A bonded structure comprising the physical and electrical connections between an integrated circuit element and substrate using a composite bump comprised of a single polymer body of low Young's Modulus and a conductive metal coating. When the bonded structure is formed the composite bump is deformed and the low Young's Modulus of the polymer body allows a very reliable bonded structure with very low bonding force. Due to the low Young's Modulus there is little tendency to separate the connections after the bonded structure is formed. The bond can be formed using thermocompression bonding, ultrasonic bonding, application of heat or application of light. The bond can also be formed using a non-conductive adhesive between the integrated circuit element and the substrate. The bond can also be formed with a conductive adhesive coating on the composite bump.

COMPOSITE BUMP BONDING

RELATED PATENT APPLICATIONS

BACKGROUND OF THE INVENTION

[0003] (1) Field of the Invention

[0004] The invention relates to the joining of integrated circuit elements to the next level of integration, or that level of integration to the following level, and more particularly to the formation of the bonded structure which comprises the physical and electrical connection between the integrated circuit element and the corresponding substrate wherein very dense wiring patterns can be accommodated economically and the resulting connections are extremely reliable.

[0010] This object is achieved with a bonded structure comprising the integrated circuit element input/output pads, composite bumps comprised of a single polymer body with a Young's Modulus which is low compared to metals and a conductive metal coating covering the polymer body, and the substrate input/output pads. The conductive metal coating covering the polymer body must be chosen to provide good adhesion to the polymer body and may include an adhesive layer and a barrier layer in addition to a conductor layer. The low Young’s Modulus of the polymer, about $0.4 \times 10^5$ to $0.5 \times 10^6$ psi, allows the bond to be made with very low bonding force and greatly reduces or eliminates the force tending to separate the connections after the bonding force is removed. This results in extremely reliable physical and electrical connections between the integrated circuit element and substrate.

[0011] It is a further object of the invention to provide a method for forming a bonded structure comprising the electrical and physical connections between integrated circuit elements and the corresponding substrate wherein very dense wiring patterns can be accommodated economically and the resulting connections are extremely reliable.

[0012] This object is achieved by forming a bonded structure comprising the integrated circuit element input/output pads, composite bumps comprised of a single polymer body with a Young’s Modulus which is low compared to metals and a conductive metal coating covering the polymer body, and the substrate input/output pads. The conductive metal coating covering the polymer body must be chosen to provide good adhesion to the polymer body and may include an adhesive layer and a barrier layer in addition to a conductor layer. The composite bump will be deformed during the bonding process and the low Young’s Modulus of the polymer, about $0.4 \times 10^5$ to $0.5 \times 10^6$ psi, allows the bond to be made with very low bonding force and greatly reduces or eliminates the force tending to separate the connections after the bonding force is removed. The polymer body and the conductive metal coating must be chosen to be compatible with the temperatures used during the bonding process.

BRIEF DESCRIPTION OF DRAWINGS

[0013] FIG. 1 is a cross sectional representation of the composite bump formed on the integrated circuit element showing the polymer interior and conductive metal coating of the composite bump.

[0014] FIG. 2 is a cross sectional representation of the bonded structure with the composite bumps formed on the integrated circuit element prior to bonding.

[0015] FIG. 3 is a cross sectional representation of the composite bump formed on the substrate showing the polymer interior and conductive metal coating of the composite bump.

[0016] FIG. 4 is a cross sectional representation of the bonded structure with the composite bumps formed on the substrate prior to bonding.

[0017] FIG. 5 is a cross sectional representation of the composite bump formed on both the integrated circuit and the corresponding substrate wherein very dense wiring patterns can be accommodated economically and the resulting connections are extremely reliable.

SUMMARY OF THE INVENTION

[0009] It is the principal object of the invention to provide a bonded structure comprising the electrical and physical connections between integrated circuit elements and the
element and the substrate showing the polymer interior and conductive metal coating of the composite bumps.

[0018] FIG. 6 is a cross sectional representation of the bonded structure with the composite bumps are formed on both the integrated circuit element and the substrate prior to bonding.

[0019] FIG. 7 is a cross sectional representation of the bonded structure wherein a conducting adhesive bonds the conducting metal coating of the composite bump to the substrate input/output pad.

[0020] FIG. 8 is a cross sectional representation of the bonded structure wherein a conducting adhesive bonds the conducting metal coating of the composite bump to the integrated circuit element input/output pad.

[0021] FIG. 9 is a cross sectional representation of the bonded structure wherein a conducting adhesive bonds the conducting metal coating of the integrated circuit element composite bump to the substrate composite bump.

[0022] FIG. 10 is a cross sectional representation of the bonded structure wherein a non conducting adhesive bonds the integrated circuit element to the substrate.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

[0023] Refer now more particularly to FIGS. 1 and 2, there is shown an embodiment for the bonded structure of the current invention. Composite bumps are formed on the integrated circuit element 30 input/output pads 26. The input/output pads are formed of a metal such as aluminum with a diameter of about 90 microns. Each composite bump comprises a single polymer body 32 and a conductive metal coating 36 covering the polymer body. The polymer body must withstand temperatures encountered during bonding and can be polyamic acid polyimide such as PROBIMIDE 7010 or PROBIMIDE 514 produced by OCG Microelectronics Materials, Inc., Tempe, Ariz. The polymer body has a thickness of about 5 and 25 microns. Input/output pads 24 are formed on the substrate 20 using a metal such as aluminum.

[0024] The conductive metal coating 36 must adhere to the polymer body and can be a metal such as aluminum or nickel; or a composite such as nickel/gold, chrome/gold, chrome/silver, or titanium/platinum. The conductive metal coating can be a composite which includes an adhesion layer/a barrier layer/a conductor layer such as chrome/copper/gold, chrome/nickel/gold, chrome/silver/gold, titanium/platinum/gold, titanium/palladium/gold, or titanium/tungsten/silver.

[0025] When the bonded structure is formed the composite bumps will contact the substrate input/output pads and will be deformed as shown in FIG. 2 so that each composite bump will contact a substrate input/output pad. Due to the low Young's Modulus of the polymer body a very small force, about one tenth that required by the traditional gold bump, is required for this deformation and there is little tendency to separate the bonded structure after it has been formed.

[0026] Refer now to FIGS. 3 and 4, there is shown another embodiment of the bonded structure. In this embodiment the composite bumps are formed on the substrate input/output pads 24. The composite bump and the structure after the bond is formed is as described above.

[0027] Another embodiment is shown in FIGS. 5 and 6, in this embodiment the composite bumps are formed on both the integrated circuit element input/output pads 26 and the substrate input/output pads 24. When the bonded structure is formed the substrate composite bumps are brought together with the integrated circuit element composite bumps. The composite bumps are deformed and due to the low Young's Modulus of the polymer body a very small force is required for this deformation and there is little tendency to separate the bonded structure after it has been formed.

[0028] The integrated circuit element 30 and the substrate 20 are brought together so that the conductive metal coating 36 on each composite bump contacts a substrate input/output pad 24 as shown in FIG. 2, an integrated circuit element input/output pad 26 as shown in FIG. 4 or a corresponding composite bump as shown in FIG. 6. The bond is then formed using a bonding process such as thermo-compression bonding, ultrasonic bonding, tape automated bonding, application of heat energy, or application of light energy.

[0029] As shown in FIGS. 7, 8, and 9 the bonding may also be accomplished using a conductive adhesive 38 between the conductive metal coating 36 of each composite bump and the corresponding substrate pad 24 shown in FIG. 7, the corresponding integrated circuit element input/output pad 26 shown in FIG. 8, or the corresponding composite bump shown in FIG. 9. As shown in FIG. 10, the bonding may also be accomplished using a nonconductive adhesive 22 between the integrated circuit element 30 and substrate 20. The conductive and nonconductive adhesives may require the application of heat energy or light energy. During the bonding process the polymer body in each composite bump is deformed as electrical connection is formed. This deformation is important in forming a good electrical contact. Due to the low Young's Modulus of the polymer body this deformation requires a very small bonding force and produces little or no tendency to separate the connection after it has been made.

[0030] While the invention has been particularly shown and described with reference to the preferred embodiments thereof, it will be understood by those skilled in the art that various changes in form and details may be made without departing from the spirit and scope of the invention.

What is claimed is:

1. A bonded structure, comprising:
   an integrated circuit element having input/output pads;
   a substrate having input/output pads; and
   a plurality of physical and electrical connections between said integrated circuit element input/output pads and said substrate input/output pads wherein each said connection includes a composite bump comprised of a polymer body and a conductive metal coating covering said polymer body, and wherein said composite bump is deformed when said connection is formed.

2. The bonded structure of claim 1 wherein said polymer is polyamic acid polyimide.
3. The bonded structure of claim 1 wherein said conductive metal coating is comprised of an adhesion layer, a barrier layer and a conductor layer.

4. The bonded structure of claim 1 wherein said composite bumps are formed on said integrated circuit element input/output pads prior to formation of said connection.

5. The bonded structure of claim 1 wherein said composite bumps are formed on said substrate input/output pads prior to formation of said connection.

6. The bonded structure of claim 1 wherein said composite bumps are formed on both said integrated circuit element input/output pads and substrate input/output pads prior to formation of said connection.

7. A method of forming a bonded structure, comprising:
   providing an integrated circuit element with input/output pads;
   providing a substrate with input/output pads;
   providing composite bumps comprised of a polymer body and a conductive metal coating covering said polymer body formed on said integrated circuit element input/output pads;
   bringing together said integrated circuit element and said substrate so that said composite bumps contact said substrate input/output pads and are deformed during said contact; and
   bonding said composite bumps to said substrate input/output pads.

8. A method of forming a bonded structure, comprising:
   providing an integrated circuit element with input/output pads;
   providing a substrate with input/output pads;
   providing composite bumps comprised of a polymer body and a conductive metal coating covering said polymer body formed on said substrate input/output pads;
   bringing together said integrated circuit element and said substrate so that said composite bumps contact said integrated circuit element input/output pads and are deformed during said contact; and
   bonding said composite bumps to said integrated circuit element input/output pads.

9. A method of forming a bonded structure, comprising:
   providing an integrated circuit element with input/output pads;
   providing a substrate with input/output pads;
   providing composite bumps comprised of a polymer body and a conductive metal coating covering said polymer body formed on said integrated circuit element input/output pads and on said substrate input/output pads;
   bringing together said integrated circuit element and said substrate so that said integrated circuit element composite bumps contact said substrate composite bumps and said integrated circuit element composite bumps and said substrate composite bumps are deformed during said contact; and
   bonding said integrated circuit element composite bumps to said substrate composite bumps.

10. The method of claim 7 wherein said polymer is polyimide.

11. The method of claim 7 wherein said conductive metal coating is comprised of an adhesion layer, a barrier layer and a conductor layer.

12. The method of claim 7 wherein said bonding is provided by a conductive adhesive between said composite bumps and said substrate input/output pads.

13. The method of claim 8 wherein said bonding is provided by a conductive adhesive between said composite bumps and said integrated circuit element input/output pads.

14. The method of claim 9 wherein said bonding is provided by a conductive adhesive between said substrate composite bumps and said integrated circuit composite bumps.

15. The method of claim 7 wherein said bonding is provided by a nonconductive adhesive between said integrated circuit element and said substrate.

16. The method of claim 7 wherein said bonding is provided by thermocompression bonding.

17. The method of claim 7 wherein said bonding is provided by application of heat energy.

18. The method of claim 7 wherein said bonding is provided by application of light energy.

19. The method of claim 7 wherein said bonding is provided by ultrasonic bonding.

20. The method of claim 7 wherein said bonding is provided by tape automated bonding.
