(54) Title: POLYESTER PRODUCTION SYSTEM EMPLOYING HORIZONTALLY ELONGATED ESTERIFICATION VESSEL

(57) Abstract: A polyester production process employing an esterification system that utilizes a horizontally elongated esterification vessel as an esterification reactor and/or a vapor-liquid disengagement vessel.

WO 2008/073288 A2

POLYESTER PRODUCTION SYSTEM EMPLOYING HORIZONTALLY ELONGATED ESTERIFICATION VESSEL

BACKGROUND OF THE INVENTION

5 1. Field of the Invention

This invention relates to a system for producing melt-phase polyesters. In another aspect, the invention concerns an esterification system utilizing a horizontally elongated vessel for esterification and/or vapor-liquid disengagement.

10 2. Description of the Prior Art

Melt-phase polymerization can be used to produce a variety of polyesters, such as, for example, polyethylene terephthalate (PET). PET is widely used in beverage, food, and other containers, as well as in synthetic fibers and resins. Advances in process technology coupled with increased
15 demand have lead to an increasingly competitive market for the production and sale of PET. Therefore, a low-cost, high-efficiency process for producing PET is desirable.

Generally, melt-phase polyester production facilities, including those used to make PET, employ an esterification stage and a polycondensation stage.
20 In the esterification stage, polymer raw materials (i.e., reactants) are converted to polyester monomers and/or oligomers. In the polycondensation stage, polyester monomers exiting the esterification stage are converted into a polymer product having the desired final chain length.

In most conventional melt-phase polyester production facilities,
25 esterification is carried out in one or more mechanically agitated reactors, such as, for example, continuous stirred tank reactors (CSTRs). However, CSTRs and other mechanically agitated reactors have a number of drawbacks that can result in increased capital, operating, and/or maintenance costs for the overall polyester production facility. For example, the mechanical agitators and various
30 control equipment typically associated with CSTRs are complex, expensive, and can require extensive maintenance. Further, conventional CSTRs frequently employ internal heat exchange tubes that occupy a portion of the reactor's internal volume. In order to compensate for the loss in effective reactor

volume, CSTRs with internal heat exchange tubes require a larger overall volume, which increases capital costs. Further, internal heat exchange coils typically associated with CSTRs can undesirably interfere with the flow patterns of the reaction medium within the vessel, thereby resulting in a loss of conversion. To increase product conversion, many conventional polyester production facilities have employed multiple CSTRs operating in series, which further increases both capital and operating costs.

Thus, a need exists for a high efficiency polyester process that minimizes capital, operational, and maintenance costs while maximizing product conversion.

SUMMARY OF THE INVENTION

In one embodiment of the present invention, there is provided a process comprising: subjecting a reaction medium to esterification in an esterification zone defined within an esterification vessel, wherein the esterification vessel has a length-to-diameter ratio less than about 10:1, wherein the reaction medium flows substantially horizontally through the esterification vessel.

In another embodiment of the present invention, there is provided a process comprising: (a) subjecting a reaction medium to esterification in an esterification reactor to thereby produce a first product; (b) introducing at least a portion of the first product into a disengagement vessel; (c) withdrawing separate liquid and vapor products from the disengagement vessel; and (d) routing at least a portion of the withdrawn liquid phase back to the first esterification reactor via a recirculation loop, wherein the internal volume defined by the disengagement vessel is at least about 50 percent of the combined internal volume defined by the recirculation loop and the esterification reactor.

In yet another embodiment of the present invention, there is provided a disengagement vessel defining a fluid inlet, a liquid outlet, and a vapor outlet. The disengagement vessel is elongated along a substantially horizontal axis and has a length-to-diameter ratio of less than about 10:1. The fluid inlet is horizontally spaced from the liquid and vapor outlets by at least about 1.25D

and the vapor and liquid outlets are vertically spaced from one another by at least about 0.5D.

5 BRIEF DESCRIPTION OF THE DRAWINGS

Certain embodiments of the present invention are described in detail below with reference to the enclosed figure, wherein:

FIG. 1 is a schematic depiction of an esterification system configured in accordance with one embodiment of the present invention and suitable for use
10 in a melt-phase polyester production facility.

DETAILED DESCRIPTION

The present invention can be employed in melt-phase polyester production facilities capable of producing a variety of polyesters from a variety
15 of starting materials. As used herein, the term “polyester” also includes polyester derivatives, such as, for example, polyetheresters, polyester amides, and polyetherester amides. Examples of melt-phase polyesters that can be produced in accordance with the present invention include, but are not limited to, homopolymers and copolymers of polyethylene terephthalate (PET), PETG
20 (PET modified with 1,4-cyclohexane-dimethanol (CHDM) comonomer), fully aromatic or liquid crystalline polyesters, biodegradable polyesters, such as those comprising butanediol, terephthalic acid and adipic acid residues, poly(cyclohexane-dimethylene terephthalate) homopolymer and copolymers, and homopolymers and copolymers of CHDM and cyclohexane dicarboxylic
25 acid or dimethyl cyclohexanedicarboxylate.

In one embodiment of the present invention, polyester starting materials comprising at least one alcohol and at least one acid are subjected to esterification in an initial stage of the process. The acid starting material can be a dicarboxylic acid such that the final polyester product comprises at least one
30 dicarboxylic acid residue having in the range of from about 4 to about 15 or from 8 to 12 carbon atoms. Examples of dicarboxylic acids suitable for use in the present invention can include, but are not limited to, terephthalic acid,

phthalic acid, isophthalic acid, naphthalene-2,6-dicarboxylic acid, cyclohexanedicarboxylic acid, cyclohexanediacetic acid, diphenyl-4,4'-dicarboxylic acid, diphenyl-3,4'-dicarboxylic acid, 2,2,-dimethyl-1,3-propandiol, dicarboxylic acid, succinic acid, glutaric acid, adipic acid, azelaic acid, sebacic acid, and mixtures thereof. In one embodiment, the acid starting material can be
 5 acid, and mixtures thereof. In one embodiment, the acid starting material can be a corresponding ester, such as dimethyl terephthalate instead of terephthalic acid.

The alcohol starting material can be a diol such that the final polyester product can comprise at least one diol residue, such as, for example, those
 10 originating from cycloaliphatic diols having in the range of from about 3 to about 25 carbon atoms or 6 to 20 carbon atoms. Suitable diols can include, but are not limited to, ethylene glycol (EG), diethylene glycol, triethylene glycol, 1,4-cyclohexane-dimethanol, propane-1,3-diol, butane-1,4-diol, pentane-1,5-diol, hexane-1,6-diol, neopentylglycol, 3-methylpentanediol-(2,4), 2-methylpentanediol-(1,4), 2,2,4-trimethylpentane-diol-(1,3), 2-ethylhexanediol-(1,3), 2,2-diethylpropane-diol-(1,3), hexanediol-(1,3), 1,4-di-(hydroxyethoxy)-benzene, 2,2-bis-(4-hydroxycyclohexyl)-propane, 2,4-dihydroxy-1,1,3,3-tetramethyl-cyclobutane, 2,2,4,4-tetramethyl-cyclobutanediol, 2,2-bis-(3-hydroxyethoxyphenyl)-propane, 2,2-bis-(4-hydroxy-propoxyphenyl)-propane,
 15 isosorbide, hydroquinone, BDS-(2,2-(sulfonylbis)4,1-phenyleneoxy))bis(ethanol), and mixtures thereof.

In addition, in one embodiment, the starting materials can comprise one or more comonomers. Suitable comonomers can include, for example, comonomers comprising terephthalic acid, dimethyl terephthalate, isophthalic acid, dimethyl isophthalate, dimethyl-2,6-naphthalenedicarboxylate, 2,6-naphthalene-dicarboxylic acid, ethylene glycol, diethylene glycol, 1,4-cyclohexane-dimethanol (CHDM), 1,4-butanediol, polytetramethyleneglycol, trans-DMCD, trimellitic anhydride, dimethyl cyclohexane-1,4 dicarboxylate, dimethyl decalin-2,6 dicarboxylate, decalin dimethanol, decahydronaphthalene
 25 2,6-dicarboxylate, 2,6-dihydroxymethyl-decahydronaphthalene, hydroquinone, hydroxybenzoic acid, and mixtures thereof.

In accordance with one embodiment of the present invention, one or more additives can be added to the starting materials, the polyester, and/or the polyester precursors at one or more locations within the process. Suitable additives can include, for example, trifunctional or tetrafunctional comonomers, such as trimellitic anhydride, trimethylolpropane, pyromellitic dianhydride, pentaerythritol, or other polyacids or polyols; crosslinking or branching agents; colorant; toner; pigment; carbon black; glass fiber; filler; impact modifier; antioxidant; UV absorbent compound; and oxygen scavenging compound.

In general, the polyester production process according to one embodiment of the present invention can comprise two main stages. The first stage reacts starting materials (also referred to herein as "raw materials" or "reactants") into monomers and/or oligomers. The second stage further reacts the monomers and/or oligomers into the final polyester product.

If the starting materials entering the first stage include acid end groups, such as, for example, terephthalic acid or isophthalic acid, the first stage is referred to as esterification. If the starting materials have methyl end groups, such as, for example, dimethyl terephthalate or dimethyl isophthalate, the first stage is referred to as ester exchange or trans-esterification. For simplicity, the term "esterification" as used herein, includes both esterification and ester exchange reactions, but it should be understood that esterification and ester exchange depend on the starting materials. According to one embodiment of the present invention, esterification can take place at a temperature in the range of from about 220°C to about 300°C, or about 235°C to about 280°C, or 245°C to 270°C and a pressure of less than about 25 psig, or a pressure in the range of from about 1 psig to about 10 psig, or 2 psig to 5 psig. In one embodiment, the average chain length of the monomer and/or oligomer exiting the esterification stage can be less than about 25, from about 1 to about 20, or from 5 to 15.

The second stage of the process can be referred to as the polycondensation stage. The polycondensation stage can be a single step process, or can be divided into a prepolycondensation (or prepolymerization) step and a final (or finishing) polycondensation step. Generally, longer chain polymers can be produced via a multi-stage polycondensation process. The

polycondensation stage can be carried out at a temperature in the range of from about 220°C to about 350°C, or about 240°C to about 320°C and a sub-atmospheric (e.g., vacuum) pressure. When polycondensation is carried out in a two-stage process, the prepolymerization (or prepolymer) reactor can convert
5 the monomer exiting the esterification stage into an oligomer having an average chain length in the range of from about 2 to about 40, from about 5 to about 35, or from 10 to 30. The finisher reactor then converts the oligomer/polymer mixture into a final polymer product having the desired average chain length.

In accordance with one embodiment of the present invention, the
10 esterification stage can be carried out in an esterification system comprising at least one esterification zone and at least one distillation zone. In the esterification zone, reactants are subjected to esterification to thereby produce a vapor byproduct and a liquid product containing polyester monomers and/or oligomers. A product portion of the liquid product exiting the esterification
15 zone can exit the esterification system for downstream processing, while a recirculation portion of the liquid product exiting the esterification zone can be recirculated back to the inlet of the esterification zone. At least a portion of the vapor byproduct exiting the esterification zone can be routed to the distillation zone, wherein water and alcohol components of the vapor byproduct can be
20 separated. A portion of the separated alcohol exiting the distillation zone can be recombined with the recirculation portion of the liquid product exiting the esterification zone. The resulting combined stream can then be reintroduced into the esterification zone, after receiving additional quantities of reactants and/or additives.

25 In one embodiment of the present invention, at least a portion of the esterification zone can be defined by equipment that imparts little or no mechanical agitation to the liquid phase of the reaction medium processed therein. Although the liquid phase of the reaction medium processed in the esterification zone may be somewhat agitated by virtue of flowing through the
30 equipment that defines the esterification zone, in one embodiment of the present invention, less than about 50 percent, less than about 25 percent, less than about 10 percent, less than about 5 percent, or 0 percent of the agitation of the liquid

phase reaction medium processed in the esterification zone is provided by mechanical agitation. This is in direct contrast to conventional esterification processes that are carried out in one or more continuous stirred tank reactors (CSTRs) under conditions of extreme mechanical agitation.

- 5 As discussed further in detail below, the present invention can employ simple, reliable, and inexpensive equipment for carrying out esterification. For example, in one embodiment of the present invention, at least a portion of the esterification zone can be defined within a simple, reliable, and relatively inexpensive heater, such as, for example, a shell-and-tube heat exchanger.
- 10 Further, in another embodiment, at least a portion of the esterification zone can be defined within a simple, reliable, and relatively inexpensive unagitated esterification vessel.

Referring now to FIG. 1, an esterification system 10 configured in accordance with one embodiment of the present invention is illustrated as

15 generally comprising a heat exchanger 12, an esterification vessel 14, a distillation column 16, and a recirculation loop 18. In general, the process carried out in esterification system 10 includes the following broad steps: (1) introducing an esterification feed into heat exchanger 12; (2) heating and partially esterifying the esterification feed in heat exchanger 12; (3) introducing

20 at least a portion of the heated and partially esterified product from heat exchanger 12 into esterification vessel 14; (4) further esterifying the partially esterified product from heat exchanger 12 in esterification vessel 14; (5) separating a liquid product from a vapor byproduct in esterification vessel 14; (6) introducing at least a portion of the vapor byproduct from esterification

25 vessel 14 into distillation column 16; (7) separating the vapor byproduct into a predominately water overhead stream and a predominately alcohol bottom stream in distillation column 16; (8) routing a recirculation portion of the liquid product from esterification vessel 14 back to heat exchanger 12 via recirculation loop 18; (9) while the recirculation portion of the liquid product is flowing

30 through recirculation loop 18, adding thereto recirculated alcohol from distillation column 16, fresh alcohol, additive(s), and/or acid; and (10)

withdrawing a product portion of the liquid product from esterification vessel 14 for further downstream processing.

As stated above, esterification can be carried out in both heat exchanger 12 and esterification vessel 14 of esterification system 10. Since esterification
5 can be carried out in both heat exchanger 12 and esterification vessel 14, each of these pieces of equipment can be referred to as “esterification reactors” that each define a portion of an “esterification zone.” However, because an additional function of heat exchanger 12 can be to heat the reaction medium processed therein, heat exchanger 12 can also be referred to as a “heater” that
10 defines a “heating zone.” Further, since an additional function of esterification vessel 14 can be to promote vapor/liquid disengagement, esterification vessel 14 can also be referred to as a “disengagement vessel” that defines a “disengagement zone.” The configuration and operation of esterification system 10, illustrated in FIG. 1, will now be described in greater detail.

15 Referring again to FIG. 1, a recirculated liquid product stream, discussed in more detail below, is transported through a recirculation conduit 100. As illustrated in FIG. 1, the following materials can be added to the recirculated liquid product stream flowing through recirculation conduit 100: (a) recirculated alcohol introduced via conduit 102, (b) additional fresh alcohol introduced via
20 conduit 104, and (c) one or more additives introduced via conduit 106. In another embodiment, at least a portion of one or more streams in conduits 102, 104, and/or 106 can be added to the stream exiting esterification vessel 14 in conduit 114, which is discussed in detail below. In yet another embodiment, at least a portion of one or more streams in conduits 102, 104, and/or 106 can be
25 introduced directly into a yet-to-be-discussed recirculation pump 40. The recirculated and fresh alcohol in conduits 102 and 104 can be any of the alcohols discussed above as being suitable for use as starting materials in the system of the present invention. According to one embodiment, the recirculated and/or fresh alcohol can be ethylene glycol. The one or more additives in
30 conduit 106 can be any of the additives discussed above as being suitable for used in the system of the present invention.

Additional acid from conduit 108 can also be added to the stream flowing through recirculation conduit 100. The acid introduced into recirculation conduit 100 via conduit 108 can be any of the acids discussed above as being suitable for use as starting materials in the system of the present invention. The acid in conduit 108 can be in the form of a liquid, slurry, paste, or dry solids. In one embodiment, the acid in conduit 108 can be solid particles of terephthalic acid.

In one embodiment of the present invention, the acid in conduit 108 is added to the recirculation stream in conduit 100 in the form of small, substantially dry, solid particles (e.g., a powder). In such an embodiment, the acid fed to conduit 100 can contain less than about 5 weight percent, less than about 2 weight percent, or less than 1 weight percent liquid. This method of dry acid addition can eliminate the need for complex and expensive mechanically agitated tanks traditionally used to convert the solid acid particles into a paste or slurry before introducing the resulting mixture into the esterification process.

As illustrated in FIG. 1, a pressure reducer 20 can be employed to permit the direct addition of a solid acid reactant into recirculation conduit 100 without being in the form of a paste or slurry. In one embodiment of the present invention, the solid acid reactant can be added to recirculation conduit 100 at a location where the pressure of the recirculation stream has been reduced via pressure reducer 20. Pressure reducer 20 can be any apparatus known in the art to be capable of reducing the pressure of a primarily fluid stream so that material can be added to the pressure-reduced stream via an opening proximate the zone of reduced pressure. An eductor is one example of an apparatus suitable for use as pressure reducer 20.

As illustrated in FIG. 1, the solid acid reactant in conduit 108 can be added to recirculation loop 18 downstream of the additional alcohol and additive injection points. Further, it can be advantageous to introduce the solid acid reactant into the top portion of recirculation conduit 100 in order to expedite the dissolution of the solid acid particles as they descend into the recirculation stream. The presence of polyester monomers and/or oligomers in the recirculation stream can also enhance the dissolution of the solid acid

particles added to recirculation conduit 100. In one embodiment of the present invention, the stream in recirculation conduit 100 can have an average chain length in the range of from about 1 to about 20, about 2 to about 18, or 5 to 15.

Generally, the amount of alcohol and acid added to the recirculation stream in recirculation conduit 100 can any amount necessary to provide the desired production rate and the desired alcohol-to-acid ratio. In one embodiment of the present invention, the molar alcohol-to-acid ratio of the esterification feed stream exiting recirculation conduit 100 is in the range of from about 1.005:1 to about 10:1, about 1.01:1 to about 8:1, or 1.05:1 to 6:1.

10 The combined stream exiting recirculation conduit 100 and/or pressure reducer 20 can be introduced as an esterification feed into an inlet 22 of heat exchanger 12 via a feed conduit 110. In heat exchanger 12, the esterification feed/reaction medium is heated and subjected to esterification conditions. In accordance with one embodiment of the present invention, the temperature increase of the reaction medium between the inlet 22 and an outlet 24 of heat exchanger 12 can be at least about 50°F, at least about 75°F, or at least 85°F. Generally, the temperature of the esterification feed entering inlet 22 of heat exchanger 12 can be in the range of from about 220°C to about 260°C, about 230°C to about 250°C, or 235°C to 245°C. Generally, the temperature of the esterification product exiting outlet 24 of heat exchanger 12 can be in the range of from about 240°C to about 320°C, about 255°C to about 300°C, or 275°C to 290°C. The reaction medium in heat exchanger 12 can be maintained at a pressure in the range of from about 5 to about 50 psig, from about 10 to about 35 psig, or from 15 to 25 psig.

25 As discussed previously, heat exchanger 12 can also be considered an esterification reactor because at least a portion of the reaction medium flowing therethrough can undergo esterification. The amount of esterification carried out in accordance with the present invention can be quantified in terms of "conversion." As used herein, the term "conversion" is used to describe a property of the liquid phase of a stream that has been subjected to esterification, wherein the conversion of the esterified stream indicates the percentage of the original acid end groups that have been converted (i.e., esterified) to ester

groups. Conversion can be quantified as the number of converted end groups (i.e., alcohol end groups) divided by the total number of end groups (i.e., alcohol plus acid end groups), expressed as a percentage. While conversion is used herein, it should be understood that average chain length, which describes
5 the average number of monomer units that a compound comprises, could also be appropriate for describing the characteristics of the streams of the present invention as well.

According to one embodiment, the esterification reaction carried out in heat exchanger 12 can increase the conversion of the reaction medium between
10 inlet 22 and outlet 24 by at least about 5, at least about 10, at least about 15, at least about 20, at least about 30, or at least about 50 percentage points. Generally, the esterification feed stream introduced into inlet 22 of heat exchanger 12 has a conversion of less than about 90 percent, less than about 75 percent, less than about 50 percent, less than about 25 percent, less than about
15 10 percent, or less than 5 percent, while the esterification product stream exiting outlet 24 of heat exchanger 12 has a conversion of at least about 50 percent, at least about 60 percent, at least about 70 percent, at least about 75 percent, at least about 80 percent, at least about 85 percent, at least about 95 percent, or at least 98 percent.

20 In one embodiment of the present invention, the esterification reaction carried out in heat exchanger 12 takes place at a significantly reduced residence time relative to conventional esterification processes. For example, the average residence time of the reaction medium flowing through heat exchanger 12 can be less than about 60 minutes, less than about 45 minutes, less than about 35
25 minutes, or less than 20 minutes. This relatively short residence time can even be achieved at high, commercial scale production rates. Thus, in one embodiment, the product stream exits outlet 24 of heat exchanger 12 at a flow rate of at least about 10,000 pounds per hour (lb/h), at least about 25,000 lb/h, at least about 50,000 lb/h, or at least 100,000 lb/h.

30 Turning now the specific configuration of heat exchanger 12. In accordance with one embodiment of the present invention, heat exchanger 12 can be a horizontally elongated, shell-and-tube heat exchanger. An internal

flow passageway through heat exchanger 12 can be defined by the heat exchange tubes through which the reaction medium flows as it is heated and esterified. This internal flow passageway can be considered to be a “first esterification zone” of esterification system 10. Generally the aggregate volume
5 of the internal flow passageway through heat exchanger can be in the range of from about 10 to about 1,500 cubic feet (ft³), about 100 to about 800 ft³, or 200 to 600 ft³. The average inner diameter of the individual heat exchange tubes can be less than about 4 inches, or in the range of from about 0.25 to about 3 inches, or 0.5 to 2 inches.

10 As shown in FIG. 1, a stream of warmed heat transfer medium (HTM) can enter the shell-side of heat exchanger 12 and at least partly surround at least a portion of the heat exchange tubes in order to heat the reaction medium flowing therethrough. In one embodiment of the present invention, the heat transfer coefficient associated with the heating of the reaction medium in heat
15 exchanger 12 can be in the range of from about 0.5 to about 200 BTU per hour per °F per square foot (BTU/h·°F·ft²), about 5 to about 100 BTU/h·°F·ft², or from 10 to 50 BTU/h·°F·ft². The total amount of heat transferred to the reaction medium in heat exchanger 12 can be in the range of from about 100 to about 5,000 BTU per pound of reaction medium (BTU/lb), about 400 to about 2,000
20 BTU/lb, or 600 to 1,500 BTU/lb.

As depicted in FIG. 1, the partially esterified product exiting heat exchanger 12 via outlet 24 can be transported to esterification vessel 14 via conduit 112. The partially esterified stream in conduit 112 can be introduced into the internal volume of esterification vessel 14 via a fluid inlet 26. As
25 discussed previously, in esterification vessel 14, the partially esterified stream is subjected to further esterification and phase separation. Thus, the internal volume defined within esterification vessel can be considered to be a “second esterification zone” and/or a “disengagement zone.” Generally, the reaction medium in esterification vessel 14 flows substantially horizontally through the
30 internal volume. As the reaction medium flows away from fluid inlet 26 and undergoes esterification, vapor byproducts escape the liquid phase and flow generally above the liquid phase. The separated liquid product can exit

esterification vessel 14 via a liquid outlet 28, while the separated vapor byproduct can exit esterification vessel 14 via vapor outlet 30.

The esterification reaction carried out in esterification vessel 14 can increase the conversion of the reaction medium processed therein so the liquid product exiting liquid outlet 28 has a conversion that is at least about 1 percentage point, at least about 2 percentage points, or at least 5 percentage points higher than the conversion of the fluid stream entering fluid inlet 26. Generally, the liquid product exiting liquid outlet 28 of esterification vessel 14 can have conversion of at least about 80 percent, at least about 85 percent, at least about 90 percent, at least 95 percent, or at least about 98 percent.

The conversion achieved in esterification vessel 14 can occur during a relatively short residence time and with little or no heat input. For example, the average residence time of the reaction medium in esterification vessel 12 can be less than about 200 minutes, less than about 60 minutes, less than about 45 minutes, less than about 30 minutes, or less than 15 minutes. Further, the amount of heat transferred to the reaction medium in esterification vessel 14 can be less than about 100 BTU per pound of reaction medium (BTU/lb), less than about 20 BTU/lb, less than about 5 BTU/lb, or less than 1 BTU/lb.

With minimal or no heat input in esterification vessel 14, the average temperature of the liquid product exiting liquid outlet 28 of esterification vessel 14 can be within about 50°C, about 30°C, about 20°C, or 15°C of the average temperature of the fluid entering esterification vessel 14 via fluid inlet 26. Generally, the average temperature of the liquid product exiting liquid outlet 28 of esterification vessel 14 can be in the range of from about 220°C to about 320°C, about 240°C to about 300°C, or about 250°C to about 275°C.

Turning now to the specific configuration of esterification vessel 14. In the embodiment illustrated in FIG. 1, esterification vessel 14 is a substantially empty, unagitated, unheated, generally cylindrical, horizontally elongated vessel. Esterification vessel 14 can have a length-to-diameter (L:D) ratio of less than about 10:1, in the range of from about 1.25:1 to about 8:1, about 1.5:1 to about 6:1, or 2:1 to 4.5:1. In one embodiment, fluid inlet 26, liquid outlet 28, and vapor outlet 30 are spaced from one another in a manner that provides

sufficient esterification and enhances disengagement/separation of the vapor, liquid, and foam phases. For example, liquid outlet 28 and vapor outlet 30 can be horizontally spaced from the fluid inlet 26 by at least about 1.25D, at least about 1.5D, or at least 2.0D. Further, liquid outlet 28 and vapor outlet 30 can be
5 vertically spaced from one another by at least about 0.5D, at least about 0.75D, or at least 0.95D.

As illustrated in FIG. 1, esterification vessel 14 can comprise a fluid distributor 32 to aid in the effective distribution of the feed to esterification vessel 14. In the embodiment illustrated in FIG. 1, fluid distributor is simply a
10 substantially horizontally extending pipe having a downwardly curved distal end that defines fluid inlet 26 with a downwardly facing orientation. Alternatively, fluid distributor 32 can define a plurality of openings for discharging the partially esterified feed at multiple horizontally spaced locations in esterification vessel 14. In one embodiment of the present invention, the
15 average depth of the reaction medium in esterification vessel 14 is maintained at less than about 0.75D, less than about 0.50D, less than about 0.25D, or less than 0.15D as it travels substantially horizontally through esterification vessel 14.

As shown in FIG. 1, upon entering esterification vessel 14, the reaction medium exiting fluid distributor 32 can begin to foam as the vapor bubbles
20 disengage from the liquid portion of the reaction medium. Generally, foam production can decrease along the length of esterification vessel 14 as the vapor disengages from the liquid phase of the reaction medium so that, in one embodiment, substantially no foam exits liquid outlet 28 and/or vapor outlet 30 of esterification vessel 14.

To help ensure that substantially no foams exits vapor outlet 30 of esterification vessel 14, a downwardly extending baffle 34 can be employed in esterification vessel 14. Baffle 34 can generally be disposed between fluid inlet 26 and vapor outlet 30 of esterification vessel 14, but closer to vapor outlet 30 than to fluid inlet 26. Baffle 34 can extend downwardly from the top of
30 esterification vessel 14 proximate vapor outlet 30 and can function to physically block the flow of foam, if any, towards vapor outlet 30. In one embodiment of the present invention, baffle 34 can present a bottom edge vertically spaced at

least about 0.25D, at least about 0.5D, or at least 0.75D from the bottom of esterification vessel 14. In the embodiment illustrated in FIG. 1, baffle includes a downwardly extending portion 36 and a laterally extending portion 38. Downwardly extending portion 36 can extend downwardly from a location proximate vapor outlet 30, while laterally extending portion 38 can extend transversely from the bottom end of downwardly extending portion 36 to a location generally under vapor outlet 30.

The total internal volume defined within esterification vessel 14 can depend on a number of factors, including, for example, the overall hydrodynamic requirements of esterification system 10. In one embodiment of the present invention, the total internal volume of esterification vessel 14 can be at least about 25 percent, at least about 50 percent, at least about 75 percent, at least about 100 percent, or at least 150 percent of the total internal volume of recirculation loop 18, described in further detail below. In yet another embodiment of the present invention, the total internal volume of esterification vessel 14 can be at least about 25 percent, at least about 50 percent, at least about 75 percent, or at least 150 percent of the aggregate internal volume of recirculation loop 18, the flow passageway within heat exchanger 12, and product conduit 112.

Referring again to FIG. 1, a liquid ester product can exit liquid outlet 28 of esterification vessel 14 and can thereafter be introduced into recirculation loop 18. Recirculation loop 18 defines a flow passageway from liquid outlet 28 of esterification vessel 14 to inlet 22 of heat exchanger 12. Recirculation loop 18 generally comprises a liquid product conduit 114, a recirculation pump 40, a pump discharge conduit 116, recirculation conduit 100, pressure reducer 20, and feed conduit 110. The liquid ester product discharged from esterification vessel 14 can flow initially through product conduit 114 to the suction of recirculation pump 40. The stream exiting pump 40 can be passed through pump discharge conduit 116 and thereafter split into a product portion transported via ester product conduit 118 and a recirculation portion transported via recirculation conduit 100. The splitting of the stream exiting pump 40 can be carried out so that the ratio of the mass flow rate of the recirculation portion in conduit 100 to

the mass flow rate of the product portion in conduit 118 can be in the range of from about 0.25:1 to about 30:1, about 0.5:1 to about 20:1, or 2:1 to 15:1. As previously discussed, the recirculation portion in conduit 100 can eventually be employed as the feed to heat exchanger 12, after the addition of recirculation
5 alcohol via conduit 102, fresh alcohol via conduit 104, additive(s) via conduit 106, and/or acid via conduit 108.

The product portion of the liquid ester product in conduit 118 can be routed to a downstream location for further processing, storage, or other use. In one embodiment, at least a fraction of the product portion in conduit 118 can be
10 subjected to further esterification in a second esterification zone. In another embodiment, at least part of the product portion in conduit 118 can be subjected to polycondensation in a downstream polycondensation zone.

As illustrated in FIG. 1, the vapor stream exiting vapor outlet 30 of esterification vessel 14 via conduit 120 can be routed to a fluid inlet 42 of
15 distillation column 16. The vapor byproduct stream in conduit 120 can comprise water and alcohol. The water and alcohol can be substantially separated from one another in distillation column 16 to thereby produce a predominately water overhead vapor stream exiting distillation column 16 via overhead outlet 44 and a predominately alcohol bottom liquid stream exiting
20 distillation column 16 via lower outlet 46. Distillation column 16 can be any device capable of separating a stream into a predominantly vapor overhead product and a predominantly liquid bottoms product based on the relative volatilities of the components of the feed stream. Distillation column 16 can comprise internals such as, for example, trays, random packing, structured
25 packing, or any combination thereof.

According to one embodiment of the present invention, the predominantly water overhead vapor stream exiting distillation column 16 via overhead outlet 44 can comprises at least about 50 mole percent, at least about 60 mole percent, or at least 75 mole percent water. The overhead vapor product
30 discharged from outlet 44 of distillation column 16 can be routed via conduit 122 to subsequent processing, storage, or disposal, such as, for example, a

wastewater processing unit or a disposal means employing, for example, incineration.

The predominately alcohol bottom liquid stream exiting distillation column 14 via lower outlet 46 can comprise at least about 50 mole percent, at least about 60 mole percent, or at least 75 mole percent alcohol (e.g., ethylene glycol). In one embodiment of the present invention, the predominantly alcohol stream withdrawn from lower outlet 46 of distillation column 16 can have a temperature of at least about 150°C, in the range of from about 175°C to about 250°C, or 190°C to 230°C and a pressure in the range of from about 0.25 psig to about 50 psig, about 0.5 psig to about 35 psig, or 1 psig to 25 psig. As shown in FIG. 1, the liquid stream discharged from lower outlet 46 of distillation column can be transported in separated liquid conduit 124 and thereafter split into a recirculated alcohol portion carried in conduit 102 and an a recovered alcohol portion carried in conduit 126. The separated liquid stream from conduit 124 can be split in a manner such that the mass flow rate of the recirculated alcohol in conduit 102 can be at least about 25 percent, at least about 50 percent, or at least 75 percent of the mass flow rate of the separated liquid product in conduit 124. The recovered alcohol in conduit 126 can be routed to further processing, storage, or reuse. The recirculated alcohol in conduit 102 can be routed to recirculation loop 18 for combination with the recirculated portion of the esterification product flowing through recirculation conduit 100, as previously described.

Conventional esterification systems require cooling of recirculated alcohol prior to reintroduction into the recirculated ester product. However, in accordance with one embodiment of the present invention, when combined with the recirculated esterification product stream flowing through conduit 116 in recirculation conduit 100, the temperature of the recirculated alcohol stream is not more than about 100°C, not more than about 75°C, not more than about 50°C, or not more than 25°C cooler than the temperature of the alcohol stream when it was withdrawn from lower outlet 46 of distillation column 16. In one embodiment, the temperature of the recirculated alcohol stream when combined with the recirculated ester product stream in recirculation conduit 100 is in the

range of from about 190°C to about 250°C, about 200°C to about 235°C, or 205°C to 220°C.

5 Numerical Ranges

The present description uses numerical ranges to quantify certain parameters relating to the invention. It should be understood that when numerical ranges are provided, such ranges are to be construed as providing literal support for claim limitations that only recite the lower value of the range as well as claims limitation that only recite the upper value of the range. For example, a disclosed numerical range of 10 to 100 provides literal support for a claim reciting “greater than 10” (with no upper bounds) and a claim reciting “less than 100” (with no lower bounds).

15 Definitions

As used herein, the terms “a,” “an,” “the,” and “said” means one or more.

As used herein, the term “and/or,” when used in a list of two or more items, means that any one of the listed items can be employed by itself, or any combination of two or more of the listed items can be employed. For example, if a composition is described as containing components A, B, and/or C, the composition can contain A alone; B alone; C alone; A and B in combination; A and C in combination; B and C in combination; or A, B, and C in combination.

As used herein, the terms “comprising,” “comprises,” and “comprise” are open-ended transition terms used to transition from a subject recited before the term to one or elements recited after the term, where the element or elements listed after the transition term are not necessarily the only elements that make up of the subject.

As used herein, the terms “containing,” “contains,” and “contain” have the same open-ended meaning as “comprising,” “comprises,” and “comprise,” provided below.

As used herein, the term “distillative separation” refers to separating one or more chemical substances from one or more other chemical substances based on the relative volatilities of the substances being separated.

As used herein, the terms “having,” “has,” and “have” have the same
5 open-ended meaning as “comprising,” “comprises,” and “comprise,” provided above

As used herein, the terms “including,” “includes,” and “include” have the same open-ended meaning as “comprising,” “comprises,” and “comprise,” provided above.

10 As used herein, the term “reaction medium” refers to a mixture of starting materials, monomer, oligomer, and/or polymer.

As used herein, the term “residue” refers to the moiety that is the resulting product of the chemical species in a particular reaction scheme or subsequent formulation or chemical product, regardless of whether the moiety is
15 actually obtained from the chemical species.

Claims Not Limited to Disclosed Embodiments

The preferred forms of the invention described above are to be used as illustration only, and should not be used in a limiting sense to interpret the
20 scope of the present invention. Modifications to the exemplary embodiments, set forth above, could be readily made by those skilled in the art without departing from the spirit of the present invention.

The inventors hereby state their intent to rely on the Doctrine of Equivalents to determine and assess the reasonably fair scope of the present
25 invention as pertains to any apparatus not materially departing from but outside the literal scope of the invention as set forth in the following claims.

What is claimed is:

1. A process comprising: subjecting a reaction medium to esterification in an esterification zone defined within an esterification vessel, wherein said esterification vessel has a length-to-diameter (L:D) ratio less than about 10:1, wherein said reaction medium flows substantially horizontally through said esterification vessel.
2. The process of claim 1, further comprising, optionally, agitating said reaction medium in said esterification vessel, wherein less than about 50 percent of the agitation is provided by mechanical agitation.
3. The process of claim 1, further comprising, optionally, adding heat to said reaction medium in said esterification vessel, wherein the amount of heat added to said reaction medium in said esterification vessel is less than about 20 BTU/pound .
4. The process of claim 1, wherein said esterification vessel is horizontally elongated.
5. The process of claim 1, wherein said esterification vessel has an L:D ratio in the range of from about 1.25:1 to about 8:1.
6. The process of claim 1, wherein the average depth of said reaction medium in said esterification vessel is less than about 0.75D.
7. The process of claim 1, wherein said esterification vessel has an L:D ratio in the range of from about 1.5:1 to about 6:1, wherein the average depth of said reaction medium in said esterification vessel is less than about 0.5D.
8. The process of claim 1, wherein said reaction medium enters said esterification vessel via a fluid inlet and exits said esterification vessel via a

liquid outlet, wherein said liquid outlet is horizontally spaced from said fluid inlet by at least $1.25D$.

9. The process of claim 8, wherein a vapor flows through said esterification vessel generally above said reaction medium.

10. The process of claim 9, wherein said vapor exits said esterification vessel via a vapor outlet that is horizontally spaced from said fluid inlet by at least about $1.25D$ and vertically spaced from said liquid outlet by at least about $0.5D$.

11. The process of claim 10, wherein said esterification vessel comprises a downwardly extending baffle around which said vapor must flow prior to exiting said vapor outlet.

12. The process of claim 10, wherein foam is generated in said esterification vessel, wherein substantially no foam exits said esterification vessel through said vapor or liquid outlets.

13. The process of claim 1, wherein said reaction medium enters said esterification vessel having a conversion of at least about 50 percent.

14. The process of claim 1, wherein the residence time of said reaction medium in said esterification vessel is less than about 45 minutes.

15. The process of claim 1, further comprising heating said reaction medium in a heat exchanger prior to introduction into said esterification vessel, wherein the conversion of said reaction medium increases by at least about 5 percentage points in said heat exchanger.

16. The process of claim 15, wherein said reaction medium exits said heat exchanger and enters said esterification vessel having a conversion of at least about 50 percent.

17. The process of claim 16, wherein the conversion of said reaction medium increases by at least about 2 percentage points in said esterification vessel.

18. The process of claim 15, wherein the temperature of said reaction medium increases by at least about 50°F in said heat exchanger.

19. The process of claim 15, wherein the residence time of said reaction medium in said heat exchanger is less than about 60 minutes.

20. The process of claim 15, wherein said heat exchanger comprises tubes at least partly surrounded by a heat transfer medium, wherein said reaction medium flows through said tubes.

21. The process of claim 20, wherein the volume of said esterification vessel is greater than the aggregate internal volume defined by all the tubes of said heat exchanger.

22. The process of claim 1, further comprising transporting at least a portion of a liquid phase of said reaction medium from a liquid outlet of said esterification vessel to a fluid inlet of said esterification vessel via a recirculation loop.

23. The process of claim 22, wherein the total volume of said esterification vessel is at least about 50 percent of the total internal volume defined by said recirculation loop.

24. The process of claim 22, wherein the total volume of said esterification vessel is at least about 75 percent of the total internal volume defined by said recirculation loop.

25. The process of claim 22, wherein said recirculation loop includes a heat exchanger for heating said reaction medium prior to introduction into said esterification vessel and a recirculation pump for pumping said at least a portion of said liquid phase.

26. The process of claim 22, further comprising withdrawing a product portion of said liquid phase from said recirculation loop and subjecting at least a fraction of said product portion to further esterification in a downstream esterification zone and/or subjecting said product portion to polycondensation in a downstream polycondensation zone.

27. The process of claim 22, further comprising introducing an acid into said recirculation loop.

28. The process of claim 27, wherein said acid is a solid when introduced into said recirculation loop, wherein said liquid phase aids in the dissolution of said acid.

29. The process of claim 27, further comprising introducing an alcohol into said recirculation loop.

30. The process of claim 1, wherein said reaction medium comprises an acid and an alcohol.

31. The process of claim 30, wherein said acid comprises terephthalic acid and said alcohol comprise ethylene glycol.

32. A process comprising:

- (a) subjecting a reaction medium to esterification in an esterification reactor to thereby produce a first product;
- (b) introducing at least a portion of said first product into a disengagement vessel;
- (c) withdrawing separate liquid and vapor products from said disengagement vessel; and
- (d) routing at least a portion of the withdrawn liquid phase back to said first esterification reactor via a recirculation loop, wherein the internal volume defined by said disengagement vessel is at least about 50 percent of the combined internal volume defined by said recirculation loop and said esterification reactor.

33. The process of claim 32, wherein the internal volume defined by said disengagement vessel is at least about 75 percent of the combined internal volume defined by said recirculation loop and said esterification reactor.

34. The process of claim 32, wherein the internal volume defined by said disengagement vessel is at least 150 percent of the combined internal volume defined by said recirculation loop and said esterification reactor.

35. The process of claim 32, wherein said disengagement vessel is horizontally elongated and has a length-to-diameter (L:D) ratio in the range of from about 1.25:1 to about 8:1.

36. The process of claim 32, wherein said reaction medium is heated by at least 50°F in said esterification reactor.

37. The process of claim 32, wherein said first product has a conversion of at least about 50 percent.

38. The process of claim 32, wherein the average residence time of said reaction medium in said esterification reactor is less than about 60 minutes.

39. The process of claim 32, wherein the average residence time of the liquid in said disengagement vessel is less than about 45 minutes.

40. The process of claim 32, subjecting at least a portion of said first product to further esterification in said disengagement vessel to thereby produce a second product having a conversion at least 2 percentage points greater than the conversion of said first product.

41. An apparatus comprising: a disengagement vessel defining a fluid inlet, a liquid outlet, and a vapor outlet, wherein said disengagement vessel is elongated along a substantially horizontal axis, wherein said disengagement vessel has a length-to-diameter (L:D) ratio of less than about 10:1, wherein said fluid inlet is horizontally spaced from said liquid and vapor outlets by at least about 1.25D, wherein said vapor and liquid outlets are vertically spaced from one another by at least about 0.5D.

42. The apparatus of claim 41, wherein said disengagement vessel has an L:D ratio in the range of from about 1.25:1 to about 8:1.

43. The apparatus of claim 41, further comprising a fluid distributor coupled to said disengagement vessel in fluid communication with said fluid inlet, wherein said fluid distributor defines at least one generally downwardly facing discharge opening.

44. The apparatus of claim 41, further comprising a baffle coupled to and extending downwardly in the disengagement vessel, wherein said baffle is disposed generally between said fluid inlet and said vapor outlet and closer to said vapor outlet than to said fluid inlet, wherein said baffle presents a bottom

edge that is vertically spaced from the bottom of said disengagement vessel by at least about 0.25D.

45. The apparatus of claim 41, further comprising a reactor defining a reactor inlet, a reactor outlet, and a flow passageway extending from said reactor inlet to said reactor outlet, wherein said reactor outlet is coupled in fluid communication with said fluid inlet, wherein the volume defined within said disengagement vessel is greater than the volume defined by said flow passageway.

46. The apparatus of claim 45, wherein said reactor is a heat exchanger comprising a plurality of tubes located inside a shell, wherein said tubes define at least a portion of said flow passageway.

47. The apparatus of claim 46, further comprising a recirculation loop for providing fluid communication between said liquid outlet and said reactor inlet, wherein the volume defined within said disengagement vessel is at least about 50 percent of the combined volume defined by said recirculation loop and said flow passageway.

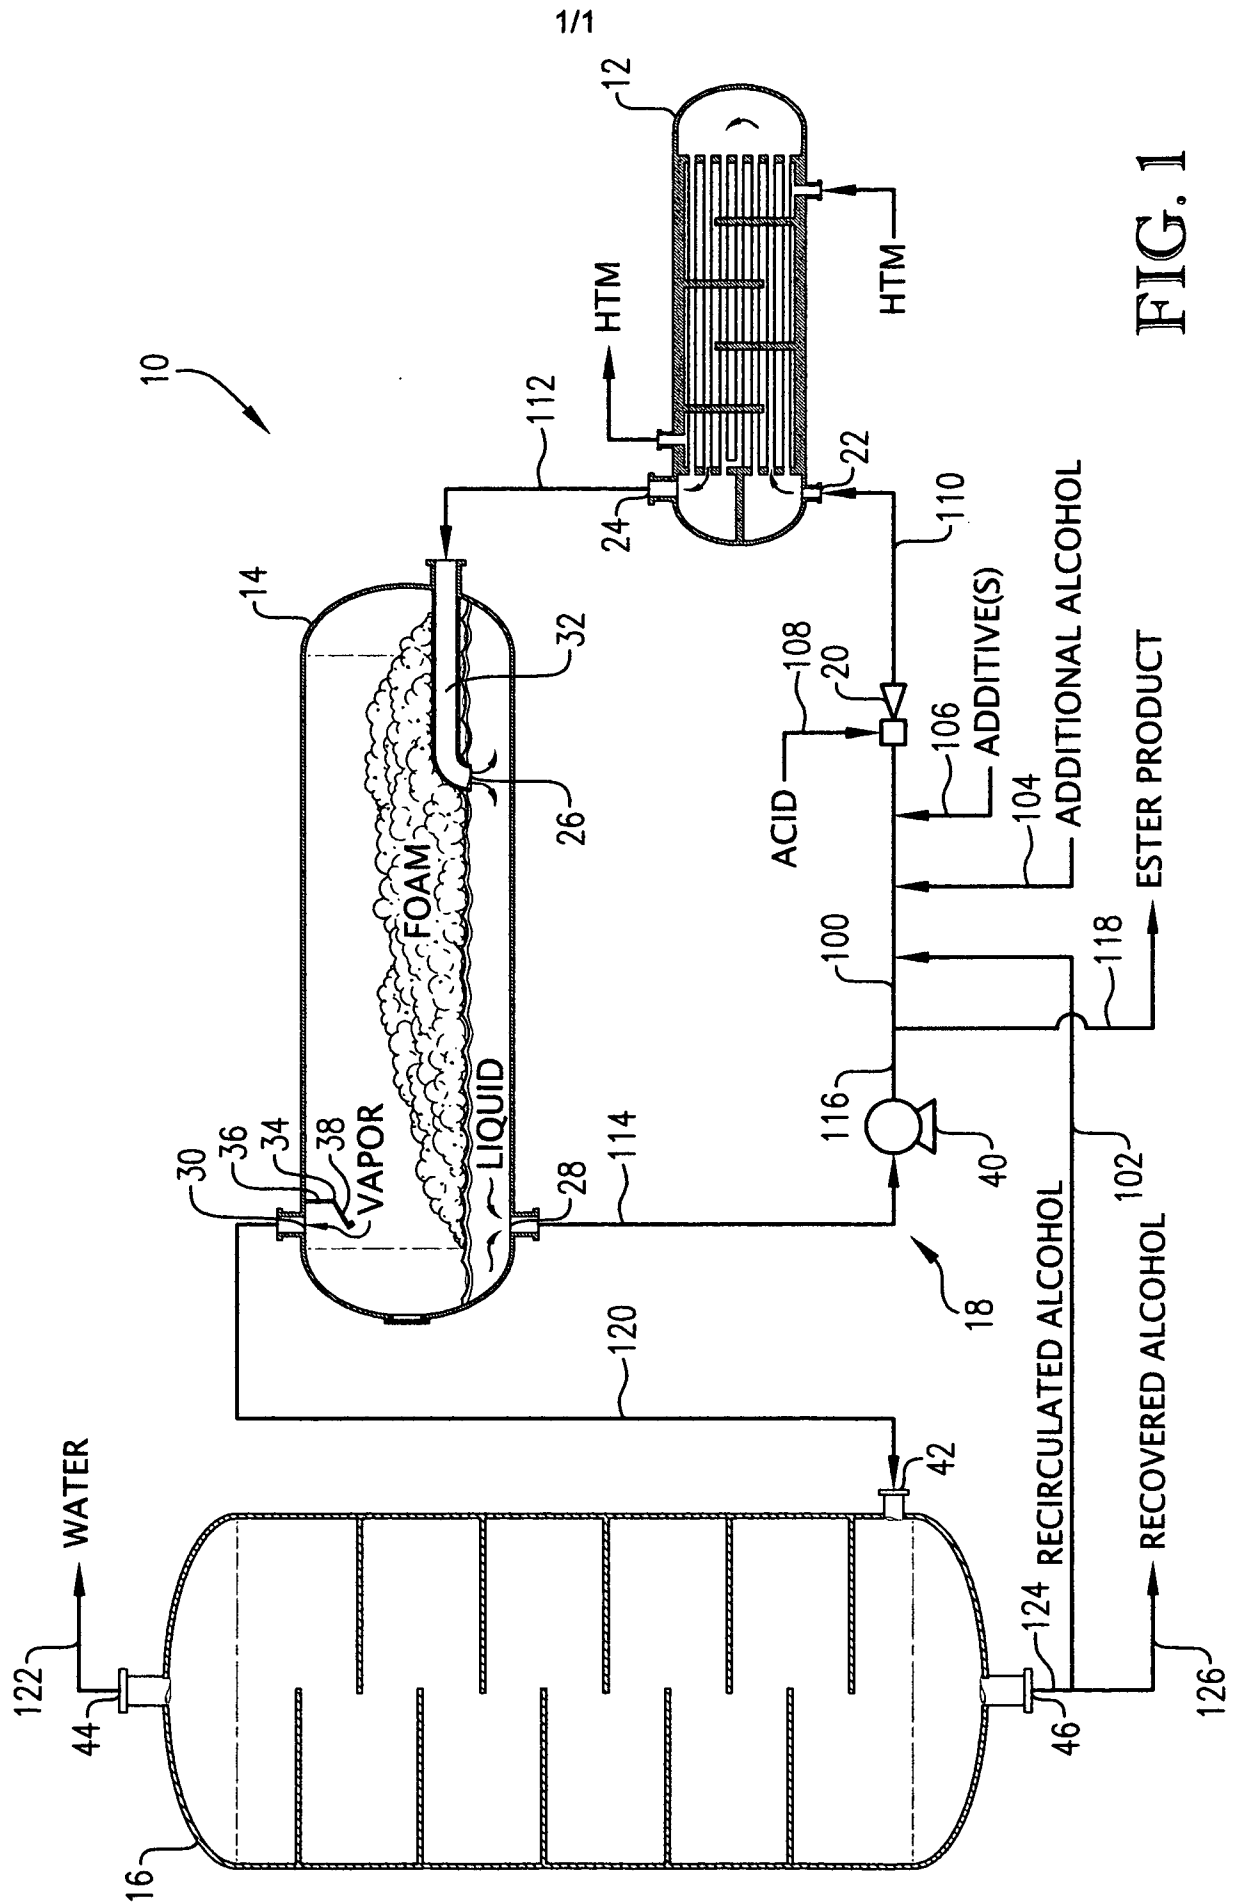

FIG. 1
