and pharmaceutically acceptable derivatives, solvates, tautomers, salts and stereoisomers thereof, including mixtures thereof in all ratios.

The compounds of formula (I) and related formulae are preferably binding on receptors for sphingosine 1-phosphate (S_1P). S_1P is a bioactive sphingolipid metabolite that is secreted by hematopoietic cells and stored and released from activated platelets. It acts as an agonist on a family of G protein-coupled receptors (GPCR). Five sphingosine 1-phosphate receptors have been identified (S_1P_1 , S_1P_2 , S_1P_3 , S_1P_4 , and S_1P_5 , also known as endothelial differentiation genes, which are Edg1, Edg5, Edg3, Edg6 and Edg8 respectively), that have widespread cellular and tissue distribution and are well conserved in human and rodent species.

S_1P is involved in a number of cellular functions such as survival, proliferation and immunological responses. The compounds of the present invention are preferably acting as S_1P_1 /Edg1 receptor agonists and thus have immunosuppressive activities by modulating leukocyte trafficking, sequestering lymphocytes in secondary lymphoid tissues, and interfering with cell-cell interactions required for an efficient immune response. The invention is also directed to pharmaceutical compositions containing such compounds and methods of treatment or prevention.

FTY720 or fingolimod, a non selective S_1P_1 agonist, exerts immunosuppressive activity and shows therapeutic effects in the treatment of relapsing-remitting multiple sclerosis. Numerous publications have been already published using this compound: Cyster JG Annu Rev Immunol 23:127-59, 2005, Rosen H Nat Rev Immunol 5:560-570, 2005, Rosen H Trends Immunol 28:102-107, 2007, Yopp AC Clin Transplant 20:788-795, 2006, Kappos L N Engl J Med 355:1124-1140, 2006, Massberg S N Engl J Med 355:1088-1089, 2006.

Immunosuppressive agents are further useful in a wide variety of autoimmune and chronic inflammatory diseases, including systemic lupus erythematosus, chronic rheumatoid arthritis, type I diabetes mellitus, inflammatory bowel diseases, biliary cirrhosis, uveitis and other disorders such as Crohn's diseases, ulcerative colitis, bullous pemphigoid, sarcoidosis, psoriasis, autoimmune myositis, Wegener's granulomatosis, ichthyosis, Graves ophthalmopathy, atopic dermatitis and asthma. They are also useful as part of chemotherapeutic regimens for the treatment of cancers, lymphomas and leukemias.

Compounds used as S1P1 agonists and similar to those of the present application are disclosed in the application WO2004/103279. These compounds are characterized in that the heterocyclic moiety linked to the oxadiazole is substituted with an amino group in ortho position with respect to the oxadiazole.

5

It has been found that the compounds of the present invention are selective S1P1 agonists with improved pharmacological and/ or other properties.

Thus, the present invention preferably comprises compounds which are agonists of the S1P1/Edg1 receptor, especially having selectivity over the S1P3/Edg3 receptor. An S1P1/Edg1 receptor selective agonist has advantages over current therapies and extends the therapeutic window of lymphocyte sequestration agents, allowing better tolerability with higher dosing and thus improving efficacy.

Preferred compounds of the present invention exhibit pronounced ability to cross the blood/brain barrier.

The invention further relates to the manufacture of a medicament for the improvement of vascular function, either alone or in combination with other active compounds or therapies.

A preferred composition is with Cyclosporin A, FK506, rapamycin or 40-(2-hydroxy)ethyl-rapamycin and Fingolimod.

The invention further relates to a kit or a set comprising at least one compound of Formula 20 (I), preferably in combination with immunomodulating agents. Alternatively, the kit consists of separate packs of :

- (a) an effective amount of a compound of the formula (I) and/or pharmaceutically usable derivatives, solvates and stereoisomers thereof, including mixtures thereof in all ratios, and
- 25 (b) an effective amount of a further medicament active ingredient.

In general, the oxadiazole compounds according to Formula (I) of this invention may be prepared from readily available starting materials. If such starting materials are not commercially available, they may be prepared by standard synthetic techniques. In general, 30 the synthesis pathways for any individual compound of Formula (I) will depend on the specific substituents of each molecule, such factors being appreciated by those of ordinary skill in the art. The following general methods and procedures described hereinafter in the examples may be employed to prepare compounds of Formula (I). Reaction conditions depicted in the following schemes, such as temperatures, solvent, or co-reagents, are given 35 as examples only and are not restrictive. It will be appreciated that where typical or preferred

experimental conditions (i.e. reaction temperatures, time, moles of reagents, solvents etc.) are given, other experimental conditions can also be used unless otherwise stated. Optimum reaction conditions may vary with the particular reactants or solvents used, but such conditions can be determined by the person skilled in the art, using routine optimisation procedures. For all the protection and deprotection methods, see Philip J. Kocienski, in "Protecting Groups", Georg Thieme Verlag Stuttgart, New York, 1994 and, Theodora W. Greene and Peter G. M. Wuts in "Protective Groups in Organic Synthesis", Wiley Interscience, 3rd Edition 1999.

Depending on the nature of R^1 , R^2 , R^a , R^b , Y, W and Z, different synthetic strategies may be selected for the synthesis of compounds of Formula (I). In the process illustrated in the following schemes R^1 , R^2 , R^a , R^b , Y, W and Z, are as above-defined in the description unless otherwise mentioned.

According to a preferred synthetic pathway, the compounds of Formula (I), wherein R^1 , R^2 , R^a , R^b , Y, W and Z are defined as above, can be obtained in a 2-step protocol as outlined in Scheme 1. The first step consists in the coupling of a carboxylic acid of Formula (III) wherein R^a , R^b and Z are as above defined, with an amidoxime of Formula (II), wherein R^1 , R^2 , Y, and W are defined as above. General protocols for such coupling are given below in the examples, using conditions and methods well known to those skilled in the art. Standard coupling agent, such as HATU, EDC or isobutyl chloroformate can be used in the presence or not of a base such as DIEA, TEA or NMM in a suitable solvent such as DMF, ACN, THF or iPrOAc at a temperature rising from about 0°C to RT, preferably at 0°C for a time of 30 minutes to a few hours. Alternatively, a carboxylic acid derivative (e.g. acyl chloride) may be coupled with the amidoxime (II), using conditions and methods well known to those skilled in the art, in the presence of a base such as pyridine or DIEA in a suitable solvent such as toluene, DCM, THF or DMF, at a temperature rising from about 0°C to RT, preferably at RT, for a few hours. The second step consists of the cyclization and dehydration of the O-substituted amidoximes (IV) to form oxadiazole (I). Conditions are given below in the examples, using methods well known to those skilled in the art to prepare oxadiazole, such as thermolysis at temperature rising from 80°C to about 120°C, typically 90°C, for a time comprised between 12 and 72 hours, preferably for 15 hours, in a suitable solvent or mixture of solvents, such as toluene, pyridine, ACN, THF, DMF or iPrOAc in the presence or not of a base such as DIEA, TEA or NMM.

In particular, but not limited to, ester derivatives of Formula (I), and preferably methyl or tert-butyl ester derivatives, may be converted into the corresponding carboxylic acid derivatives of Formula (I), using conditions well known to those skilled in the art, such as a metal hydroxide (e.g. lithium hydroxide, sodium hydroxide or potassium hydroxide), in a suitable solvent such as THF, methanol, ethanol or water or mixtures thereof, or using an acid (e.g. HCl or TFA), in a suitable solvent such as dioxane, DCM, at a temperature between about 20°C to about 50°C, preferably at RT, for a few hours.

Compounds of Formula (III), wherein R^a , R^b and Z are defined as above, may be prepared by standard synthetic techniques, as hereinafter described in the examples, using conditions and methods well known to those skilled in the art (Scheme 3). In a first synthetic pathway, compounds of Formula (III), wherein R^a , R^b and Z are defined as above, may be obtained by metal catalyzed cross-coupling reaction, followed by hydrolysis of the resulting ester (VI). More particularly, they may be obtained by Suzuki-Miyura coupling reaction between an alkyl benzoate (VII), where LG_1 may preferably be Br, I or a sulfonate ester such as triflate, and a boronic acid or ester of Formula (XII) (Miyaura, N.; Suzuki, A. Chem. Rev. 1995, 95, 2457;

Takahiro I. and Toshiaki M., Tetrahedron Lett. 2005, 46, 3573-3577). In a typical procedure, alkyl benzoate (VII) and boronic acid (XII) are heated in a suitable solvent, such as a mixture of toluene and water, in the presence of a base, such as K_2CO_3 , and a catalytic amount of a palladium catalyst, such as $Pd(PPh_3)_4$, with the possible addition of a phosphine ligand, such as PPh_3 . The resulting ester (VI) may be hydrolyzed using a metal hydroxide, such as NaOH, in a suitable solvent, such as MeOH, EtOH, water or mixtures thereof, at a temperature rising from about 20°C to 60°C, preferably at RT, for a few hours.

Scheme 3

In a second synthetic pathway, compounds of Formula (III), wherein R^a , R^b and Z are defined as above, may be obtained by a coupling reaction, followed by hydrolysis of the resulting nitrile (VIII). More particularly, according to Scheme 3, compounds of Formula (VIII), wherein R^a and R^b are defined as above and Z is Het including a nitrogen atom at the position adjacent to R^b making a bond with the aryl moiety, may be prepared by a SN_{Ar} reaction between a compound of Formula (XIII), wherein R^b is defined as above and Z is Het including a secondary amine at the position adjacent to R^b , and a benzonitrile of Formula (IX), wherein R^a is defined as above and LG_2 is a suitable leaving group. In a third synthetic pathway, according to Scheme 3, compounds of Formula (III), wherein R^a, R^b and Z are defined as above, may be prepared from arylbromide of Formula (XI) in a two steps process. The first step is an halogen-metal exchange with a lithiated alkyl, such as nBuLi or tBuLi, in a suitable solvent, such as Et₂O, at low temperature, preferably at -78°C. The second step is the quench of the organolithiated derivative by addition of CO₂, as gas or in solid state, as electrophile.

Compounds of Formulae (V), (VII), (IX), (XI), (XII) and (XIII) may be obtained either from commercial sources or they may be prepared from known compounds using procedures

such as those described hereinafter in the examples, or conventional procedures, well known by one skilled in the art.

Compounds of Formulae (III), (V), (VI), (VII), (VIII), (IX), (XI), (XII) and (XIII), wherein R¹, R², R^a, R^b, Y, W, Z, LG₁ and LG₂ are as above defined, may be converted to alternative compounds of Formulae (III), (V), (VI), (VII), (VIII), (IX), (XI), (XII) and (XIII) respectively, using suitable interconversion procedures such as those described hereinafter in the examples, or conventional interconversion procedures well known by one skilled in the art.

If the above set of general synthetic methods is not applicable to obtain compounds according to Formula (I) and/or necessary intermediates for the synthesis of compounds of Formula (I), suitable methods of preparation known by a person skilled in the art should be used.

Compounds of this invention can be isolated in association with solvent molecules by crystallization from an appropriate solvent or by evaporation of an appropriate solvent.

The pharmaceutically acceptable anionic salts of the compounds of Formula (I), which contain a basic center, may be prepared in a conventional manner. For example, a solution of the free base may be treated with a suitable acid, either neat or in a suitable solution, and the resulting salt isolated either by filtration or by evaporation under vacuum of the reaction solvent.

The pharmaceutically acceptable cationic salts of the compounds of Formula (I), which contain an acidic center, may be prepared in a conventional manner. For example, a solution of the free acid may be treated with a suitable base, either neat or in a suitable solution, and the resulting salt isolated either by filtration or by evaporation under vacuum of the reaction solvent. In some cases, salts can be prepared by mixing a solution of the acid with a solution of the cation (sodium ethylhexanoate, magnesium oleate), employing a solvent in which the desired cationic salt precipitates, or can be otherwise isolated by concentration and addition of a non-solvent.

Both types of salts may be formed or interconverted using ion-exchange resin techniques.

The compounds of invention have been named according the standards used in the program "ACD/Name Batch" from Advanced Chemistry Development Inc., ACD/Labs (7.00 Release). Product version: 7.10, build: 15 Sep 2003.

- 5 Depending on the conditions used, the reaction times are generally between a few minutes and 14 days, and the reaction temperature is between about -30°C and 140°C, normally between -10°C and 90°C, in particular between about 0°C and about 70°C.

Compounds of the formula (I) and related formulae can furthermore be obtained by liberating
10 compounds of the formula (I) from one of their functional derivatives by treatment with a solvolysing or hydrogenolysing agent.

Preferred starting materials for the solvolysis or hydrogenolysis are those which conform to the formula (I) and related formulae, but contain corresponding protected amino and/or
15 hydroxyl groups instead of one or more free amino and/or hydroxyl groups, preferably those which carry an amino-protecting group instead of an H atom bonded to an N atom, in particular those which carry an R'-N group, in which R' denotes an amino-protecting group, instead of an HN group, and/or those which carry a hydroxyl-protecting group instead of the H atom of a hydroxyl group, for example those which conform to the formula (I), but carry a -
20 COOR" group, in which R" denotes a hydroxyl-protecting group, instead of a -COOH group.

It is also possible for a plurality of – identical or different – protected amino and/or hydroxyl groups to be present in the molecule of the starting material. If the protecting groups present are different from one another, they can in many cases be cleaved off selectively.

25 The term "amino-protecting group" is known in general terms and relates to groups which are suitable for protecting (blocking) an amino group against chemical reactions, but which are easy to remove after the desired chemical reaction has been carried out elsewhere in the molecule. Typical of such groups are, in particular, unsubstituted or substituted acyl, aryl, aralkoxymethyl or aralkyl groups. Since the amino-protecting groups are removed after the
30 desired reaction (or reaction sequence), their type and size are furthermore not crucial; however, preference is given to those having 1-20, in particular 1-8, carbon atoms. The term "acyl group" is to be understood in the broadest sense in connection with the present process. It includes acyl groups derived from aliphatic, araliphatic, aromatic or heterocyclic
35 carboxylic acids or sulfonic acids, and, in particular, alkoxycarbonyl, aryloxycarbonyl and

especially aralkoxycarbonyl groups. Examples of such acyl groups are alkanoyl, such as acetyl, propionyl and butyryl; aralkanoyl, such as phenylacetyl; aroyl, such as benzoyl and tolyl; aryloxyalkanoyl, such as POA; alkoxycarbonyl, such as methoxycarbonyl, ethoxycarbonyl, 2,2,2-trichloroethoxycarbonyl, BOC (tert-butoxycarbonyl) and 2-iodoethoxycarbonyl; aralkoxycarbonyl, such as CBZ ("carbobenzoxyl"), 4-methoxybenzyloxycarbonyl and FMOC; and arylsulfonyl, such as Mtr. Preferred amino-protecting groups are BOC and Mtr, furthermore CBZ, Fmoc, benzyl and acetyl.

The term "hydroxyl-protecting group" is likewise known in general terms and relates to groups which are suitable for protecting a hydroxyl group against chemical reactions, but are easy to remove after the desired chemical reaction has been carried out elsewhere in the molecule. Typical of such groups are the above-mentioned unsubstituted or substituted aryl, aralkyl or acyl groups, furthermore also alkyl groups. The nature and size of the hydroxyl-protecting groups are not crucial since they are removed again after the desired chemical reaction or reaction sequence; preference is given to groups having 1-20, in particular 1-10, carbon atoms. Examples of hydroxyl-protecting groups are, inter alia, benzyl, 4-methoxybenzyl, p-nitrobenzoyl, p-toluenesulfonyl, tert-butyl and acetyl, where benzyl and tert-butyl are particularly preferred.

The compounds of the formula (I) and related formulae are liberated from their functional derivatives – depending on the protecting group used – for example using strong acids, advantageously using TFA or perchloric acid, but also using other strong inorganic acids, such as hydrochloric acid or sulfuric acid, strong organic carboxylic acids, such as trichloroacetic acid, or sulfonic acids, such as benzene- or p-toluenesulfonic acid. The presence of an additional inert solvent is possible, but is not always necessary. Suitable inert solvents are preferably organic, for example carboxylic acids, such as acetic acid, ethers, such as tetrahydrofuran or dioxane, amides, such as DMF, halogenated hydrocarbons, such as dichloromethane, furthermore also alcohols, such as methanol, ethanol or isopropanol, and water. Mixtures of the above-mentioned solvents are furthermore suitable. TFA is preferably used in excess without addition of a further solvent, and perchloric acid is preferably used in the form of a mixture of acetic acid and 70% perchloric acid in the ratio 9:1. The reaction temperatures for the cleavage are advantageously between about 0 and about 50°C, preferably between 15 and 30°C (room temperature).

The BOC, OtBu and Mtr groups can, for example, preferably be cleaved off using TFA in dichloromethane or using approximately 3 to 5N HCl in dioxane at 15-30°C, and the Fmoc group can be cleaved off using an approximately 5 to 50% solution of dimethylamine, diethylamine or piperidine in DMF at 15-30°C.

5

Protecting groups which can be removed hydrogenolytically (for example CBZ, benzyl or the liberation of the amidino group from the oxadiazole derivative thereof) can be cleaved off, for example, by treatment with hydrogen in the presence of a catalyst (for example a noble-metal catalyst, such as palladium, advantageously on a support, such as carbon). Suitable solvents here are those indicated above, in particular, for example, alcohols, such as methanol or ethanol, or amides, such as DMF. The hydrogenolysis is generally carried out at temperatures between about 0 and 100°C and pressures between about 1 and 200 bar, preferably at 20-30°C and 1-10 bar. Hydrogenolysis of the CBZ group succeeds well, for example, on 5 to 10% Pd/C in methanol or using ammonium formate (instead of hydrogen) on Pd/C in methanol/DMF at 20-30°C.

10

15

Examples of suitable inert solvents are hydrocarbons, such as hexane, petroleum ether, benzene, toluene or xylene; chlorinated hydrocarbons, such as trichloroethylene, 1,2-dichloroethane, tetrachloromethane, trifluoromethylbenzene, chloroform or dichloromethane; alcohols, such as methanol, ethanol, isopropanol, n-propanol, n-butanol or tert-butanol; ethers, such as diethyl ether, diisopropyl ether, tetrahydrofuran (THF) or dioxane; glycol ethers, such as ethylene glycol monomethyl or monoethyl ether or ethylene glycol dimethyl ether (diglyme); ketones, such as acetone or butanone; amides, such as acetamide, dimethylacetamide, N-methylpyrrolidone (NMP) or dimethylformamide (DMF); nitriles, such as acetonitrile; sulfoxides, such as dimethyl sulfoxide (DMSO); carbon disulfide; carboxylic acids, such as formic acid or acetic acid; nitro compounds, such as nitromethane or nitrobenzene; esters, such as ethyl acetate, or mixtures of the said solvents.

20

25

Esters can be saponified, for example, using acetic acid or using LiOH, NaOH or KOH in water, water/THF, water/THF/ethanol or water/dioxane, at temperatures between 0 and 100°C.

30

Free amino groups can furthermore be acylated in a conventional manner using an acid chloride or anhydride or alkylated using an unsubstituted or substituted alkyl halide or reacted with $\text{CH}_3\text{-C(=NH)-OEt}$, advantageously in an inert solvent, such as dichloromethane

35

or THF and/or in the presence of a base, such as triethylamine or pyridine, at temperatures between -60°C and +30°C.

Throughout the specification, the term leaving group preferably denotes Cl, Br, I or a
5 reactively modified OH group, such as, for example, an activated ester, an imidazolidine or alkylsulfonyloxy having 1-6 carbon atoms (preferably methylsulfonyloxy or trifluoromethylsulfonyloxy) or arylsulfonyloxy having 6-10 carbon atoms (preferably phenyl- or p-tolylsulfonyloxy).

Radicals of this type for activation of the carboxyl group in typical acylation reactions are
10 described in the literature (for example in the standard works, such as Houben-Weyl, Methoden der organischen Chemie [Methods of Organic Chemistry], Georg-Thieme-Verlag, Stuttgart).

Activated esters are advantageously formed in situ, for example through addition of HOBt or N-hydroxysuccinimide.

15 The formula (I) and related formulae also encompasses the optically active forms (stereoisomers), the enantiomers, the racemates, the diastereomers and the hydrates and solvates of these compounds. The term "solvates of the compounds" is taken to mean adductions of inert solvent molecules onto the compounds which form owing to their mutual
20 attractive force. Solvates are, for example, mono- or dihydrates or alcoholates.

The term "pharmaceutically usable derivatives" is taken to mean, for example, the salts of the compounds of the formula (I) and so-called prodrug compounds.

The term "prodrug derivatives" or "prodrug" is taken to mean compounds of the formula (I)
25 which have been modified with, for example, alkyl or acyl groups, sugars or oligopeptides and which are rapidly cleaved in the organism to form the active compounds.

These also include biodegradable polymer derivatives of the compounds according to the invention, as described, for example, in Int. J. Pharm. 115, 61-67 (1995).

30 The formula (I) and related formulae also encompasses mixtures of the compounds of the formula I, for example mixtures of two diastereomers, for example in the ratio 1:1, 1:2, 1:3, 1:4, 1:5, 1:10, 1:100 or 1:1000.

These are particularly preferably mixtures of stereoisomeric compounds.

When in a ring, the substituent is not specifically localised, it can take the place of a H atom linked to any H-bearing atom of the ring. The same is true for the connexion of 2 moieties of the chemical structure. Pharmaceutical salts and other forms

The said compounds of the formula I can be used in their final non-salt form. On the other hand, the present invention also relates to the use of these compounds in the form of their pharmaceutically acceptable salts, which can be derived from various organic and inorganic acids and bases by procedures known in the art. Pharmaceutically acceptable salt forms of the compounds of the formula I are for the most part prepared by conventional methods. If the compound of the formula I contains an acidic center, such as a carboxyl group, one of its suitable salts can be formed by reacting the compound with a suitable base to give the corresponding base-addition salt. Such bases are, for example, alkali metal hydroxides, including potassium hydroxide, sodium hydroxide and lithium hydroxide; alkaline earth metal hydroxides, such as barium hydroxide and calcium hydroxide; alkali metal alkoxides, for example sodium- or potassiummethoxide and sodium or potassiumpropoxide, alkalihydrides, such as sodium- or potassiumhydride; and various organic bases, such as piperidine, diethanolamine and N-methyl-glutamine, benzathine, choline, diethanolamine, ethylenediamine, meglumine, benethamine, diethylamine, piperazine and tromethamine. The aluminium salts of the compounds of the formula I are likewise included. In the case of certain compounds of the formula I, which contain a basic center, acid-addition salts can be formed by treating these compounds with pharmaceutically acceptable organic and inorganic acids, for example hydrogen halides, such as hydrogen chloride, hydrogen bromide or hydrogen iodide, other mineral acids and corresponding salts thereof, such as sulfate, nitrate or phosphate and the like, and alkyl- and monoaryl-sulfonates, such as ethanesulfonate, toluenesulfonate and benzene-sulfonate, and other organic acids and corresponding salts thereof, such as acetate, trifluoro-acetate, tartrate, maleate, succinate, citrate, benzoate, salicylate, ascorbate and the like. Accordingly, pharmaceutically acceptable acid-addition salts of the compounds of the formula I include the following: acetate, adipate, alginate, arginate, aspartate, benzoate, benzene-sulfonate (besylate), bisulfate, bisulfite, bromide,

butyrate, camphorate, camphor-sulfonate, caprylate, chloride, chlorobenzoate, citrate, cyclo-pentane-propionate, digluconate, dihydrogen-phosphate, dinitrobenzoate, dodecyl-sulfate, ethanesulfonate, fumarate, galacterate (from mucic acid), galacturonate, glucoheptanoate, gluco-nate, glutamate, glycerophosphate, hemi-succinate, hemisulfate, 5 heptanoate, hexanoate, hippurate, hydro-chloride, hydrobromide, hydroiodide, 2-hydroxy-ethane-sulfonate, iodide, isethionate, isobutyrate, lactate, lactobionate, malate, maleate, malonate, mandelate, metaphosphate, methanesulfonate, methylbenzoate, mono-hydrogen-phosphate, 2-naphthalenesulfonate, nicotinate, nitrate, oxalate, oleate, palmo-ate, pectinate, persulfate, phenylacetate, 3-phenylpropionate, phosphate, 10 phosphonate, phthalate, but this does not represent a restriction. Both types of salts may be formed or interconverted preferably using ion-exchange resin techniques.

Furthermore, the base salts of the compounds of the formula I include aluminium, ammonium, calcium, copper, iron (III), iron(II), lithium, magne-sium, manganese(III), 15 manganese(II), potassium, sodium and zink salts, but this is not intended to represent a restriction. Of the above-mentioned salts, preference is given to ammonium; the alkali metal salts sodium and potassium, and the alkaline earth metal salts calcium and magnesium. Salts of the compounds of the formula I which are derived from pharmaceutically acceptable organic non-toxic bases include salts of primary, secondary and tertiary amines, substituted 20 amines, also including naturally occurring substituted amines, cyclic amines, and basic ion exchanger resins, for example arginine, betaine, caffeine, chlorprocaine, choline, N,N'-dibenzyl-ethylen-ediamine (benzathine), dicyclohexylamine, diethanol-amine, diethyl-amine, 2-diethyl-amino-ethanol, 2-dimethyl-amino-ethanol, ethanolamine, ethylenediamine, N-ethylmorpholine, N-ethyl-piperidine, glucamine, glucosamine, histidine, hydrabamine, 25 isopropyl-amine, lido-caine, lysine, meglumine (N-methyl-D-glucamine), morpholine, piperazine, piperidine, polyamine resins, procaine, purines, theobromine, triethanol-amine, triethylamine, trimethylamine, tripropyl-amine and tris(hydroxy-methyl)-methylamine (tromethamine), but this is not intended to represent a restriction.

30 Compounds of the formula (I) of the present invention which contain basic N-containing groups can be quaternised using agents such as (C1-C4)-alkyl halides, for example methyl, ethyl, isopropyl and tert-butyl chloride, bromide and iodide; di(C1-C4)alkyl sulfates, for example dimethyl, diethyl and diamyl sulfate; (C10-C18)alkyl halides, for example decyl, do-decyl, lauryl, myristyl and stearyl chloride, bromide and iodide; and aryl-(C1-C4)alkyl

halides, for example benzyl chloride and phenethyl bromide. Both water- and oil-soluble compounds of the formula I can be prepared using such salts.

The above-mentioned pharmaceutical salts which are preferred include acetate,
5 trifluoroacetate, besylate, citrate, fumarate, gluconate, hemisuccinate, hippurate, hydrochloride, hydrobromide, isethionate, mandelate, me-glumine, nitrate, oleate, phosphonate, pivalate, sodium phosphate, stearate, sulfate, sulfosalicylate, tartrate, thiomalate, tosylate and tro-meth-amine, but this is not intended to represent a restriction.

10 The acid-addition salts of basic compounds of the formula (I) are prepared by bringing the free base form into contact with a sufficient amount of the desired acid, causing the formation of the salt in a conventional manner. The free base can be regenerated by bringing the salt form into contact with a base and isolating the free base in a conventional manner. The free base forms differ in a certain respect from the corresponding salt forms thereof with respect
15 to certain physical properties, such as solubility in polar solvents; for the purposes of the invention, however, the salts other-wise correspond to the respective free base forms thereof.

As mentioned, the pharmaceutically acceptable base-addition salts of the compounds of the
20 formula I are formed with metals or amines, such as alkali metals and alkaline earth metals or organic amines. Preferred metals are sodium, potassium, magnesium and calcium. Preferred organic amines are N,N'-dibenzylethylenediamine, chlorprocaine, choline, diethanol-amine, ethylenediamine, N-methyl-D-glucamine and procaine.

25 The base-addition salts of acidic compounds of the formula (I) are prepared by bringing the free acid form into contact with a sufficient amount of the desired base, causing the formation of the salt in a conventional manner. The free acid can be regenerated by bringing the salt form into contact with an acid and isolating the free acid in a conventional manner. The free acid forms differ in a certain respect from the corresponding salt forms thereof with respect to
30 certain physical properties, such as solubility in polar solvents; for the purposes of the invention, however, the salts other-wise correspond to the respective free acid forms thereof.

If a compound of the formula I contains more than one group which is capable of forming pharmaceutically acceptable salts of this type, the formula (I) also encompasses multiple
35 salts. Typical multiple salt forms include, for example, bitartrate, diacetate, difumarate,

dimeglumine, di-phosphate, disodium and trihydrochloride, but this is not intended to represent a restriction.

With regard to that stated above, it can be seen that the term "pharmaceutically acceptable salt" in the present connection is taken to mean an active ingredient which comprises a compound of the formula I in the form of one of its salts, in particular if this salt form imparts improved pharmacokinetic properties on the active ingredient compared with the free form of the active ingredient or any other salt form of the active ingredient used earlier. The pharmaceutically acceptable salt form of the active ingredient can also provide this active ingredient for the first time with a desired pharmacokinetic property which it did not have earlier and can even have a positive influence on the pharmacodynamics of this active ingredient with respect to its therapeutic efficacy in the body.

Owing to their molecular structure, the compounds of the formula I can be chiral and can accordingly occur in various enantiomeric forms. They can therefore exist in racemic or in optically active form.

Since the pharmaceutical activity of the racemates or stereoisomers of the compounds according to the invention may differ, it may be desirable to use the enantiomers. In these cases, the end product or even the Intermediates can be separated into enantiomeric compounds by chemical or physical measures known to the person skilled in the art or even employed as such in the synthesis.

In the case of racemic amines, diastereomers are formed from the mixture by reaction with an optically active resolving agent. Examples of suitable resolving agents are optically active acids, such as the R and S forms of tartaric acid, diacetyltartaric acid, dibenzoyltartaric acid, mandelic acid, malic acid, lactic acid, suitable N-protected amino acids (for example N-benzoylproline or N-benzenesulfonylproline), or the various optically active camphorsulfonic acids. Also advantageous is chromatographic enantiomer resolution with the aid of an optically active resolving agent (for example dinitrobenzoylphenylglycine, cellulose triacetate or other derivatives of carbohydrates or chirally derivatised methacrylate polymers immobilised on silica gel). Suitable eluents for this purpose are aqueous or alcoholic solvent mixtures, such as, for example, hexane/isopropanol/ acetonitrile, for example in the ratio 82:15:3.

The invention furthermore relates to the use of compounds of formula (I), in combination with at least one further medicament active ingredient, preferably medicaments used in the treatment of multiple sclerosis such as cladribine or another co-agent, such as interferon, e.g. pegylated or non-pegylated interferons, preferably interferon beta and/or with
5 compounds improving vascular function. These further medicaments, such as interferon beta, may be administered concomitantly or sequentially, e.g. by subcutaneous, intramuscular or oral routes.

These compositions can be used as medicaments in human and veterinary medicine.

- 10 Pharmaceutical formulations can be administered in the form of dosage units, which comprise a predetermined amount of active ingredient per dosage unit. Such a unit can comprise, for example, 0.5 mg to 1 g, preferably 1 mg to 700 mg, particularly preferably 5 mg to 100 mg, of a compound according to the invention, depending on the disease condition treated, the method of administration and the age, weight and condition of the patient, or
15 pharmaceutical formulations can be administered in the form of dosage units which comprise a predetermined amount of active ingredient per dosage unit. Preferred dosage unit formulations are those which comprise a daily dose or part-dose, as indicated above, or a corresponding fraction thereof of an active ingredient. Furthermore, pharmaceutical formulations of this type can be prepared using a process, which is generally known in the
20 pharmaceutical art.

- Pharmaceutical formulations can be adapted for administration via any desired suitable method, for example by oral (including buccal or sublingual), rectal, nasal, topical (including buccal, sublingual or transdermal), vaginal or parenteral (including subcutaneous,
25 intramuscular, intravenous or intradermal) methods. Such formulations can be prepared using all processes known in the pharmaceutical art by, for example, combining the active ingredient with the excipient(s) or adjuvant(s).

- Pharmaceutical formulations adapted for oral administration can be administered as separate
30 units, such as, for example, capsules or tablets; powders or granules; solutions or suspensions in aqueous or non-aqueous liquids; edible foams or foam foods; or oil-in-water liquid emulsions or water-in-oil liquid emulsions.

- Thus, for example, in the case of oral administration in the form of a tablet or capsule, the
35 active-ingredient component can be combined with an oral, non-toxic and pharmaceutically

acceptable inert excipient, such as, for example, ethanol, glycerol, water and the like.

Powders are prepared by comminuting the compound to a suitable fine size and mixing it with a pharmaceutical excipient comminuted in a similar manner, such as, for example, an edible carbohydrate, such as, for example, starch or mannitol. A flavour, preservative,
5 dispersant and dye may likewise be present.

Capsules are produced by preparing a powder mixture as described above and filling shaped gelatine shells therewith. Glidants and lubricants, such as, for example, highly disperse silicic acid, talc, magnesium stearate, calcium stearate or polyethylene glycol in solid form, can be
10 added to the powder mixture before the filling operation. A disintegrant or solubiliser, such as, for example, agar-agar, calcium carbonate or sodium carbonate, may likewise be added in order to improve the availability of the medica-ment after the capsule has been taken.

In addition, if desired or necessary, suitable binders, lubricants and disintegrants as well as
15 dyes can likewise be incorporated into the mixture. Suitable binders include starch, gelatine, natural sugars, such as, for example, glucose or beta-lactose, sweeteners made from maize, natural and synthetic rubber, such as, for example, acacia, tragacanth or sodium alginate, carboxymethylcellulose, polyethylene glycol, waxes, and the like. The lubricants used in these dosage forms include sodium oleate, sodium stearate, magnesium stearate, sodium
20 benzoate, sodium acetate, sodium chloride and the like. The disintegrants include, without being restricted thereto, starch, methylcellulose, agar, bentonite, xanthan gum and the like. The tablets are formulated by, for example, preparing a powder mixture, granulating or dry-pressing the mixture, adding a lubricant and a disintegrant and pressing the entire mixture to give tablets. A powder mixture is prepared by mixing the compound comminuted in a suitable
25 manner with a diluent or a base, as described above, and optionally with a binder, such as, for example, carboxymethylcellulose, an alginate, gelatine or polyvinyl-pyrrolidone, a dissolution retardant, such as, for example, paraffin, an absorption accelerator, such as, for example, a quaternary salt, and/or an absorbant, such as, for example, bentonite, kaolin or dicalcium phosphate. The powder mixture can be granulated by wetting it with a binder, such
30 as, for example, syrup, starch paste, acacia mucilage or solutions of cellulose or polymer materials and pressing it through a sieve. As an alternative to granulation, the powder mixture can be run through a tableting machine, giving lumps of non-uniform shape which are broken up to form granules. The granules can be lubricated by addition of stearic acid, a stearate salt, talc or mineral oil in order to prevent sticking to the tablet casting moulds. The
35 lubricated mixture is then pressed to give tablets. The active ingredients can also be

combined with a free-flowing inert excipient and then pressed directly to give tablets without carrying out the granulation or dry-pressing steps. A transparent or opaque protective layer consisting of a shellac sealing layer, a layer of sugar or polymer material and a gloss layer of wax may be present. Dyes can be added to these coatings in order to be able to differentiate
5 between different dosage units.

Oral liquids, such as, for example, solution, syrups and elixirs, can be prepared in the form of dosage units so that a given quantity comprises a pre-specified amount of the compounds. Syrups can be prepared by dissolving the compounds in an aqueous solution with a suitable
10 flavour, while elixirs are prepared using a non-toxic alcoholic vehicle. Suspensions can be formulated by dispersion of the compounds in a non-toxic vehicle. Solubilisers and emulsifiers, such as, for example, ethoxylated isostearyl alcohols and polyoxyethylene sorbitol ethers, preservatives, flavour additives, such as, for example, peppermint oil or natural sweeteners or saccharin, or other artificial sweeteners and the like, can likewise be
15 added.

The dosage unit formulations for oral administration can, if desired, be encapsulated in microcapsules. The formulation can also be prepared in such a way that the release is extended or retarded, such as, for example, by coating or embedding of particulate material
20 in polymers, wax and the like.

The compounds of the formula (I) and salts, solvates and physiologically functional derivatives thereof and the other active ingredients can also be administered in the form of liposome delivery systems, such as, for example, small unilamellar vesicles, large
25 unilamellar vesicles and multilamellar vesicles. Liposomes can be formed from various phospholipids, such as, for example, cholesterol, stearylamine or phosphatidylcholines.

The compounds of the formula (I) and the salts, solvates and physiologically functional derivatives thereof and the other active ingredients can also be delivered using monoclonal
30 antibodies as individual carriers to which the compound molecules are coupled. The compounds can also be coupled to soluble polymers as targeted medicament carriers. Such polymers may encompass polyvinylpyrrolidone, pyran copolymer, polyhydroxypropyl-methacrylamidophenol, polyhydroxyethylaspartamidophenol or polyethylene oxide polylysine, substituted by palmitoyl radicals. The compounds may
35 furthermore be coupled to a class of biodegradable polymers which are suitable for achieving

controlled release of a medicament, for example polylactic acid, poly-epsilon-caprolactone, polyhydroxybutyric acid, poly-orthoesters, polyacetals, polydihydroxypyranes, polycyanoacrylates and crosslinked or amphipathic block copolymers of hydrogels.

- 5 Pharmaceutical formulations adapted for transdermal administration can be administered as independent plasters for extended, close contact with the epidermis of the recipient. Thus, for example, the active ingredient can be delivered from the plaster by iontophoresis, as described in general terms in *Pharmaceutical Research*, 3(6), 318 (1986).
- 10 Pharmaceutical compounds adapted for topical administration can be formulated as ointments, creams, suspensions, lotions, powders, solutions, pastes, gels, sprays, aerosols or oils.

- For the treatment of the eye or other external tissue, for example mouth and skin, the
- 15 formulations are preferably applied as topical ointment or cream. In the case of formulation to give an ointment, the active ingredient can be employed either with a paraffinic or a water-miscible cream base. Alternatively, the active ingredient can be formulated to give a cream with an oil-in-water cream base or a water-in-oil base.

- 20 Pharmaceutical formulations adapted for topical application to the eye include eye drops, in which the active ingredient is dissolved or suspended in a suitable carrier, in particular an aqueous solvent.

- Pharmaceutical formulations adapted for topical application in the mouth encompass
- 25 lozenges, pastilles and mouthwashes.

Pharmaceutical formulations adapted for rectal administration can be administered in the form of suppositories or enemas.

- 30 Pharmaceutical formulations adapted for nasal administration in which the carrier substance is a solid comprise a coarse powder having a particle size, for example, in the range 20-500 microns, which is administered in the manner in which snuff is taken, i.e. by rapid inhalation via the nasal passages from a container containing the powder held close to the nose. Suitable formulations for administration as nasal spray or nose drops with a liquid as carrier
- 35 substance encompass active-ingredient solutions in water or oil.

Pharmaceutical formulations adapted for administration by inhalation encompass finely particulate dusts or mists, which can be generated by various types of pressurised dispensers with aerosols, nebulisers or insufflators.

5

Pharmaceutical formulations adapted for vaginal administration can be administered as pessaries, tampons, creams, gels, pastes, foams or spray formulations.

Pharmaceutical formulations adapted for parenteral administration include aqueous and non-
10 aqueous sterile injection solutions comprising antioxidants, buffers, bacteriostatics and solutes, by means of which the formulation is rendered isotonic with the blood of the recipient to be treated; and aqueous and non-aqueous sterile suspensions, which may comprise suspension media and thickeners. The formulations can be administered in single-dose or multidose containers, for example sealed ampoules and vials, and stored in freeze-dried
15 (lyophilised) state, so that only the addition of the sterile carrier liquid, for example water for injection purposes, immediately before use is necessary.

Injection solutions and suspensions prepared in accordance with the recipe can be prepared from sterile powders, granules and tablets.

20

It goes without saying that, in addition to the above particularly mentioned constituents, the formulations may also comprise other agents usual in the art with respect to the particular type of formulation; thus, for example, formulations which are suitable for oral administration may comprise flavours.

25

A therapeutically effective amount of a compound of the formula (I) and of the other active ingredient depends on a number of factors, including, for example, the age and weight of the animal, the precise disease condition which requires treatment, and its severity, the nature of the formulation and the method of administration, and is ultimately determined by the treating
30 doctor or vet. However, an effective amount of a compound is generally in the range from 0.1 to 100 mg/kg of body weight of the recipient (mammal) per day and particularly typically in the range from 1 to 10 mg/kg of body weight per day. Thus, the actual amount per day for an adult mammal weighing 70 kg is usually between 70 and 700 mg, where this amount can be administered as an individual dose per day or usually in a series of part-doses (such as, for
35 example, two, three, four, five or six) per day, so that the total daily dose is the same. An

effective amount of a salt or solvate or of a physiologically functional derivative thereof can be determined as the fraction of the effective amount of the compound *per se*.

The microwave chemistry is performed on a single mode microwave reactor EmrysTM Optimiser from Personal Chemistry.

Method A: General procedure for the amidoxime moiety formation

- 10 To a solution of nitrile derivative (1 eq) in EtOH or THF (1-5 mL / mmol of nitrile derivative) was added a 50% aqueous solution of NH_2OH (5 eq). The resulting mixture was stirred at a temperature comprised between RT and 80°C for 1 to 72 hours. In case of precipitation of the expected compound, the precipitate was filtered off and washed with an adequate solvent, such as EtOH, iPrOH or water, and then dried under reduced pressure to give the
- 15 expected amidoxime derivative. In all other cases, the reaction mixture was concentrated under reduced pressure, diluted with an adequate solvent, such as water or iPrOH, until precipitation. The precipitate was filtered off and washed with an adequate solvent, such as iPrOH or water, and then dried under reduced pressure to give the expected amidoxime derivative.

Method B: General procedure for the oxadiazole ring formation

- DIEA (2.0 to 2.2 eq) and HATU (1.0 to 1.1 eq) were added into a solution of the carboxylic acid derivative (1 eq) in anhydrous DMF (4 mL / mmol of carboxylic acid derivative) cooled at
- 25 0°C. The resulting mixture was stirred at 0°C for a period of 5 to 30 minutes. Then the amidoxime derivative (1.0 to 1.2 eq) was added neat or as a DMF solution. The resulting mixture was stirred at 0°C or RT for a period of 30 minutes to 2 hours. The reaction mixture was diluted with an adequate solvent, such as Et_2O , MTBE or EtOAc, and then washed with water and brine. The aqueous layers were extracted once. The organic layers were
- 30 combined, dried (MgSO_4 or Na_2SO_4) and the solvents were removed under reduced pressure. The residue was taken up with toluene (6 mL / mmol of carboxylic acid derivative) and pyridine (2 mL / mmol of carboxylic acid derivative). The resulting mixture was heated at a temperature between 80°C to reflux for a period of 12 to 72 hours. The reaction mixture was diluted with an adequate solvent, such as Et_2O , MTBE or EtOAc, and then washed with
- 35 water and brine. The aqueous layers were extracted once. The organic layers were

combined, dried (MgSO_4 or Na_2SO_4) and the solvents were evaporated under reduced pressure. Purification by flash chromatography or precipitation gave the expected oxadiazole derivative.

- 5 Method C: General procedure for the oxadiazole ring formation using isobutyl chloroformate
NMM (3 to 5 eq) and isobutyl chloroformate (1.0 to 1.1 eq) were added into a solution of the
carboxylic acid derivative (1.0 eq) in a suitable solvent, such as dioxane or isopropyl acetate
and stirred at a temperature comprised between 0°C and RT for 10 minutes to a few hours.
Then the amidoxime derivative (1.0 to 1.2 eq) was added in one portion and the reaction
10 mixture was stirred at a temperature comprised between 0°C and RT for 20 min to a few
hours, and then heated at a temperature comprised between 80°C to reflux for a period of 12
to 24 hours. The reaction mixture was diluted with an adequate solvent, such as Et_2O , MTBE
or EtOAc, and then washed with water and brine. The aqueous layers were extracted once.
The organic layers were combined, dried (MgSO_4 or Na_2SO_4) and the solvents were
15 evaporated under reduced pressure. Purification by flash chromatography or precipitation
gave the expected oxadiazole derivative.

20 dioxane (5-30 mL / mmol of tert-butyl ester) and stirred at RT for a period of 2 to 48 hours, in
presence or not of a few drops of water. In case of a significant precipitation of the carboxylic
acid, the precipitate was filtered off. In all other cases, the reaction mixture was concentrated
under reduced pressure. Then the expected compound was crystallized or precipitated from
an adequate solvent or a mixture of them, such as ACN, water, MTBE or EtOAc, and then
25 dried under reduced pressure.

Method E: General procedure for the amidoxime moiety formation using hydroxylamine
hydrochloride

30 added $\text{NH}_2\text{OH}\cdot\text{HCl}$ (1.5-2.5 eq) and Et_3N (1.5-2.5 eq). The resulting mixture was stirred at RT
for 12 to 72 hours. The precipitate was filtered off and washed with an adequate solvent,
such as EtOH, iPrOH, water or MTBE, or a mixture of them, and then dried under reduced
pressure to give the expected amidoxime derivative.

Example 97: in vitro assays

- Membranes Preparation: Membranes were prepared from CHO cells expressing S1P1 or
- 30 S1P3 for use in ligand and 35S-GTP γ S binding studies. Cells were suspended in 50 mM

TRIS, pH 7.4, 2 mM EDTA, 250 mM Sucrose (buffer A) and 1× Complete protease inhibitor cocktail (Roche), and disrupted at 4°C by N₂ decompression using a cell disruption bomb (Parr Instrument). Following centrifugation at 1000 RPM for 10 min at 4°C, the supernatant was diluted (2x) in buffer A and centrifuged again at 19000 RPM for 75 min at 4°C. The pellet
5 was then suspended in 10 mM HEPES, pH 7.4, 1 mM EDTA, 250 mM Sucrose (Buffer B), and 1× Complete EDTA-free protease inhibitor cocktail and homogenized using a potter. Membranes were flash frozen in liquid N₂ and stored at -80°C.

Receptor binding assay: [33P]sphingosine 1-phosphate (3000 Ci/mmol; American Radiolabeled Chemicals, Inc.) was added to test compounds in 20% DMSO by competition.

10 Membranes and WGA SPA beads (GE Healthcare) were added to give a final volume of 100 µl in 96-well plates or 50 µl in 384-well plates with assay concentrations of 30 pM or 15 pM [33P]sphingosine 1-phosphate (respectively for S1P₁ or S1P₃), 50 mM HEPES, pH 7.5, 5 mM MgCl₂, 100 mM NaCl, 0.4% fatty acid-free BSA, 1-5 µg/well of proteins in 96-well plates vs 0.6-1 µg/well of proteins in 384-well plates and 100 µg/well of WGA SPA beads in 96-well
15 plates vs 75 µg/well of WGA SPA beads in 384-well plates. Binding was performed for 60 min at RT on a shaker and bound radioactivity was measured on a PerkinElmer 1450 MicroBeta counter. Triplicate samples were averaged and normalized as percentage of inhibition relative to total binding (only DMSO in well) and non specific binding (1000-fold excess of unlabeled S1P). Binding data were analyzed using the GraphPad Prism program
20 or Genedata software.

Measurements of 35S-GTPγS Binding: Membranes (1 to 10 µg protein) prepared as described above, were incubated in 96-well Scintiplates (PerkinElmer) with test compounds diluted in DMSO, in 140 µl of 20 mM HEPES, pH 7.4, 10 mM MgCl₂, 2 µg/well Saponin, 0.2% fatty acid free BSA (Assay buffer), 125 mM NaCl and 1.5 µM GDP. The assay was
25 initiated with the addition of 60 µl of 1.5 nM [35S]-GTPγS (1100 Ci/mmol; GE Healthcare) in assay buffer. After 60 min incubation at 30°C on a shaker, plates were centrifuged for 10 min at 2000 RPM. Supernatant was discarded and membrane bound radioactivity was measured on a PerkinElmer 1450 MicroBeta counter. Triplicate samples were averaged and expressed as % response relative to S1P activation in absence of compound (n = 2).

30 Cellular functional assays: Internalization of Sphingosine-1-phosphate receptor 1 (S1P₁) in a human Cell line (U2OS) in a 384-well format using a Cell Imaging analysis.

The S1P₁ internalization assay was performed in 384 well plates (Corning® 384 black with clear bottom 3712) using S1P₁-U2OS cells from BiImage (C039A), a human epithelial cell
35 line (Human Bone Osteosarcoma Epithelial Cells). These cells expressed the human S1P₁

Receptor fused to the green fluorescent protein (EGFP). A standard CMV promoter (cytomegalovirus promoter) controls the expression of S1P₁-EGFP and continuous expression was maintained by addition of geneticin to the culture medium.

S1P₁ Receptor desensitization induced the internalization of the membrane-localized S1P₁-EGFP fusion protein to endosomes, which can be monitored by cell imaging analysis.

The cells are plated in low serum medium (Dulbecco's Modified Eagle Medium (DMEM) with Glutamax-1 and high glucose, 1% Penicillin/Streptomycin, 1% Fetal Calf Serum (FCS), 0.5 mg/ml Geneticin) overnight.

The next day, S1P₁-U2OS cells are incubated in 20 µl serum free medium (DMEM with Glutamax-1 and high glucose, 0.1% of fatty-acid free Bovin Serum Albumin (BSA), 10 mM, N'-2-Hydroxyethylpiperazine-N'-2 ethanesulphonic acid (HEPES) 1M) for 2 hours at 37°C/5%CO₂.

The cells are then treated with 4 µl compounds/agonists (6x/3%DMSO) for a total volume of 24 µl, and plates are incubated for 1 hour at 37°C/5%CO₂.

S1P₁-U2OS cells are fixed with 25 µl Paraformaldehyde 8% and stained with Hoechst 33345 dye (1:1000) for 20 minutes.

They were then washed 3 times with Phosphate Buffered Saline (PBS) and plates are sealed.

The internalization of the receptor S1P₁-EGFP is measured on Cellomics by calculating the "spot count per object" ("object" corresponds to nuclear and "spot" corresponds to S1P₁-EGFP receptor). Internalization data were observed thanks to vHCS View and analyzed using Genedata® software.

The compounds of formula (I) have utility as immunoregulatory agents as demonstrated by their activity as potent and selective agonists of the S1P₁ receptor over the S1P₃ receptor as measured in the assays described above. In particular, the compounds of formula (I) exhibit a selectivity for the S1P₁ receptor over the S1P₃ receptor as measured by the ratio of EC₅₀ for the S1P₁ receptor to the EC₅₀ for the S1P₃ receptor as evaluated in the 35S-GTPγS binding assay described above.

The "potency" or the "activity" of the compounds is determined by the EC₅₀ values as evaluated in the above described 35S-GTPγS binding assay. The lowest EC₅₀ values characterize the most potent or active compounds, according to the present invention.

Model of S1P agonists-induced lymphopenia in mice

Model of MOG-induced Experimental Autoimmune Encephalomyelitis (EAE) in mice

Clinical score:

25	- Score = 0 A normal mouse holds its tail erect when moving. - Score = 1 If the extremity of the tail is flaccid with a tendency to fall. - Score = 2 If the tail is completely flaccid and drags on the table.
----	---

30

- Score = 0 A normal mouse has an energetic walk and doesn't drag his paws.
- Score = 1 Either one of the following tests is positive:
 - a- Flip test: while holding the tail between thumb and index finger, flip the animal on his back and observe the time it takes

- to right itself. A healthy mouse will turn itself immediately. A delay suggests hind-limb weakness.
- b- Place the mouse on the wire cage top and observe as it crosses from one side to the other. If one or both limbs frequently slip between the bars we consider that there is a partial paralysis.
- 5
- Score = 2 Both previous tests are positive.
 - Score = 3 One or both hind limbs show signs of paralysis but some movements are preserved; for example: the animal can grasp and hold on to the underside of the wire cage top for a short moment before letting go
- 10
- Score = 4 When both hind legs are paralyzed and the mouse drags them when moving.
- 15
- 3- Fore limbs:
- Score = 0 A normal mouse uses his front paws actively for grasping and walking and holds his head erect.
 - Score = 1 Walking is possible but difficult due to a weakness in one or both of the paws, for example, the front paws are considered weak when the mouse has difficulty grasping the underside of the wire top cage. Another sign of weakness is head drooping.
- 20
- Score = 2 When one forelimb is paralyzed (impossibility to grasp and the mouse turns around the paralyzed limb). At this time the head has also lost much of its muscle tone.
- 25
- Score = 3 Mouse cannot move, and food and water are unattainable.
- 4- Bladder:
- Score = 0 A normal mouse has full control of his bladder.
 - Score = 1 A mouse is considered incontinent when his lower body is soaked with urine.
- 30
- 5- Death:
- Score = 15

The final score for each animal is determined by the addition of all the above-mentioned categories. The maximum score for live animals is 10.

At day 12 (first signs of paralysis) the mice were stratified in experimental groups (n = 10) according to the clinical score and the body weight loss. The semi-curative treatment started at day 14.

Example 99: Preparation of a pharmaceutical formulation

Formulation 1 – Tablets

A compound of formula (I) is admixed as a dry powder with a dry gelatin binder in an approximate 1:2 weight ratio. A minor amount of magnesium stearate is added as a lubricant. The mixture is formed into 240-270 mg tablets (80-90 mg of active compound according to the invention per tablet) in a tablet press.

Formulation 2 – Capsules

A compound of formula (I) is admixed as a dry powder with a starch diluent in an approximate 1:1 weight ratio. The mixture is filled into 250 mg capsules (125 mg of active compound according to the invention per capsule).
