is covalently bound to a fatty acid, where the covalent
bond is generated through a grafting reaction of a propagating vinyl radical onto the
unsaturated fatty acid. In the latter case the fatty acid can either be a free unsaturated
fatty acid or an unsaturated fatty which is part of a polymeric structure. Most preferably
there is no grafting of vinyl monomers to the fatty acid at all.

Preferably the aqueous coating composition when coated onto a
substrate is water resistant for 30 minutes, more preferably for 1 hour and most
preferably for 3 hours after 24 hrs of drying the coating.

Preferably the aqueous coating composition when coated onto a
substrate is block resistant at ambient temperature with a rating of 3 or more and more
preferably the coating is block resistant at 52 °C with a rating of 3 or more after 24 hrs
drying.

One aspect of the invention provides a method for preparing an
autoxidisable polyvinyl polymer the process comprising the steps of:

i) polymerising ethylenically unsaturated vinyl monomers to form a polyvinyl
   polymer; and

II) reacting the polyvinyl polymer obtained in step i) with fatty acids having an
average iodine value in the range of 80 to 180 g b/100 g fatty acid;

35 to obtain an autoxidisable polyvinyl polymer with the properties described herein (such
as being capable of forming a coating composition which when in the form of the film
has a telegraphing value (as defined in claim 1) of less than 10 gloss units).

A further aspect of the invention provides a coating obtained and/or obtainable by a coating composition of the invention and having a telegraphing value (as defined herein) of less than 10 gloss units.

Another aspect of the invention provides a substrate coated with a coating of the invention.

A still other aspect of the invention provides a method of coating a substrate comprising the steps of i) applying a coating composition of the invention to the substrate; ii) drying the substrate to form a coating thereon; where the coating has a telegraphing value (as defined herein) of less than 10 gloss units.

Yet another aspect of the invention provides use of an autoxidisable vinyl polymer and/or a coating composition of the invention for the purpose of obtaining coatings having a telegraphing value (as defined herein) of less than 10 gloss units.

A still yet other aspect of the invention provides a method of manufacture of an autoxidisable vinyl polymer and/or a coating composition of the invention for the purpose of obtaining coatings having a telegraphing value (as defined herein) of less than 10 gloss units.

Many other variations embodiments of the invention will be apparent to those skilled in the art and such variations are contemplated within the broad scope of the present invention. Further aspects of the invention and preferred features thereof are given in the claims herein.

The present invention is now illustrated by reference to the following non-limiting example. Various registered trademarks, other designations and/or abbreviations are used herein to denote some of ingredients used to prepare polymers and compositions of the invention. These are identified below by chemical name and/or trade-name and optionally their manufacturer or supplier from whom they are available commercially. However where a chemical name and/or supplier of a material described herein is not given it may easily be found for example in reference literature well known to those skilled in the art: such as: 'McCutcheon's Emulsifiers and Detergents', Rock Road, Glen Rock, NJ. 07452-1700, USA, 1997 and/or Hawley's Condensed Chemical Dictionary (14th Edition) by Lewis, Richard J., Sr.; John Wiley & Sons.

'AlBN' denotes azobisisobutyronitrile;

'3,5-BHT' denotes 3,5-di-tert-butyl-4-methylphenol (also known as butyl hydroxy toluene);
'BMA' denotes n-butylmethacrylate;
'CoF' denotes the catalyst Co II (bis 4,4'-dimethylbenzil dioxime) diborondifluoride, as described in EP1742973-A, US2007219328 and WO2005105855;
'Dowanol PnP' denotes that propylene glycol n-propyl ether mixture commercially available from Dow Chemicals under this trade name;
'FES 993' denotes ammonium lauryl ether sulphate which is available commercially from Cognis under the trade name Disponil FES 993 IS;
'GMA' denotes glycidyl methacrylate;
'HHPA' denotes hexahydro phtalic anhydride;
'MMA' denotes methyl methacrylate;
'PAA' denotes a polyacrylic acid with weight average molecular weight (Mw) of from 200-250 KDalton which has been prepared by the applicant;
'PVC' denotes polyvinyl chloride
'TEA' denotes triethyl amine;
'THF' denotes tetrahydrofuran; and
'TRAP' denotes triphenyl ethyl phosphonium bromide.

TEST METHODS:
STANDARD CONDITIONS

As used herein, unless the context indicates otherwise, standard conditions (e.g. for drying a film) means a relative humidity of 50% ±5%, ambient temperature (23°C ±2°) and an air flow of ≤ 0.1 m/s.

PARTICLE SIZE

The particle sizes given herein are the size of a weight averaged particle and are quoted as a linear dimension which is a particle diameter as the particles can be considered to be essentially spherical. Weight average particle size may be measured using Scanning/Transmission Electron Microscope and Photon Correlation Spectroscopy.

IODINE NUMBER

The iodine value (also referred to herein as iodine number) is a measure of the amount of ethylenic unsaturated double bonds in a sample and increases with a greater degree of unsaturation. Iodine value may be defined according to DIN 53241-1 as the quotient of that mass mi of iodine which is added on to the
olefinic double bonds, with decolorisation, of a sample to be analysed and the mass \( m_B \) of this sample (mass of the solid in the sample in the case of solutions or dispersions). Iodine values may be quoted either in units of centigrams of iodine per gram of sample (eg \( I_2 / g \)) or in units of grams of iodine per 100 gram of sample (g \( I_2 / 100g \)). Standard methods for analysis may be used such as for example ASTM D5768-02(2006) and DIN 53241. One common method (and that used to measure the iodine values given herein) is the Wijss method in which iodine absorption is determined by titrating unreacted reagent with sodium thiosulfate and the iodine value is then calculated as follows:

\[
\text{Iodine value} = \frac{(12.69) \times (\text{ml of thiosulfate}) \times (\text{normality})}{\text{mass of sample (g)}}
\]

TELEGRAPHING

Two types of PVC substrates are used to determine the degree of telegraphing of an unpigmented coating comprising the autoxidisable resin:

The first PVC type is the 2 mm thick rough PVC substrate with a well defined and uniform rough surface that is available commercially from Vink Kunststoffen B.V (Didam, Holland) under the trade name Vikupor white PVC film type JD1 1. An area of 1.9 x 2.5 mm of the substrate surface is analysed with a Wyko optical profilometer NT1 100 at a magnification of 2.5 to give \( R_z = 25\mu m \pm 5\mu m \). \( R_z \) denotes the 'ten-point height', which is the average of the five greatest peak-to-valley separations in the scanned area, and is regarded as a general value for surface roughness. The second PVC type is a 3 mm thick smooth PVC substrate with a well defined smooth surface that is also available commercially from Vink Kunststoffen under the trade name Vikunyl white PVC film glossy type 206221. \( R_z = 1\mu m \pm 0.25\mu m \) (measured as for rough PVC).

The unpigmented coating comprising (optionally comprising flow and wetting agents and thickeners if needed) is cast on both PVC substrates (rough and smooth) and a smooth and defect free film is obtained, resulting in a theoretical dry film thickness between 52\( \mu m \pm 6\mu m \). The film is dried under standard conditions for 24 hours and the gloss is measured at a 20° angle. This gloss measurement is repeated after 4 days, 7 days and 14 days. The difference in gloss readings between the films on rough and smooth PVC is a quantitative measure of the extent to which the rough surface of the PVC is telegraphed to the surface of the dried coating. The smaller the difference in these gloss values, the smaller the degree of telegraphing and the better the coating hides the substrate roughness.
Also the absolute value for gloss reading on rough PVC should not decrease significantly in time so that the reduced telegraphing is maintained.

**DRYING TIME:**

To test the dust-free and tack-free drying stages of the aqueous compositions prepared in the Example as described below, the aqueous composition is formulated and applied to a glass plate at a wet film thickness of 80 µm. Tests for drying times are performed at regular time intervals under standard conditions.

**DUST-FREE TIME:**

The dust-free time is determined by dropping a piece of cotton wool (about 1 cm³ i.e. 0.1g) on to the drying film from a distance of 25 cm. If the piece of cotton wool can be immediately blown from the substrate by a person without leaving any wool or marks in or on the film, the film is considered to be dust-free.

**TACK-FREE TIME:**

The tack-free time is determined by placing a piece of cotton wool (about 1 cm³, 0.1g) on the drying film and placing a weight of 1kg onto the piece of cotton wool (for 10 seconds). If the piece of cotton wool can be removed from the substrate by hand without leaving any wool or marks in or on the film, the film is considered to be tack-free.

**MOLECULAR WEIGHT DETERMINATION:**

Gel permeation chromatography (GPC) analyses for the determination of polymer molecular weights are performed on an Alliance Waters 2695 GPC with three consecutive PL-gel columns (type Mixed-B, l/d = 300/7.5 mm) using tetrahydrofuran (THF, HPLC grade, stabilized with 3,5-di-tert-butyl-4-hydroxytoluene (BHT), preferably with 1.0 vol% acetic acid) as the eluent at 1 cm³/min and using an Alliance Waters 2410 refractive index detector. A set of polystyrene standards (analysed according to DIN 55672) is used to calibrate the GPC. Samples corresponding to about 16 mg of solid material were dissolved in 8 cm³ of THF. The samples were regularly shaken and dissolved for at least 24 hours for complete "uncoiling" and placed on the auto-sampling unit of the Alliance Waters 2695. The injection volume was 150 µL and the column oven was established at 35°C.
GLASS TRANSITION TEMPERATURE ($T_g$)

The $T_g$ was measured by DSC using the TA Instruments DSC Q1000 with the standard TA Instruments alumina cups of 50 µl. The flow rate was 50 ml/min of nitrogen and the sample was loaded at a temperature range 20 to 25 °C. The sample is cooled until it reached an equilibrium temperature of -90 °C and then heated at a rate of 10 °C/min to 100 °C, kept for 5 minutes at 100 °C, cooled to -90 °C at a rate of 20 °C/min, kept for 5 minutes at -90 °C and subsequently heated at a rate of 10 °C/min to 100 °C.

GLOSS MEASUREMENT METHOD:

Gloss measurements are carried out on a BYK Gardner micro-TRI-gloss 20-60-85 glossmeter in accordance with ASTM D523-89.

Example 1

1a PREPARATION OF AN EPOXY FUNCTIONAL VINYL POLYMER

A 2L round bottom reactor, equipped with stirrer, baffle and cooler, was loaded with water (867.8 g), $\text{Na}_2\text{SO}_4$ (1.59 g) and PAA (0.79 g) under nitrogen. The mixture was neutralized with NaOH until pH > 8 and brought to 60°C. A homogeneous mixture of MMA (190.17 g), BMA (127.19 g) and GMA (317.99 g), AIBN (4.77 g) and CoPhMeBF (0.064 g) was transferred to the reactor and the reaction temperature was brought to 80 °C. After 90 minutes a mixture of FES993 (0.53 g) and water (79.5 g) was added to the reactor. After another 10 minutes, the temperature was raised to 85 °C and kept at that temperature for 60 minutes. Subsequently, the reactor was cooled to ambient temperature and the beads were washed and dried.

The Mn was 1736 g/mol, Mw was 3589 g/mol and the PDi was 2.07. The $T_g$ was 24°C (midpoint) as measured by DSC.

1b PREPARATION OF THE AQUEOUS AUTOXIDISABLE VINYL POLYMER

The vinyl polymer prepared as described in step 1a above (500.0 g) was dissolved in toluene (332.59 g). Sunflower fatty acid (492.85 g) and TRAP (4.93 g) were added to the resulting solution. The mixture was heated at 120°C under nitrogen. The reaction was continued until the acid value reached 5.7 mg KOH/g.

The $M_n$ was 2736 g/mol, $M_w$ was 7662 g/mol and the PDi was 2.8. The $T_g$ was -12°C (midpoint) as measured by DSC.
Page blank upon filling
**1c FUNCTIONALISATION AND DISPERSING.**

HHPA (44.19 g) was added to the polymer solution resulting from step 1b above (340.0 g, 75% solids in toluene). The mixture was kept at 110°C until virtually all anhydride was reacted as judged from the Infra Red spectrum of the reaction mixture (the anhydride groups typically show two absorptions at 1785 cm⁻¹ and 1865 cm⁻¹, which disappeared and were replaced by a new ester carbonyl absorption at 1740 cm⁻¹). Then the toluene was removed by distillation under reduced pressure to obtain a fatty acid functional acrylic with an acid value of 59.4 mg KOH/g. Dowanol PnP (75.0 g) and TEA (28.9 g) was added to the fatty acid functional acrylic (300.0 g) followed by water (453.0 g) to obtain an aqueous composition having a 35% solid content, pH of 7.8 and Tᵣ = -1°C (midpoint) as measured by DSC.

Key

'DFT' denotes dust free time defined and measured as described herein.
TFT' denotes tack free time defined and measured as described herein.
'G(r)' denotes the initial rough gloss value as defined herein (measured in gloss units 1 day after film formation).
'G(s)' denotes the initial smooth gloss value as defined herein (measured in gloss units 1 day after film formation).
Telg.' denotes the telegraphing value as defined herein in gloss units (i.e. G(s), G(r)).
'G decay ('n' d)' denotes the gloss decay value as defined herein after 'n' days (i.e. G(r) minus the rough gloss measured 'n' days after film formation).
CLAIMS

1. An aqueous coating composition that comprises an autoxidisable polymer that comprises plurality of vinyl groups where:

   i) said autoxidisable polyvinyl polymer has:
      a) fatty acid residue in an amount greater than or equal to 20% by weight of said autoxidisable polyvinyl polymer
      b) a glass transition temperature \(T_g\) from -60°C to +20°C;
      c) an acid value from 5 to 75, optionally from 15 to 75 mg KOH / g;
      d) a weight average molecular weight \(M_w\) from 2500 to 100000 g/mol; and
      e) a polydispersity (PDI) less than or equal to 30;

   II) said composition has:
      a) a co-solvent content less than 25% by weight of solids;
      b) a solids content greater than or equal to 30% by the total weight of said composition; and

   III) said composition when in the form of the film has a telegraphing value of less than 10 gloss units,

   where the telegraphing value is the difference between an initial smooth gloss value minus an initial rough gloss value of the film, where the initial smooth gloss value is the gloss when the film is cast on smooth PVC \(R_z = 1\mu m \pm [0.25 \mu m]\); the initial rough gloss value is the gloss when the film is cast on rough PVC \(R_z = 25\) microns \([\mu m]\) \pm [5\mu m]\); and where each film has a dry film thickness of 52\mu m \pm [6\mu m]; and each initial gloss value is measured at a 20° angle, one day (24 hours) after the film has been cast.

2. An aqueous coating composition according to claim 1 wherein the autoxidisable polymer if carboxylic acid functional has an ND x AV value of > 22 and \(\leq 65\); where ND = neutralization degree of the acid groups on the polymer and AV= acid value.

3. An aqueous coating composition according to either preceding claim, which comprises < 13% N-methylpyrrolidone by weight of the composition.

4. An aqueous coating composition according to any preceding claim comprising < 13% by weight of polymer solids of nitrogen containing molecules with an
evaporation rate < 0.1 which are either aromatic, heterocyclic or which are aromatic and aliphatic primary and secondary (di)amines with the proviso that the weight % of nitrogen in such molecules is > 5%.

5. An aqueous coating composition according any preceding claim comprising.

5 i) 35% to 50% of the autoxidisable polyvinyl polymer by weight of the composition;

ii) 0 to 20% of co-solvent by weight of the composition; and

iii) 35% to 65% of water by weight of the composition;

6. An aqueous coating composition as claimed in any preceding claim where the autoxidisable polyvinyl polymer has:

i) fatty acid residue in an amount greater than or equal to 25% by weight of said autoxidisable polyvinyl polymer;

ii) a glass transition temperature \( (T_g) \) from -40°C to +10°C;

iii) an acid value from 5 to 50 mg KOH/g;

iv) a weight average molecular weight \( (M_w) \) from 6000 to 40000 g/mol; and

v) a polydispersity \( (PDI) \) less than or equal to 20; and

where the composition has a co-solvent content < 6% by weight of solids.

7. An aqueous coating composition according to any preceding claim, comprising:

i) 15% to 40% of \( \text{TiO}_2 \).

ii) 15% to 40% of polymer solids;

iii) 0 to 10% of co-solvent by weight of solids;

iv) 0.1 to 3% of thickener;

v) 0 to 5% dispersing agent;

vi) 25% to 70% water;

where unless indicated all percentages are by weight of the composition and

\[ i) + ii) + iii) + iv) + v ) + vi) = 100\% . \]

8. An autoxidisable polyvinyl polymer having:

i) fatty acid residue in an amount greater than or equal to 20% by weight of said autoxidisable polyvinyl polymer;

ii) a glass transition temperature \( (T_g) \) from -60°C to +20°C;

iii) an acid value from 5 to 75, optionally from 15 to 75 mg KOH/g; not.

iv) a weight average molecular weight \( (M_w) \) from 2500 to 100000 g/mol; and

v) a polydispersity \( (PDI) \) less than or equal to 30; and

where the polymer is capable of forming a coating composition which when in
the form of the film has a telegraphing value (as defined in claim 1) of less than 10 gloss units.

9. A method for preparing an autoxidisable polyvinyl polymer the process comprising the steps of:

5
i) polymerising ethylenically unsaturated vinyl monomers to form a polyvinyl polymer; and

5
ii) reacting the polyvinyl polymer obtained in step i) with fatty acids having an average iodine value in the range of 80 to 180 g I₂/100 g fatty acid; to obtain an autoxidisable polyvinyl polymer having

i) fatty acid residue in an amount greater than or equal to 20% by weight of said autoxidisable polyvinyl polymer;

ii) a glass transition temperature \(T_g\) from -60°C to +20°C;

iii) an acid value from 5 to 75, optionally from 15 to 75 mg KOH / g;

iv) a weight average molecular weight \(M_w\) from 2500 to 100000 g/mol; and

v) a polydispersity (PDI) less than or equal to 30; and

where the polymer is capable of forming a coating composition which when in the form of the film has a telegraphing value (as defined in claim 1) of less than 10 gloss units.

10. An autoxidisable polyvinyl polymer obtained and/or obtainable by a process as claimed in claim 9.

11. A coating composition comprising an autoxidisable polyvinyl polymer as claimed in either claim 8 or 10.

12. A coating composition as claimed in any of claims 1 to 7 or 11 to 12 where the composition comprises:

a) a co-solvent content \(\leq 15\%\) by weight of solids;

b) a N-methylpyrrolidone content \(\leq 13\%\) by weight of solids;

c) heterocyclic amine containing solvent content of 0 wt% by weight of solids;

d) a solids content \(\geq 30\%\) by weight of the composition; and

e) a pH from 4.1 to 8.4; and

where said composition is in the form of the film, the film has a telegraphing value (as defined in claim 1) of less than 10 gloss units.

13. A coating composition as claimed in any of claims 1 to 7 or 11 to 12, in which the autoxidisable polyvinyl polymer is present in an amount from 38 to 65% by
weight of the composition.

14. A coating obtained and/or obtainable by a coating composition as claimed in any of claims 1 to 7 or 11 to 13, the coating having a telegraphing value (as defined in claim 1) of less than 10 gloss units.

15. A substrate coated with a coating as claimed in claim 14.

16. A method of coating a substrate comprising the steps of
   i) applying a coating composition as claimed in any of claims 1 to 7 or 11 to 13 to a substrate;
   ii) drying the substrate to form a coating thereon;
where the coating has a telegraphing value (as defined in claim 1) of less than 10 gloss units.

17. Use of an autoxidisable polyvinyl polymer as claimed in either claim 8 or 10 and/or a coating composition as claimed in any of claims 1 to 7 or 11 to 13 for the purpose of obtaining coatings having a telegraphing value (as defined in claim 1) of less than 10 gloss units.

18. A method of manufacture of an autoxidisable polyvinyl polymer as claimed in either claim 8 or 10 and/or a coating composition as claimed in any of claims 1 to 7 or 11 to 13 for the purpose of obtaining coatings having a telegraphing value (as defined in claim 1) of less than 10 gloss units.
**INTERNATIONAL SEARCH REPORT**

**A. CLASSIFICATION OF SUBJECT MATTER**

INV. C08L67/08 C08L77/12 C09D167/08

According to International Patent Classification (IPC) or to both national classification and IPC

**B. RELDS SEARCHED**

Minimum documentation searched (classification system followed by classification symbols)

C08L C09D

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

EPO-Internal, WPI Data

**C. DOCUMENTS CONSIDERED TO BE RELEVANT**

<table>
<thead>
<tr>
<th>Category</th>
<th>Citation of document, with indication, where appropriate, of the relevant passages</th>
<th>Relevant to claim No</th>

**D.** Further documents are listed in the continuation of Box C

- Special categories of cited documents
  
  - 'A' document defining the general state of the art which is not considered to be of particular relevance
  
  - 'C' earlier document but published on or after the international filing date
  
  - 'L' document which may throw doubts on priority date (am(s)) or which is cited to establish the publication date of another citation or other special reason (as specified)
  
  - 'O' document referring to an oral disclosure, use, exhibition or other means
  
  - 'P' document published prior to the international filing date but later than the priority date claimed

- 'N' later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

- 'X' document of particular relevance, the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

- 'Y1' document of particular relevance, the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

- 'Z' document member of the same patent family

Date of the actual completion of the international search: **1 July 2009**

Date of mailing of the international search report: **09/07/2009**
