On a single chip are formed a plurality of magnetoresistance effect elements provided with pinned layers having fixed magnetization axes in the directions that cross each other. On a substrate **10** are formed magnetic layers that will become two magnetic tunnel effect elements **11**, **21** as magnetoresistance effect elements. Magnetic-field-applying magnetic layers made of NiCo are formed to sandwich the magnetic layers in plan view. A magnetic field is applied to the magnetic-field-applying magnetic layers. The magnetic field is removed after the magnetic-field-applying magnetic layers are magnetized in the direction shown by arrow A. As a result of this, by the residual magnetization of the magnetic-field-applying magnetic layers, magnetic fields in the directions shown by arrows B are applied to the magnetic layers that will become magnetic tunnel effect elements **11**, **21**, whereby the magnetization of the pinned layers of the magnetic layers that will become magnetic tunnel effect elements **11**, **21** is pinned in the directions shown by arrows B.

MAGNETIC SENSOR AND METHOD OF PRODUCING THE SAME

CROSS REFERENCE TO RELATED APPLICATIONS

[0001] This Application is a Division of application Ser. No. 10/052,525 filed on Jan. 23, 2002, claiming the priority of Japanese Application No. 2001-281703, dated Sep. 17, 2001, and Japanese Application No. 2001-15805, dated Jan. 24, 2001.

BACKGROUND OF THE INVENTION

[0002] 1. Field of the Invention

[0003] The present invention relates to a magnetic sensor using a magnetoresistance effect (magnetoresistive effect) element containing a pinned layer and a free layer, and more particularly to a magnetic sensor having two or more magnetoresistance effect elements formed on a single chip where the magnetization directions of the pinned layers of the magnetoresistance effect elements cross each other, as well as a method of producing the same

[0004] 2. Description of the Background Art

[0005] Hitherto, as an element usable in a magnetic sensor, there are known a giant magnetoresistance element (GMR element), a magnetic tunnel effect element (TMR element, tunneling GMR), and others. These magnetoresistance effect elements are provided with a pinned layer whose magnetization direction is pinned (fixed) in a predetermined direction and a free layer whose magnetization direction changes in accordance with an external magnetic field, thereby exhibiting a resistance value that accords with the relative relationship between the magnetization direction of the pinned layer and the magnetization direction of the free layer.

[0006] However, it is difficult to form two or more magnetoresistance effect elements on a single minute chip where the magnetization directions of the pinned layers of the magnetoresistance effect elements cross each other. Such a single chip has not been proposed yet, and therefore there arises a problem such that a magnetic sensor made of a single chip using a magnetoresistance effect element cannot have a wider application range due to the restriction imposed on the magnetization direction of the pinned layer.

SUMMARY OF THE INVENTION

[0007] A characteristic feature of the present invention lies in a magnetic sensor including a magnetoresistance effect element that contains a pinned layer and a free layer, said magnetoresistance effect element having a resistance value that changes in accordance with a relative angle formed by (or between) the magnetization direction of the pinned layer and the magnetization direction of the free layer, said magnetic sensor being formed in such a manner that a plurality of said magnetoresistance effect elements are provided on a single chip (one and the same substrate), and the pinned layers of at least two of said plurality of magnetoresistance effect elements have magnetization directions that cross each other.

[0008] This allows that, since magnetoresistance effect elements in which the magnetization directions of the pinned

layers cross each other are formed on one and the same substrate, a magnetic sensor having a small size and a wide application range is provided.

[0009] Another characteristic feature of the present invention lies in a method of producing a magnetic sensor including a magnetoresistance effect element that contains a pinned layer and a free layer, said magnetoresistance effect element having a resistance value that changes in accordance with a relative angle formed by the magnetization direction of the pinned layer and the magnetization direction of the free layer, said method including the steps of: forming a layer containing a magnetic layer that will become said pinned layer (for example, an antiferromagnetic layer and a ferromagnetic layer) in a predetermined configuration on a substrate; forming magnetic-field-applying magnetic layers for applying a magnetic field to the layer containing the magnetic layer that will become said pinned layer: magnetizing said magnetic-field-applying magnetic layers; and pinning the magnetization direction of the magnetic layer that will become said pinned layer with the residual magnetization of said magnetic-field-applying magnetic layers.

[0010] According to the method above, the magnetic-field-applying magnetic layers for applying a magnetic field to the layer containing the magnetic layer that will become the pinned layer are formed, for example, by plating or the like, and thereafter these magnetic-field-applying magnetic layers are magnetized. The magnetic field produced by the residual magnetization of the aforesaid magnetic-field-applying magnetic layers then pins the magnetization direction of the magnetic layer that will become the aforesaid pinned layer. In this case, the step of forming said magnetic-field-applying magnetic layers is advantageously a step of forming said magnetic-field-applying magnetic layers so as to sandwich the layer containing the magnetic layer that will become said pinned layer in a plan view, and the magnetization direction of said magnetic-field-applying magnetic layers is advantageously different from a direction of the magnetic field produced by said residual magnetization.

[0011] The direction of the magnetic field produced by the residual magnetization of the aforesaid magnetic-field-applying magnetic layers is dependent on the shape of the end surface of the magnetic-field-applying magnetic layers. Therefore, by making a suitably shaped end surface or by suitably placing the layer containing the magnetic layer that will become the pinned layer with respect to the end surface, the layer containing the magnetic layer that will become the pinned layer can be imparted with a magnetization having an arbitrary direction. This allows that two or more magnetoresistance effect elements having pinned layers with magnetizations pinned in different directions from each other can be easily produced on one and the same substrate.

[0012] Still another characteristic feature of the present invention lies in a method of producing a magnetic sensor including a magnetoresistance effect element that contains a pinned layer and a free layer, said magnetoresistance effect element having a resistance value that changes in accordance with a relative angle formed by a magnetization direction of the pinned layer and a magnetization direction of the free layer, said method including the steps of preparing a magnet array constructed in such a manner that a plurality of permanent magnets are arranged at lattice points of a square lattice, where a polarity of a magnetic pole of

each permanent magnet is different from a polarity of other magnetic poles that are adjacent thereto and spaced apart therefrom by the shortest distance; disposing a wafer in which a layer containing a magnetic layer that will at least become said pinned layer has been formed, above said magnet array; and pinning the magnetization direction of the magnetic layer that will become said pinned layer by using a magnetic field formed between one of said magnetic poles and another of said magnetic poles that is adjacent thereto and spaced apart therefrom by the shortest distance.

[0013] The above-mentioned magnet array is constructed in such a manner that a plurality of permanent magnets are disposed at lattice points of a square lattice, where a polarity of a magnetic pole of each permanent magnet is different from a polarity of other magnetic poles that are adjacent thereto and spaced apart therefrom by the shortest distance. Therefore, above the magnet array, in a plan view of the magnet array, a magnetic field in the rightward direction from one N-pole to the S-pole located on the right side of the N-pole, a magnetic field in the upward direction from the N-pole to the S-pole located on the upside of the N-pole, a magnetic field in the leftward direction from the N-pole to the S-pole located on the left side of the N-pole, and a magnetic field in the downward direction from the N-pole to the S-pole located on the downside of the N-pole are formed (See FIGS. 56 and 57). Similarly, to one S-pole, a magnetic field in the leftward direction from the N-pole located on the right side of the S-pole, a magnetic field in the downward direction from the N-pole located on the upside of the S-pole, a magnetic field in the rightward direction from the N-pole located on the left side of the S-pole, and a magnetic field in the upward direction from the N-pole located on the downside of the S-pole are formed. The above-described method pins the magnetization direction of the layer that will become the pinned layer by using these magnetic fields, whereby a magnetic sensor in which the magnetization directions of the pinned layers cross each other (in this case, perpendicular to each other) can be easily produced on a single chip.

BRIEF DESCRIPTION OF THE DRAWINGS

[0014] These and other objects, features, aspects, and advantages of the present invention will become more apparent from the following detailed description of the present invention when taken in conjunction with the accompanying drawings, in which,

[0015] FIG. 1 is a conceptual plan view illustrating a magnetic sensor according to embodiment 1 and embodiment 2 of the present invention;

[0016] FIG. 2 is an enlarged view of the magnetic tunnel effect element (group) shown in FIG. 1;

[0017] FIG. 3 is a cross-sectional view of the magnetic tunnel effect element (group) shown in FIG. 2 and cut with a plane along the line 1-1;

[0018] FIG. 4 is a schematic plan view of the magnetic tunnel effect element shown in FIG. 3, illustrating an antiferromagnetic film and a ferromagnetic film (pinned layer) of the element;

DESCRIPTION OF THE PREFERRED EMBODIMENTS

[0074] Hereafter, embodiments of the magnetic sensor according to the present invention will be described with reference to the attached drawings. The magnetic sensor according to the first embodiment includes a generally square-shaped substrate 10 made of, for example, SiO.sub.2/Si, glass, or quartz, two magnetic tunnel effect elements (groups) 11, 21, a coil 30 for bias magnetic field, and a plurality of electrode pads 40a to 40f, as illustrated in the plan view of FIG. 1. Magnetic tunnel effect elements (groups) 11, 21 and coil 30 for bias magnetic field are connected respectively to electrode pads 40a, 40b, 40c, 40d, and 40e, 40f. Since magnetic tunnel effect element (group) 11 and magnetic tunnel effect element (group) 21 are identical in structure, magnetic tunnel effect element (group) 11 will be described hereafter as a representative example, and the description of magnetic tunnel effect element (group) 21 will be omitted.

[0075] Magnetic tunnel effect element (group) 11 is made of a plurality of (in this example, twenty) magnetic tunnel effect elements that are connected in series, as illustrated in the enlarged plan view of FIG. 2. Each magnetic tunnel effect element includes a plurality of lower electrodes 12 having a rectangular shape in a plan view on substrate 10, as illustrated in FIG. 3 showing a partial cross-sectional view along the 1-1 plane of FIG. 2. Lower electrodes 12 are arranged in a row and spaced apart from each other by a predetermined distance in the lateral direction. Lower electrodes 12 are made of Ta (which may be Cr or Ti), which is an electrically conductive non-magnetic metal material, and are formed to have a thickness of about 30 nm. On each lower electrode 12 is respectively laminated an antiferromagnetic film 13 made of PtMn having a thickness of about 30 nm and formed to have the same planar shape as lower electrode 12.

[0076] A pair of ferromagnetic films 14, 14 made of NiFe having a thickness of about 20 nm is laminated at an interval on each antiferromagnetic film 13. These ferromagnetic films 14, 14 have a rectangular shape in a plan view and are arranged so that the longer sides thereof oppose each other in parallel. The ferromagnetic films 14, 14 constitute a pinned layer in which the magnetization direction is pinned by the antiferromagnetic film 13. The ferromagnetic films 14, 14 are magnetized in the direction of arrows in the partially enlarged plan view of FIG. 4 (i.e. in the rightward direction). Here, the antiferromagnetic film 13 and the ferromagnetic films (pinned layers) 14, 14 constitute a fixed magnetization layer in which the magnetization direction of the ferromagnetic films 14, 14 is substantially fixed (i.e. having a fixed magnetization axis).

[0077] On each ferromagnetic film 14 is formed an insulating layer 15 having the same planar shape as the ferromagnetic film 14. This insulating layer 15 is made of Al.sub.2O.sub.3 (Al—O), which is an insulating material, and is formed to have a thickness of about 1 nm.

[0078] On the insulating layer 15 is formed a ferromagnetic film 16 having the same planar shape as the insulating layer 15 and made of NiFe with a thickness of about 80 nm. This ferromagnetic film 16 constitutes a free layer (free magnetization layer) whose magnetization direction changes in accordance with the direction of an external magnetic field, and constitutes a magnetic tunnel junction structure together with the pinned layer made of the aforesaid ferromagnetic film 14 and the aforesaid insulating layer 15. In other words, the antiferromagnetic film 13, the ferromagnetic film 14, the insulating layer 15, and the ferromagnetic film 16 constitute one magnetic tunnel effect element (excluding the electrodes and others).

[0079] On each ferromagnetic film 16 is respectively formed a dummy film 17 having the same planar shape as each ferromagnetic film 16. This dummy film 17 is constituted with an electrically conductive non-magnetic metal material made of a Ta film having a thickness of about 40 nm.

[0080] An interlayer insulating layer 18 for insulated separation of the plurality of lower electrodes 12 and the antiferromagnetic film 13 and for respective insulated separation of the pair of ferromagnetic films 14, the insulating layers 15, the ferromagnetic films 16, and the dummy films 17 disposed on each antiferromagnetic film 13 is formed in a region that covers the substrate 10, lower electrode 12, antiferromagnetic film 13, ferromagnetic films 14, insulating layers 15, ferromagnetic films 16, and dummy films 17. The interlayer insulating layer 18 is made of SiO.sub.2 and has a thickness of about 250 nm.

[0081] Through this interlayer insulating layer 18, a contact hole 18a is respectively formed on each dummy film 17. Upper electrodes 19, 19 made of, for example, Al having a thickness of about 300 nm are respectively formed so as to fill in the contact hole 18a and to electrically connect each one of the pair of dummy films 17, 17 disposed on a different lower electrode 12 (and antiferromagnetic film 13). Thus, by electrically connecting each of the ferromagnetic films 16, 16 (each of the dummy films 17, 17) and each of the antiferromagnetic films 13, 13 of a pair of adjacent magnetic tunnel junction structures alternately and successively with the lower electrode 12, antiferromagnetic film 13, and upper

electrode **19**, there is formed a magnetic tunnel effect element (group) **11** in which a plurality of magnetic tunnel junction structures whose pinned layers have the same magnetization direction are connected in series. Here, a protective film made of SiO and SiN (illustration omitted) is formed on the upper electrodes **19**, **19**.

[0082] The coil **30** is for imparting a bias magnetic field of alternating current to the above-described magnetic tunnel effect elements (groups) **11**, **21**, and is buried in the upper part of substrate **10** so as to extend under the magnetic tunnel effect elements (groups) **11**, **21** in a direction parallel to the magnetization direction of the pinned layer of the magnetic tunnel effect elements (groups) **11**, **21**.

[0083] Next, a method of producing the above-mentioned magnetic tunnel effect elements will be described with reference to FIGS. **5** to **17**. Here, in FIGS. **5** to **12** and FIGS. **14** to **17**, a magnetic tunnel effect element group made of four magnetic tunnel effect elements that are connected in series is shown for the sake of description. Further, in these Figures, illustration of coil **30** is omitted.

[0084] First, as illustrated in FIG. **5**, a film made of Ta constituting the lower electrode **12** is formed to a thickness of about 30 nm by sputtering on a substrate **10** (which is, at this stage, one sheet of substrate from which a plurality of magnetic sensors will be obtained by a later dicing process). Then, a film made of PtMn and a film made of NiFe for constructing the antiferromagnetic film **13** and the ferromagnetic film (pinned layer) **14** of the fixed magnetization layer are formed to have a thickness of 30 nm and 20 nm, respectively, by sputtering. In this description, the lower electrode **12**, the PtMn film which will be the antiferromagnetic film **13**, and the FeNi film which will be the ferromagnetic film **14** are referred to as a lower magnetic layer SJ.

[0085] Thereafter, Al is laminated for only 1 μm , and this is oxidized by oxygen gas to form an Al₂O₃ (Al—O) film which will become the insulating layer **15**. Subsequently, a film made of NiFe constituting the ferromagnetic film **16** of the free layer is formed, for example, to have a thickness of 80 nm by sputtering, and a film made of Ta constituting the dummy film **17** is formed to have a thickness of 40 nm thereon. Here, the ferromagnetic film **16** and the dummy film **17** are referred to as an upper magnetic layer UJ. Next, by ion milling or the like, the upper magnetic layer UJ is processed for separation, as illustrated in FIG. **6**, and the lower magnetic layer SJ is processed for separation, as illustrated in FIG. **7**. As a result, the layer having a predetermined configuration, which will be the magnetic tunnel effect elements, is formed.

[0086] Next, as illustrated in FIG. **8**, a film made of SiO₂ constituting the interlayer insulating layer **18** is formed by sputtering so that the thickness thereof on the elements will be 250 nm, and a film made of Cr and a film made of NiFe are formed thereon by sputtering to have a thickness of 100 nm and 50 nm, respectively, as a plating underlayer film. Next, a resist **51** is applied, as illustrated in FIG. **9**. The resist **51** is patterned into a predetermined shape so as not to cover the part where the plating will be carried out later.

[0087] Next, as illustrated in FIG. **10**, the wafer is plated with NiCo as a magnetic-field-applying magnetic layer. The

thickness of NiCo is, for example, set to be 10 μm . Then, after the resist is removed as illustrated in FIG. **11**, the entire surface is subjected to milling (Ar milling) to remove NiFe formed as the plating underlayer film, as illustrated in FIG. **12**.

[0088] FIG. **13** is a plan view of the wafer in this state. Here, in FIG. **13**, each of the substrates that will be separated from each other by a later dicing process are denoted with the reference numeral **10** for convenience sake. Referring to FIG. **13**, by the previous patterning of the resist, the magnetic-field-applying magnetic layers (NiCo) are each formed to have a generally square shape with its center located at the center of four adjacent substrates **10** which will be separated from each other later, and are disposed so as to exclude parts (its portions) located immediately above the magnetic tunnel effect elements (groups) **11**, **21** in the longitudinal direction and in the lateral direction (i.e. so as to sandwich the layer, having the predetermined configuration, that will be the magnetic tunnel effect elements (groups) **11**, **21** where the lower magnetic layer SJ including the magnetic layer that will be the pinned layer is formed in a plan view). In this state, a magnetic field having a strength of about 1000 (Oe) is given in the direction parallel to the diagonal line of the square that each magnetic-field-applying magnetic layer forms, so as to magnetize the magnetic-field-applying magnetic layer in the direction shown by arrow A in FIG. **13**.

[0089] Next, the aforesaid magnetic field is removed. At this time, the residual magnetization of the magnetic-field-applying magnetic layer generates a magnetic field in the direction from the upper side of each magnetic-field-applying magnetic layer to the lower side of an adjacent magnetic-field-applying magnetic layer and a magnetic field in the direction from the right side of each magnetic-field-applying magnetic layer to the left side of an adjacent magnetic-field-applying magnetic layer, as shown by arrows B in FIG. **13**. For this reason, to the parts that will become the magnetic tunnel effect elements (groups) **11**, **21**, a magnetic field parallel to the longitudinal direction of the parts is applied. Then, in order to form the antiferromagnetic film **13** made of PtMn into an ordered alloy and to impart an exchange coupling magnetic field Hex, a high-temperature annealing process is carried out to put the wafer into a high-temperature environment. As a result of this, the magnetic tunnel effect elements (groups) **11**, **21** formed on one and the same substrate **10** will have pinned layers that are magnetized (pinned) in different directions from each other (in this case, in the directions that are perpendicular to each other). In other words, the magnetic tunnel effect elements (groups) **11**, **21** will each have a fixed magnetization axis in the direction shown by the arrows in FIG. **1**.

[0090] Subsequently, as illustrated in FIG. **14**, the NiCo which is the plating film and the sputtered NiFe (which is the plating underlayer film) are removed by acid, and Cr is removed by milling, as illustrated in FIG. **15**. Thereafter, as illustrated in FIG. **16**, a contact hole **18a** is formed through the interlayer insulating film **18**; an Al film is formed to have a thickness of 300 nm by sputtering as illustrated in FIG. **17**; and the Al film is processed in a wiring pattern to form an upper electrode **19**.

[0091] Then, electrode pads **40a** to **40f** illustrated in FIG. **1** are formed on the substrate **10**, and the electrode pads **40a**

to **40f** are respectively connected to the magnetic tunnel effect elements (groups) **11**, **21** and the coil **30**. Finally, a film (not illustrated) made of SiO having a thickness of 150 nm and a film (not illustrated) made of SiN having a thickness of 1000 nm are formed as a protective film (passivation film) by CVD. Thereafter, a part of the protective film is opened by milling, RIE, or etching using a resist mask to expose the electrode pads **40a** to **40f**. Subsequently, the substrate is subjected to back grinding (thinning by grinding); the substrate is separated into individual magnetic sensors by dicing; and finally, the packaging is carried out.

[0092] To the magnetic tunnel effect element (group) **11** thus produced and shown in **FIG. 1**, external magnetic fields changing in magnitude along the respective axes in the X-axis direction shown in **FIG. 1** and in the Y-axis direction perpendicular to the X-axis were applied, so as to measure the resistance changing ratio MR (MR ratio) at the time the magnetic fields were applied. The results are shown in **FIGS. 18 and 19**. As will be clear from **FIGS. 18 and 19**, the MR ratio of the magnetic tunnel effect element (group) **11** changed more greatly in response to the external magnetic field changing in the X-axis direction than to the external magnetic field changing in the Y-axis direction. This has confirmed that, in the magnetic tunnel effect element (group) **11**, the magnetization direction of the pinned layer thereof is parallel to the X-axis.

[0093] Similarly, to the magnetic tunnel effect element (group) **21** shown in **FIG. 1**, external magnetic fields changing in magnitude along the respective axes in the X-axis direction and in the Y-axis direction were applied, so as to measure the resistance changing ratio MR (MR ratio) at the time the magnetic fields were applied. The results are shown in **FIGS. 20 and 21**. As will be clear from **FIGS. 20 and 21**, the MR ratio of the magnetic tunnel effect element (group) **21** changed more greatly in response to the external magnetic field changing in the Y-axis direction than to the external magnetic field changing in the X-axis direction. This has confirmed that, in the magnetic tunnel effect element (group) **21**, the magnetization direction of the pinned layer thereof is parallel to the Y-axis. In other words, it has been confirmed that, on one and the same substrate **10**, this magnetic sensor has two magnetic tunnel effect elements (magnetoresistance effect elements) having pinned layers that are pinned so that the magnetization directions thereof are different from each other (i.e. so that the magnetization directions thereof cross each other).

[0094] Next, a magnetic sensor according to the second embodiment will be described. The second embodiment is different from the first embodiment only in that, whereas the fixed magnetization layer of the first embodiment is constituted with PtMn and NiFe, the fixed magnetization layer of the second embodiment is constituted with a film made of MnRh having a thickness of 30 nm and a film made of NiFe (pinned layer) having a thickness of 40 nm. On the other hand, by this difference in the material of the fixed magnetization layer, the method of producing the second embodiment is a little different from that of the first embodiment, which will be described as follows.

[0095] Namely, in the second embodiment, as illustrated in **FIG. 22**, a film made of Ta having a thickness of 30 nm, a film made of MnRh having a thickness of 30 nm, and a film made of NiFe having a thickness of 40 nm are formed on a

substrate **10** by sputtering so as to form a lower magnetic layer SJ. Subsequently, an Al film of 1 nm is formed and oxidized to form an insulating layer **15**. A film made of NiFe having a thickness of 40 nm and a film made of Ta having a thickness of 40 nm are formed thereon so as to form an upper magnetic layer UJ.

[0096] Subsequently, as illustrated in **FIG. 23**, the upper magnetic layer UJ is processed for separation, and the lower magnetic layer SJ is processed for separation, as illustrated in **FIG. 24**. Next, as illustrated in **FIG. 25**, SiO.sub.2 is sputtered to form a film having a thickness of 250 nm so as to form an interlayer insulating layer **18**, and successively a contact hole **18a** is formed through the interlayer insulating layer **18**, as illustrated in **FIG. 26**. Subsequently, as illustrated in **FIG. 27**, Al is sputtered to form a film having a thickness of 300 nm and processed in a wiring pattern to form an upper electrode **19**. Then, as illustrated in **FIG. 28**, a protective film **20** made of SiO and SiN is formed by CVD.

[0097] Next, as illustrated in **FIG. 29**, a film made of Cr and a film made of NiFe are formed by sputtering to have a thickness of 100 nm and 50 nm, respectively, as a plating underlayer film, and successively, a resist **51** is applied, as illustrated in **FIG. 30**. The resist **51** is patterned into a predetermined shape so as not to cover the part where the plating will be carried out later.

[0098] Next, as illustrated in **FIG. 31**, the wafer is plated with NiCo as a magnetic-field-applying magnetic layer. The thickness of NiCo is, for example, set to be 10 .mu.m. Then, after the resist is removed as illustrated in **FIG. 32**, the entire surface is subjected to ruing (Ar milling) to remove NiFe formed as the plating underlayer film, as illustrated in **FIG. 33**. At this stage, the wafer is in the state shown in **FIG. 13**. In this state, a magnetic field having a strength of about 1000 (Oe) is given in the direction parallel to the diagonal line of the square that each magnetic-field-applying magnetic layer forms, so as to magnetize the magnetic-field-applying magnetic layer in the direction shown by arrow A in **FIG. 13**. Thereafter, the magnetic field is removed.

[0099] At this time, to the parts that will later become the magnetic tunnel effect elements (groups) **11'**, **21'**, a magnetic field parallel to the longitudinal direction of the parts is applied by the residual magnetization of NiCo. Then, a high-temperature annealing process is carried out to put the wafer into a high-temperature environment. As a result of this, the magnetic tunnel effect elements (groups) **11'**, **21'** formed on one and the same substrate **10'** will have pinned layers that are magnetized (pinned) in different directions from each other (in this case, in the directions that are perpendicular to each other). After the high-temperature annealing process is finished, the plating film NiCo and the plating underlayer film NiFe are removed by acid as illustrated in **FIG. 34**, and the plating underlayer film Cr is removed by milling, as illustrated in **FIG. 35**. Thereafter, a process similar to that of the first embodiment is carried out.

[0100] To the magnetic tunnel effect element (group) **11'** thus produced and shown in **FIG. 1**, external magnetic fields changing in magnitude along the respective axes in the X-axis direction and in the Y-axis direction were applied, so as to measure the resistance changing ratio MR (MR ratio) at the time the magnetic fields were applied. The results are shown in **FIGS. 36 and 37**. As will be clear from **FIGS. 36 and 37**, the MR ratio of the magnetic tunnel effect element

(group) **11'** changed more greatly in response to the external magnetic field changing in the X-axis direction than to the external magnetic field changing in the Y-axis direction. This has confirmed that, in the magnetic tunnel effect element (group) **11'**, the magnetization direction of the pinned layer thereof is parallel to the X-axis.

[0101] Similarly, to the magnetic tunnel effect element (group) **21'** shown in **FIG. 1**, external magnetic fields changing in magnitude along the respective axes in the X-axis direction and in the Y-axis direction were applied, so as to measure the resistance changing ratio MR (MR ratio) at the time the magnetic fields were applied. The results are shown in **FIGS. 38 and 39**. As will be clear from **FIGS. 38 and 39**, the MR ratio of the magnetic tunnel effect element (group) **21'** changed more greatly in response to the external magnetic field changing in the Y-axis direction than to the external magnetic field changing in the X-axis direction. This has confirmed that, in the magnetic tunnel effect element (group) **21'**, the magnetization direction of the pinned layer thereof is parallel to the Y-axis. In other words, it has been confirmed that, on one and the same substrate **10'**, this magnetic sensor according to the second embodiment has two magnetic tunnel effect elements (magnetoresistance effect elements) having pinned layers that are pinned so that the magnetization directions thereof cross each other (i.e. are different from each other).

[0102] As described above, the magnetic sensors according to the first and second embodiments have, on one and the same substrate (on a single chip), magnetic tunnel effect elements in which the magnetization directions of the pinned layers cross each other (i.e. the magnetization directions of at least two of the pinned layers form an angle other than 0.degree. and 180.degree.). For this reason, these magnetic sensors can be used as a small magnetic sensor (for example, as a geomagnetism sensor or the like) that is requested to detect magnetic fields in different directions. Also, according to the methods of the above-described embodiments, these sensors can be easily produced.

[0103] Here, in the first embodiment, since PtMn is used in the fixed magnetization layer as a pinning layer, the magnetization direction of the pinned layer in the fixed magnetization layer must be pinned at the timing at which the wafer is initially brought to a high temperature. Therefore, in the first embodiment, the wafer is subjected to a high-temperature annealing process at a stage prior to the high-temperature process by CVD or the like that is carried out for forming the protective film. In contrast, in the second embodiment, MnRh is used as a pinning layer of the fixed magnetization layer. The MnRh film will be deteriorated in quality if another high-temperature process is carried out after the high-temperature annealing process. Therefore, in the second embodiment, the high-temperature annealing process is carried out after the high-temperature process by CVD or the like for forming the protective film is carried out.

[0104] Further, according to the above-described production methods of the first and second embodiments, one can obtain a magnetic tunnel effect element (group) that exhibits an even-function property to an external magnetic field to be detected. In other words, when a magnetic field changing in magnitude within the direction perpendicular to the magnetization direction of the pinned layer is applied to the

magnetic tunnel effect element groups **11, 21, 11', 21'**, the magnetization of the pinned layer changes smoothly as illustrated by the line LP of **FIG. 40**. On the other hand, the free layer of these elements reacts sensitively to the direction of the aforesaid external magnetic field due to the shape anisotropy, and the magnetization of the free layer changes in a stepwise manner when the magnitude of the external magnetic field approaches the neighborhood of "0", as illustrated by the line LF of **FIG. 40**. As a result of this, the relative angle formed between the magnetization direction of the pinned layer and the magnetization direction of the free layer attains the maximum value (approximately 90.degree.) when the external magnetic field is "0" and, according as the magnitude (absolute value) of the external magnetic field increases, the relative angle decreases. This can be confirmed by **FIGS. 19, 20, 37, and 38**.

[0105] Further, as will be also clear from **FIG. 13**, when a plating film (NiCo) constituting each magnetic-field-applying magnetic layer is magnetized in a predetermined direction shown by arrow A in **FIG. 13**, the direction of the magnetic field generated between the plating films by the residual magnetization of the plating films will be different from the magnetization direction of the plating films but will be the direction perpendicular to the end surfaces of the plating films M as shown by arrows B in **FIG. 13**. Therefore, if the end surface shape of the plating films M is designed, for example, as shown in **FIG. 41** and the plating films are magnetized in the direction shown by arrow C, a magnetic field having a desired direction (direction shown by arrows D) can be locally generated at a suitable position on the wafer. Therefore, by using this, one can produce magnetic tunnel effect elements TMR1, TMR2 having fixed magnetization axes in desired directions on a single substrate (magnetic tunnel effect elements TMR1, TMR2 in which the magnetization directions of the pinned layers cross each other on a single chip).

[0106] Next, a magnetic sensor according to the third embodiment of the present invention will be described. While the magnetic sensors of the above-described first and second embodiments are constituted with TMR elements, the magnetic sensor of the third embodiment is constituted with GMR elements. Further, this magnetic sensor is provided with an X-axis magnetic sensor for detecting a magnetic field in the X-axis direction and a Y-axis magnetic sensor for detecting a magnetic field in the Y-axis direction perpendicular to the aforesaid X-axis.

[0107] More specifically described, this magnetic sensor **60** has a rectangular (generally square) shape having sides along the X-axis and the Y-axis that are perpendicular to each other in a plan view as illustrated in **FIG. 42**, and includes a single chip (same substrate) **60a** made of quartz glass having a small thickness in the Z-axis direction perpendicular to the X-axis and the Y-axis, a sum of eight GMR elements **61 to 64, 71 to 74** formed on the chip **60a**, a sum of eight pads **65 to 68, 75 to 78** formed on the chip **60a**, and a connecting line that connects the pads and the elements.

[0108] The first X-axis GMR element **61** is formed in a neighborhood of the end of the chip **60a** in the negative direction of the X-axis and a little below a generally central part of the chip **60a** in the Y-axis direction, and the pinned magnetization direction of the pinned layer is in the negative direction of the X-axis, as illustrated by an arrow in **FIG. 42**.

The second X-axis GMR element **62** is formed in a neighborhood of the end of the chip **60a** in the negative direction of the X-axis and a little above a generally central part of the chip **60a** in the Y-axis direction, and the pinned magnetization direction of the pinned layer is in the negative direction of the X-axis, as illustrated by an arrow in **FIG. 42**. The third X-axis GMR element **63** is formed in a neighborhood of the end of the chip **60a** in the positive direction of the X-axis and a little above a generally central part of the chip **60a** in the Y-axis direction, and the pinned magnetization direction of the pinned layer is in the positive direction of the X-axis, as illustrated by an arrow in **FIG. 42**. The fourth X-axis GMR element **64** is formed in a neighborhood of the end of the chip **60a** in the positive direction of the X-axis and a little below a generally central part of the chip **60a** in the Y-axis direction, and the pinned magnetization direction of the pinned layer is in the positive direction of the X-axis, as illustrated by an arrow in **FIG. 42**.

[0109] The first Y-axis GMR element **71** is formed in a neighborhood of the end of the chip **60a** in the positive direction of the Y-axis and a little to the left of a generally central part of the chip **60a** in the X-axis direction, and the pinned magnetization direction of the pinned layer is in the positive direction of the Y-axis, as illustrated by an arrow in **FIG. 42**. The second Y-axis GMR element **72** is formed in a neighborhood of the end of the chip **60a** in the positive direction of the Y-axis and a little to the right of a generally central part of the chip **60a** in the X-axis direction, and the pinned magnetization direction of the pinned layer is in the positive direction of the Y-axis, as illustrated by an arrow in **FIG. 42**. The third Y-axis GMR element **73** is formed in a neighborhood of the end of the chip **60a** in the negative direction of the Y-axis and a little to the right of a generally central part of the chip **60a** in the X-axis direction, and the pinned magnetization direction of the pinned layer is in the negative direction of the Y-axis, as illustrated by an arrow in **FIG. 42**. The fourth Y-axis GMR element **74** is formed in a neighborhood of the end of the chip **60a** in the negative direction of the Y-axis and a little to the left of a generally central part of the chip **60a** in the X-axis direction, and the pinned magnetization direction of the pinned layer is in the negative direction of the Y-axis, as illustrated by an arrow in **FIG. 42**.

[0110] The GMR elements **61** to **64**, **71** to **74** have substantially the same structure with each other except that the position thereof on the chip **60a** and the pinned magnetization direction of the pinned layer relative to the chip **60a** are different. Therefore, the structure thereof will be described hereafter using the first X-axis GMR element **61** as a representative example.

[0111] The first X-axis GMR element **61** includes a plurality of narrow band-shaped parts **61a** . . . **61a** made of a spin valve film SV and having a longitudinal direction in the Y-axis direction and bias magnet films (hard ferromagnetic thin film layers) **61b** . . . **61b** made of a hard ferromagnetic material such as CoCrPt formed under the two ends of each narrow band-shaped part **61a** in the Y-axis direction and having a high magnetic coercive force and a high square ratio, as illustrated in **FIG. 43** which is a plan view and in **FIG. 44** which is a schematic cross-sectional view of the first X-axis GMR element **61** cut with a plane along the line 2-2 of **FIG. 43**. Each of the narrow band-shaped parts **61a** . . . **61a** extends in the X-axis direction on the upper surface

of each bias magnet film **61b** and is bonded to an adjacent narrow band-shaped part **61a**.

[0112] The spin valve film SV of the first X-axis GMR element **61** is, as shown by the film construction in **FIG. 45**, composed of a free layer (free magnetization layer) F, an electrically conductive spacer layer S made of Cu having a thickness of 2.4 nm (24 .ANG.), a fixed magnetization layer P, and a cap layer C made of titanium (Ti) or tantalum (Ta) having a thickness of 2.5 nm (25 .ANG.) which are successively laminated on a chip **60a** constituting a substrate.

[0113] The free layer F is a layer whose magnetization direction changes in accordance with the direction of an external magnetic field, and is composed of a CoZrNb amorphous magnetic layer **61-1** formed immediately above the substrate **60a** and having a thickness of 8 nm (80 .ANG.), a NiFe magnetic layer **61-2** formed on the CoZrNb amorphous magnetic layer **61-1** and having a thickness of 3.3 nm (33 .ANG.), and a CoFe layer **61-3** formed on the NiFe layer **61-2** and having a thickness of about 1 to 3 nm (10 to 30 .ANG.). The CoZrNb amorphous magnetic layer **61-1** and the NiFe magnetic layer **61-2** constitute a soft ferromagnetic thin film layer. The CoFe layer **61-3** is for preventing diffusion of Ni in the NiFe layer **61-2** and Cu **61-4** in the spacer layer S. Here, the above-described bias magnet films **61b** . . . **61b** apply a bias magnetic field to the free layer F in the Y-axis direction (right and left directions shown by arrows in **FIG. 43**) for maintaining the uniaxial anisotropy of the free layer F.

[0114] The fixed magnetization layer P is a lamination of a CoFe magnetic layer **61-5** having a thickness of 2.2 nm (22 .ANG.) and an antiferromagnetic film **61-6** formed from a PtMn alloy containing 45 to 55 mol % of Pt and having a thickness of 24 nm (240 .ANG.). The CoFe magnetic layer **61-5** is lined with the magnetized antiferromagnetic film **61-6** in an exchange coupling manner so as to constitute a pinned layer whose magnetization direction (magnetization vector) is pinned (fixed) in the negative direction of the X-axis.

[0115] The first X-axis GMR element **61** thus constructed exhibits a resistance value that changes generally in proportion to an external magnetic field that changes along the X-axis in the range from $-H_c$ to $+H_c$, as shown by a solid line in **FIG. 46**, and exhibits a generally constant resistance value to an external magnetic field that changes along the Y-axis, as shown by a broken line in **FIG. 46**.

[0116] The X-axis magnetic sensor is constructed by full bridge connection of the first to fourth X-axis GMR elements **61** to **64**, as shown by an equivalent circuit in **FIG. 47**. Here, in **FIG. 47**, the arrows show pinned magnetization directions of the pinned layers of the GMR elements **61** to **64**. In such a construction, the pad **67** and the pad **68** are connected respectively to the positive electrode and the negative electrode of a constant power source (not illustrated) so as to give a voltage V_{xin+} (5 V in this example) and a voltage V_{xin-} (0 V in this example). Then, the voltages of the pad **65** and the pad **66** are taken out as a voltage V_{xout+} and a voltage V_{xout-} , and the voltage difference thereof ($V_{xout+} - V_{xout-}$) is taken out as a sensor output V_{xout} . As a result of this, the X-axis magnetic sensor shows an output voltage V_{xout} that changes generally in proportion to an external magnetic field that changes along the X-axis in the range from $-H_c$ to $+H_c$, as shown by a solid

line in **FIG. 48**, and shows a generally “0” output voltage to an external magnetic field that changes along the Y-axis, as shown by a broken line in **FIG. 48**.

[0117] The Y-axis magnetic sensor is constructed by full bridge connection of the first to fourth Y-axis GMR elements **71** to **74** in the same manner as the X-axis magnetic sensor. Further, the pad **77** and the pad **78** are connected respectively to the positive electrode and the negative electrode of a constant power source (not illustrated) so as to give a voltage $V_{\text{yin+}}$ (5 V in this example) and a voltage $V_{\text{yin-}}$ (0 V in this example). Then, the voltage difference between the pad **75** and the pad **76** is taken out as a sensor output V_{yout} . As a result of this, the Y-axis magnetic sensor shows an output voltage V_{yout} that changes generally in proportion to an external magnetic field that changes along the Y-axis in the range from $-H_c$ to $+H_c$, as shown by a broken line in **FIG. 49**, and shows a generally “0” output voltage to an external magnetic field that changes along the X-axis, as shown by a solid line in **FIG. 49**.

[0118] Next, a method of producing the magnetic sensor **60** constructed in the aforesaid manner will be described. First, a plurality of films **M**, which are made of the aforesaid spin valve film **SV** and the aforesaid bias magnet film **61b**, and which will constitute individual GMR elements, are formed in a manner like islands on a rectangular quartz glass **60a1**, as illustrated by the plan view of **FIG. 50**. The films **M** are formed by successive lamination to precise thicknesses using a ultra high vacuum apparatus. These films **M** are formed so that the films **M** will be located at the positions of the GMR elements **61** to **64**, **71** to **74** shown in **FIG. 42** when the quartz glass **60a1** is cut along the broken line of **FIG. 50** by a cutting process carried out later and separated into individual chips **60a** shown in **FIG. 42**. Further, alignment (positioning) marks **60b** having a rectangular shape excluding a shape of a cross are formed at the four corners of the quartz glass **60a1**.

[0119] Next, as shown in **FIG. 51** which is a plan view and in **FIG. 52** which is a cross-sectional view cut with the cross section along the line 3-3 of **FIG. 51**, a rectangular metal plate **81** is prepared in which a plurality of square through-holes are formed in a square lattice configuration (namely, square through-holes having sides parallel to the X-axis and the Y-axis are formed to be equally spaced apart from each other along the X-axis and the Y-axis). Then, permanent bar magnets **82** . . . **82** having a rectangular parallelepiped shape and having approximately the same square cross section as the through-holes are inserted into the through-holes of the metal plate **81** so that the end surfaces of the permanent bar magnets **82** . . . **82**, where the magnetic poles are formed, will be parallel to the metal plate **81**. At this time, the permanent bar magnets **82** . . . **82** are arranged so that the polarity of the magnetic pole of each permanent bar magnet **82** will be different from the polarity of the magnetic pole of the other permanent bar magnets **82** adjacent thereto and spaced apart therefrom by the shortest distance. Here, the permanent bar magnets **82** . . . **82** to be used have a magnetic charge of the same magnitude.

[0120] Next, as shown in a plan view of **FIG. 53**, a plate **83** is prepared which has a thickness of about 0.5 mm and which is made of transparent quartz glass having approximately the same rectangular shape as the aforesaid metal plate **81**. This plate **83** is let to have alignment (positioning)

marks **83a** having a shape of a cross on the four corners for positioning in cooperation with the alignment marks **60b** of the aforesaid quartz glass **60a1**. Further, in the central part, alignment marks **83b** are formed at positions corresponding to the outer shape of the permanent bar magnets **82** . . . **82** that are inserted into the aforesaid metal plate **81**. Subsequently, as illustrated in **FIG. 54**, the upper surface of the permanent bar magnets **82** . . . **82** are bonded to the lower surface of the plate **83** by means of an adhesive. At this time, the relative position of the permanent bar magnets **82** . . . **82** to the plate **83** is determined by using the alignment marks **83b**. Then, the metal plate **81** is removed from the lower side. At this stage, the permanent bar magnets **82** . . . **82** and the plate **83** form a magnet array constructed in such a manner that a plurality of permanent magnets having square end surfaces constituting the magnetic poles are disposed at lattice points of a square lattice and the polarity of the magnetic pole of each permanent magnet is different from the polarity of the magnetic pole of the other permanent magnets adjacent thereto and spaced apart therefrom by the shortest distance.

[0121] Next, as illustrated in **FIG. 55**, the quartz glass **60a1**, on which the films to become the GMR elements (the layer containing the magnetic layer to become the pinned layer, that is, the layer containing the magnetic layer to become the fixed magnetization layer) are formed, is positioned so that the surface on which the films to become the GMR elements are formed will be brought into contact with the upper surface of the plate **83**. The relative position of the quartz glass **60a1** to the plate **83** is exactly determined by bringing the cross shape of the alignment marks **83a** into respective coincidence with the part of the aforesaid alignment marks **60b** where the cross shape has been removed.

[0122] **FIG. 56** is a perspective view illustrating a state in which four of the aforesaid permanent bar magnets **82** . . . **82** have been taken out. As will be clear from this figure, above the upper surface of the permanent bar magnets **82** . . . **82**, magnetic fields are formed from one N-pole towards the four S-poles adjacent to the N-pole by the shortest distance, i.e. in four directions that are different from each other by 90.degree.. Therefore, as illustrated by a model view of **FIG. 57**, in the state in which the quartz glass **60a1** is placed on the upper surface of the plate **83** shown in **FIG. 55**, magnetic fields in the positive direction of the Y-axis, in the positive direction of the X-axis, in the negative direction of the Y-axis, and in the negative direction of the X-axis are applied to the films which are placed in parallel to each side of the square end surface of one N-pole and which will become the GMR elements.

[0123] In this embodiment, by using such magnetic fields, a thermal treatment is carried out to fix the magnetization direction of the fixed magnetization layer **P** (the pinned layer of the fixed magnetization layer **P**). Namely, in the state shown in **FIG. 55**, the plate **83** and the quartz glass **60a1** are fixed to each other by a clamp **CL**, heated to 250.degree. C. to 280.degree. C. in vacuum, and left to stand in this state for about four hours.

[0124] Thereafter, the quartz glass **60a1** is taken out; the pads **65** to **68**, **75** to **78** shown in **FIG. 42** are formed; a wiring connecting these is formed; and finally the quartz glass **60a1** is cut along the broken lines shown in **FIG. 50**. The above process completes the production of the magnetic sensor **60** shown in **FIG. 42**.

[0125] Next, the result of measurement of geomagnetism using the aforesaid magnetic sensor 60 will be described. In this measurement, the azimuth θ (measurement angle) is defined as 0.degree. when the positive direction of the Y-axis of the magnetic sensor 60 is directed to the south, as illustrated in FIG. 58. The measurement results are shown in FIG. 59. As will be clear from FIG. 59, the X-axis magnetic sensor output S_x shown by a solid line changes like a sine curve, and the Y-axis magnetic sensor output S_y shown by a broken line changes like a cosine curve. This result is exactly as expected from the characteristics shown in FIGS. 48 and 49.

[0126] In this case, the azimuth can be determined by (1) $\theta = \arctan(S_x/S_y)$ when the X-axis magnetic sensor output S_x and the Y-axis magnetic sensor output S_y both assume positive values; (2) $\theta = 180.\text{degree} + \arctan(S_x/S_y)$ when the Y-axis magnetic sensor output S_y assumes a negative value; and (3) $\theta = 360.\text{degree} + \arctan(S_x/S_y)$ when the X-axis magnetic sensor output S_x assumes a negative value and the Y-axis magnetic sensor output S_y assumes a positive value. Therefore, the magnetic sensor 60 can be used, for example, as a geomagnetism (azimuth) sensor that can be mounted onto portable type electronic devices such as a portable telephone. Here, if the representation in the range from $-90.\text{degree}$ to $0.\text{degree}$ is permitted when the azimuth is within the range from $270.\text{degree}$ to $360.\text{degree}$, the azimuth may be determined by $\theta = \arctan(S_x/S_y)$ when the output S_y is positive, and by $\theta = 180.\text{degree} + \arctan(S_x/S_y)$ when the output S_y is negative.

[0127] As described above, according to the third embodiment, a magnet array is prepared which is constructed in such a manner that a plurality of permanent magnets are disposed at lattice points of a square lattice and the polarity of the magnetic pole of each permanent magnet is different from the polarity of the magnetic pole of the other permanent magnets adjacent thereto and spaced apart therefrom by the shortest distance, and the magnetization direction of the magnetic layer that will become the aforesaid pinned layer is pinned with the use of the magnetic fields formed by the magnet array. Therefore, on a single chip, one can easily form GMR elements in which the pinned magnetization directions of the pinned layers are different from each other (perpendicular to each other). Further, by this method, one can produce single chips each having GMR elements in which the pinned magnetization directions of the pinned layers are different from each other, at a time and in a large amount, thereby leading to reduction in the cost of producing the single chips.

[0128] Here, the present invention is by no means limited to the aforesaid embodiments, and various modifications may be made within the scope of the present invention. For example, though NiCo having a large residual magnetization is adopted as a plating film in the aforesaid first and second embodiments, other materials (for example, Co) having a large residual magnetization may be adopted in place of NiCo. Further, the method of fixing the magnetization direction of the fixed magnetization layer in the first and second embodiments can be applied to other magnetoresistance effect elements having pinned layers (layers having a fixed magnetization axis) such as in the third embodiment. Furthermore, though PtMn is used as a pinning layer of the

fixed magnetization layer P in the aforesaid three embodiments, FeMn, IrMn, or the like may be used in place of this PtMn.

1. (Canceled).
2. A magnetic sensor comprising;

a magnetoresistance effect element that contains a free layer and a pinned layer whose magnetization direction is pinned, said magnetoresistance effect element having a resistance value that changes in accordance with a relative angle formed by the magnetization direction of the pinned layer and a magnetization direction of the free layer;

said magnetic sensor being formed in such a manner that a plurality of said magnetoresistance effect elements are provided in a single plane on a single chip having a generally square shape, said magnetoresistance effect elements are placed symmetrically with respect to center lines of said generally square chip, and the pinned layers of at least two of said plurality of magnetoresistance effect elements have the pinned magnetization directions that cross each other.

3. The magnetic sensor according to claim 2, including four of said magnetoresistance effect elements constructing a X-axis or a Y-axis magnetic sensor by full bridge connection of the four elements, said pinned magnetization directions of the pinned layers of the four elements being parallel to each other.

4. A magnetic sensor comprising eight magnetoresistance effect elements including a first through an eight element, each of said elements containing a free layer and a pinned layer whose magnetization direction is pinned and each having a resistance value that changes in accordance with a relative angle formed by a magnetization direction of said pinned layer and a magnetization direction of said free layer;

said magnetic sensor being formed in such a manner that said magnetoresistance effect elements are provided in a single plane on a single chip having a generally square shape having sides along an X-axis and a Y-axis that are perpendicular to each other in a plan view;

- (a) said first element being formed in a neighborhood of an end of the chip in a negative direction of the X-axis and a little below a generally central part of the chip in the Y-axis direction, and having a pinned magnetization direction of said first element's pinned layer in a direction of the X-axis;
- (b) said second element being formed in a neighborhood of an end of the chip in a negative direction of the X-axis and a little above a generally central part of the chip in the Y-axis direction, and having a pinned magnetization direction of said second element's pinned layer in the direction of the X-axis;
- (c) said third element being formed in a neighborhood of an end of the chip in the positive direction of the X-axis and a little above a generally central part of the chip in the Y-axis direction, and having a pinned magnetization direction of said third element's pinned layer in the direction of the X-axis;
- (d) said fourth element being formed in a neighborhood of an end of the chip in the positive direction of the X-axis and a little below a generally central part of the chip in

the Y-axis direction, and having a pinned magnetization direction of said fourth element's pinned layer in the direction of the X-axis;

- (e) said fifth element being formed in a neighborhood of an end of the chip in the positive direction of the Y-axis and a little to the left of a generally central part of the chip in the X-axis direction, and having a pinned magnetization direction of said fifth element's pinned layer in the direction of the Y-axis;
 - (f) said sixth element being formed in a neighborhood of an end of the chip in the positive direction of the Y-axis and a little to the right of a generally central part of the chip in the X-axis direction, and having a pinned magnetization direction of said sixth element's pinned layer in the direction of the Y-axis;
 - (g) said seventh element being formed in a neighborhood of an end of the chip in the negative direction of the Y-axis and a little to the right of a generally central part of the chip in the X-axis direction, and having a pinned magnetization direction of said seventh element's pinned layer in the direction of the Y-axis; and
 - (h) said eighth element being formed in a neighborhood of an end of the chip in the negative direction of the Y-axis and a little to the left of a generally central part of the chip in the X-axis direction, and having a pinned magnetization direction of said eighth element's pinned layer in the direction of the Y-axis.
5. The magnetic sensor according to claim 4 wherein:
- (a) said first to fourth elements construct an X-axis magnetic sensor for detecting a magnetic field in the X-axis direction by full bridge connection of the first to fourth elements; and
 - (b) said fifth to eighth elements construct a Y-axis magnetic sensor for detecting a magnetic field in the Y-axis direction by full bridge connection of the fifth to eighth elements.
6. The magnetic sensor according to claim 5, wherein:
- (a) the pinned magnetization direction of the pinned layer of the first and the second elements are in the negative direction of the X-axis;

- (b) the pinned magnetization direction of the pinned layer of the third and the fourth elements are in the positive direction of the X-axis;

- (c) the pinned magnetization direction of the pinned layer of the fifth and the sixth elements are in the positive direction of the Y-axis; and
- (d) the pinned magnetization direction of the pinned layer of the seventh and the eighth elements are in the negative direction of the Y-axis.

7. A magnetic sensor comprising a plurality of magnetoresistance effect elements, each element containing a pinned layer and a free layer and having a resistance value that changes in accordance with a relative angle formed by a magnetization direction of the pinned layer and a magnetization direction of the free layer:

- (a) said magnetic sensor being formed in such a manner that said magnetoresistance effect elements are provided on a single chip;
 - (b) an X-axis group of said magnetoresistance effect elements constructing a X-axis magnetic sensor for detecting a magnetic field in the X-axis direction; and
 - (c) a Y-axis group of said magnetoresistance effect elements constructing a Y-axis magnetic sensor for detecting a magnetic field in the Y-axis direction perpendicular to the X-axis.
8. The magnetic sensor according to claim 7, wherein:
- (a) said X-axis group of magnetoresistance effect elements construct the X-axis magnetic sensor by full bridge connection, and the pinned magnetization directions of these magnetoresistance effect elements are in the X-axis direction; and
 - (b) said Y-axis group of magnetoresistance effect elements construct the Y-axis magnetic sensor by full bridge connection, and the pinned magnetization directions of the magnetoresistance effect elements are in the Y-axis direction.
