METHYL SULFANYL PYRMIDMES USEFUL AS ANTIINFLAMMATORIES, ANALGESICS, AND ANTIEPILEPTICS

5

BACKGROUND OF THE INVENTION

The present invention relates to pharmaceutical compositions and methods for treating or preventing pain, inflammation, and epilepsy.

Pain is a common form of physical suffering and distress and is one of the most
10 common reasons patients report to physicians. It may be categorized in terms of 5 form
(nociceptive or neuropathic), duration (chronic or acute), and degree (mild, moderate or
severe). Typically, nociceptive pain is acute, and results from injury, such as burns,
sprains, fractures, or inflammation (inflammatory pain, including from osteo- and
rheumatoid arthritis). Neuropathic pain, on the other hand, is defined by the
15 International Association for the Study of Pain as a form of chronic pain that is caused
by a lesion or dysfunction of the nervous system. Commonly, neuropathic pain results
from diabetic neuropathy, HIV infections, or post-herpetic neuralgia. Other disorders
that are associated with neuropathic pain include complex regional pain syndromes,
trigeminal neuralgia, low back pain, sciatica, phantom limb pain, blast pain,
20 fibromyalgia, and other conditions that result in chronic pain. Few therapeutics are
approved by the U.S. Food and Drug Administration and other regulatory agencies for
the treatment of neuropathic pain. Those that are approved exhibit, at best, a modest
efficacy in terms of pain reduction (see Jensen, *Eur. J. Pain* 2002; 6 Suppl A:61-68).

DETAILED DESCRIPTION OF THE INVENTION

The present invention features compounds having the Formula (Ia) and use of these compounds in pharmaceutical compositions and methods of treatment or prevention of disease:

(Ia), including tautomers, stereoisomers, prodrugs, and pharmaceutically acceptable salts thereof.

In some embodiments, the compounds of (Ia) have structures according to the following formulas:

(Ia-2),

(Ia-3),

(Ia-4),

(Ia-5),

(Ia-6),

(Ia-7),

(Ia-8),

(Ia-9),

including stereoisomers, tautomers, prodrugs, and pharmaceutically acceptable salts thereof.

The invention further provides methods for treating disease by administering a compound having the Formula (IIa), depicted below,

including stereoisomers, tautomers, prodrugs, and pharmaceutically acceptable salts thereof.

In some embodiments, the compound of Formula (IIa) has a structure according to the following formulas

including stereoisomers, tautomers, prodrugs, and pharmaceutically acceptable salts thereof.

Exemplary compounds of the invention are shown herein.

Synthesis

In general, the compounds of the invention can be obtained via standard, well-known synthetic methodology (e.g., *March's Advanced Organic Chemistry*:

Reactions, Mechanisms, and Structure, 6th ed., 2007). Illustrative methods are described below. Starting materials useful for preparing the compounds of the invention and intermediates therefore, are commercially available or can be prepared from commercially available materials using known synthetic methods and reagents.

5 It is understood that the methods of synthesis provided below also encompass the synthesis of isomers and tautomers (e.g., compounds having structures according to Formulas (Ib) and (IIb)).

An example of a synthetic pathway useful for making the compounds is set forth below and generalized in **Scheme 1**. The compounds of Formula (Ia) or (IIa) can be obtained via conventional organic synthesis, e.g., as described below. Scheme 1 indicates a general method by which the compounds can be obtained, wherein Q₁, W (which is V for Ia), A₁₋₃, and R₁₋₃ are defined above for the compounds of Formula (Ia) and (IIa).

For example, a commercially available or synthetically prepared compound of Formula (IV) is subjected to alkylation reaction with a commercially available or synthetically prepared compound of Formula (III) under basic conditions in a polar solvent such as ethanol.

A second example of a synthetic pathway useful for making the compounds is set forth below and generalized in **Scheme 2**. The compounds of Formula (Ia) or (IIa) can be obtained via conventional organic synthesis, e.g., as described below. Scheme 2 provides a second general method by which the compounds can be obtained, wherein Q₁, W (which is V for Ia), A₁₋₃, and R₁₋₃ are defined above for the compounds of Formula (Ia) and (IIa).

Scheme 2

5 For example, a commercially available or synthetically prepared compound of Formula (IV) is subjected to alkylation reaction with a compound of Formula (III), which itself is obtained from free radical bromination of a suitably functionalized compound of Formula (V) with, for example, NBS in a solvent such as CCl₄.

10 Scheme 3 provides a variation of scheme 2 for the preparation of compounds of Formula (Ia) and (IIa) when A₁ and A₂ are both -H, wherein Q₁, Z, W (which is V for Ia), A₃, and R₁₋₃ are defined above for the compounds of Formula (Ia) and (IIa). Hence, the prerequisite intermediate of Formula (III) is obtained following treatment with a Lewis acid, such as BBr₃, of a compound of Formula (VI), which itself was obtained via reduction of a commercially available or synthetically prepared

15 compound of Formula (VII) with a reducing agent, such as NaBH₄, in a solvent, such as methanol.

Scheme 3

20

The formation of a compound of Formula (Ia) or (IIa) can be monitored using conventional analytical techniques, including, but not limited to, thin-layer chromatography, high-performance liquid chromatography, gas chromatography, and nuclear magnetic resonance spectroscopy, such as ¹H or ¹³C NMR.

10 compositions may also include a solubilizing agent. Compositions for intravenous administration may optionally include a local anesthetic, such as lignocaine to ease pain at the site of the injection. Generally, the ingredients are supplied either separately or mixed together in unit dosage form, for example, as a dry lyophilized powder or water free concentrate in a hermetically sealed container, such as an
15 ampoule or sachette indicating the quantity of active agent. Where the compound of the invention is to be administered by infusion, it can be dispensed, for example, with an infusion bottle containing sterile pharmaceutical grade water or saline. Where the compound of the invention is administered by injection, an ampoule of sterile water for injection or saline can be provided so that the ingredients may be mixed prior to
20 administration.

Compositions for oral delivery may be in the form of tablets, lozenges, aqueous or oily suspensions, granules, powders, emulsions, capsules, syrups, or elixirs, for example. Orally administered compositions may contain one or more optional agents, for example, sweetening agents, such as fructose, aspartame or
25 saccharin; flavoring agents, such as peppermint, oil of wintergreen, or cherry; coloring agents; and preserving agents, to provide a pharmaceutically palatable preparation. Moreover, where in tablet or pill form, the compositions may be coated to delay disintegration and absorption in the gastrointestinal tract, thereby providing a sustained action over an extended period of time. Selectively permeable membranes
30 surrounding an osmotically active driving compound are also suitable for orally administered compounds. In these later platforms, fluid from the environment

surrounding the capsule is imbibed by the driving compound, which swells to displace the agent or agent composition through an aperture. These delivery platforms can provide an essentially zero order delivery profile as opposed to the spiked profiles of immediate release formulations. A time-delay material, such as glycerol

5 monostearate or glycerol stearate, may also be used. Oral compositions can include standard carriers, such as mannitol, lactose, starch, magnesium stearate, sodium saccharine, cellulose, or magnesium carbonate. Such carriers can be of pharmaceutical grade.

The amount of the compound of the invention that will be effective in the

10 treatment of a particular disorder or condition will depend on the nature of the disorder or condition, and can be determined by standard clinical techniques. In addition, in vitro or in vivo assays may optionally be employed to help identify optimal dosage ranges. The precise dose to be employed in the compositions will also depend on the route of administration, and the seriousness of the disease or disorder,

15 and should be decided according to the judgment of the practitioner and each patient's circumstances. However, suitable effective dosage ranges for intravenous (i.v.) administration are generally about 0.001 to about 5 g, preferably about 0.001 to about 1 g of the compound per kilogram body weight. In specific embodiments, the i.v. dose is about 0.001 to about 0.5 g/kg, about 0.01 to about 0.3 g/kg, about 0.025 to

20 about 0.25 g/kg, about 0.04 to about 0.20 g/kg, or about 0.05 to about 0.20 g/kg (or the equivalent doses expressed per square meter of body surface area). Alternatively, a suitable dose range for i.v. administration may be obtained using doses of about 1 to about 2000 mg, without adjustment for a patient's body weight or body surface area. Suitable dosage ranges for intranasal administration are generally about 0.01 pg/kg

25 body weight to 10 mg/kg body weight. Suppositories generally contain 0.5% to 20% by weight of one or more compounds of the invention alone or in combination with another therapeutic agent. Oral compositions can contain about 10% to about 95% by weight of one or more compounds alone or in combination with another therapeutic agent. In specific embodiments of the invention, suitable dose ranges for oral

30 administration are generally about 0.1 to about 200 mg, preferably about 0.5 to about 100 mg, and more preferably about 1 to about 50 mg of pyrimidine heterocycle per

kilogram body weight or their equivalent doses expressed per square meter of body surface area. In specific embodiments, the oral dose is about 0.25 to about 75 mg/kg, about 1.0 to about 50 mg/kg, about 2.0 to about 25 mg/kg, about 2.5 to about 15 mg/kg, or about 5.0 to about 20 mg/kg (or the equivalent doses expressed per square meter of body surface area). In another embodiment, a suitable dose range for oral administration is from about 10 to about 4000 mg, without adjustment for a patient's body weight or body surface area. Other effective doses may be extrapolated from dose-response curves derived from in vitro or animal model test systems. Such animal models and systems are well known in the art.

10 The invention also provides pharmaceutical packs or kits comprising one or more containers containing one or more compounds of the invention. Optionally associated with such container(s) can be a notice in the form prescribed by a governmental agency regulating the manufacture, use or sale of pharmaceuticals or biological products, which notice reflects approval by the agency of manufacture, use or sale for human administration. In certain embodiments, e.g., when administered for the treatment or prevention of pain, the kit may also contain one or more analgesic agents useful for treating pain to be administered in combination with a pyrimidine heterocycle.

20 The compounds of the invention are preferably assayed in vivo, for the desired therapeutic or prophylactic activity, prior to use in humans. For example, in vivo assays can be used to determine whether administration of a specific compound or combination of compounds is preferred.

invention with carboxyl functional groups are the lower alkyl esters of the carboxylic acid. The carboxylate esters are conveniently formed by esterifying any of the carboxylic acid moieties present on the molecule. Prodrugs can typically be prepared using well-known methods, such as those described by *Burger's Medicinal Chemistry and Drug Discovery* 6th ed. (Ed. Donald J. Abraham, Wiley, 2001) and *Design and Application of Prodrugs* (Ed. H. Bundgaard, Harwood Academic Publishers Gmhf, 1985). Biohydrolyzable moieties of a compound of the invention either do not interfere with the biological activity of the compound but can confer upon that compound advantageous property in vivo, such as uptake, duration of action, or onset of action or are biologically inactive but are converted in vivo to the biologically active compound. Example 177: Determination of Analgesic Effect in an Experimental Model of Neuropathic Pain

The analgesic effect of a representative number of the compounds of the invention was determined using the procedures described hereafter.

5 Adult, male Sprague-Dawley rats were obtained from Charles River Laboratories (Wilmington, MA) and housed under standard conditions at the Institut Armand-Frappier (Laval, QC). Food and water were provided to experimental animals *ad libitum*, and rats weighed 175-200 grams at the time of assessment.

10 Compounds were prepared for intraperitoneal administration by dissolving them in a vehicle of hydroxypropyl methylcellulose (Sigma, St-Louis, MO); total volume of solution administered to rats was 10ml/kg.

15 Neuropathic pain was induced in rats via spared nerve injury (SNI) of the left sciatic nerve in accordance with the procedure described by Decosterd & Woolf (*Pain* 2000;87(2):149-58). Briefly, under isoflurane anesthesia, the sciatic nerve was exposed by dissection at the level of lower thigh, and a lesion of two of the three terminal branches of the nerve (tibial and common peroneal nerves) were performed leaving the remaining sural nerve intact. The incision was closed-up using simple suturing, and the rats allowed to recover.

20 Alternatively, neuropathic pain was induced in rats via chronic constriction injury (CCI) of the left sciatic nerve with the procedure described by Bennett & Xie (*Pain* 1988;33(1):87-107). Briefly, under isoflurane anaesthesia, the sciatic nerve was exposed by dissection at the level of the lower thigh and four loose ligatures (USP 4/0, Braun Melsaugen, FRG) were implanted around the nerve - with due attention not to interrupt the epineural circulation. The incision was closed-up using simple suturing, and the rats allowed to recover.

25 After approximately two weeks, a stable allodynia to blunt mechanical stimuli was identified in the hind paw ipsilateral to the SNI or CCI, manifested as a reduction of 50% withdrawal threshold, and identified using the Von Frey technique, as described by Chaplan et al. (*J. Neurosci. Methods* 1994;53(1):55-63), or the Hargreaves method, as described by Hargreaves et al. (*Pain* 1988;32(1):77-88). Rats were considered to be fully neuropathic upon displaying a 50% withdrawal threshold of ≤ 3.5 grams consistently over the course of 72 hours.

Compounds were administered to neuropathic rats via acute local delivery in the intraperitoneal space or by oral gavage.

Compounds of the invention that demonstrated efficacy in this assay include:

5

Table 1 presents the peak efficacy of several representative compounds in rats rendered neuropathic via the SNI Model, in terms of 50% withdrawal threshold. Data are presented as mean efficacy $\pm$ standard error of the mean. Note that in all cases the peak efficacy shown for the compounds was significantly different from the 50% withdrawal threshold of neuropathic rats administered vehicle control ($p < 0.05$, as assessed by repeated-measures ANOVA).

Table 2 presents the peak efficacy of several representative compounds in rats rendered neuropathic via the CCI model, in terms of 50% withdrawal threshold. Data are presented as mean efficacy $\pm$ standard error of the mean. Note that in all cases the peak efficacy shown for the compounds was significantly different from the 50% withdrawal threshold of neuropathic rats administered vehicle control ($p < 0.05$, as assessed by repeated-measures ANOVA).

Example 178: Determination of Anti-Convulsant Effect in an Experimental Psychomotor Seizure Model of Partial Epilepsy (Minimal Clonic Seizure Test)

The anti-convulsant effect of a representative number of the compounds of the invention was determined using the procedures described hereafter.

Adult mice are pretreated with 100 mg/kg of test compound, acutely administered intraperitoneally. At varying times (15, 30, 60, 120 and 240 minutes post-treatment), animals are challenged with sufficient current (32 mA, 6 Hz, for 3 seconds) delivered through corneal electrodes to elicit a psychomotor seizure. Untreated mice will display seizures characterized by a minimal clonic phase

followed by stereotyped, automatistic behaviors similar to the aura of human patients with partial seizures. Animals not displaying this behavior are considered protected (Barton et al., *Epilepsy Res.* 2001;47(3):217-27). Results are expressed as the number of animal protected out of the number of animal tested over time.

5 Compounds of the invention that demonstrated efficacy in this assay include:

Table 3 presents the peak protection of representative compounds in mice subjected to the Minimal Clonic Seizure model. Data are presented as number of protected animals out of number of tested animals over time.

It should also be noted that for in vivo medicinal uses, potency is not the only factor to be considered to estimate the suitability of a compound as a pharmaceutical agent. Other factors such as toxicity and bioavailability also determine the suitability of a compound as a pharmaceutical agent. Toxicity and bioavailability can also be tested in any assay system known to the skilled artisan.

The present invention is not to be limited in scope by the specific embodiments disclosed in the examples, which are intended as illustrations of a few aspects of the invention and any embodiments that are functionally equivalent are

within the scope of this invention. Indeed, various modifications of the invention in addition to those shown and described herein will become apparent to those skilled in the art and are intended to fall within the scope of the appended claims.
