(57) **ABSTRACT**

Systems and methods are used to provide distributed processing on a service provider network that includes a plurality of remotely located consumer devices. Each of the remotely located consumer devices includes a processing device. A service is provided from the service provider network to the remotely located consumer devices. Distributed processing of a task on the processing devices of the remotely located consumer devices occurs, the distributed processing being unrelated to the service provided to the consumers. The distributed processing occurs even when the processing devices are in use by corresponding remotely located consumer devices.

METHODS AND SYSTEMS FOR DISTRIBUTED PROCESSING ON CONSUMER DEVICES

CROSS REFERENCE TO RELATED APPLICATIONS

This application claims priority from U.S. provisional application 60/656,897, filed Mar. 1, 2005, which is incorporated herein in its entirety.

TECHNICAL FIELD

The present invention relates to methods and systems for distributed processing on consumer devices. In particular, the present invention relates methods and systems for distributed processing even when the consumer devices are in use by a consumer.

BACKGROUND OF THE INVENTION

There has been a large growth in the deployment of consumer electronic devices by service providers such as cable, satellite and phone companies. These service providers are installing digital consumer electronic devices to millions of homes annually. In many cases these consumer electronic devices are dedicated for the delivery of digital television programming or other interactive entertainment services.

These consumer electronic devices are being equipped with faster and more powerful processors. These processors often have more speed and power than is used by the consumer electronic devices, even during peak usage. Further, the processors may have periods during a day where they are not used at all, such as during times when the consumer is sleeping or away from home. It would be advantageous if the service provider could find a way to use the extra speed and power of the processor not being utilized by the consumer.

In the cable industry, it is common for a cable service provider to provide a cable box to a consumer so that the consumer may receive cable service. Typically, the cable service provider will retain ownership of the cable box, and may charge the consumer a monthly fee for each box provided. These cable boxes are being equipped with faster and more powerful processors. While the cable boxes of today provide more services than in the past, such as interactive guides, pay per view, movies on demand, etc., even these extra services may often under utilize the processor. Further, because the cable service provider usually retains ownership of the cable box and the processor it is equipped with, it would be advantageous if the cable service provider could find a way to use the extra speed and power of the processor not being utilized by the consumer.

SUMMARY OF THE INVENTION

Systems and methods are used to provide distributed processing on a service provider network that includes a plurality of remotely located consumer devices. Each of the remotely located consumer devices includes a processing device. A service is provided from the service provider network to the remotely located consumer devices. Distributed processing of a task on the processing devices of the remotely located consumer devices occurs, the distributed processing being unrelated to the service provided to the consumers. The distributed processing occurs even when the processing devices are in use by corresponding remotely located consumer devices.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a block diagram in accordance with an embodiment of the present invention.

FIG. 2 is a system in accordance with an embodiment of the present invention.

FIG. 3 illustrates a system in conjunction with embodiments of the present invention.

FIG. 4 illustrates a system in accordance with embodiments of the present invention.

FIG. 5 illustrates a flowchart in accordance with embodiments of the present invention.

FIG. 6 illustrates a flowchart in accordance with embodiments of the present invention.

DETAILED DESCRIPTION

The present invention provides systems and methods for distributed processing on a service provider network that includes a plurality of remotely located consumer devices. Distributed processing of a task on the processing devices of the remotely located consumer devices occurs, the distributed processing being unrelated to the service provided to the consumers. The distributed processing occurs even when the processing devices are in use by corresponding remotely located consumer devices.

Currently, there is a need for processing tasks to be performed that require extremely high processing speeds or processing of extremely large data space. For example, such needs exist in the following areas: Bioinformatics, Chemical, and Drug Research in areas such molecular modeling to screen millions of compounds from a chemical database; Financial Services for portfolio optimization, risk analytics, and trade analysis; Energy in areas such as seismic processing and reservoir simulation calculations; Government in areas such as econometric modeling, imagery analysis, geospatial intelligence, weather, astronomy, physics, and other scientific research; and Application Service Providers for database intensive applications such as search engines. The present invention provides for distributed processing on a large scale to provide such extremely high processing speeds.

FIG. 1 depicts a block diagram of an embodiment of the present invention. Computing device 100 is suitable for use with the present invention. The computing device 100 may include a processor 110, a memory 120, a user input 130 and a display 140. The memory 120 may contain software to be run in conjunction with processor 110, and may cause images to be displayed on display 140. The software may be specifically designed to cause computing device 100 to implement the present invention. Computing device 100 may be one of various types of computing devices, such as a workstation, a personal computer, a server, a head-end in a cable system, or any other type of computing device.

The processor 110 may be any type of processor, such as a general-purpose microprocessor (i.e., a Pentium series microprocessor manufactured by the Intel Corporation of Santa Clara, Calif.). In another embodiment, the processor 110 can be an Application Specific Integrated Circuit (ASIC), which has been designed to implement in its hardware and/or firmware at least a part of a method in accordance with embodiments of the present invention, or a RISC (reduced instruction set computer) processor.

Memory 120 can be any device capable of storing analog or digital information, such as a hard disk, Random Access Memory (RAM), Read Only Memory (ROM), flash memory, a compact disk, a magnetic tape, a floppy disk, and any combination thereof, for example.

3

User input **130** can be any type of input device, such as a keyboard, keypad, pointing device, microphone, mouse, wired or wireless remote control, touch pad, touch screen, a port(s) to attach other input devices, voice recognition software, etc. Any type of input device will function in accordance with embodiments of the present invention.

The display **140** can be any type of display or screen that is capable of displaying images. For example, the display may be a CRT or LCD monitor, a heads-up display, a television, etc. The display **140** may be structurally included as part of the electronic device, or may be physically separated from but connected with the other components of device **100**, such as a monitor in a desktop computer.

FIG. **2** depicts a block diagram of an embodiment of the present invention. The system **200** includes a service provider network **210**, and a plurality of consumer devices **220**. The service provider network **210** may include one or more of the following: a processor, a memory, a display, and software programmed to carry out the functionality of the present invention. For example, the service provider network **210** may include elements such as illustrated in FIG. **1**.

The service provider network **210** may be any type of service provider network that provides a service to consumers on a consumer device. For example, the service provider network **210** may be a cable or satellite television network, an Internet Service Provides (ISP), a cellular phone service provider, a portable computer service provider, etc. the service provider network may provide a service to the consumer devices by any means, such as over wired or fiber optic cables, wirelessly, by satellite transmission, through a phone network, etc.

The consumer devices **220** include a processor **230**, and may include other elements, such as the elements illustrated in FIG. **1**, as well as software to carry out required functionality. The consumer devices **220** receive a consumer service from the service provider network **210**. The consumer devices **220** may be any type of consumer device that can receive a consumer service, such as a cellular phone, a computer, a portable computing device, a set top box in a cable television or satellite system (or hardware/software built in to a television to receive such cable or satellite television), a camera, a combination of any of the above, etc. The consumer device **220** receives a service from the service provider network **210** as described above.

The consumer device may be purchased by the consumer, or may often be rented by the consumer from the service provider. For example, cable or satellite boxes are usually rented from a service provider by the consumer. The processor **230** of the functions with other elements of the consumer device **220** to provide the desired service to a consumer. The processor **230** may be a powerful processor that may be greatly underutilized even when the consumer device **220** is utilizing the processor **230** to it's fullest extent. Further, when the consumer is not utilizing the consumer device at all, the power of the processor is not used. The present invention utilizes the processor **230** on consumer devices **220** in a service provider network **200** to perform distributed processing, even when the processor **230** is being utilized by the consumer device **220**, as further explained below.

FIG. **3** illustrates a system **300** in conjunction with embodiments of the present invention. The system **300** includes consumer devices **310**, network distribution system **340**, device management system **350** and service management system **360**. The consumer devices **310** may be any type of consumer device that includes a processor and is configured to receive a service from a service provider, as described above. As one example of consumer devices **310**, there is

4

illustrated digital set-top boxes **320** and digital TVs, such as may be used with a cable or satellite television system, for example. The consumer devices **310** may be connected to the network distribution system **340** by any means, such as by satellite, wireless, cables such as fiber optic cables, etc.

The network distribution system **340** may provide two-way connectivity of these consumer devices **310** to a service provider. The service provider systems may include a device management system **350** and a service management system **360** as shown in FIG. **3**. These elements may be used to control delivery of service and distributed processing on the consumer devices. The distributed processing is processing in addition to and unrelated to services provided to the consumer devices **310**, as further discussed below.

As an example, in a system such as a cable television system, the consumer devices **310** may receive cable television service, where the consumer device may be a set-top box **320**, for example. A large number of customers are connected to the cable television system, all receiving cable television service from the service provider. Such cable television systems typically utilize set-top boxes in conjunction with delivery of the cable television service. The set-top boxes are typically rented from the service provider, and will be equipped with various software and hardware to allow delivery of the service to the consumer via the consumer device. The set-top boxes will include one or more processor, such as processor **230** illustrated in FIG. **2**. These processors are typically much more powerful than needed to accomplished the needed functionality of delivering the service to the consumer, even when the consumer is actively using the set-top box to view programs, to view program guides, to view the internet, etc. Further, when the set-top box is not in use, even more power from the processor goes unused.

Accordingly, the present invention will utilize the unused power of the processors of one or more of the consumer devices to perform distributed processing. This distributed processing may occur even when the processor is actively engaged in processing, such as when delivery various consumer services. This is possible due to the excess power of the individual processors. The system of the present invention can take a processing task that would normally take enormous processing power, break that task in smaller portions, and distribute the processing to the various consumer devices **310**. The device management system may include the functionality to receive a large processing task, to subdivide that large processing task into smaller tasks, and to direct the smaller processing tasks to processors on individual processing devices. Over the network distribution system **340**. The results of the individual processing tasks may then be directed back to the device management system **350** over the network distribution system **340**, and aggregated to complete the larger processing task.

Alternatively, the first subtask can be sent to a first group of the consumer devices, and the second subtask can be sent to a second group of the consumer devices. In this way, the subtasks can be processed on more than one processor at the same time, which can provide increased quality of service and fault tolerance.

The service provider or another entity may operate the elements described to provide the distributed processing. The distributed processing may be offered to entities outside the service provider organization who need but do not have the large processing power.

FIG. **4** illustrates a system **400** that may be used in conjunction with embodiments of the present invention. Each of the elements of FIG. **4** will contain the needed hardware and software to perform the described functionality. Consumer

5

devices **410**, **412**, etc. are connected to a regional distribution system **414**. Other consumer devices may be connected to other regional distribution systems, such as regional distribution system **416**. Any number of regional distribution systems may be used. The regional distribution systems may be part of one service provider, or may be from separate service providers. The regional distribution systems are responsible for providing the interface with each individual consumer device to the network aggregation system **419**. Typically, the regional distribution systems will be geographically dispersed.

Typically, a larger number of networks or systems must be aggregated at a central set of network facilities that have larger capacity. The network aggregation system **419** includes the components necessary to combine any number of regional distribution systems into a smaller composed set, or provide the inverse operation of fanning out a small set of larger networks into many. Two way communication of signals occurs from the regional distribution systems to the network aggregation system **419**.

The consumer devices have a primary function to support services provided by content providers or other communication services. The entertainment processing subsystem **422** is connected to the network aggregation system **419** and abstracts all the necessary facilities required for the delivery of such services. For example, the entertainment processing subsystem **422** may include the necessary facilities for delivery of cable or satellite television services. Such facilities are well known and not described further here.

The central device control system **418** is connected to the network aggregation system **419**. The central device control system **418** is responsible for managing the operational delivery of device parameters, signaling, security, and control state to the consumer electronic devices for their proper operation on the service provider platform.

The central device network system **420** is connected to the network aggregation system **419**. The central device network system **420** may include the network layer, physical layer, and control processing of network elements and their subsystems. This might include facilities to support internet protocol delivery over radio frequency broadband, fiber optically, satellite, and wireless networking as well as digital broadcast streams over MPEG.

The device resource management **424** is connected to the central device network system **420**, to the central device control system **418** and to the service application process management system **430**. The device resource management **424** is responsible for intelligently managing the consumer device resource pools as a function of dynamic device parameters, such as CPU load, memory utilization and device availability. The device resource management **424** interacts with the service application process management system **430**, providing real time data to optimize the execution of the underlying network of consumer devices.

The process partitioning system **426** is connected to the central device network system **420**, to the central device control system **418** and to the service application process management system **430**. Application processes are partitioned and then mapped onto device resources. Partitioning is the task of taking a single virtualized service process, and breaking it up, where possible, into multiple processes which can be executed in parallel on different consumer devices. The process partitioning system **426** also performs mapping in conjunction with real time data from the device resource management system **424** to optimally dispatch the individual processes on the best set of consumer devices as determined by service criteria metrics. Mapping criteria may be based in

6

terms of meeting performance or fault tolerance targets. In the case of meeting a performance target, process partitioning and mapping will be optimized for execution concurrency and time. Likewise, a fault tolerance target will require optimization for execution redundancy.

The device scheduling management system **428** is responsible for managing the flow of processes in and out of the consumer devices. It controls when processes are executed and terminated. To facilitate this, the system will interact with the other systems described to insure processes are scheduled appropriately.

A service that will be executed is transposed into one or more application processes which must be controlled, synchronized, managed, and executed. Thus, the service process management system **430** deals with the lifecycle management of all processes associated with the set of services currently being executed and control of the other subsystems involved with any work flow necessary for completion.

The service virtualization layer system **432** is responsible for semantically expressing all computational and application services that outside entities can interact with. Typically a client outside the virtualization layer will negotiate for access to a processing service for some fee. The service is then invoked and any responses are aggregated and provided back to the requesting client. The goal of the virtualization layer is to provide a single transparent view of the underlying consumer device application computation processing fabric hiding service implementation details. It also provides the interaction framework with outside entities for the purposes of providing and transacting services.

The business services interface system **434** provides a well defined physical interaction layer for the transacting of services between the service provider and outside entities wishing to acquire services. It defines the protocols and mechanism for access and delivery of services.

Thus, the present invention provides for distributed processing on one or more service provider networks. The service provider networks may be of the same type or different types. For example, one service provider network could be for delivery of cable television, while another service provider network could be for delivery of cellular phone service.

The tasks or subtasks may be sent to the consumer devices over the service provider networks in known formats such that they can be recognized by the processors on the consumer devices. For example, the processing tasks or subtasks could be sent in a series of packets, with appropriate header information and needed instructions to cause processing at the processor of the consumer device, and to direct the consumer device to return the results. Additionally, the consumer devices can have appropriate software loaded into their memory to cause proper receipt, processing and return of the tasks or subtasks. This software could be preloaded or downloaded to the consumer devices.

FIG. 5 illustrates a flowchart in accordance with embodiments of the present invention. In step **510**, a service is provided from a service provider network to the remotely located consumer devices capable of receiving the service. Each of the remotely located consumer devices includes a processing device. In step **520**, distributed processing of a task on the processing devices of the remotely located consumer devices occurs. The distributed processing is unrelated to the service provided to the consumers. The distributed processing occurs even when the processing devices are in use by the corresponding remotely located consumer devices.

FIG. 6 illustrates a flowchart in accordance with embodiments of the present invention. In step **610**, a service is provided from a first service provider network to a first group of

remotely located consumer devices. In step 620, a service is provided from a second service provider network to a second group of remotely located consumer devices. A task which is to be processed by distributed processing is broken into sub-tasks. In step 630, distributed processing is caused on the consumer devices, by sending a first subtask to a consumer device in the first group of consumer devices, and sending a second subtask to a consumer device in the second group of consumer devices. The consumer devices execute the sub-tasks and send the results back to the service provider networks, where the results can be aggregated as described above to complete processing of a tasks. Alternatively, the first subtask can be sent to a first group of the consumer devices, and the second subtask is sent to a second group of the consumer devices. In this way, the subtasks can be processed on more than one processor at the same time, which can provide increased quality of service and fault tolerance.

Several embodiments of the present invention are specifically illustrated and described herein. However, it will be appreciated that modifications and variations of the present invention are covered by the above teachings and within the purview of the appended claims without departing from the spirit and intended scope of the invention.

What is claimed is:

1. A method of distributed processing on a service provider network that includes a plurality of remotely located consumer devices, each of the remotely located consumer devices including a processing device, comprising:

providing a service from the service provider network to the remotely located consumer devices;
receiving one or more tasks for processing;
breaking one of the one or more tasks into subtasks;
causing by the service provider network, distribution of subtasks of differentiable tasks to at least some of the processing devices of the remotely located consumer devices, including distributing a first one of the subtasks to a first processing device and distributing a second one of the subtasks to a second processing device; and
causing, by the service provider network, distributed processing of the subtasks of the differentiable tasks on the at least some of the processing devices of the remotely located consumer devices, the distributed processing and the distributed subtasks of the differentiable tasks being unrelated to the service provided to the consumer devices by the service provider network, the distributed processing occurring even when the processing devices are in use by the corresponding remotely located consumer devices.

2. The method of claim 1, further comprising receiving results of the distributed processing from the first processing device and from the second processing device.

3. The method of claim 2, further comprising aggregating the results of the distributed processing from the results received from the first processing device and from the second processing device.

4. The method of claim 1, wherein the service provider network is one of a cable television network, a satellite television network, a phone network, and an internet service provider network.

5. The method of claim 1, further comprising:

providing services from a plurality of service provider networks to a plurality of consumer devices, a first group of the consumer devices connected to a first one of the service provider networks and a second group of the consumer devices connected to a second one of the service provider networks; and

causing distributed processing on the first group of the consumer devices and on the second group of the consumer devices.

6. The method of claim 5, wherein causing distributed processing on the first group of the consumer devices and on the second group of the consumer devices comprises:

receiving a task for processing;
breaking the task into subtasks; and
sending, from the first service provider, a first one of the subtasks to a consumer device in the first group of consumer devices, and sending, from the second service provider, a second one of the subtasks to a consumer device in the second group of consumer devices.

7. The method of claim 5, wherein the first and second service networks provide different types of services.

8. The method of claim 1, wherein the distributed processing and the distributed task unrelated to the service provided to the consumer devices by the service provider network are performed on behalf of an entity other than the service provider network.

9. A system for providing distributed processing, comprising:

a service provider network that provides a service;
a management system that performs the following operations:

receives one or more tasks for processing;
breaks one of the one or more tasks into subtasks;
distributes a first one of the subtasks to a first processing device of the remotely located consumer devices and distributes a second one of the subtasks to a second processing device of the remotely located consumer devices; and

causes distributed processing of parts of differentiable tasks sent from the service provider network to at least some of a plurality of remotely located consumer devices, each of the remotely located consumer devices including a processing device, the distributed processing and the distributed parts of differentiable tasks being unrelated to the service provided to the consumer devices by the service provider network, the distributed processing occurring even when the processing devices are in use by the corresponding remotely located consumer devices.

10. The system of claim 4, wherein the management system receives results of the distributed processing from the first processing device and from the second processing device.

11. The system of claim 10, wherein the management system aggregates the results of the distributed processing from the results received from the first processing device and from the second processing device.

12. The system of claim 10, wherein the service provider network is one of a cable television network, a satellite television network, a phone network, and an internet service provider network.

13. The system of claim 9, wherein the distributed processing and the distributed task unrelated to the service provided to the consumer devices by the service provider are performed on behalf of an entity other than the service provider network.

14. A system for providing distributed processing, comprising:

a plurality of service provider networks each providing a service to a plurality of consumer devices, a first group of the consumer devices connected to a first one of the service provider networks and a second group of the

9

consumer devices connected to a second one of the service provider networks; and
 a management system that breaks the task into a plurality of differentiable subtasks and sends, from the first service provider network, a first one of a plurality of differentiable subtasks unrelated to the service provided from the first service provider network to a consumer device in the first group of consumer devices, and sends, from the second service provider network, a second one of a plurality of differentiable subtasks unrelated to the service provided from the second service provider network to a consumer device in the second group of consumer devices.

15 15. The system of claim 14, wherein the first and second service networks provide different types of services.

16. The system of claim 14, wherein the subtasks unrelated to the service provided to the consumer devices by the service provider are performed on behalf of an entity other than the service provider network.

17. A non-transitory machine-readable medium having stored thereon a plurality of executable instructions for causing distributed processing on a service provider network that includes a plurality of remotely located consumer devices, each of the remotely located consumer devices including a processing device, the plurality of instructions comprising instructions to:

provide a service from the service provider network to the remotely located consumer devices;

receive one or more differentiable tasks for processing;

break one of the tasks into subtasks;

causing by the service provider network, distribution of subtasks of differentiable tasks to at least some of the processing devices of the remotely located consumer devices, including distributing a first one of the subtasks to a first processing device of the remotely located consumer devices and distributes a second one of the subtasks to a second processing device of the remotely located consumer devices; and

cause, by the service provider network, distributed processing of the differentiable tasks on at least some of the processing devices of the remotely located consumer devices, the distributed processing and the differentiable tasks being unrelated to the service provided to the consumer devices by the service provider network, the distributed processing occurring even when the processing devices are in use by the corresponding remotely located consumer devices.

18. A method of distributed processing on a service provider network that includes a plurality of remotely located consumer devices, each of the remotely located consumer devices including a processing device, comprising:

providing a service from the service provider network to the remotely located consumer devices;

receiving tasks for processing;

breaking one of the tasks into subtasks;

causing by the service provider network, distribution of subtasks of differentiable tasks to at least some of the processing devices of the remotely located consumer devices, including distributing a first one of the subtasks to a first group of processing devices, and distributing a second one of the subtasks to a second group of processing devices; and

10

causing, by the service provider network, distributed processing of the subtasks of the differentiable tasks on the at least some of the processing devices of the remotely located consumer devices,

the distributed processing and the distributed parts of differentiable tasks being unrelated to the service provided to the consumer devices by the service provider network, the distributed processing occurring even when the processing devices of the consumer devices are in use by the corresponding remotely located consumer devices.

19. A system for providing distributed processing, comprising:

a service provider network that provides a service;

a management system that performs the following operations:

receives tasks for processing;

breaks one or more of the tasks into subtasks;

distributes a first one of the subtasks to a first group of processing devices of the remotely located consumer devices and distributes a second one of the subtasks to a second group of processing devices of the remotely located consumer devices; and

causes distributed processing of subtasks of differentiable tasks sent from the service provider network to at least some of a plurality of remotely located consumer devices, each of the remotely located consumer devices including a processing device, the distributed processing and the distributed subtasks of differentiable tasks being unrelated to the service provided to the consumer devices by the service provider network, the distributed processing occurring even when the processing devices of the consumer devices are in use by the corresponding remotely located consumer devices.

20. A non-transitory machine-readable medium having stored thereon a plurality of executable instructions for causing distributed processing on a service provider network that includes a plurality of remotely located consumer devices, each of the remotely located consumer devices including a processing device, the plurality of instructions comprising instructions to:

provide a service from the service provider network to the remotely located consumer devices;

receive tasks for processing;

break one or more of the tasks into subtasks;

causing by the service provider network, distribution of subtasks of differentiable tasks to at least some of the processing devices of the remotely located consumer devices, including distributing a first one of the subtasks to a first group of processing devices of the remotely located consumer devices and distributes a second one of the subtasks to a second group of processing devices of the remotely located consumer devices; and

cause, by the service provider network, distributed processing of the differentiable tasks on at least some of the processing devices of the remotely located consumer devices, the distributed processing and the differentiable tasks being unrelated to the service provided to the consumer devices by the service provider network, the distributed processing occurring even when the processing devices are in use by the corresponding remotely located consumer devices.
