(54) Title: COMPOSITIONS FOR REDUCING BACTERIAL CARRIAGE AND CNS INVASION AND METHODS OF USING SAME

(57) Abstract: Provided herein are compositions designed to reduce or prevent bacterial infections (for example, pneumococcal infections), nasal carriage, nasal colonization, and central nervous system invasion. Provided herein is a composition comprising a pneumococcal neuraminidase, phosphocholine, pneumococcal teichoic acid, pneumococcal lipoteichoic acid, or an antigenic portion of either neuraminidase, phosphocholine, pneumococcal teichoic acid, pneumococcal lipoteichoic acid. Optionally, the composition can comprise any combination of a pneumococcal neuraminidase, a phosphocholine, a pneumococcal teichoic acid, a pneumococcal lipoteichoic acid or an antigenic portion of any one of these. Optionally the agents are detoxified. Further provided are methods of making and using the compositions disclosed herein. Specifically provided are methods of generating antibodies in a subject comprising administering to the subject an agent or composition taught herein. Also provided are methods of reducing or preventing nasal carriage or pneumococcal infection in a subject comprising administering to the subject a composition taught herein.
Designated States (unless otherwise indicated, for every kind of regional protection available): ARIPO (BW, GH, GM, KE, LS, MW, MZ, NA, SD, SL, SZ, TZ, UG, ZM, ZW), Eurasian (AM, AZ, BY, KG, KZ, MD, RU, TJ, TM), European (AT, BE, BG, CH, CY, CZ, DE, DK, EE, ES, FI, FR, GB, GR, HU, IE, IS, IT, LU, MC, NL, PL, PT, RO, SE, SI, SK, TR), OAPI (BF, BJ, CF, CG, CI, CM, GA, GN, GQ, GW, ML, MR, NE, SN, TD, TG).

Published: without international search report and to be republished upon receipt of that report

For two-letter codes and other abbreviations, refer to the "Guidance Notes on Codes and Abbreviations" appearing at the beginning of each regular issue of the PCT Gazette.
COMPOSITIONS FOR REDUCING BACTERIAL CARRIAGE AND CNS INVASION AND METHODS OF USING SAME

CROSS-REFERENCE TO RELATED APPLICATION

This application claims the benefit of U.S. Provisional Application No. 60/518,799, filed on November 10, 2003, which is hereby incorporated herein by reference in its entirety.

ACKNOWLEDGEMENTS

This invention was made with government support under Grants DC 04976, AI 21548, and P30 DK 54781 from the National Institutes of Health and under contract NO1 AI 65299 from the National Institute of Allergy and Infectious Diseases. The government has certain rights in the invention.

BACKGROUND

*S. pneumoniae* is a rather ubiquitous human pathogen, which can infect several organs including lungs, the central nervous system (CNS), the middle ear, and the nasal tract. Infection of these tissues results in various symptoms such as bronchitis, pneumonia, meningitis, and sinus infection. *S. pneumoniae* is a major cause of bacterial meningitis in humans and is associated with significant mortality and morbidity despite antibiotic treatment. Quagliarello et al., (1992) N. Eng. J. Med. 327:869-872. *S. pneumoniae* meningitis can cause persistent neurological sequelae. The incidence of *S. pneumoniae* meningitis in developed versus developing countries are 1-2 and 20 per 100,000 population, respectively. Anon, (2000) CDSC European Bacterial Meningitis Surveillance Project. The fatality rate of pneumococcal meningitis in the USA is approximately 18%. Fedson et al., (1994) Arch. Intern. Med. 154:2531-2535. The highest incidence of pneumococcal meningitis occurs in children between 1-4 years of age (30 % of all bacterial meningitis), followed by 15-19 year olds (14 %) and 1-11 month old infants (13 %). Anon, (2000) CDSC European Bacterial Meningitis...

The major reservoir of pneumococci in the world resides in human nasal carriage. Acquisition of infection is generally from a carrier and infection is always preceded by nasal carriage. The colonization of the nasopharynx is considered a prerequisite for the spread of pneumococci to the lower respiratory tract, the nasal sinuses, and the middle ear. Thus, any medical intervention that prevented carriage would not only eliminate the risk of disease in the treated individuals but would also result in herd immunity and greatly lower the risk of infection even in untreated members of the community. Although S. pneumoniae is an important human pathogen, relative little is known about the mechanisms by which S. pneumoniae causes either nasal carriage or meningitis.

Some data exist to suggest that neuraminidases are unique virulence factors for the nasal tract. One such observation comes from the study of the NanA-deficient, S. pneumoniae strain D39, which is eliminated faster from the nasopharynx than is its parent strain. Tong et al., (2002) Infect. Immun. 68: 921-924. Neuraminidase cleaves terminal sialic acid residues from a wide variety of glycolipids, glycoproteins, and oligosaccharides on the host cell surfaces and in body fluids. Elevated levels of free sialic acid in the cerebrospinal fluid (CSF) of patients with pneumococcal meningitis are associated with a poor prognosis. O'Toole et al., (1971) J. Clin. Invest. 50: 979-985. The importance of this enzyme for S. pneumoniae virulence in humans is further illustrated by the findings of two independent studies where every new clinical isolate of S. Pneumoniae had neuraminidase activity. O'Toole et al., (1971) J. Clin. Invest. 50: 979-985; Kelly et al., J. Bacteriol. 94: 272-273. Moreover, mouse passage of isolates of pneumococci, which frequently increases their virulence, has been reported to also result in 2-5-fold increase of neuraminidase activity. Vishniakova et al., (1992) Zhurnal Mikrobiologii, Epidemiologii i Immunobiologii 9-10: 26-9. Pneumococcal C-polysaccharide, also known as teichoic acid, is structurally identical to the polysaccharide portion of pneumococcal F-antigen, also known as lipoteichoic acid. Fischer et al., (1993) Eur. J. Biochem 215: 851-857. These molecules are unique

The mechanisms by which *S. pneumonia* causes nasal carriage and subsequent disease are relatively unknown. No studies to date have determined a mechanism by which nasal carriage is reduced or prevented. Since colonization of the nasopharynx is considered a prerequisite for the spread of pneumococci to the lower respiratory tract, the nasal sinus, systemically, and to the brain, what is needed in the art is a means of providing mucosal immunity at the site of initial pneumococcal colonization. Preventing initial pneumococcal colonization in the nasopharynx, will prevent nasal carriage and reduce spread of *S. pneumoniae* between individuals. Moreover, providing immunity at the mucosal surfaces of the nasopharynx would prevent or reduce subsequent disease caused by *S. pneumoniae*.

**SUMMARY OF THE INVENTION**

Provided herein are compositions designed to reduce or prevent bacterial infections (for example pneumococcal infections), nasal carriage, nasal colonization, and CNS invasion. Optionally, the compositions are designed for mucosal administration. Provided herein are detoxified pneumococcal neuraminidase, phosphorylcholine, pneumococcal teichoic acid, pneumococcal lipoteichoic acid, or an antigenic portion of any one of these and compositions comprising these detoxified agents.

Also provided are compositions comprising a pneumococcal neuraminidase, phosphorylcholine, pneumococcal teichoic acid, pneumococcal lipoteichoic acid, or an antigenic portion of any one of these and a pharmaceutically acceptable carrier.
Optionally, the composition can comprise any combination of a pneumococcal neuraminidase, a phosphocholine, a pneumococcal teichoic acid, a pneumococcal lipoteichoic acid or an antigenic portion of any one of these. Also provided are detoxified pneumococcal neuraminidase, phosphocholine, pneumococcal teichoic acid, pneumococcal lipoteichoic acid, or an antigenic portion of any one of these as well as compositions containing the detoxified agents and methods of using the agents.

Also provided are methods of generating in a subject antibodies to pneumococcal neuraminidase, phosphocholine, pneumococcal teichoic acid, pneumococcal lipoteichoic acid, or an antigenic portion of any one of pneumococcal neuraminidase, phosphocholine, pneumococcal teichoic acid, or pneumococcal lipoteichoic acid comprising administering to the subject a composition comprising the agents. Optionally, the composition is suitable for administration to a mucosal surface or for systemic administration.

Further provided is a composition comprising antibodies to a pneumococcal neuraminidase, phosphocholine, pneumococcal teichoic acid, pneumococcal lipoteichoic acid, or an antigenic portion of any one of these, along with a pharmaceutically acceptable carrier. Optionally the composition is suitable for administration to a mucosal surface or for systemic administration.

Further provided are methods of reducing or preventing nasal carriage, nasal colonization, or bacterial infection (for example pneumococcal infection) in a subject comprising contacting the nasal mucosa of the subject with a composition taught herein.

Additional advantages will be set forth in part in the description which follows, and in part will be obvious from the description, or may be learned by practice of the aspects described below. The advantages described below will be realized and attained by means of the elements and combinations particularly pointed out in the appended claims. It is to be understood that both the foregoing general description and the following detailed description are exemplary and explanatory only and are not restrictive.
BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings, which are incorporated in and constitute a part of this specification, illustrate several aspects described below.

Figure 1 shows nasal delivery of $3 \times 10^6$ CFU of either the nonencapsulated R36A strain or the virulent EF3030 strain of S. pneumoniae to xid mice. The neuronal tissues ON/E, OBs, brain and the lymphoid tissues (NALT, CLN and lungs) were collected, minced and analyzed for the presence of live pneumococci at 1 and 4 days after nasal challenge. Indicated is the mean of $\log_{10}$ colony forming units (CFUs) $\pm$ one standard error (SE). The 0 value on the Y-axis represents the absence of detectable CFUs. Indicated are the mean CFUs $\pm$ SE of 5 mice per group and are representative of three different experiments.

Figure 2 shows the kinetics of organ distribution of S. pneumoniae strain EF3030 CFUs after nasal challenge. The ON/E, OBs, brain, blood, NW, NALT, CLN, and lung tissues were collected on days 4, 11, 18, 25, and 39 and were analyzed for the presence of S. pneumoniae. An aliquot of $3 \times 10^6$ CFU of S. pneumoniae resulted in the colonization of the nasal tract and a subsequent infection of the OBs. The 0 value on the Y-axis represents the absence of detectable CFUs. Indicated are the mean CFU $\pm$ SE of three separate experiments. Each time point represents 10 mice with the exception of day 39, which represents 5 mice.

Figure 3 shows the distribution of S. pneumoniae strain EF3030 following preincubation with GLSs. Aliquots ($3 \times 10^7$ CFUs) of S. pneumoniae were incubated for 30 minutes with 20 $\mu$g asialo-GM1 (a-GM1) or 125 $\mu$g of mixed GLSs (MG) prior to nasal application. The ON/E, OBs, brain and NW, NALT and lungs were collected four days later and analyzed for numbers of S. pneumoniae. The 0 value on the Y-axis represents the absence of detectable CFUs. Indicated are the mean $\pm$ one SE of 5 mice and the P-values were obtained following statistical analysis. The data are representative of two separate experiments.

Figure 4 shows detection of the TIGR4 strain of S. pneumoniae in the OBs following nasal challenge. An aliquot of $5 \times 10^5$ CFU was given nasally and the blood, NWs, ON/E, OBs and brain tissues were analyzed for colonization one week after challenge (panels A and B). These tissues (10 $\mu$g DNA) were also analyzed for the
presence of the pneumolysin gene by PCR (panel C). In addition, the *S. pneumoniae*
were visualized by immunofluorescence with PspA-specific Abs in the OBs of control
(D) or *S. pneumoniae* challenged mice (panels E and F). Indicated are the mean ± one
SE. The data are representative of three separate experiments.

Figure 5 shows a comparison in the motifs for secreted NanA, TIGR4, and for a
R6 (type 2), which has the LPXTG (SEQ ID NO:14) motif for attachment to the cell
wall. The TIGR4 gene includes a stop-codon prior to the sequence encoding the LPETG
(SEQ ID NO:13) motif. Without this motif, NanA is secreted into the environment by
TIGR4.

Figure 6A shows the kinetics of viable pneumococci in the nasal wash of
CBA/N mice infected i.n. with the *S. pneumoniae* parental strain TIGR4 (■) or the
NanA isogenic mutant TIGR4/nanA- (○). Each point represents the total number of
bacteria per ml of nasal wash fluid from each mouse. * P<0.05; ** P< 0.01; *** P<
0.005, compared with mice inoculated with TIGR4.

Figure 6B shows nasal colonization kinetics in CBA/N mice infected i.n. with
the *S. pneumoniae* parental strain TIGR4 (■) or the NanA isogenic mutant
TIGR4/nanA- (○). Each point represents the total number of bacteria per gram of
tissue from each mouse. * P<0.05; ** P< 0.01; *** P< 0.005, compared with mice
inoculated with TIGR4.

Figure 6C shows the kinetics of CFU in the olfactory bulb of CBA/N mice
infected i.n. with the *S. pneumoniae* parental strain TIGR4 (■) or TIGR4/nanA- (○).
Each point represents the total number of bacteria per gram of tissue from each mouse.
* P<0.05; ** P< 0.01; *** P< 0.005, compared with mice inoculated with TIGR4.

Figure 7A shows nasal colonization kinetics in CBA/N mice infected i.n. with
the *S. pneumoniae* parental strain EF3030 (■) or EF3030/nanA- (○). Each point
represents the total number of bacteria per ml of nasal wash from each mouse. * P<0.05;
** P< 0.01; *** P< 0.005, compared with mice inoculated with EF3030.

Figure 7B shows nasal colonization kinetics in CBA/N mice infected i.n. with
the *S. pneumoniae* parental strain EF3030 (■) or EF3030/nanA- (○). Each point
represents the total number of bacteria per gram of tissue from each mouse. * P<0.05;
** P< 0.01; *** P< 0.005, compared with mice inoculated with EF3030.
Figure 7C shows nasal colonization kinetics in CBA/N mice infected i.n. with the *S. pneumoniae* parental strain EF3030 (■) or the NanA isogenic mutant EF3030/nanA- (○). Each point represents the total number of bacteria per gram of tissue from each mouse. * P<0.05; ** P< 0.01; *** P< 0.005, compared with mice inoculated with EF3030. When wild type and mutant data are pooled for all time points the comparison between EF3030 and EF3030 NanB- was P = 0.001.

Figure 8 shows nasal colonization kinetics in CBA/N mice infected i.n. with the *S. pneumoniae* parental strain TIGR4 (■) or TIGR4/nanB- (○) at 4 days post inoculation. Each point represents the total number of bacteria per ml of nasal wash or gram of tissue from each mouse. In no case was the difference between TIGR4 and TIGR4/nanB- statistically significant.

Figure 9 shows nasal colonization kinetics in CBA/N mice infected i.n. with the *S. pneumoniae* parental strain TIGR4 (■) TIGR4/nanA- (○) or TIGR4/AB- at 4 days post inoculation. Each point represents the total number of bacteria per ml of nasal wash or gram of tissue from each mouse. In no case was the difference between TIGR4/nanA- and the double mutant TIGR4/nanAB- statistically significant.

Figure 10 shows inhibition of nasal colonization of *S. pneumoniae* by anti-phosphocholine-specific monoclonal antibodies after nasal challenge. Inhibition of nasal colonization of *S. pneumoniae* by anti-PC-specific mAbs after nasal challenge. A total of 1 X 10^6 CFU of the TIGR4 strain were incubated with 5 μg of anti-PC mAbs of either the IgG3 subclass or IgM isotype. A total of 5 μl was administered per nare. Indicated are the CFU in 500 μl nasal wash respectively 9 and 12 hours after application. Indicated are the mean + SD of five mice per group.

**DETAILED DESCRIPTION**

Before the present compounds, compositions, articles, devices, and/or methods are disclosed and described, it is to be understood that the aspects described below are not limited to specific synthetic methods or specific administration methods, as such may, of course, vary. It is also to be understood that the terminology used herein is for the purpose of describing particular aspects only and is not intended to be limiting.

It must be noted that, as used in the specification and the appended claims, the singular forms “a,” “an” and “the” include plural referents unless the context clearly
dictates otherwise. Thus, for example, reference to "an antigenic fragment" includes mixtures of antigenic fragments, reference to "a pharmaceutical carrier" or "adjuvant" includes mixtures of two or more such carriers or adjuvants, and the like.

As used throughout, by a "subject" is meant an individual. Thus, the "subject" can include domesticated animals, such as cats, dogs, etc., livestock (e.g., cattle, horses, pigs, sheep, goats, etc.), laboratory animals (e.g., mouse, rabbit, rat, guinea pig, etc.) and birds. In one aspect, the subject is a mammal such as a primate or a human.

"Optional" or "optionally" means that the subsequently described event or circumstance can or cannot occur, and that the description includes instances where the event or circumstance occurs and instances where it does not. For example, the phrase "optionally the composition can comprise a combination" means that the composition may comprise a combination of different molecules or may not include a combination such that the description includes both the combination and the absence of the combination (i.e., individual members of the combination).

Ranges may be expressed herein as from "about" one particular value, and/or to "about" another particular value. When such a range is expressed, another aspect includes from the one particular value and/or to the other particular value. Similarly, when values are expressed as approximations, by use of the antecedent "about," it will be understood that the particular value forms another aspect. It will be further understood that the endpoints of each of the ranges are significant both in relation to the other endpoint, and independently of the other endpoint.

Provided herein are compositions and methods designed to reduce or prevent bacterial infections (for example pneumococcal infections), nasal carriage, nasal colonization, and CNS invasion. *S. pneumoniae* colonizes the nasal tract in part by crossing the epithelial barrier through C-polysaccharide-ganglioside interactions with subsequent endocytosis into epithelial cells. C-polysaccharide binds to asialo-GM1, asialo-GM2, and fucosyl-asialo-GM1 through binding to a terminal or internal GalNAcβ1-4Gal sequence in the ganglioside. Although the abundance of these asialogangliosides in the plasma membrane of cells is normally low, with the exception of the human lungs *S. pneumoniae* has two neuraminidases, NanA and NanB (Berry et al., (1996) J. Bacteriol. 178: 4854-4860), which can each cleave α2,3- and α2,6-
linkages of N-acetylneuraminic acid to galactose, and α2,6-linkage to N-acetyl-
gangliosides are α2,3 linked to galactose. Neuraminidases of S. pneumoniae remove
end-terminal sialic acid residues, which are present on all monosialogangliosides, and
galactose-linked multiple sialic acid residues, as seen in the di- and trisialogangliosides.
Thus, they should be able to expose the GaINAcβ1-4Gal sequence found in the most
common mammalian cell surface gangliosides. These residues are the presumed C-
polysaccharide binding site on the cell surface. Using its NanA, which is normally
more cell wall associated, and NanB, which is thought to be secreted, S. pneumoniae
generates its own attachment sites on epithelial cells in the respiratory tract. Thus,
pneumococcal C-polysaccharide binds to asialo-gangliosides, in particular asialo-GM1,
and the neuraminidases, which can convert the rather abundant GM1 into asialo-GM1,
may create abundant binding sites on ON/E for the C-polysaccharide. This mechanism
facilitates nasal carriage and provides access for S. pneumoniae to the CNS through the
nasal olfactory nerves and epithelium covering the nasal turbinates (ON/E), olfactory
bulbs (OB). Similarly, otitis media and other infections involving S. pneumoniae can
similarly gain access to the CNS through nerves innervating the middle ear. Other
bacteria in addition to S. pneumoniae have comparable neuraminidases, thus the same
mechanism occurs in other bacteria as well. Thus disclosed herein are compositions
and methods targeting this mechanism in a variety of bacteria. The agents,
compositions, and methods taught herein are directed to interrupting this mechanism to
reduce carriage and to prevent CNS invasion.

Optionally, the compositions are designed for mucosal administration. For
example, provided herein is a composition comprising a pneumococcal neuraminidase,
a phosphocholine, a pneumococcal teichoic acid, a pneumococcal lipoteichoic acid or
an antigenic portion of any one of these and a pharmaceutically acceptable carrier,
wherein the composition is suitable for administration to a mucosal surface. Optionally,
the composition can comprise any combination of a pneumococcal neuraminidase, a
phosphocholine, a pneumococcal teichoic acid, a pneumococcal lipoteichoic acid or an
antigenic portion of any one of these.
Optionally, the composition is in the form of an aerosol, nasal mist, nasal spray, nasal drops, a nebulizer solution, an aerosol inhalant, a suppository, or any form appropriate for mucosal administration (including oral administration). Optionally, the compositions can be in microspheres or in liposomes for delivery. By “administration to a mucosal surface” is meant administration to any mucosal surface including the respiratory system, the gastrointestinal system, or the urogenital system. Examples of mucosal surfaces include but are not limited to the nasal cavity (including to the olfactory neuroepithelium), the nasopharynx, the rectum, the vagina, the larynx, the mouth, the Eustachian tube, the trachea, the bronchi and other airways, and the intestinal mucosa.

For administration to a mucosal surface a mucosal adjuvant can be used. The adjuvant can administered concomitantly with the composition of the invention, immediately prior to, or after administration of the composition. Optionally, the composition further comprises the adjuvant. Mucosal adjuvant formulations include, for example, an agent that targets mucosal inductive sites. The adjuvant may optionally be selected from the group including, but not limited to, cytokines, chemokines, growth factors, angiogenic factors, apoptosis inhibitors, and combinations thereof. When a cytokine is chosen as an adjuvant, the cytokine may be selected from the group including, but not limited to, interleukins including IL-1, IL-1γ, IL-1β, IL-2, IL-5, IL-6, IL-12, IL-15 and IL-18; transforming growth factor-beta (TGF-β); granulocyte macrophage colony stimulating factor (GM-CSF); interferon- gamma (IFN-γ); or other cytokine which has adjuvant activity. Portions of cytokines, or mutants or mimics of cytokines (or combinations thereof), having adjuvant activity or other biological activity can also be used in the compositions and methods of the present invention.

When a chemokine is chosen as an adjuvant, the chemokine may optionally be selected from a group including, but not limited to, Lymphotactin, RANTES, LARC, PARC, MDC, TAR.C, SLC and FKN. When an apoptosis inhibitor is chosen as an adjuvant, the apoptosis inhibitor may optionally be selected from the group including, but not limited to, inhibitors of caspase-8, and combinations thereof. When an angiogenic factor is chosen as an adjuvant, the angiogenic factor may optionally be selected from the group including, but not limited to, a basic fibroblast growth factor
(FGF), a vascular endothelial growth factor (VEGF), a hyaluronan (HA) fragment, and combinations thereof. Indeed, plus (+) and minus (-) angiogenic factors may be chosen as adjuvants.

Other examples of substantially non-toxic, biologically active mucosal adjuvants of the present invention include hormones, enzymes, growth factors, or biologically active portions thereof. Such hormones, enzymes, growth factors, or biologically active portions thereof can be of human, bovine, porcine, ovine, canine, feline, equine, or avian origin, for example, and can be tumor necrosis factor (TNF), prolactin, epidermal growth factor (EGF), granulocyte colony stimulating factor (GCSF), insulin-like growth factor (IGF-1), somatotropin (growth hormone) or insulin, or any other hormone or growth factor whose receptor is expressed on cells of the immune system.

Adjuvants for mucosal administration also include bacterial toxins, e.g., the cholera toxin (CT), the E. coli heat-labile toxin (LT), the Clostridium difficile toxin A and the pertussis toxin (PT), or combinations, subunits, toxoids, chimera, or mutants thereof. For example, a purified preparation of native cholera toxin subunit B (CTB) can be used. Fragments, homologs, derivatives, and fusions to any of these toxins are also suitable, provided that they retain adjuvant activity. Preferably, a mutant having reduced toxicity is used. Suitable mutants are described, e.g., in WO 95/17211 (Arg-7-Lys CT mutant), WO 96/6627 (Arg-192-Gly LT mutant), and WO 95/34323 (Arg-9-Lys and Glu-129-Gly PT mutant). Additional LT mutants that can be used in the methods and compositions of the invention include, e.g., Ser-63-Lys, Ala-69-Gly, Glu-110-Asp, and Glu-112-Asp mutants. Other adjuvants, such as RH3-ligand; CpG-motif oligonucleotide; a bacterial monophosphoryl lipid A (MPLA) of, e.g., E. coli, Salmonella minnesota, Salmonella typhimurium, or Shigella flexneri; saponins (e.g., QS21), or polylactide glycolide (PLGA) microspheres, can also be used in mucosal administration. Possible other mucosal adjuvants are defensins and CpG motifs containing oligonucleotides.

As used throughout, a “pharmacologically acceptable carrier” is meant as a material that is not biologically or otherwise undesirable, i.e., the material can be administered to an individual along with the selected compound without causing any
undesirable biological effects or interacting in a deleterious manner with any of the other components of the pharmaceutical composition in which it is contained.

Any of the compositions described herein can be used therapeutically with a pharmaceutically acceptable carrier. The compounds described herein can be conveniently formulated into pharmaceutical compositions composed of one or more of the compounds in association with a pharmaceutically acceptable carrier. See, e.g., *Remington's Pharmaceutical Sciences*, latest edition, by E.W. Martin Mack Pub. Co., Easton, PA, which discloses typical carriers and conventional methods of preparing pharmaceutical compositions that can be used in conjunction with the preparation of formulations of the compounds described herein and which is incorporated by reference herein. These most typically would be standard carriers for administration of compositions to humans. In one aspect, humans and non-humans, including solutions such as sterile water, saline, and buffered solutions at physiological pH. Other compounds will be administered according to standard procedures used by those skilled in the art.

The pharmaceutical compositions described herein can include, but are not limited to, carriers, thickeners, diluents, buffers, preservatives, surface active agents and the like in addition to the molecule of choice. Pharmaceutical compositions can also include one or more active ingredients such as antimicrobial agents, antiinflammatory agents, anesthetics, and the like.

By a pneumococcal neuraminidase is meant any neuraminidase molecule found in pneumococcal bacteria. Table 1 shows the alignment of neuraminidases from several species. Neuraminidase molecules also include, for example, SP1326. The SP1326 amino acid sequence can be accessed via GenBank Accession No. AAK75424. Tettelin, H., et al., (2001) Science 293: 498-506. All of the information, including any amino acid and nucleic acid sequences provided for SP1326 under GenBank Accession No. AAK75424 is hereby incorporated in its entirety by this reference. As identified throughout, the amino acid residues for all amino acid sequences are numbered in accordance with the amino acid sequence of pneumococcal strain R6 as shown in Table 1.

</table>
Any antigenic variant of neuraminidase could also be used in the compositions or methods taught herein. Thus, the naturally occurring neuraminidase can be modified by substitution, deletion, or alteration of amino acid residues in accordance with the methods taught herein. Optionally, such modifications will be designed to detoxify the neuraminidase. By "detoxification" is meant a reduction or elimination in enzymatic activity, while maintaining antigenicity or immunogenicity. This is accomplished by substitution, deletion, or alteration of amino acids in the active site of the neuraminidase using site specific mutagenesis. Preferably, such substitutions, deletions, or alterations will be within the Asp boxes (i.e., within amino acid residues 460-480, 530-560, or 600-620). See Cremer et al., PNAS 90:9852-9856, which is incorporated herein by reference in its entirety for the neuraminidase structure taught therein. Such substitutions, deletions, or alterations can also occur within the Asp boxes within amino acid residues 383-387, 467-473, 541-546, or 610-616. Alterations in the Asp boxes can include replacement of aspartic acid with glutamic acid or threonine, for example. Other conservative or non-conservative amino acid replacements can also be used at the aspartic acid residue or any other residue in the Asp boxes to reduce toxicity. Other regions of the neuraminidase are optionally targeted for site specific mutagenesis. For example, modifications within the region corresponding to residues 570-580, including for example conservative and non-conservative amino acid substitutions of valine or glutamine at position 572 are disclosed. Also disclosed are neuraminidases with modifications in the regions corresponding to residues 750-760, and more specifically the tyrosine at position 754. Conservative amino acid substitutions for the tyrosine residue include, for example, serine or threonine. Also provided are neuraminidases with modifications in the regions corresponding to amino acid residues 340-350, 600-610, or 360-370. More specifically, the arginines at positions 347, 605, 366, or 367 can be substituted with lysine or glutamine, or any other conservative or non-conservative amino acids. The various modifications taught herein can be used in combination. Thus, one or more conservative or non-conservative amino acid substitutions are optionally present in the same neuraminidase.

As described above, a detoxified neuraminidase is a neuraminidase that exhibits
decreased activity as compared to non-detoxified neuraminidase as measured by the assay of Lock, et al. (Microb. Pathog. 4: 33-43, 1988), which is well-known in the art. Using the Lock assay, NanA activity in lysates, serum, or blood are measured using 2'-
(4-methyl-umbelliferyl)-α-D-N-acetylneuraminic acid as the substrate in a enzyme assay (Lock et al. 1988). Ten microliters of substrate are combined with 10µL of serum and incubated for 5 minutes at 37°C. The reaction is stopped using 0.5M sodium carbonate. Neuraminidase activity is measured in terms of the amount of 4-
methylumbelliferone (MU) released per minute. MU has an excitation wavelength of 366nm and an emission wavelength of 445nm. It is preferred that the detoxified neuraminidase retain antigenicity or immunogenicity comparable to that of non-detoxified neuraminidase, such that it may be combined with a pharmaceutically acceptable carrier to form an immunological composition. For purposes of comparison, non-detoxified neuraminidase includes, but is not limited to, R6 NanA as shown in Table 1. In preferred embodiments, detoxified neuraminidase exhibits at least 60%, 70%, 80%, or 90% of the activity of a non-detoxified neuraminidase.

Detoxified neuraminidase includes alterations (i.e., substitutions, modifications, or deletions) in its amino acid sequence as compared to non-detoxified neuraminidase. In preferred embodiments, detoxified neuraminidase includes alteration of approximately 7%, 10%, 15% or 20% of the amino acids found within non-detoxified neuraminidase. Preferred amino acid deletions include the deletion of approximately 5, 10 or 15 amino acids from the N-terminus of non-detoxified neuraminidase. Other preferred embodiments include the deletion of approximately 60, 50, 40, 30, 20, 10 or 5 amino acids of the C-terminus of non-detoxified neuraminidase (for the purposes of this application, the C-terminus begins at amino acid 800 of R6 NanA as shown in Table 1). In yet other preferred embodiments, detoxified neuraminidase includes deletion of 17, 9, 8, 7, 4 or 2 amino acids of the C-terminus of non-detoxified neuraminidase. Certain exemplary preferred deletions are illustrated in Table 1 (i.e., the TIGR4 NanA amino acid sequence). Any of these alterations may be combined with one or more other alterations. It is preferred that such detoxified neuraminidase species exhibit approximately 60%, 70%, 80% or 90% of the activity of non-detoxified neuraminidase.
Other conservative and non-conservative substitutions in neuraminidase may be used so long as the neuraminidase maintains its antigenicity or immunogenicity. These conservative substitutions are such that a naturally occurring amino acid is replaced by one having similar properties. Such conservative and nonconservative substitutions optionally alter the enzymatic function of the polypeptide. For example, conservative substitutions can be made according to Table 2.

It is understood that, where desired, modifications and changes may be made in the nucleic acid encoding the polypeptides of this invention and/or amino acid sequence of the polypeptides of the present invention and still obtain a polypeptide having like or otherwise desirable characteristics (e.g., antigenicity or immunogenicity). Such changes may occur in natural isolates or may be synthetically introduced using site-specific mutagenesis, the procedures, such as miss-match polymerase chain reaction (PCR), are well known in the art. For example, certain amino acids may be substituted
for other amino acids in a polypeptide without appreciable loss of functional activity. It is thus contemplated that various changes may be made in the amino acid sequence of the polypeptides of the present invention (or underlying nucleic acid sequence) without appreciable loss of biological utility or activity and possibly with an increase in such utility or activity.

Deletions of the nanA gene or any portion of the nanA gene are carried out using the method described by Sung et al., (2001) Appl Environ Microbiol 67: 5190-5196, which is incorporated herein by reference in its entirety for the methods taught therein. The reagent 2, 3 butadione, which specifically reacts with Arg residues of proteins, is used to assess the importance of Arg residues to the folding of the NanA molecule. Site-directed mutagenesis is used to alter specific amino-acids.

The neuraminidase can also be detoxified by chemical treatment, including for example denaturation. Chemical treatment can also be combined with site-specific mutagenesis to further reduce negative side effects and improving antigenicity or immunogenicity. The detoxified neuraminidase can be treated with an agent such as formalin, glutaraldehyde, heat, or with other agents known to those skilled in the art, prior to immunization of a subject with the detoxified neuraminidase.

Thus provided herein is a detoxified pneumococcal neuraminidase or an antigenic or immunogenic portion thereof. Also provided are compositions comprising the detoxified pneumococcal neuraminidase and a pharmaceutically acceptable carrier. Optionally the composition further comprises an adjuvant (including, for example, a mucosal adjuvant).

Furthermore, moieties can be added to the neuraminidase, including, for example, moieties that increase antigenicity or immunogenicity. Such moieties include, for example, cytokines, chemokines, growth factors, angiogenic factors, apoptosis inhibitors, hormones, toxins, or other moieties discussed herein for use as adjuvants. The moieties can optionally be modified or truncated for use in the altered molecules. Thus provided herein is a pneumococcal neuraminidase chimera comprising the neuraminidase or an antigenic or immunogenic fragment thereof and a moiety that enhances antigenicity or immunogenicity. Also provided are compositions comprising the pneumococcal neuraminidase derivatives and a pharmaceutically acceptable carrier.
Optionally the composition further comprises an adjuvant (including, for example, a
mucosal adjuvant).

Optionally the modified neuraminidase fragment or portion thereof of the
invention has an amino acid sequence with at least about 70% homology with a
naturally occurring pneumococcal neuraminidase or fragment thereof. Further provided
are nucleic acids that encode the modified neuraminidases or fragments thereof. It is
understood that one way to define any known variants and derivatives or those that
might arise, of the disclosed nucleic acids and proteins herein is through defining the
variants and derivatives in terms of homology to specific known sequences. For
example, the amino acid sequence encoded by the nanA gene of the R6 pneumococcal
strain as shown in Table 1 sets forth a particular sequence of a pneumococcal
neuraminidase and sets forth a particular amino acid sequence of the protein.
Specifically disclosed are variants of this sequence herein disclosed which have at least,
70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92,
93, 94, 95, 96, 97, 98, 99 percent homology to the stated sequence. Those of skill in the
art readily understand how to determine the homology of two proteins or nucleic acids.
For example, the homology can be calculated after aligning the two sequences so that
the homology is at its highest level.

Another way of calculating homology can be performed by published
algorithms. Optimal alignment of sequences for comparison may be conducted by the
the homology alignment algorithm of Needleman and Wunsch, J. Mol Biol. 48: 443
Sci. U.S.A. 85: 2444 (1988), by computerized implementations of these algorithms
(GAP, BESTFIT, FASTA, and TFASTA in the Wisconsin Genetics Software Package,
Genetics Computer Group, 575 Science Dr., Madison, WI), or by inspection. The same
types of homology can be obtained for nucleic acids by for example the algorithms
are herein incorporated by reference for at least material related to nucleic acid
alignment.
By "a pneumococcal phosphocholine, a pneumococcal teichoic acid, a pneumococcal lipoteichoic acid" is meant a phosphocholine, a teichoic acid, or a lipoteichoic acid present in pneumococcal bacteria. These compounds can be modified, detoxified, or enhanced as described above for the neuraminidase. Provided herein are compositions comprising the modified, detoxified, and enhanced compounds.

By "an antigenic portion thereof" is meant any epitope of a molecule or compound (e.g., neuraminidase, phosphocholine, a pneumococcal teichoic acid, a pneumococcal lipoteichoic acid) that elicits antibody production, wherein the antibody is directed to the molecule. Preferably, the antigenic portion elicits immunity to the molecule or to \textit{S. pneumoniae}. Preferably the antibodies are directed to or interfere with active sites of the neuraminidase. Examples of antigenic fragments include, but are not limited to, residues corresponding to residues 63-361 of the NanA-R6 amino acid sequence, in the presence or absence of conservative amino acid substitutions or modifications. Other examples include the Asp regions of neuraminidase (corresponding to residues 460-480, 530-560, 610-620 of the NanA-R6 amino acid sequence) and regions corresponding to 340-350, 360-370, 600-610, 570-580 and 750-760 of the NanA-R6 amino acid sequence, in the presence or absence of conservative amino acid substitutions or modifications. Optionally, the antibodies directed to interfere with active sites of neuraminidase can bind to or prevent binding to arginine residues of NanA located at residue 347, 367 or 605 of SEQ ID NO:15, or to Asp-boxes of NanA located at residues 383-387, 467-473, 541-546 and 610-616 of SEQ ID NO:15. Moreover, the antibodies can also bind or prevent binding to valine located at residue 575 of SEQ ID NO:15 or tyrosine located at residue 752 of SEQ ID NO:15. The antibody can also bind to or prevent binding to any combination of the above listed residues of SEQ ID NO:15.

Other examples of NanA fragments include amino acids 1 to 340, 330 to 630, 620 to 800, 700 to 1030 and 330 to 800. Further provided are fragments that are fusions of two or more of these fragments. Fused fragments include, but are not limited to, regions 1 to 340 fused with regions 620-680. Fused fragments are expressed as a recombinant protein. Fragments that encode these fragments are cloned into an expression vector (pET Vectors; Novagen, Inc.) and the protein is purified.
Alternatively, fragments are generated as a synthetic polypeptide from a vendor. Fragments are used to immunize animals to generate antibodies and to crystallize in order to assess three-dimensional structures. Further provided are nucleic acids encoding the fragments in the presence or absence of conservative or non-conservative amino acid modifications, or substitutions, as described herein. Also provided are vectors or expression systems comprising the nucleic acids.

Provided herein are compositions comprising isolated antibodies that specifically bind pneumococcal neuraminidase, phosphocholine, teichoic acid, lipoteichoic acid, or an antigenic portion of one or both of these. Also provided is a composition comprising any combination of the antibodies. Such antibodies are useful in developing passive immunity to \textit{S. pneumoniae}. The antibody compositions further comprise a pharmaceutically acceptable carrier. Optionally, the composition is suitable for administration to a mucosal surface, but other routes of administration are disclosed, including systemic administration as described herein.

Also disclosed herein are methods of generating antibodies specific to pneumococcal neuraminidase, phosphocholine, teichoic acid, lipoteichoic acid, or any epitope of pneumococcal neuraminidase, phosphocholine, teichoic acid, or lipoteichoic acid. Optionally, the antibodies are generated in a subject (i.e., \textit{in vivo}) by contacting the nasal mucosa of the subject with an effective amount of a composition disclosed herein. Also, disclosed is a method of generating antibodies specific to any combination of pneumococcal neuraminidase, phosphocholine, teichoic acid, lipoteichoic acid, or any epitope of pneumococcal neuraminidase, phosphocholine, teichoic acid, or lipoteichoic acid by contacting the nasal mucosa of the subject with an effective amount of a composition comprising a combination of target molecules or antibodies that target the molecules.

Optionally, the agents described herein, whether naturally occurring, detoxified or otherwise modified, can optionally be administered as a nucleic acid, for example, within a vector. Expression of the nucleic acid would then result in contacting the subject with the desired nucleic acid expressed thereby. Thus, for example, if a nucleic acid encoding pneumococcal neuraminidase is administered to a subject in a form that
can be expressed within the subject, then the subject is contacted with the neuraminidase.

In the methods described herein which include the administration and uptake of exogenous DNA into the cells of a subject (i.e., gene transduction or transfection), the disclosed nucleic acids can be in the form of naked DNA or RNA, or the nucleic acids can be in a vector for delivering the nucleic acids to the cells, whereby the antibody-encoding DNA fragment is under the transcriptional regulation of a promoter, as would be well understood by one of ordinary skill in the art. The vector can be a commercially available preparation, such as an adenovirus vector (Quantum Biotechnologies, Inc. (Laval, Quebec, Canada). Delivery of the nucleic acid or vector to cells can be via a variety of mechanisms. As one example, delivery can be via a liposome, using commercially available liposome preparations such as LIPOFECTIN, LIPOFECTAMINE ( Gibco-BRL, Inc., Gaithersburg, MD), SUPERFECT (Qiagen, Inc. Hilden, Germany) and TRANSFECTAM (Promega Biotech, Inc., Madison, WI), as well as other liposomes developed according to procedures standard in the art. In addition, the disclosed nucleic acid or vector can be delivered in vivo by gene gun or other delivery methods such as electroporation, the technology for which is available from Genetronics, Inc. (San Diego, CA) as well as by means of a SONOPORATION machine (ImaRx Pharmaceutical Corp., Tucson, AZ).

As one example, vector delivery can be via a viral system, such as a retroviral vector system which can package a recombinant retroviral genome (see e.g., Pastan et al., Proc. Natl. Acad. Sci. U.S.A. 85:4486, 1988; Miller et al., Mol. Cell. Biol. 6:2895, 1986). The recombinant retrovirus can then be used to infect and thereby deliver to the infected cells nucleic acid encoding for example pneumococcal neuraminidase or a broadly neutralizing antibody (or active fragment thereof). The exact method of introducing the altered nucleic acid into mammalian cells is, of course, not limited to the use of retroviral vectors. Other techniques are widely available for this procedure including the use of adenoviral vectors (Mitani et al., Hum. Gene Ther. 5:941-948, 1994), adeno-associated viral (AAV) vectors (Goodman et al., Blood 84:1492-1500, 1994), lentiviral vectors (Naidini et al., Science 272:263-267, 1996), pseudotyped retroviral vectors (Agrawal et al., Exper. Hematol. 24:738-747, 1996). Physical
transduction techniques can also be used, such as liposome delivery and receptor-mediated and other endocytosis mechanisms (see, for example, Schwartenberger et al., Blood 87:472-478, 1996). This disclosed compositions and methods can be used in conjunction with any of these or other commonly used gene transfer methods.

As one example, if the antibody-encoding nucleic acid is delivered to the cells of a subject in an adenovirus vector, the dosage for administration of adenovirus to humans can range from about $10^7$ to $10^9$ plaque forming units (pfu) per injection but can be as high as $10^{12}$ pfu per injection (Crystal, Hum. Gene Ther. 8:985-1001, 1997; Alvarez and Curiel, Hum. Gene Ther. 8:597-613, 1997). A subject can receive a single injection, or, if additional injections are necessary, they can be repeated at six month intervals (or other appropriate time intervals, as determined by the skilled practitioner) for an indefinite period and/or until the efficacy of the treatment has been established.

Parenteral administration of the nucleic acid or vector, if used, is generally characterized by injection. Injectables can be prepared in conventional forms, either as liquid solutions or suspensions, solid forms suitable for solution of suspension in liquid prior to injection, or as emulsions. A more recently revised approach for parenteral administration involves use of a slow release or sustained release system such that a constant dosage is maintained. See, e.g., U.S. Patent No. 3,610,795, which is incorporated by reference herein. For additional discussion of suitable formulations and various routes of administration of therapeutic compounds, see, e.g., Remington: The Science and Practice of Pharmacy (19th ed.) ed. A.R. Gennaro, Mack Publishing Company, Easton, PA 1995.

Also disclosed is a method of reducing or preventing pneumococcal nasal carriage in a subject comprising contact of the nasal mucosa of the subject with an effective amount of a composition disclosed herein. Such administration can be useful in generating active or passive immunity to or protection against pneumococcal infection or nasal carriage.

Further provided is a method of reducing or preventing pneumococcal infection in a subject comprising contact of a mucosal surface of the subject with an effective amount of a composition disclosed herein. For example, the method can prevent pneumococcal meningitis, otitis media, pneumonia, or hemolytic uremia. Prevention or
reduction can occur by reducing nasal carriage and or preventing CNS invasion, systemic invasion, or invasion of the Eustachian tubes or lower airways.

By the term “effective amount” of a compound as provided herein is meant a nontoxic but sufficient amount of the compound to provide the desired result. As will be pointed out below, the exact amount required will vary from subject to subject, depending on the species, age, and general condition of the subject, the severity of the disease that is being treated, the particular compound used, its mode of administration, and the like. Thus, it is not possible to specify an exact “effective amount.” However, an appropriate effective amount can be determined by one of ordinary skill in the art using only routine experimentation.

The dosages or amounts of the compositions described herein are large enough to produce the desired effect in the method by which delivery occurs. The dosage should not be so large as to cause adverse side effects, such as unwanted cross-reactions, anaphylactic reactions, and the like. Generally, the dosage will vary with the age, condition, sex and extent of the disease in the subject and can be determined by one of skill in the art. The dosage can be adjusted by the individual physician based on the clinical condition of the subject involved. The dose, schedule of doses and route of administration can be varied. Preferred dosages include for nasal applications of antigen between about 1-1000 µg per immunization or any amount in between, including for example 10-100 µg.

The efficacy of administration of a particular dose of the compounds or compositions according to the methods described herein can be determined by evaluating the particular aspects of the medical history, signs, symptoms, and objective laboratory tests that are known to be useful in evaluating the status of a subject with pneumococcal infection or who is a pneumococcal carrier. These signs, symptoms, and objective laboratory tests will vary, depending upon the particular disease or condition being treated or prevented, as will be known to any clinician who treats such patients or a researcher conducting experimentation in this field. For example, if based on a comparison with an appropriate control group and/or knowledge of the normal progression of the disease in the general population or the particular individual: 1) a subject’s physical condition is shown to be improved (e.g., nasal carriage is reduced or
eliminated), 2) the progression of the disease, infection, or nasal carriage is shown to be stabilized, slowed, or reversed, or 3) the need for other medications for treating the disease or condition is lessened or obviated, then a particular treatment regimen will be considered efficacious. For example, reducing or preventing nasal carriage in a subject or in a population, avoiding or reducing the occurrence of CNS invasion or other secondary pneumococcal infections would indicate efficacy. Such effects could be determined in a single subject (e.g., by reducing the number of bacteria detected with a traditional swab of the mucosal surface) or in a population (e.g., using epidemiological studies).

The compounds and pharmaceutical compositions described herein can be administered to the subject in a number of ways depending on whether local or systemic treatment is desired, and on the area to be treated. Thus, for example, a compound or pharmaceutical composition described herein can be administered intravenously, subcutaneously, intramuscularly, encapsulated in liposomes or microspheres, as an ophthalmic solution and/or ointment to the surface of the eye, as a nasal spray, as a nebulized solution, or as an aerosol to the nasal cavities or airways. Moreover, a compound or pharmaceutical composition can be administered to a subject vaginally, rectally, intranasally, orally, by inhalation, orally, or by intubation. Optionally, the composition is administered by intravenous, subcutaneous, intramuscular, or intraperitoneal injection. The composition can be prepared in conventional forms, either as liquid solutions or suspensions, solid forms suitable for solution or suspension in liquid, or as emulsions. Optionally, administration is by slow release or sustained release system such that a constant dosage is maintained. See, e.g., U.S. Patent No. 3,610,795, which is incorporated by reference herein for the methods taught therein.

The compositions taught herein include sterile aqueous or non-aqueous solutions, suspensions, and emulsions which can also contain buffers, diluents and other suitable additives. Examples of non-aqueous solvents are propylene glycol, polyethylene glycol, vegetable oils such as olive oil, and organic esters such as ethyl oleate. Aqueous carriers include water, alcoholic/aqueous solutions, emulsions or suspensions, including saline and buffered media. Vehicles include sodium chloride solution, Ringer's dextrose, dextrose and sodium chloride, lactated Ringer's, or fixed.
oils. Preservatives and other additives can also be present such as, for example, antimicrobials, anti-oxidants, chelating agents, and inert gases and the like.

Formulations for local administration can include ointments, lotions, creams, gels, drops, suppositories, sprays, liquids, aerosols, nebulizer solutions and powders. Conventional pharmaceutical carriers, aqueous, powder or oily bases, thickeners and the like can be necessary or desirable.

Compositions for oral administration can include powders or granules, suspensions or solutions in water or non-aqueous media, capsules, sachets, or tablets. Thickeners, flavorings, diluents, emulsifiers, dispersing aids or binders can be desirable.

Provided herein are methods of reducing or preventing nasal carriage or pneumococcal infection in a subject comprising administering to a subject an effective amount of a neuraminidase inhibitor. Preferably, the neuraminidase inhibitor inhibits pneumococcal neuraminidase activity without significantly reducing the subject's endogenous neuraminidase. Thus, for example, if the neuraminidase is administered to a human, the inhibitor will preferably inhibit pneumococcal neuraminidase without reducing the human neuraminidase activity, or without reducing human neuraminidase activity such that negative side-effects results in the human. Examples of known neuraminidase inhibitors include DANA, NANA, zanamivir and oseltamivir.

Provided herein is a method of reducing or preventing nasal carriage or pneumococcal infection in a subject comprising administering to a subject an effective amount of a composition comprising antibodies or fragments thereof against pneumococcal neuraminidase, phosphocholine, pneumococcal teichoic acid, pneumococcal lipoteichoic acid, or antibodies against a portion of any one of these. Optionally this administration comprises contacting a mucosal surface of the subject with the composition. Also provided are compositions and containers containing the antibodies.

The term “phosphocholine antibody” as used herein refers to an antibody that preferentially binds to phosphocholine or an antigenic fragment thereof. Antibodies of the invention can also preferentially bind to pneumococcal teichoic acid or
pneumococcal lipoteichoic acid or antigenic portions thereof or to a neuraminidase or a fragment thereof.

The term “antibodies” is used herein in a broad sense and includes both polyclonal and monoclonal antibodies. Chimeric antibodies, and hybrid antibodies, with dual or multiple antigen or epitope specificities, and fragments, such as F(ab′)2, Fab′, Fab, scFv, and the like, including hybrid fragments can also be used in the compositions and methods described herein. Thus, fragments of the antibodies that retain the ability to bind their specific antigens are provided. For example, fragments of antibodies which maintain neuraminidase, phosphocholine, teichoic acid, or lipoteichoic acid binding activity are included within the meaning of the term “antibody fragment.” Such antibodies and fragments can be made by techniques known in the art and can be screened for specificity and activity according to the methods set forth in the Examples and in general methods for producing antibodies and screening antibodies for specificity and activity (See Harlow and Lane. Antibodies, A Laboratory Manual. Cold Spring Harbor Publications, New York, (1988)).

Conjugates of antibody fragments and antigen binding proteins (single chain antibodies) can be used in the composition of the invention. Such conjugates are described, for example, in U.S. Pat. No. 4,704,692, the contents of which are hereby incorporated by reference. The antibodies can be tested for their desired activity using in vitro assays, or by analogous methods, after which their in vivo therapeutic and/or prophylactic activities are tested according to known clinical testing methods.

The term “monoclonal antibody” as used herein refers to an antibody obtained from a substantially homogeneous population of antibodies, i.e., the individual antibodies within the population are identical except for possible naturally occurring mutations that may be present in a small subset of the antibody molecules. The disclosed monoclonal antibodies can be made using any procedure which produces monoclonal antibodies. For example, disclosed monoclonal antibodies can be prepared using hybridoma methods, such as those described by Kohler and Milstein, Nature, 256:495 (1975). In a hybridoma method, a mouse or other appropriate host animal is typically immunized with an immunizing agent to elicit lymphocytes that produce or are capable of producing antibodies that will specifically bind to the immunizing agent.
Alternatively, the lymphocytes may be immunized \textit{in vitro}, e.g., using the HIV Env-CD4-co-receptor complexes described herein.

The monoclonal antibodies may also be made by recombinant DNA methods, such as those described in U.S. Pat. No. 4,816,567 (Cabilly et al.). DNA encoding the disclosed monoclonal antibodies can be readily isolated and sequenced using conventional procedures (e.g., by using oligonucleotide probes that are capable of binding specifically to genes encoding the heavy and light chains of murine antibodies). Libraries of antibodies or active antibody fragments can also be generated and screened using phage display techniques, e.g., as described in U.S. Patent No. 5,804,440 to Burton et al. and U.S. Patent No. 6,096,441 to Barbas et al.

\textit{In vitro} methods are also suitable for preparing monovalent antibodies. Digestion of antibodies to produce fragments thereof, particularly, Fab fragments, can be accomplished using routine techniques known in the art. For instance, digestion can be performed using papain. Examples of papain digestion are described in WO 94/29348 published Dec. 22, 1994 and U.S. Pat. No. 4,342,566. Papain digestion of antibodies typically produces two identical antigen binding fragments, called Fab fragments, each with a single antigen binding site, and a residual Fc fragment. Pepsin treatment yields a fragment that has two antigen combining sites and is still capable of cross linking antigen.

The antibody fragments, whether attached to other sequences or not, can also include insertions, deletions, substitutions, or other selected modifications of particular regions or specific amino acids residues, provided the activity of the antibody or antibody fragment is not significantly altered or impaired compared to the non-modified antibody or antibody fragment. These modifications can provide for some additional property, such as to remove/add amino acids capable of disulfide bonding, to increase its bio-longevity, to alter its secretory characteristics, etc. In any case, the antibody or antibody fragment must possess a bioactive property, such as specific binding to its cognate antigen. Functional or active regions of the antibody or antibody fragment may be identified by mutagenesis of a specific region of the protein, followed by expression and testing of the expressed polypeptide. Such methods are readily apparent to a skilled practitioner in the art and can include site-specific mutagenesis of the nucleic acid

As used herein, the term “antibody” or “antibodies” can also refer to a human antibody and/or a humanized antibody. Many non-human antibodies (e.g., those derived from mice, rats, or rabbits) are naturally antigenic in humans, and thus can give rise to undesirable immune responses when administered to humans. Therefore, the use of human or humanized antibodies in the methods serves to lessen the chance that an antibody administered to a human will evoke an undesirable immune response. Thus, the compositions comprising antibodies optionally comprise humanized or fully human antibodies. Antibody humanization techniques generally involve the use of recombinant DNA technology to manipulate the DNA sequence encoding one or more polypeptide chains of an antibody molecule. Accordingly, a humanized form of a non-human antibody (or a fragment thereof) is a chimeric antibody or antibody chain (or a fragment thereof, such as an Fv, Fab, Fab', or other antigen binding portion of an antibody) which contains a portion of an antigen binding site from a non-human (donor) antibody integrated into the framework of a human (recipient) antibody.

The disclosed human antibodies can also be obtained from transgenic animals. For example, transgenic, mutant mice that are capable of producing a full repertoire of human antibodies, in response to immunization, have been described (see, e.g., Jakobovits et al., Proc. Natl. Acad. Sci. USA, 90:2551 255 (1993); Jakobovits et al., Nature, 362:255 258 (1993); Bruggemann et al., Year in Immunol., 7:33 (1993)). Specifically, the homozygous deletion of the antibody heavy chain joining region (JH) gene in these chimeric and germ line mutant mice results in complete inhibition of endogenous antibody production, and the successful transfer of the human germ line
antibody gene array into such germ line mutant mice results in the production of human antibodies upon antigen challenge. Antibodies having the desired activity are selected using Env-CD4-co-receptor complexes as described herein.

To generate a humanized antibody, residues from one or more complementarity determining regions (CDRs) of a recipient (human) antibody molecule are replaced by residues from one or more CDRs of a donor (non human) antibody molecule that is known to have desired antigen binding characteristics (e.g., a certain level of specificity and affinity for the target antigen). In some instances, Fv framework (FR) residues of the human antibody are replaced by corresponding non human residues. Humanized antibodies may also contain residues which are found neither in the recipient antibody nor in the imported CDR or framework sequences. Generally, a humanized antibody has one or more amino acid residues introduced into it from a source which is non human. In practice, humanized antibodies are typically human antibodies in which some CDR residues and possibly some FR residues are substituted by residues from analogous sites in rodent antibodies. Humanized antibodies generally contain at least a portion of an antibody constant region (Fc), typically that of a human antibody (Jones et al., Nature, 321:522 525 (1986), Reichmann et al., Nature, 332:323 327 (1988), and Presta, Curr. Opin. Struct. Biol., 2:593 596 (1992)).

Administration of the antibodies can be done as disclosed herein. Nucleic acid approaches for antibody delivery also exist. The antibodies and antibody fragments can also be administered to patients or subjects as a nucleic acid preparation (e.g., DNA or
RNA) that encodes the antibody or antibody fragment, such that the subject’s own cells take up the nucleic acid and produce and secrete the encoded antibody or antibody fragment. The delivery of the nucleic acid can be by any means known in the art.

Also disclosed herein are containers comprising the agents and compositions taught herein. Specifically, the container can be a nasal sprayer, a nebulizer, an inhaler, a bottle, or any other means of containing the composition in a form for administration to a mucosal surface. Optionally, the container can deliver a metered dose of the composition.

**EXAMPLES**

The following examples are put forth so as to provide those of ordinary skill in the art with a complete disclosure and description of how the compounds, compositions, articles, devices, and/or methods described and claimed herein are made and evaluated, and are intended to be purely exemplary and are not intended to limit the scope of what the inventors regard as their invention. Efforts have been made to ensure accuracy with respect to numbers (e.g., amounts, temperature, etc.) but some errors and deviations should be accounted for. Unless indicated otherwise, parts are parts by weight, temperature is in °C or is at ambient temperature, and pressure is at or near atmospheric. There are numerous variations and combinations of reaction conditions, e.g., component concentrations, desired solvents, solvent mixtures, temperatures, pressures and other reaction ranges and conditions that can be used to optimize the product purity and yield obtained from the described process. Only reasonable and routine experimentation will be required to optimize such process conditions.

**Example 1**

**Nasal Pneumococci Penetrate Olfactory Tissues During Carriage**

Materials and Methods

Pneumococcal Strains

The studies employed two encapsulated strains of *S. pneumoniae* EF3030, serotype 19F, and TIGR4 strain, serotype 4 and the avirulent, non-capsular strain R36A derived from the parent strain D39, serotype 2. Avery et al., (1944) J. Exp. Med. 79: 137-158. The EF3030 strain was chosen since it readily colonizes the respiratory tract in the absence of bacteremia (Briles et al., (1992) Infect. Immun. 60: 111-116) and is
incapable of sustained bacteremia following intravenous inoculation. The TIGR4 strain was more virulent, but with a modest nasal inoculum colonizes without bacteremia.

Mice

The CBA/CAHN/xid (xid) mouse strain was obtained from the Jackson Laboratory (Bar Harbor, ME). The mutation in the Bruton’s tyrosine kinase gene of these mice results in an inability to respond to thymus-independent type II antigens (Amsbaugh et al., (1972) J. Exp. Med. 136: 931-949; Berning et al., (1980) J. Immunol. 46: 506-513), but permits relatively normal T cell-dependent immune responses. These mice fail to respond to capsular polysaccharides and are reproducibly susceptible to pneumococcal infection. The xid mice were maintained under pathogen-free conditions and were used at 7-12 weeks of age.

Tissue Collection

The blood was collected into a heparinized capillary tube from the retroorbital plexus. Mice were disinfected with 70 % ethanol prior to collection of nasal wash (NW), kidney, spleen, and lungs. To prevent blood contamination of the NW an incision was made into the trachea and a 2.0 cm long Tygon tube with an outer diameter of 0.075 cm (Cole-Parmer, Vernon Hills, IL) was inserted into the nasopharynx while attached to a syringe filled with Ringer’s solution. Fluid from the syringe was expelled through the nose and three drops were collected.

The nasopharyngeal-associated lymphoreticular tissue (NALT), ON/E, OBs and remainder of the brain were obtained as described. van Ginkel et al., (2000) J. Immunol. 165: 4778-4782; Wu et al., (1997) Scand. J. Immunol 46: 506-513. The trigeminal ganglia were carefully excised from the brain with a dissection microscope. The ON/E, OBs, trigeminal ganglia, NALT and cervical lymph nodes CLNs were each homogenized in 0.5 ml Ringer’s solution and the brain and kidney each homogenized in 1.0 ml of Ringer’s solution.

Quantity of Pneumococci In Tissue Minces / Blood / External Excretions

Eight serial, three-fold dilutions were made of tissues and body fluids in sterile Ringer’s solution and plated on blood agar plates containing 4 μg/ml of gentamicin sulfate. The CFU were enumerated 24 hr after plating and incubation in a candle jar. The results were expressed as CFUs/organ, per NW or per ml of blood.
GLS Preincubation of *S. pneumoniae* Strain EF3030

To block GLS binding sites, 3X10^7 CFU of *S. pneumoniae* strain EF3030 were incubated for 30 min on ice with either 20 µg asialo-GM1 from human brain or 125 µg of mixed GLSs (18% GM1, 55% GD1a, 15% GD1b, 10% GT1b, 2% other GLSs) from bovine brain (Calbiochem-Novabiochem Corporation, Inc., La Jolla, CA). GLSs were dissolved in PBS and extensively mixed a day prior to use. The amphiphilic GLSs formed micelles in PBS allowing interaction of pneumococci with the carbohydrate moiety. Following incubation, 5 µl per nare was applied nasally to *xid* mice without further washing. Tissues were analyzed for CFUs four days later.

Detection of *S. pneumoniae* Pneumolysin Gene By PCR

To detect *S. pneumoniae* by PCR, tissues were lysed in 1% SDS with 0.1% deoxycholic acid by freeze-thawing, and incubated at 37° C for 1 hr. Proteins were removed using the cetyltrimethylammoniumbromide/NaCl precipitation method (Ausubel et al., 1987) Current Protocols in Molecular Biology, 2nd: 2.4.4, which is incorporated herein by reference for teaching of the cetyltrimethylammoniumbromide/NaCl precipitation method). Ten µg of DNA was used for PCR amplification. The pneumolysin(ply)-specific primers Ply1 5’- ATTTCTGTAAACAGCTACCAACGA-3’ (SEQ ID NO:1) and Ply2 5’- GAATTCCTGTCTTCTTTCAAGTC-3’ (SEQ ID NO:2) were added to the PCR mixture to amplify a 400 bp fragment. The PCR reaction involved a 5 min denaturation step at 94° C followed by the amplification cycle: 94° C (1 min), 55° C (1 min), and 72° C (1 min) for 30 cycles. Images of the ethidium bromide stained PCR fragments were collected on an Alpha Imager TM IS-3400 (Alpha Innotech Corporation, San Leandro, CA).

Immunofluorescent Staining Of OBs With PspA-specific Abs

Mice were nasally challenged with 5 X 10^5 CFU of the TIGR4 strain. The OBs were fixed in 10 % buffered formalin. Four µm paraffin sections (van Ginkel (2000) J. Immunol. 165: 4778-4782) were stained for PspA family 2 Abs (1:100) by incubating them for 4 hr at room temperature in a humidified chamber. Slides were washed in PBS, stained with biotinylated goat F(ab’)2 anti-rabbit IgG (1:200) (Southern Biotechnology Associates, Inc., Birmingham, AL), washed and stained with

33
streptavidin-FITC (1:100) (BD-PharMingen, San Diego, CA). Fluorescent images were collected with a Nikon microscope using a DEI-750 CE digital color video camera (Optronics, Goleta, CA) and processed with the Scion Image software (Scion Corporation, Frederick, MD).

Statistics

The data are expressed as the mean ± one standard error and the results were compared by statistical analysis to determine significant differences in CFUs using the unpaired Mann Whitney two sample rank test or student t-test.

RESULTS

The Role of the Pneumococcal Capsule in Nasal Colonization and CNS Invasion

To examine the up-take of pneumococci through primary sensory olfactory neurons, the ability of EF3030 and a non-encapsulated strain R36A to colonize the nasal tract and enter the CNS were measured at days 1 and 4 (Fig. 1). Although high CFU for both strains were observed in the ON/E on day 1, the R36A were largely absent by day 4 from the ON/E and all other tissues, consistent with earlier results indicating that some capsule is required for prolonged colonization. Magee and Yother (2001) Infect. Immun. 69: 3755-3761. EF3030 showed a clear presence in the OB and brain on both days and were present in high numbers in the NWs and NALT on day 4. These findings were consistent with axonal transport of EF3030 pneumococci into the OBs and brain after nasal challenge.

Kinetics of Nasal Colonization and CNS Invasion

EF3030 was maintained in the ON/E, OBs, NWs, and NALT at all time points over the 39 days of observation (Fig. 2). Much lower numbers of CFU were seen in the brain and CLN, and those CFU present were generally seen at 18 and 25 days.

Interestingly, the lungs did not exhibit pneumococci except at day 1 (Fig. 1) and at days 18, 25 and 39 (Fig. 2). Bacteremia did not contribute to the neuronal tissue distribution, since no CFU were detected in the bloodstream of mice during any of the experiments performed with strain EF3030 at the nasal dose used (Fig. 2). Blood was monitored for bacteremia at 1, 3, 6, 12 and 24 hr after nasal application and every subsequent day for one week. No bacteria were detected in the blood.
**S. pneumoniae Infection of Trigeminal Ganglia**

The trigeminal neurons innervate the nasopharynx and thus, *S. pneumoniae* would be expected in the trigeminal ganglia after infection of the nasal mucosa. To test this, various tissues and blood were isolated four days after inoculation and analyzed for the presence of EF3030 in new experiments. The EF3030 strain was detected in ON/E and OBs and in trigeminal ganglia (Table 3). This finding further supported that asialo-GM1 function as receptors for neuronal targeting by *S. pneumoniae*. Other GLSs likely play a role as well.

Table 3 shows the distribution of *S. pneumoniae* strain EF3030 in various tissues after nasal delivery. Tissues were isolated on day 4 after nasal application of 1 x 10^7 CFUs of strain EF3030. Blood (50 µl), ON/E, OBs, and brain tissue minces were diluted and then plated on blood agar. The trigeminal ganglia were pooled, homogenized and then plated on this medium. Indicated are the mean pneumococcal CFUs ± SE of 5 mice and are representative of three separate experiments. In the brain and blood no pneumococci were detected.

**Gangliosides Inhibit Pneumococcal Colonization**

The EF3030 strain was incubated with asialo-GM1 or mixed GLSs micelles in PBS prior to nasal application. The GLS mixture displayed the strongest inhibitory effect and reduced CFU in NW by 10 fold (*P* = 0.0365) when assessed four days after nasal application. The largest decline in CFU as a result of mixed GLS preincubation was seen in the ON/E (617-fold decline; *P* = 0.0134). Just as striking were the differences in the lungs (*P* = 0.0320) (Fig. 3B) and CNS tissue (*P* = 0.0078) (Fig. 3A), where an average of 204 and 166 CFU were present in the controls, while pneumococci
were undetectable (detection limit = 3 CFU) when incubated with GLSs. The asialo-GM1 preincubation was less efficient than mixed GLSs but still reduced colonization 25- and 63-fold in CNS (Fig. 3A) and lungs (Fig. 3B), respectively. The lungs were infected by inhaled pneumococci and their attachment to asialo-GM1, relatively abundantly present in lungs, was apparently inhibited by GLSs. This indicates that GLSs play a role in the initial attachment to epithelial cells. GLS treatments did not change pneumococcal viability. No pneumococci were detected in the blood during these experiments. Thus, GLSs constitute an important target for pneumococcal attachment to neuro-epithelium of the nasal tract and infection of lungs and CNS.

Detection of *S. pneumoniae* Accumulation in the OBs Following Nasal Challenge

The numbers of EF3030 in OBs were generally too low to make visualization of bacteria by microscopy feasible. To visualize *S. pneumoniae* in the OBs after nasal application, a more virulent strain, TIGR4, was used. Blood samples were tested from representative mice at 1, 3, 6, 12 or 24 hrs after challenge and on every subsequent day. No bacteremia was observed. The mice were sacrificed one week after challenge and tissues were analyzed for CFU (Fig. 4A and 4B). A dose of only 5 X 10^5 TIGR4 CFU resulted in ~300 CFU in the OBs (Fig. 3). The pneumococci were visualized by staining with PspA-specific Abs in the OBs (Fig. 4D-F). Pneumococci were detected in the OBs, i.e., the glomerular layer (Fig. 4F) and the external plexiform layer (Fig. 4E) of challenged mice. Pneumococci were absent in the OBs of control mice (Fig. 4D).

The TIGR4 strain was also detected by PCR amplification of the pneumolysin gene from the NWs, ON/E and OBs 6 days after nasal administration (Fig.4C). No PCR-detectable pneumococci were present in the bloodstream taken at this interval, or in any samples from non-infected mice.

**Example 2**

The role of Pneumococcal-NanA in nasopharyngeal carriage and targeting of the CNS

NanA mutants were generated in three strains of *S. pneumoniae* differing both in genetic background and localization of NanA. Strains EF3030 (type 19F) and D39 (type 2) both express a NanA that is covalently attached to the cell wall whereas the TIGR4 strain (type 4) expresses a truncated NanA that is secreted into the environment.
The role of NanB in colonization was also assessed.

**Bacterial strains and growth conditions.**

Strains used in this study are listed in Table 4.

---

All pneumococcal strains were stored at −80°C in 10% glycerol and cultured by transfer to blood agar plates and incubated at 37°C in a 5% CO2 atmosphere overnight. Cultures of pneumococci were grown in Todd-Hewitt Medium containing 0.5% yeast extract to an OD660 of 0.5 and stored frozen in aliquots at −80°C in the same broth supplement to 10% with sterile glycerol. Mutants carrying antibiotic resistant inserts were grown in the appropriate antibiotics to insure stability of the mutations.

**Construction of nanA mutants.**

NanA mutant strains JW001, SAM001, and JCP001 of parental backgrounds TIGR4, EF3030 and D39, respectively, were derived through insertion duplication mutagenesis techniques (Yother et al. (1992) J. Bact. 174:610-618, which is incorporated by reference herein in its entirety for the techniques taught therein) (Table 4). Strains TIGR4 and EF3030 were used as recipients for the transformation of donor chromosomal DNA prepared from the isogenic nanA strain D39 (Berry et al. (2000) Infect. Immun. 68:133-140). In each case, the mutants were backcrossed three times into the parental strain. The D39 mutant was also backcrossed three times into our D39 parental strain to make sure it was isogenic with the parental strain used in these studies. The mutation of D39 was made by insertion duplication mutagenesis allowed the deletion of all but an N-terminal fragment of about 650 amino acids of the mature protein (Berry et al. (2000) Infect. Immun. 68:133-140). A TIGR4/nanB isogenic mutant was constructed using insertion duplication mutagenesis techniques (Balachandran et al (2002) Infect. Immun. 70:2536-2534; Yother et al. (1992) J. Bact. 174:610-618). A 461-bp internal portion of nanB was amplified using the primers: nanBF and nanBR (Table 1), PCR was carried out using Taq PCR Mastermix (Invitrogen) and 30 cycles at 95°C 1 min., 45°C 1 min., 72°C 1 min. The fragment was cloned into pSF152. Transformation of the TIGR4 strain with the plasmid DNA were as before (Balachandran et al. (2002) Infect. Immun. 70:2526-2534). A nanA/nanB-TIGR4 double mutant was derived by transformation of the nanB/TIGR4 mutant with chromosomal DNA prepared from strain JW001.

**Mouse virulence assays.**

Female 6-12 week old CBA/CaHN-XID/J (CBA/N) mice were obtained from The Jackson Laboratory (Bar Harbor, MA). The mutation in the Bruton's tyrosine kinase gene of these mice results in an inability to respond to thymus-independent type II

**Tissue Collection.**

All mice were euthanized prior to performing nasal washes and tissue collection. The blood was collected into a heparinized capillary tube from the retroorbital plexus. Mice were disinfected with 70% ethanol before collection of nasal wash (NW), nasal tissue (including the olfactory epithelium (NT) olfactory bulbs (OB), and brain. These fluid and tissues were obtained as described above. To prevent blood contamination of the NW, an incision was made into the trachea and a 2.0-cm-long Tygon tube with an outer diameter of 0.075 cm (Cole-Parmer) was inserted into the nasopharynx while attached to a syringe filled with Ringer’s solution. Fluid from the syringe was expelled through the nose, and three drops were collected. The ON/E and OB were each homogenized in 0.5 ml of Ringer’s solution while the remainder of the brain was homogenized in 1.0 ml of Ringer’s injection solution.

**Quantitation of viable pneumococci**

Eight serial, 3-fold dilutions were made of tissues and body fluids in sterile Ringer’s solution and plated on blood agar plates containing 4 μg/ml gentamicin sulfate. The colony forming units (CFU) were enumerated 24 h after plating and incubation at 37°C in a candle jar. The assay used for neuraminidase activity has been previously described (Lock et al 1988 Microb Pathog 4:33-43, which is incorporated herein by reference in its entirety for the assay methods). Significance of results was assessed by analysis with a two sample Mann-Whitney rank test making comparisons between wild
type pneumococci and mutant pneumococci.

**In vitro studies**

The ability of the TIGR4, and its nanA and nanB mutants to bind to specific gangliosides is measured. The gangliosides used include mixed gangliosides, asialo-GM1, GM1, GD1a, GD1b, GT1 (Calbiochem) and the GM3 ganglioside (Sigma). The GM3 ganglioside lacks the terminal or internal GalNAcβ1-4Gal sequence involved in pneumococcal binding and is used as a negative control. These mixed, mono-, di- or trisialic acid containing gangliosides bind readily to ELISA plates. Initial data following short-term incubation with the TIGR4 strain indicates that pneumococci bind to asialo-GM1-coated plates but not to BSA-, GM-3, or GM1-coated plates. Using ganglioside-coated plates, the ability to attach to these plates by wildtype TIGR4 strain, the stable opaque and transparent phase variants of the TIGR4 strain, the nanA, nanB, and nanA/nanB mutant strains is compared. These analyses include short-term incubation (1 hr) and extended incubations (24 hrs) on ganglioside-coated plates. Attached pneumococci are removed from the ganglioside plates by short incubation (10-15 min.) in Todd Hewitt medium containing 0.5% yeast extract followed by repeated pipetting and plating the released bacteria on blood agar plates. Alternatively 41° C Todd Hewitt broth agar containing 0.5% yeast extract is poured on top of the attached pneumococci and the colonies are counted through the bottom of the plate. Controls include plates with no pneumococci and plates with no gangliosides but with pneumococci.

Subsequent to testing ganglioside binding, different cell lines are tested for their ability to attach pneumococci to their cell surface and internalize them. These studies focus on the rat neuronal pheochromocytoma cell line PC12 (ATCC) and the macrophage cell line P388D1. These two cell lines were chosen because of their specific attributes. The P388D1 cell line expresses high affinity PAF-R (Valone (1988) J. Immunol. 140: 2389-2394), which has been reported to be present on microglia. The PC12 cell line does not express detectable PAF-R. Brewer et al., (2002) J. NeuroChem 82: 1502-1511. Between $10^2$-$10^5$ pneumococcal CFU are added to these cell lines grown in 6 well or 24 well tissue culture plates and are incubated at 37° C for between 15 min. to 6 hrs after which the cells are extensively washed and adherent pneumococci analyzed. To determine internalization into the cells a 2 hr wash with penicillin and gentamicin is
performed prior to plating the cells on blood agar or over-laying them with 41°C Todd Hewitt broth agar containing 0.5% yeast extract. The two cell lines used reflect in vivo expression of the PAF-R normally observed in the CNS. While activated microglia abundantly express this receptor as does the P388D1 cell line, the PAF-R receptor is either absent on neuronal cells, such as the PC12 cell line, or is only expressed at low levels by discrete neuronal subpopulations. Mori et al., (1996) J. Neurosci 16: 3590-3600; Bennett et al., (1998) Cell Dath Differ. 5: 867-875. Adherence of pneumococci to both cell lines would indicate that the PAF-R is not essential for adherence and alternative receptor exist. The TIGR4 opaque and transparent variants and the nanA-, nanB-mutants and nanA/nanB double mutant are tested for adherence to these cell lines relative to that observed with the wildtype TIGR4 strain. To further analyze the role of PAF-R versus gangliosides in pneumococcal adherence, the COS-7 cell line (Gerard and Gerard (1994) J. Immunol. 152: 793-800; Honda et al., (1992) J. Lipid Med. 5: 105-107), which lack PAF-R, are transfected with the human PA4R open reading frame of 1029 bp using the pcDNA3.1/GS plasmid as previously reported (Brewer et al., (2002) J. Neuro Chem 82: 1502-1511, which is incorporated herein by reference in its entirety for the methods taught therein) and transfected using Transfast reagent (Promega). The plasmid alone is used as a control and the parameters influencing pneumococcal adherence are analyzed in the presence or absence of PAF-R. This experiment provides unequivocal data regarding the importance of PAF-R in adherence. Any adherence in PAF-R deficient cell lines is mediated by gangliosides and is subsequently blocked by preincubation with gangliosides. To further address the ability of pneumococci to attach to and penetrate epithelial cells the Detroit 562 human pharyngeal epithelial cell line (ATCC) and A549 human pulmonary epithelial cell line (ATCC) is employed using a transwell system. The Millicell®-PCF Culture (Millipore, Billerica, Mass.) plate inserts are used to grow the epithelial cell lines to confluency. Confluence is determined by measuring the transepithelial resistance using a Millipore Millicell® electrical resistance system. A resistance of at least 500 Ω per cm² indicates that a fully confluent epithelial monolayer is achieved. These cells are exposed to pneumococci to test their ability to attach to, enter into and penetrate this epithelial layer. To distinguish attachment versus internalization the epithelial cells are washed and incubated for 2 hrs with medium
containing penicillin and gentamycin. The initial focus is on the TIGR4 strain, its nanA and nanB mutants, and the double mutant. Stable transparent and opaque variants of the TIGR4 strain have been generated by sequential passages until stable variants were obtained that did not reverse following in vivo challenge. These TIGR4 variants are compared for their ability to adhere to, enter and transverse epithelial cells. Wells are loaded with $10^3$-$10^6$ CFU/well in EMEM media. At 0.5, 1, 2, 4, 8, and 24 hrs cultures are harvested both above and below the epithelial layer and analyzed for CFU. The cell layers are washed 5-6 times prior to overlaying the cells with Todd-Hewitt broth supplemented with 0.5 % yeast extract and 0.5% agar cooled to 41°C to determine the pneumococcal CFUs associated with the monolayer. The plates are incubated overnight at 37°C and 5% CO2 after which the CFU are counted. The cell lines are analyzed for expression of the PAF-R. Total RNA derived from these cell lines are analyzed by RT-PCR using the two primers, PAF-1 (5'-CCGATACACTCTCTTCCCGA-3' (SEQ ID NO:3); nucleotides 151 to 170) and PAF-2 (5'-ACAGTTGGTCTAAGGAGGC-3' (SEQ ID NO:4); nucleotides 970 to 951) resulting in a 838 bp PCR product (Stengel et al., (1997) Arterioscler. Thromb. Vasc. Biol. 17: 954-962, which is incorporated herein in its entirety for the methods taught therein). If the PAF receptor is present PAF receptor inhibitors such as octylonium bromide (Biomol Research Laboratories, Inc. Plymouth meeting, PA) or PAF (Biomol) are added to the cultures to determine the contribution of the PAF-R on epithelial adhesion and penetration. The octylonium bromide binds with high affinity to the PAF-R. Alternatively the above mentioned COS7 cells are used for this purpose and compare pneumococcal adherence in the presence and absence of PAF-R.

The degree of invasiveness of the different pneumococcal strains is correlated with production of inflammatory cytokines in both the apical and basolateral compartment of the Transwell system. The culture supernatants are collected at the various timepoints in both the upper and lower compartment and analyzed by ELISA (BD PharMingen) to determine the concentration of the inflammatory cytokines IL-1β, IL-6, IL-8, IL-10 and TNF-α. The epithelial monolayers are fixed in acetic alcohol and analyzed for the intracellular presence of pneumococci using PspA-specific immunofluorescent staining as previously used for visualization of pneumococci in OBs.
Fluorescent images are visualized with a Leica / Leitz DMRB microscope equipped with appropriate filter cubes (Chromotechnology, Battleboro, VT) as previously described (Martin et al., 1998) J. Immunol. 160: 3748-3758, which is incorporated herein by reference for the methods taught therein). Images are collected with a C5810 digital color camera (Mamamatsu Photonic System) and processed with Adobe photoshop and IP LAB Spectrum software.

RESULTS

Colonization of NanA and NanB mutants.

The effects of NanA mutations on the ability of S. pneumoniae to colonize the nasopharynx of CBA/N mice was assessed by comparing the numbers of pneumococcal cells isolated from nasal washes of mice that had been infected intranasally (i.n.) with those infected with NanA mutant-strains. Three different pneumococcal strains were included, thus, allowing for the effects of NanA mutations to be investigated on strains differing in capsular serotype and genetic background. TIGR4/NanA (JW001), EF3030/NanA (SAM001) and D39/NanA (JCP001) are capsular type 4, 19F and 2, respectively (Table 4). In the case of the capsular type 4 clinical isolate, TIGR4, there is a stop-codon prior to the sequence encoding the LPETG (SEQ ID NO:13) motif. Without this motif, NanA is expected to be secreted into the environment by TIGR4. Examination of the other four pneumococcal-NanA sequences currently available, G54 (type19F), R6 (type 2), Spanish 23F and 670 (type 6B) (Berry et al. Gene 71:299-305; Hoskins et al. 2001 J. Bacteriol 183:5709-17; Tettelin et al. 2001 Science 293:498-506) indicated that they have the LPXTG (SEQ ID NO:14) motif for covalent attached to the cell wall (Fig. 5). Therefore, strains included here provided a comparison for mutations in strains where NanA is secreted and where it is surface bound.

A dramatic decrease in colonization was observed in the NanA mutants of both TIGR4 and EF3030 (Figs. 6 and 7).

S. pneumoniae expresses another neuraminidase, NanB. A similar degree of homology is shared between NanB relative to NanA. NanB shares 43% homology (24% identity) with NanA. Shared residues between the proteins have suggested that it is a sialidase (Berry et al. 1996 J. Bacteriol. 178:4854-4860). NanB has been found to have a
pH optimum of 4.5 as compared to the pH optimum of NanA between 6.5 and 7. Even at its optimal pH, NanB is about 1/100th as active as a sialidase as is NanA at its pH optimum. Even so, to see if there is a requirement of NanB for colonization and direct invasion of the CNS, strains TIGR4/NanB- (JW002), a mutant was constructed in the TIGR4 genetic background deficient in NanB as well as strain TIGR4/NanAB- (JW003), which is deficient in both NanA and NanB expression. Infection of mice with JW002 resulted in a level of colonization nearly identical to the TIGR4 strain (Fig. 8). Moreover, no significant reduction in colonization occurred in the double mutant (JW003) relative to the NanA mutant (Fig. 9).

**Entrance of pneumococci into the CNS.**

In order to track the movement of *S. pneumoniae* to the nasal tissue (including the olfactory nerves) the olfactory bulb and the remainder of the brain were tested for the presence of *S. pneumoniae*. NanA mutants, regardless of genetic background, were found in significantly reduced numbers relative to wild type strains in the nasal tissue and olfactory bulb. At the time of sacrifice, all mice were bled and none exhibited detectable pneumococci in the blood (<12 CFU/ml blood), indicating that pneumococci move directly into the CNS tissue from the nasal cavity. The NanB mutant had no effect on the entry of the pneumococci into the nasal tissue or the olfactory bulb (Fig.8).

NanA mutants are clearly attenuated in their ability to colonize and persist in the nasopharynx and the CNS. This was observed in strains differing in both capsular serotype and attachment of NanA to the surface. Although NanA is but one of many surface structures that influence the intimacy between the bacterial cell surface and the host, its involvement is essential in nasal carriage as well as targeting of pneumococci to the CNS. Disruption of NanA significantly reduced colonization and targeting to the CNS. This result was observed in both TIGR4 and EF3030.

Strain EF3030 (type 19F) colonizes the nasopharynx with great efficiency for over a month. However, despite the ability of EF3030 to persist, mutations in NanA significantly reduced numbers of pneumococcal cells in the nose. Attenuation was even more dramatic in the TIGR4/NanA– strain where numbers of cells isolated from the nasal wash fell to close to the detectable limit after 14 days.

In the natural setting the pneumococcus co-exists with other bacterial species.
Thus NanA’s other functions may include altering the function of host proteins and contributing to the long term stability of carriage. NanA may also enhance pneumococci’s ability to compete with other oral microbes including *N. meningitidis* and *H. influenzae* or by making host glycoproteins available as a carbon source.

Although the major result of these studies has been the demonstration that NanA expression was required for optimal carriage in mice, these data also demonstrated that pneumococci lacking NanA were found in much lower numbers in the olfactory bulbs. It is difficult at this point to know if an active NanA is important for survival of *S. pneumoniae* in CNS tissues. Although the numbers of NanA mutants recovered from these tissues are much less than the parental strain, their very presence in neuronal tissues argues an additional virulence effect of NanA once the pneumococci enter the brain. The decreased level of neuraminidase-mutants in the OB is very likely to be the result of diminished carriage. This finding underscores the principle that carriage is a prerequisite for more invasive diseases and that interventions capable of reducing carriage, such as immunization with NanA, will offer protection against pneumoniae, meningitis, otitis-media and sepsis.

Of the known sequences for nanA, the TIGR sequence is the only one that does not contain a surface anchor. In this strain, a frame shift results in truncation of the molecule prior to the LPETG (SEQ ID NO:13) motif (Tettelin et al. 2001 Science 293:498-506). For most strains a significant portion of the NanA is expected to be covalently attached to the cell wall by sortase (Mazmanian et al. 1999 Science 285:760-63) where it has been detected in electron micrographs (Camara et al. Infect. Immun. 62:3688-95). In these studies, TIGR4 as well as EF3030 exhibited NanA dependent carriage and presence in the olfactory bulbs. From studies of the localization of NanA activity in the supernatant or bacterial pellet, it was shown that, unlike TIGR4, the NanA activity of EF3030 is cell associated. Thus, NanA can facilitate colonization whether it is surface bound or whether it is secreted.

**Example 3**

**The Role of Gangliosides in *S. pneumoniae* Pathogenesis**

Purified neuraminidase, NanA (Calbiochem), is administered at 1, 10 and 50 μg
in 10 µl PBS nasally 15, 30 and 60 minutes prior to isolating the ON/E. The tissues are fixed in 4 % paraformaldehyde, and paraffin sections made. GM1 is stained for using biotinylated-CT-B followed by Streptavidin-FITC and the intensity of staining is analyzed. The section is also stained by asialo-GM1-specific Abs conjugated to rodamine to confirm a decrease of GM1 staining coincident with increase of asialo-GM1 staining in these tissues. Parallel groups of mice undergoing the same treatment are analyzed for colonization by S. pneumoniae strain TIGR4 and EF3030 at days 1 and 4, to assure that neuraminidase treatment resulted in elevated levels of nasal colonization. Mice are given a high dose of strain EF3030 (1 x 10⁸ CFU) nasally and the ON/E is isolated at the following intervals: 1, 3, 6, and 12 hrs, 1 and 4 days after nasal challenge. The ON/E is stained as outlined above and analyzed for GM1 and asialo-GM1 expression. If decreased GM1 and elevated asialo-GM1 expression are observed in the nasal tissues, then the NanA- and NanB-deficient strains are also tested since they would be expected not to alter GM1 expression in the nasal tract. The removal of sialic acid residues exposes the subterminal disaccharide, β-D-galactopyranosyl-(1-3)N-acetyl-D-galactosamine, which represents an immunodominant group of the Thompson-Friedenreich antigen, for which PNA has high affinity. Thus, changes in the PNA-binding sites in the ON/E is another measure of neuraminidase activity. Frozen sections made from these tissues are readily stained with PNA-FITC or PNA-HRP (Medac, Hamburg, Germany) to determine if an increase in PNA-binding sites occurs based on microscopy (Black et al., (2000) Pediatr. Infect. Dis J. 19: 187-195; Klein et al. (1978) Klin. Wochenschr. 56: 761-765, which are incorporated herein by reference in their entirety for the methods taught therein).

The GM1 site is specifically blocked prior to nasal administration of strain TIGR4 or EF3030. This is approached in three ways by using: 1) CT-B versus a non-ganglioside control protein e.g. ovalbumin, 2) Abs to GM1 (Calbiochem) versus normal rabbit immunoglobulins, or 3) GM1-specific peptides synthesized in the UAB Protein Analysis and Peptide Synthesis Core Facility. The inhibition with the GM1-specific peptide is the best approach since CT-B and possibly Abs to GM1 is expected to cause concomitant inflammation. In these experiments the ON/E and OBs are analyzed 1 and 4 days after application for pneumococcal CFU. An alternative approach of blocking GM1
is the use of a GM1-binding peptide that was discovered by use of a phage-display pentadecapeptide library selecting for GM1-binding peptides. This GM1-binding peptide VWRLLAPPFSNRLLP (SEQ ID NO: 5) has high affinity (10^{10} M^{-1}) for GM1 and an IC_{50} of 1.0 \mu M. Matsubara et al., (1999) FEBS Letters 456: 253-256. A peptide of the same length and composed of the same amino acids in a randomly selected sequence is used as control. The GM1-binding ability of both peptides is confirmed by ELISA prior to use \textit{in vivo}. Initially, 100 \mu g of these two peptides is administered nasally in 10 \mu l Ringer’s solution or PBS, 10 minutes prior to applying 3 \times 10^6 CFU of strain EF3030. The ON/E is analyzed for CFU on days 1 and 4 after application for numbers of CFU relative to untreated CBA/N mice.

Blocking experiments are performed with PAF (Biomol Research Laboratories, Inc. Plymouth meeting, PA) and the PAF-R antagonist octylonium bromide (Biromol). This compound binds with high affinity to the PAF-R. Each ganglioside is tested individually. Besides mixed gangliosides, asialo-GM1, GM1, GD1a, GD1b, GT1 (Calbiochem) and the GM3 (Sigma) are tested for their ability to inhibit nasal colonization as assessed on day 1 and 4 after challenge. Various gangliosides are able to block this process. The GM3 ganglioside functions as a negative control since it lacks the published C-polysaccharide binding motif. Based on the data presented on colonization with EF3030 following ganglioside preincubation, mixed gangliosides are more effective than asialo-GM1 at blocking colonization. This indicates that other gangliosides besides asialo-GM1 are involved in the process of pneumococcal colonization of the nasal tract, lungs and brain. These ganglioside inhibition studies focus on the TIGR4 strain and its neuraminidase mutants. Short term \textit{in vitro} incubation with the TIGR4 strain on ganglioside-coated ELISA plates demonstrated attachment of the TIGR4 strain to the asialo-GM1. Enterotoxins provide another means of differentially blocking pneumococci-ganglioside interactions in the nasal tract. Both CT and LTh-1 are both serogroup I heat-labile enterotoxins (Pickett et al., (1986) J. Bacteriol 165: 348-352) and display similar, although slightly different, ganglioside binding specificities. Fukuta et al., (1988) Infect Immun. 56: 1748-1753. CT (List Biological Laboratories, Inc., Campbell, CA) binds to GM1 and to a lesser extent to GD1b. LTh-1 displays preferential binding to GM1 and GD1b and binds weakly to GM2 and asialo-GM1.
Fukuta et al., (1988) Infect Immun. 56: 1748-1753. If GM1 is the main ganglioside interacting with *S. pneumoniae*, the use of LTh-1 would not only block the GM1 ganglioside but might also block asialo-GM1, which could represent a natural low frequency binding site not requiring neuraminidase activity. The heat-labile enterotoxins from serogroup II display different ganglioside binding specificities, in particular the heat-labile enterotoxin LT-IIb. This toxin binds to GD1a and to a lesser extent to GT1b and showed no affinity for GM1. Fukuta et al., (1988) Infect Immun. 56: 1748-1753. The LT-IIa binds with high affinity to GD1b and with a lower affinity to GM1, GT1b, GQ1b, GD2, GD1a, and GM2. Fukuta et al., (1988) Infect Immun. 56: 1748-1753. The LT-II toxins have been kindly provided by Dr. T.D. Connell. To optimize the nasal dose and the optimal time period to observe inhibition of pneumococcal attachment to ON/E, a dose response study (1.0 or 10 μg) is initially performed on a selected enterotoxin, which is given during nasal application of *S. pneumoniae*. If inhibition of nasal colonization is observed on day 4 the observations are extended to day 11 during which enterotoxin is given every other day. The CFU in ON/E and OBs of CBA/N mice are measured.

**Example 4**

**The Role of C-Polysaccharide-Specific Antibodies in Pneumococcal Pathogenesis**

Pneumococcal C-polysaccharide, also known as teichoic acid, is structurally identical to the pneumococcal F-antigen, also known as lipoteichoic acid. Fischer et al. (1993) Eur. J. Biochem 215: 851-857. This is a unique feature of *S. pneumoniae* among gram-positive bacteria. The immunodominant determinants on these molecules are the phosphorylcholine (PC) residues and Abs to PC are protective against i.p. or nasal pneumococcal challenge. Briles et al., (1984) Eur. J. Immunol. 14: 1027-1030; Briles et al., (1981) Nature 294: 88-90; Yother et al., (1982) Infect. Immun. 36: 184-188; Briles et al., (1984) J. Mol. Cell. Immunol. 1:305-309. Thus, the role of PC-specific Abs, either obtained by passive transfer or active nasal immunization, is explored. For passive transfer of protective PC-specific Abs, i.e., T15 idiotypic monoclonal Abs (mAbs) of both the IgG3 (59.6C5) and IgM (22.1A4) isotypes are used. Briles et al., (1981) Nature 294: 88-90. The T15 idiotypic has been shown to be more protective than the M603 or
M511 idiotypes against pneumococcal infection in mice (Briles et al., (1984) Eur. J. Immunol. 14: 1027-1030), presumably by more efficiently binding the C-polysaccharide. Passive Ab transfer involves the direct application of T15 Abs (100 μg) with nasally applied pneumococci and is compared to i.v. or i.p. administered Abs for reducing nasal colonization. Colonization is monitored over time (day 4, 11, 18) and if no significant difference is observed between the different groups in these experiments mAbs (20 μg) are applied nasally every other day. CBA/N mice, do not produce T15 idiotypic anti-PC Abs. Passive transfer of anti-PC-specific Abs is not expected to induce mucosal IgA or other isotypes of PC-specific Abs in the nasal tract. In order to induce nasal Abs, two different approaches are taken. One is the direct nasal application of the protease treated R36A strain, which is known to induce Ab responses to C-polysaccharide. Although protective immunity of anti-PC Abs has been studied, no data is available on their role at mucosal surfaces such as the nasal tract. The CBA/N mice X-chromosome-linked immunodeficiency results in an inability to generate anti-PC Abs of the T15-idiotype. To determine the importance of this inability CBA/N mice are compared to their wildtype counterpart the CBA/J mice (Jackson Laboratories). Immunization with strain R36A for induction of anti-PC Abs involves proteolytic removal of surface protein. Krause (1970) Adv. Immunol. 12: 1-56. The alternative approach for nasal immunization is coupling of PC to the protein keyhole limpet hemocyanin (KLH) as previously described (Krause (1970) Adv. Immunol 12: 1-56; Chesebro and Metzger (1972) Biochemistry 11: 766-771, which are incorporated herein by reference for the methods taught therein). Nasal immunization with PC-KLH is performed with the mucosal adjuvant CT to optimize mucosal immune responses. The mice are challenged 2-3 weeks after the last immunization to prevent effects of CT on colonization. Three nasal immunizations are performed at one week intervals. The serum Ab titers are monitored using a C-polysaccharide and PC-specific ELISA as routinely performed by those skilled in the art. For the PC-specific ELISA, PC is coupled to BSA as described previously (Chesebro and Metzger (1972) Biochemistry 11: 766-771, which is incorporated herein by reference for the methods taught therein). In addition to serum, the Ab titers in nasal washes, saliva, and bronchial lavages are measured. These analyses include IgA, IgM, IgG, and IgG-subclass distribution in both mucosal secretions and serum. The protocol that
induces the most optimal mucosal Ab titers is used to perform mucosal challenge studies with the TIGR4 strain, which is administered nasally at \( \sim 5 \times 10^6 \) CFU to mice after which colonization is monitored on day 4 and 11. In the immunization studies normal, fully immunocompetent mice (CBA/J strain) as well as CBA/N mice are used as in previous studies. Wallick et al., (1983) J. Immunol. 130: 2871-2875.

**Example 5**

**The Role of Neuraminidase-Specific Antibodies in *S. pneumoniae* Pathogenesis**

To nasally immunize the mice prior to nasal challenge commercially available *S. pneumoniae*-derived neuraminidase is used (Calbiochem). However, the NanA gene is cloned and expressed in E. coli using a histidine-tag containing expression vector (Invitrogen) in order to obtain sufficient amounts of protein for the proposed studies. Nasal immunization of 3.4% formaldehyde-treated neuraminidase is compared versus-untreated neuraminidase in the presence or absence of CT in order to optimize the mucosal immune responses. These immunizations are performed in both CBA/N and CBA/J mice. Three nasal immunizations are given one week apart during which serum and saliva Abs titers are monitored by ELISA. The immune mice are challenged with the TIGR4 strain and the colonization of ON/E, OB, brain, blood, spleen, and lungs is compared on days 4 and 11. To block host interaction, both neuraminidase and C-polysaccharide-specific Abs are induced simultaneously. A combined regimen of nasal immunization with neuraminidase and passive immune protection by transfer of T15 idiotypic mAbs is used.

**Example 6**

**The Efficacy of Neuraminidase-PC Conjugate to Protect Against Nasal Challenge with *S. pneumoniae***

Mice are immunized with neuraminidase and PC-KLH in combination with CT as nasal adjuvant to assess enhancement of protection and decrease nasal colonization by the EF3030 and TIGR4 strains on day 11 compared to each antigen used alone. In addition, Ab titers in nasal washes, saliva, and serum are analyzed as indicated above to correlate immune parameters with degree of protection to pneumococci in the nasal tract. To generate a more optimal immune response phosphocholine is directly coupled to
neuraminidase. This construct is tested for immunogenicity when delivered with or without CT as adjuvant after nasal and systemic immunization in both CBA/N and CBA/J mice. The Ab titers in nasal washes, saliva, and plasma are measured by ELISA. Challenge studies are performed with $10^7$ CFU of strains EF3030 or $10^6$ TIGR4. The mice are sacrificed on day 11 after challenge and analyzed for CFUs observed in blood, nasal washes, ON/E, OB, and brain. Immunization with neuraminidase coupled to PC enhances protection by increasing mucosal and systemic Ab levels to these two virulence components. The antigen-specific IgG subclass distribution are altered by using other mucosal adjuvants. CT generates a Th2-, LT a mixed Th2/Th1-, and CpG motifs such as the DNA oligonucleotide (ODN) 1826 a Th1-type response with associated changes in IgG subclass distribution. Different adjuvants further enhance the ability of neuraminidase-C-polysaccharide-specific immunity to protect against nasal colonization by *S. pneumoniae* and lead to the formulation of new pneumococcal vaccine approaches.

**Example 7**

**Inhibition of nasal colonization of *S. pneumoniae* by anti-phosphocholine-specific monoclonal antibodies after nasal challenge.**

A total of $1 \times 10^6$ CFU of the TIGR4 strain were incubated with 5 μg of anti-phosphocholine monoclonal antibodies of either the IgG3 subclass or IgM isotype. A total of 5 μl was administered per nare. Indicated are the CFUs in 500 ml nasal wash respectively 9 and 12 hours after application. A significant over 80% decrease was observed for both monoclonal antibodies. Indicated are the mean ± SD of five mice per group. The data are shown in Figure 10.

**Example 8**

**Neuronal damage and inflammation after nasal *S. pneumoniae* application**

The ON/E, OB, and brain are isolated from treated mice at days 1, 3, 7, and 14 after nasal application of *S. pneumoniae* strain EF3030 and analyzed histologically for inflammatory responses. The D39 or TIGR4 strains are compared to their nanA mutant strains for their ability to generate inflammatory responses. At sacrifice, the mice are perfused with PBS at 25°C, followed by perfusion with 10 ml of Zamboni’s fixative (4
% paraformaldehyde, 15 % picric acid in 0.1 M phosphate buffer. The OB and ON/E are
removed and then placed in fresh 4 % paraformaldehyde (PFA) at 4° C overnight. The
tissue is then transferred to a 30 % sucrose solution at 4° C for 48 hr to cryoprotect it
prior to sectioning. The tissues are then frozen in OCT and sections (6 μm) are placed on
previously coated microscope slides (10 % BSA in saline). Initially, hematoxylin and
eosin (H&E) staining are performed to detect any inflammatory cell infiltrates in the OB,
trigeminal ganglia and ON/E during this time period. In order to assess neuronal
damage, nerve growth factor β1 (NGF-β1) is stained for. NGF-β1 is produced after
neuronal damage and functions to prevent apoptosis and to stimulate new growth of
nerve cells. Trigeminal ganglia and OB sections are stained with a biotinylated rabbit
anti-human NGF-β 1 Ab at a concentration 0.2 μg/ml. The Ab-stained sections are
incubated at 4° C overnight. The slides are rinsed with PBS and then reacted with
avidin-biotin-complex (ABC) Vectastain (Vector Laboratories, Burlingame, CA) for 30
min at 25° C. The tissue is rinsed 3 times with PBS and then reacted with
diaminobenzidine (DAB) for 5 - 10 min as previously reported. The slides are rinsed 3
more times and sections counterstained with C.S. hematoxylin for 30 sec. After washing
in H2O, the slides are dehydrated in 100 % alcohol and xylene. An increase in NGF-β 1
provides an indication of the degree of damage in neuronal tissues. Another indicator for
neuronal involvement is the activation of microglia. Activated microglia display an
amoeboid, spherical shape while resting cells (in G0/G1) have an arborized, ramified
appearance. This change upon activation allows one to distinguish resting and activated
microglia. For microglia, F4/80 antibody or anti-MAC-1 (MI/70) are used to address the
activation state after S. pneumoniae challenge. In addition to neuronal damage and
microglia activation, the induction of apoptosis in OB is assessed. To this end, the
induction of active Caspase 3, an Asp-Glu-Val-Asp specific protease, is analyzed
because it is important in the initiation of apoptotic pathways. An Ab specific for active
Caspase 3 (Cell Signaling Technology, Inc., Beverly, MA) can be used in
immunohistochemistry for detection of apoptosis. If Caspase 3 activity is detected in
neuronal tissues by immunohistochemistry, activity is quantified using a Caspase-3
Assay kit (Molecular probes, Eugene, OR) based on a fluorescent signal induced after
proteolysis of the substrate.
Example 9

Ability of *S. Pneumoniae* to target olfactory bulbs by retrograde axonal transport

First, accumulation of pneumococci in the neuronal tissues, OB and brain, of treated mice following nasal and i.v. inoculation is assessed. Following i.v. inoculation, any pneumococci in the neuronal tissues has entered through the blood. Tissues at 1, 4, 11 and 18 days following nasal challenge are collected. In that case the numbers of bacteria per gram of brain and OB should be similar at all time points post injection. In contrast, for bacteria entering through the nasal tract following intranasal inoculation, an accumulation in the OB (expressed per weight of tissue) precedes and in general remains ahead the accumulation observed in the brain.

Second, *in vivo* imaging of pneumococci after nasal application is performed. Technetium-99 (Tc-99m)-labeled TIGR4, stable opaque and transparent variants, EF3030, and TIGR4 mutants lacking *nanA* and/or *nanB* are used to visualize their presence in mice using gamma camera imaging as previously performed with adenovirus using a strategy originally described by Waibel et al. (1999) Nature Biotechnol. 17:897-901. This allows imaging for approximately the first 24 hrs following nasal application due to the short half live (6 hrs) of this isotope and allows analysis of the early events taking place in the nasal tract. For long term imaging of the pneumococci, a luciferase-or GFP-expressing pneumococcal EF3030 (or TIGR4) strain are used to visualize the bioluminescence *in vivo*. A luciferase-expressing pneumococci strain EF3030, commercially available from the Xenogen corporation (Alameda, California), is used. Successful *in vivo* imaging with this pneumococcal strain has been previously reported. The mice are imaged using a bioluminescence imaging system (IVIS system, Xenogen, Inc.) to detect luciferase expression. Images are collected on mice oriented in the same position and always at 10 min after i.p. injection of 2.5 mg luciferin. During imaging the mice are maintained under enflurane anesthesia at 37° C. Imaging is performed several times on each mouse, beginning at 2 days to 18 days after nasal challenge with luciferase-expressing pneumococci. Image acquisition times for imaging are in the range of 20 sec to 10 min. Data acquisition software insures that no pixels are saturated during image collection. Light emission from the regions of interest (relative photons/sec) are quantitated using software provided by Xenogen. The intensity of light emission is
represented with a pseudocolor scaling of the bioluminescent images. The bioluminescent images are typically over-layered on black and white photographs of the mice that are collected at the same time. This \textit{in vivo} imaging focuses on analyzing the ability of pneumococci to enter the OBs from the nasal tract. This bioluminescence studies extend to the \textit{nanA} TIGR4 mutant after successful transfer of the luciferase gene.

Throughout this application, various publications are referenced. The disclosures of these publications in their entireties are hereby incorporated by reference into this application in order to more fully describe the compounds, compositions and methods described herein.

Various modifications and variations can be made to the compounds, compositions and methods described herein. Other aspects of the compounds, compositions and methods described herein will be apparent from consideration of the specification and practice of the compounds, compositions and methods disclosed herein. It is intended that the specification and examples be considered as exemplary.

\textbf{References}

Fedson, D. S., Scott, J.A. and Scott, G. 1999. The burden of pneumococcal disease among adults in developed and developing countries: what is and is not known [In Process Citation]. Vaccine. 17 Suppl. 1:S11-18.

What is claimed is:

1. A detoxified pneumococcal neuraminidase or an antigenic portion thereof.

2. A detoxified pneumococcal neuraminidase or an antigenic portion thereof, wherein the neuraminidase has approximately 60% of the activity of non-detoxified neuraminidase.

3. A detoxified pneumococcal neuraminidase or an antigenic portion thereof, wherein the neuraminidase has approximately 70% of the activity of non-detoxified neuraminidase.

4. A detoxified pneumococcal neuraminidase or an antigenic portion thereof, wherein the neuraminidase has approximately 80% of the activity of non-detoxified neuraminidase.

5. A detoxified pneumococcal neuraminidase or an antigenic portion thereof, wherein the neuraminidase has approximately 90% of the activity of non-detoxified neuraminidase.

6. A detoxified pneumococcal neuraminidase or an antigenic portion thereof, wherein the neuraminidase comprises deletion of at least 7% of the naturally occurring amino acids of non-detoxified neuraminidase.

7. A detoxified pneumococcal neuraminidase or an antigenic portion thereof, wherein the neuraminidase comprises deletion of at least 7% of the naturally occurring amino acids of non-detoxified neuraminidase and exhibits approximately 60% of the activity of non-detoxified neuraminidase.

8. A detoxified pneumococcal neuraminidase or an antigenic portion thereof, wherein the neuraminidase comprises deletion of at least 7% of the naturally occurring amino acids of non-detoxified neuraminidase and exhibits approximately 70% of the activity of non-detoxified neuraminidase.

9. A detoxified pneumococcal neuraminidase or an antigenic portion thereof, wherein the neuraminidase comprises deletion of at least 7% of the naturally occurring amino acids of non-detoxified neuraminidase and exhibits approximately 80% of the activity of non-detoxified neuraminidase.
10. A detoxified pneumococcal neuraminidase or an antigenic portion thereof, wherein the neuraminidase comprises deletion of at least 7% of the naturally occurring amino acids of non-detoxified neuraminidase and exhibits approximately 90% of the activity of non-detoxified neuraminidase.

11. A detoxified pneumococcal neuraminidase or an antigenic portion thereof, wherein the neuraminidase comprises a deletion of at least 5 N-terminal amino acids of non-detoxified neuraminidase.

12. A detoxified pneumococcal neuraminidase or an antigenic portion thereof, wherein the neuraminidase comprises a deletion of at least 10 N-terminal amino acids of non-detoxified neuraminidase.

13. A detoxified pneumococcal neuraminidase or an antigenic portion thereof, wherein the neuraminidase comprises a deletion of at least 15 N-terminal amino acids of non-detoxified neuraminidase.

14. A detoxified pneumococcal neuraminidase or an antigenic portion thereof, wherein the neuraminidase comprises a deletion of at least 10% of the C-terminal amino acids of non-detoxified neuraminidase.

15. A detoxified pneumococcal neuraminidase or an antigenic portion thereof, wherein the neuraminidase comprises a deletion of at least 20% of the C-terminal amino acids of non-detoxified neuraminidase.

16. A detoxified pneumococcal neuraminidase or an antigenic portion thereof, wherein the neuraminidase comprises a deletion of at least 30% of the C-terminal amino acids of non-detoxified neuraminidase.

17. A detoxified pneumococcal neuraminidase or an antigenic portion thereof, wherein the neuraminidase comprises a deletion of at least 35% of the C-terminal amino acids of non-detoxified neuraminidase.

18. A composition comprising a detoxified pneumococcal neuraminidase or an antigenic portion thereof and a pharmaceutically acceptable carrier.

19. The composition of claim 18, further comprising an adjuvant.

20. A method of generating antibodies specific to pneumococcal neuraminidase in a subject comprising administering to the subject a detoxified pneumococcal neuraminidase or an antigenic portion thereof.
21. A method of reducing pneumococcal nasal carriage in a subject comprising administering to the subject a detoxified pneumococcal neuraminidase or an antigenic portion thereof.

22. A method of preventing pneumococcal infection in a subject comprising administering to the subject a detoxified pneumococcal neuraminidase or an antigenic portion thereof.

23. The method of claim 22, wherein the pneumococcal infection is meningitis.

24. The method of claim 22, wherein the pneumococcal infection is otitis media.

25. The method of claim 22, wherein the pneumococcal infection is pneumonia.

26. The method of claim 22, wherein the pneumococcal infection is hemolytic uremia.

27. A method of reducing or preventing pneumococcal nasal carriage in a subject comprising administering to the subject a pneumococcal neuraminidase or an antigenic fragment thereof under conditions that reduce or prevent the nasal carriage.

28. A method of reducing or preventing pneumococcal infection in a subject comprising administering to the subject a pneumococcal neuraminidase or an antigenic fragment thereof under conditions that reduce or prevent the infection.

29. The method of claim 28, wherein the pneumococcal infection is meningitis.

30. The method of claim 28, wherein the pneumococcal infection is otitis media.

31. The method of claim 28, wherein the pneumococcal infection is pneumonia.

32. The method of claim 28, wherein the pneumococcal infection is hemolytic uremia.

33. A method of reducing or preventing pneumococcal infection in a subject comprising administering to the subject a pneumococcal neuraminidase antibody or a fragment thereof under conditions that reduce or prevent the infection, wherein the administration step comprises contacting a mucosal surface of the subject with the antibody.

34. The method of claim 33, wherein the pneumococcal infection is meningitis.
35. The method of claim 33, wherein the pneumococcal infection is otitis media.
36. The method of claim 33, wherein the pneumococcal infection is pneumonia.
37. The method of claim 33, wherein the pneumococcal infection is hemolytic uremia.
38. A composition comprising a pneumococcal neuraminidase or an antigenic portion thereof and a pharmaceutically acceptable carrier, wherein the composition is suitable for administration to a mucosal surface.
39. The composition of claim 38, wherein the composition is a nasal spray.
40. The composition of claim 38, wherein the composition is a nebulizer solution.
41. The composition of claim 38, wherein the composition is an aerosol inhalant.
42. A container comprising the composition of claim 38.
43. The container of claim 42, wherein the container is a nasal sprayer.
44. The container of claim 42, wherein the container is a nebulizer.
45. The container of claim 42, wherein the container is an inhaler.
46. A method of generating antibodies specific to pneumococcal neuraminidase in a subject comprising contacting the nasal mucosa of the subject with a detoxified pneumococcal neuraminidase or an antigenic portion thereof.
47. A method of reducing pneumococcal nasal carriage in a subject comprising contacting the nasal mucosa of the subject with a detoxified pneumococcal neuraminidase or an antigenic portion thereof.
48. A method of preventing pneumococcal infection in a subject comprising contacting a mucosal surface of the subject with a detoxified pneumococcal neuraminidase or an antigenic portion thereof.
49. The method of claim 48, wherein the pneumococcal infection is meningitis.
50. The method of claim 48, wherein the pneumococcal infection is otitis media.
51. The method of claim 48, wherein the pneumococcal infection is pneumonia.
52. The method of claim 48, wherein the pneumococcal infection is hemolytic uremia.
53. A composition comprising a phosphocholine or an antigenic portion thereof of pneumococcal teichoic acid or pneumococcal lipoteichoic acid and a
pharmaceutically acceptable carrier, wherein the composition is suitable for administration to a mucosal surface.

54. The composition of claim 53, wherein the composition is a nasal spray.
55. The composition of claim 53, wherein the composition is a nebulizer solution.
56. The composition of claim 53, wherein the composition is an aerosol inhalant.
57. A container comprising the composition of claim 53.
58. The container of claim 57, wherein the container is a nasal sprayer.
59. The container of claim 57, wherein the container is a nebulizer.
60. The container of claim 57, wherein the container is an inhaler.
61. A method of generating antibodies specific to pneumococcal neuraminidase in a subject comprising contacting the nasal mucosa of the subject with the composition of claim 53.
62. A method of reducing pneumococcal nasal carriage in a subject comprising contacting the nasal mucosa of the subject with the composition of claim 53.
63. A method of reducing or preventing pneumococcal infection in a subject comprising contacting a mucosal surface of the subject with the composition of claim 53.
64. The method of claim 63, wherein the pneumococcal infection is meningitis.
65. The method of claim 63, wherein the pneumococcal infection is otitis media.
66. The method of claim 63, wherein the pneumococcal infection is pneumonia.
67. The method of claim 63, wherein the pneumococcal infection is hemolytic uremia.
68. A composition comprising a pneumococcal neuraminidase or an antigenic portion thereof, a phosphocholine or an antigenic portion thereof of pneumococcal teichoic acid or pneumococcal lipoteichoic acid, and a pharmaceutically acceptable carrier, wherein the composition is suitable for administration to a mucosal surface.
69. The composition of claim 68, wherein the composition is a nasal spray.
70. The composition of claim 68, wherein the composition is a nebulizer solution.
71. The composition of claim 68, wherein the composition is an aerosol inhalant.
72. A container comprising the composition of claim 68.
73. The container of claim 72, wherein the container is a nasal sprayer.
74. The container of claim 72, wherein the container is a nebulizer.
75. The container of claim 72, wherein the container is an inhaler.
76. A method of generating antibodies specific to pneumococcal neuraminidase in a subject comprising contacting the nasal mucosa of the subject with the composition of claim 68.
77. A method of reducing pneumococcal nasal carriage in a subject comprising contacting the nasal mucosa of the subject with the composition of claim 68.
78. A method of preventing pneumococcal infection in a subject comprising contacting a mucosal surface of the subject with the composition of claim 68.
79. The method of claim 78, wherein the pneumococcal infection is meningitis.
80. The method of claim 78, wherein the pneumococcal infection is otitis media.
81. The method of claim 78, wherein the pneumococcal infection is pneumonia.
82. The method of claim 78, wherein the pneumococcal infection is hemolytic uremia.
83. A composition comprising a non-phosphocholine antigenic portion of pneumococcal teichoic acid or pneumococcal lipoteichoic acid and a pharmaceutically acceptable carrier, wherein the composition is suitable for administration to a mucosal surface.
84. The composition of claim 83, wherein the composition is a nasal spray.
85. The composition of claim 83, wherein the composition is a nebulizer solution.
86. The composition of claim 83, wherein the composition is an aerosol inhalant.
87. A container comprising the composition of claim 83.
88. The container of claim 87, wherein the container is a nasal sprayer.
89. The container of claim 87, wherein the container is a nebulizer.
90. The container of claim 87, wherein the container is an inhaler.
91. A method of generating antibodies specific to pneumococcal neuraminidase in a subject comprising contacting the nasal mucosa of the subject with the composition of claim 83.
92. A method of reducing pneumococcal nasal carriage in a subject comprising contacting the nasal mucosa of the subject with the composition of claim 83.
93. A method of preventing pneumococcal infection in a subject comprising contacting a mucosal surface of the subject with the composition of claim 83.

94. The method of claim 93, wherein the pneumococcal infection is meningitis.

95. The method of claim 93, wherein the pneumococcal infection is otitis media.

96. The method of claim 93, wherein the pneumococcal infection is pneumonia.

97. The method of claim 93, wherein the pneumococcal infection is hemolytic uremia.

98. A composition comprising a pneumococcal neuraminidase or an antigenic portion thereof, a non-phosphocholine antigenic portion of pneumococcal teichoic acid or pneumococcal lipoteichoic acid, and a pharmaceutically acceptable carrier, wherein the composition is suitable for administration to a mucosal surface.

99. The composition of claim 98, wherein the composition is a nasal spray.

100. The composition of claim 98, wherein the composition is a nebulizer solution.

101. The composition of claim 98, wherein the composition is an aerosol inhalant.

102. A container comprising the composition of claim 98.

103. The container of claim 102, wherein the container is a nasal sprayer.

104. The container of claim 102, wherein the container is a nebulizer.

105. The container of claim 102, wherein the container is an inhaler.

106. A method of generating antibodies specific to pneumococcal neuraminidase in a subject comprising contacting the nasal mucosa of the subject with the composition of claim 98.

107. A method of reducing pneumococcal nasal carriage in a subject comprising contacting the nasal mucosa of the subject with the composition of claim 98.

108. A method of preventing pneumococcal infection in a subject comprising contacting a mucosal surface of the subject with the composition of claim 98.

109. The method of claim 108, wherein the pneumococcal infection is meningitis.

110. The method of claim 108, wherein the pneumococcal infection is otitis media.

111. The method of claim 108, wherein the pneumococcal infection is pneumonia.

112. The method of claim 108, wherein the pneumococcal infection is hemolytic uremia.
113. A composition comprising a phosphocholine antibody or a fragment thereof and a pharmaceutically acceptable carrier.

114. The composition of claim 113, wherein the composition is suitable for administration to a mucosal surface.

115. The composition of claim 113, wherein the composition is a nasal spray.

116. The composition of claim 113, wherein the composition is a nebulizer solution.

117. The composition of claim 113, wherein the composition is an aerosol inhalant.

118. A container comprising the composition of claim 113.

119. The container of claim 118, wherein the container is a nasal sprayer.

120. The container of claim 118, wherein the container is a nebulizer.

121. The container of claim 118, wherein the container is an inhaler.

122. A method of reducing pneumococcal nasal carriage in a subject comprising administering to the subject a phosphocholine antibody or a fragment thereof.

123. The method of claim 122, wherein the administration comprising contacting the nasal mucosa of the subject with the antibody or fragment thereof.

124. A method of preventing pneumococcal infection in a subject comprising administering to the subject a phosphocholine antibody or a fragment thereof.

125. The method of claim 124, wherein the administration comprises contacting the nasal mucosa of the subject with the antibody or fragment thereof.
