(54) Title: DATA BACKUP AND RESTORE SYSTEM FOR A COMPUTER NETWORK

(57) Abstract

A computer network having a number of workstations running disparate operating systems and a file server having a tape driver for backup and restore of data on the network. The filter server runs a generic remote file system (GRFS) and workstations run GRFS agent programs which allow the GRFS file system to access data within a workstation having a given GRFS agent program. The GRFS file system interfaces with each GRFS agent program via a command/response paradigm, with the messages being structured to support the disparate operating systems for backup and restore, to allow data to be interchanged between the disparate operating systems, and to allow independent multiple users of the network to request simultaneously backup or restore.

DATA BACKUP AND RESTORE SYSTEM FOR A COMPUTER NETWORK

BACKGROUND OF THE INVENTION

5 Field of the Invention

The present invention relates to a system for protecting data through backup and restore operations, and more particularly to backup and restore software for protecting data which is processed on a computer network

10

15

20

25

30

35

Description of the Related Art

In order to ensure that original data stored on a medium such as a disk is not lost or damaged, a copy of that data is stored on another medium. Should the original data be lost or damaged, then the copy may be accessed to reproduce the original data. This process of copying and reproducing is generally known as backup and restore. Typically, original data are stored on a hard or floppy disk of a computer disk drive and are backed up to and restored from tape media of a tape drive.

Backup and restore of the data are simple in a system that has a single standalone computer, having a given operating system and one or more disk drives, that interfaces with a tape drive system. A relatively simple backup and restore program can be used that interfaces with the computer operating system to backup data including files and directories stored on a hard disk to the tape drive and to restore such data from the tape drive onto the hard disk.

Computer networks have evolved and this has placed greater demands on backup and restore systems. A computer network may include a number of computers each with its own hard and/or floppy disk drive, all of which are networked together on a common bus. For example, the computers on the network may include one or more

5

10

15

20

25

30

35

workstations and one or more file servers, each with its own hard disk drive. The file server may also have a tape drive upon which to backup and restore its own data as well as data stored on the disk drives of the workstations on the network. Backup and restore operations are still relatively simple for a computer network in which each workstation is running the same operating system or environment, such as that known as DOS. However, computer networks exist in which workstations and file servers on the network may be running disparate operating systems. For example, a computer network may have, or may be expanded to have, workstations running different operating including those known as DOS, Windows, OS/2, Macintosh, and UNIX. The computer network also may have, or may be expanded to have, file servers running networking operating systems software, including those known as NetWare, Lotus Notes, and LAN Manager.

In one particular example, a computer network having workstations and a file server running disparate operating systems may be supported by NetWare, which is an operating system made and sold by Novell, Inc. of Provo, Utah. NetWare is designed to manage the programs and data among several computers on a network, unlike, for example, DOS, which is an operating system for standalone personal computers. Novell also provides, for example, SBACKUP software, which is a NetWare Loadable Module (NLM) that can be loaded onto a NetWare file server to backup data to and restore data from a tape storage device attached to the NetWare server. has limited capabilities; for example, it is designed to backup and restore only NetWare server data and workstations running DOS, OS/2, and Windows.

The difficulty in providing backup and restore operations to protect data on a computer network

obviously increases as more and more disparate operating systems are added to the network via the computers on which they run.

In general, prior backup and restore systems for computer networks are limited to the number of different types of operating systems that can be supported. places expansion limitations on the network in terms of adding computers running additional types of operating systems. Also, these backup and restore systems do not have the capability of interchanging data between different operating systems. Furthermore, bottlenecks occur and productivity is limited with prior backup and restore operations since multiple users simultaneously request these operations.

SUMMARY OF THE INVENTION

The present invention provides a backup and restore system for use on a computer network having computers running disparate operating systems. Backup and restore software has modules including a backup containing, among other components, a generic remote file system (GRFS file system) and GRFS agents, being loadable on a computer network having a plurality of computers including, for example, at least one file server and at least one workstation. The GRFS file system may run on one computer, e.g., the file server of the network, and each GRFS agent may run on another computer, e.g., a workstation, on the network. The GRFS file system running on the one computer, i.e., the file server in this example, is allowed to access a file system of the other computer via the GRFS agent on that other computer to backup and restore data on that computer.

The GRFS file system and each GRFS agent interface with one another over the computer network by a set of defined messages. This messaging system is based on a

command/response paradigm, such that the GRFS file system will send a given GRFS command message to a given GRFS agent and wait for a GRFS response message from the GRFS agent in order to backup or restore data. These messages are defined structurally in a manner that enables (1) backup and restore of data for a wide variety of disparate operating systems, (2) data to be interchanged between the different operating systems, and (3) simultaneous request for backup or restore by independent multiple users of the computer network.

Consequently, with the present invention, a computer network can be expanded to support computers running the major operating systems including DOS, Windows, OS/2, UNIX, and Macintosh. Also, data can be backed up from one computer, e.g., a Macintosh workstation, and restored to another, e.g., a DOS workstation, and multiple users working on the various computers in the network can simultaneously request backup and restore operations.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

Fig. 1 illustrates one example of a computer network 10 which stores, manipulates, and otherwise processes data. The network 10 has a number of computers 12 which can communicate with one another over a network bus 14. In the example of Fig. 1, the computers 12 include a file server FS and a plurality of workstations WS_1 , WS_2 , WS_3 , WS_4 ,... WS_n . Each of the workstations WS_1 - WS_n has a display monitor M and the workstations WS_1 - WS_n include hard disk drives HDD_1 - HDD_n . The file server FS has its own large file server disk drive FSDD and a tape drive TD upon which to backup to and restore from data on the network 10.

Every workstation WS₁-WS_n may be running the same operating system OS, or each workstation WS, through WS, may be running a disparate operating system, or there may be disparate groups of workstations with each group running the same operating system. For example, workstation WS₁ and workstation WS₂ may both be running the operating system known as DOS, workstation WS3 may be running the operating system known as OS/2, workstation WS4 may be running the operating system known as UNIX, workstation WS, may be running the operating system known as Macintosh, and other workstations, not shown, or which may be added to the network 10, may run the operating system known as Windows. Furthermore, the computers 12 in the network 10 may be utilizing user interfaces such as those known as the DOS user interface, Windows graphical user interface, and a server-based NLM (NetWare Loadable Module) interface.

The computer network 10 may be, for example, running the operating system software known as NetWare 3.X or 4.X which is produced by Novell, Inc., of Provo, Utah. NetWare is designed to manage programs and data among the several computers 12 of the network 10. Fig. 1 also

5

10

15

20

25

30

35

illustrates a portion of the NetWare software including individual network protocols SPX, TCP, and ADSP. As shown, these three protocols are associated with the file server FS, while the respective protocols are associated with each respective type of workstation. For example, NetWare supports the protocol SPX for DOS, Windows, and OS/2 workstations, and the protocol TCP for UNIX workstations. Also shown is a network resource layer (NRL) which is an interface module which provides for accessing network messages and advertising resources available on the network 10.

The general operation of a computer network 10 including one that is running NetWare is well-known. As one brief example of the operation, a user who is using a workstation WS_1 - WS_n may want to access data that is currently stored on the disk drive of the file server FS. Upon request by the user of, for example, DOS workstation WS_1 , the file server FS will set up a connection and protocol via its network resource layer NRL, its network protocol SPX, and the network protocol SPX and network resource layer NRL of the workstation WS_1 . Via this connection and protocol, data can then be transferred over the network 14 between the file server disk drive FSDD and the workstation WS_1 disk drive HDD₁ for processing by that user.

Fig. 2 illustrates a software package 16 of the present invention. In the specific embodiment, the package 16 is a NetWare Loadable Module (NLM), which, therefore, can be loaded onto NetWare. The package 16 includes multiple user interfaces 18, including a Windows graphical user interface, a DOS interface, and a serverbased NLM interface. The package 16 also include GRFS agents 20 including, respectively, DOS, OS/2, UNIX, Macintosh, and Windows agents. Each agent 20 is a respective program designed to run on a computer 12

5

10

15

20

25

30

35

having the corresponding operating system in order to access the file system of that given computer. Thus, for example, the DOS GRFS agent 20 will run on a DOS workstation WS₁, the OS/2 GRFS agent will run on the OS/2 workstation WS₂, etc. The package 16 also has a backup engine 22 running on the file server FS and includes a tape controller device driver and tape positioner to control the mechanical operation of the tape drive TD, a common file system, and at least one device specific file system. The latter is a GRFS file system which interfaces with GRFS agents 20 via messages described in more detail below.

Fig. 3 illustrates the network 10, but modified to include the software 16. As shown, the backup engine 22 is installed at the file server FS, while the DOS, OS/2, UNIX, and Macintosh GRFS agents are installed on the respective workstations WS_1-WS_2 , WS_3 , WS_4 , and WS_n . In this example, the computer network 10 does not have a computer 12 running a Windows operating system. Should the network 10 be expanded to include a Windows workstation, then the Windows GRFS agent of the software 16 would be installed at that workstation. While not specifically illustrated, a workstation user also can opt to have installed one of the user interfaces 18 for tape backup and restore purposes, that is the same as that already on a workstation for other purposes.

As indicated above, a GRFS agent is a program which runs on a network computer such as the given workstation WS, and which allows the GRFS file system running on another computer, such as the file server FS, to access the file system within the given GRFS agent's computer. This access is accomplished by use of an interface between the GRFS file system and the given GRFS agent over the network bus 14. Specifically, the interface is defined by a set of GRFS messages which are documented in

5

10

15

20

25

30

detail as described more fully below. The GRFS messages include GRFS command messages that are produced by the GRFS file system and GRFS response messages produced by the given GRFS agent.

The GRFS messages are based upon a simple command/response paradigm. For backup or restore, the GRFS file system of the file server FS sends a command message over bus 14 to a given GRFS agent of the workstation WS and then waits for that agent to respond over bus 14 with a GRFS response message. A GRFS agent does not send a GRFS response message without first receiving the corresponding GRFS command message from the GRFS file system.

There are several characteristics of the GRFS messages that allow independent multiple users on the network 10 to simultaneously request backup and restore of data, allow for backup and restore of almost all types of disparate workstation and file server operating systems, and allow data to be backed up from a GRFS agent running on one operating system and be restored to a GRFS agent running on a different operating system. However, before these message characteristics are further described, an overview of the message structures will first be given. Reference should be made below under the "Specific Description of Command/Response Messages" for a detailed description of the message structures.

All GRFS messages (command and response) are structured to begin with the same four fields. These four fields of the common structure are as follows:

msg_type: This UINT8 field contains the command or status id number.

35 reserved: This UINT8 field is not currently used.

retcode: This UINT16 field is used by GRFS status

messages to hold the return code of the

GRFS command.

5 request_id: This UINT32 field contains a value which

is generated by the GRFS file system for GRFS command messages and must be returned unchanged in the corresponding GRFS

response message.

10

15

20

25

30

35

In the detailed description of the specific GRFS messages below under the heading "Specific Description of Command/Response Messages", the number of parameters associated with a given GRFS agent is assumed not to include the above GRFS common message header. The messages use two major structures to define GRFS objects. These two major GRFS object types are a drive list element (DLE) objects, which are logical devices, and file system objects, which are files and directories. The GRFS messages use DLE structures to reference drive list element objects and DBLK (descriptor block) structures to reference file system objects.

A DLE is a structure that contains information about individual data storage devices which can be accessed for backup and restore. The DLE structure contains the following types of information: logical device name, access password, file system delimiter, etc.

A DLE structure also supports a hierarchical structure. A DLE can be a "parent" DLE and can have "children" DLEs associated with it. For example, this is the case for a Novell server file system. For a Novell server, a DLE structure is created which is associated with the server and then DLEs for each volume on the server are created. The same situation can occur with a GRFS agent should that agent advertise or publish on the network 10 the workstation name as a DLE and then use children DLEs to advertise individual areas which can be accessed as logical units.

5

10

15

20

25

30

35

Security considerations such as passwords and user names may be enforced at each DLE level within a hierarchical structure. This means that a single GRFS agent can advertise on the network 10 a workstation name with multiple children DLEs and each child DLE would have a unique password.

While DLEs contain information about individual storage devices, a DBLK structure contains information about specific file system objects, which are the things in the file systems that are actually backed up and restored. As already mentioned, these objects include files and directories. The contents of a DBLK structure include items such as: the object's type, the object's name, and the object's attributes. A DBLK structure can also contain operating software specific information.

There are several other aspects of a DLE structure and a DBLK structure to discuss. A DLE does not have both children DLEs and file system objects associated with it. In other words, if a GRFS agent advertised itself over the network 10 as a "workstation", as will be described further below, and had a child DLE for each disk drive at the workstation, then the workstation DLE will have no file system objects associated with it. This is because the backup application descends to the bottom of DLE trees before attempting to find any objects. Most GRFS agents will support multiple levels of DLEs, but if the file system of the agent platform is very flat, i.e., there are no sub-devices and all objects can be enumerated with a single handle, then a single level DLE structure will suffice.

A DBLK structure has a common structure area followed immediately by the variable length DBLK data area. The DBLKs are limited to a maximum of 1,024 bytes in the specific embodiment, which means that the sum of the space required for the DBLK common structure and the

5

10

15

20

25

data area is at most 1,024 bytes. Furthermore, there are several fields within the DBLK structure, which are actually pointers to information within the DBLK data area. These pointers are generated as offsets from the beginning of the DBLK structure. For example, if the DBLK common area is 80 bytes long and the first item within the data area is the object's name, then the object name field would be set to 80 in order to point to the first byte following the DBLK common structure. The individual fields within the common DBLK structure that are manipulated by the GRFS agent programs are described in detail below under the heading "DBLK Fields".

In order to implement a backup and restore function for a given computer 12, that computer 12 should advertise its capability for this purpose. Not every computer 12 in the network 10 is necessarily running a GRFS agent program so as to be able to have its data backed up. Consequently, the GRFS agent programs will "advertise" their capability as a GRFS agent over the This may be accomplished using the NRL network 10. resource advertisement function. The GRFS agent resource advertisement publishes the logical name particular agent's root DLE, as well as various flags which are used by the GRFS file system to control access to the GRFS agent. The format of the GRFS agent advertisement structure is as follows:

GRFS agents use character representations of the values in the version and flags fields. For example, the major.minor version of a particular GRFS agent might be

1.3, so that agent would advertise the version numbers as "1" and "3", respectively.

The GRFS major version number is used to control which GRFS agents can be accessed by the GRFS file system. The GRFS major version number of the GRFS file system and the GRFS agent must match exactly or no information of the existence of that GRFS agent will be given. The GRFS minor version number may be used for informational purposes only.

The agent_type field is used to define the type of GRFS agent. For example, the following values may be defined for this field:

DOS 1 OS2 2 15 MACINTOSH 3 UNIX 4

5

25

The GRFS flags field is a bit-mapped value with the following flags currently defined:

20 GRFS_WS_PASSWORD_REQ 0x01 GRFS_WS_USER_REQ 0x02

Combining all the GRFS resource advertisement fields leads to the following examples of GRFS agent advertisements:

	NRL Resource	Decoded As
30	"1211RATBOY_486"	<pre>major version = 1 minor version = 2 DOS agent no user name required password required DLE name = "RATBOY_486"</pre>
4 0	"1020SLEDGEHAMMER"	<pre>major version = 1 minor version = 0 OS/2 agent no user name required no password required DLE name = "SLEDGEHAMMER"</pre>

"0043ONE_WOLF"

major version = 0
minor version = 0
Unix agent
user name required
password required
DLE name = "ONE_WOLF"

5

20

25

30

35

response messages in simplified form to backup data on the tape drive TD of the file server FS. This Fig. 4 gives the example of backing up a 5000 byte file named COMMAND.COM which is stored on a "DRIVEC" of a given workstation named "DougCompaq". It is assumed that the given workstation WS has advertised over the network 10 sufficient information so that the GRFS file system can create the first command message shown in Fig. 4 as ATTACH_DLE(.

To begin the 5000 byte backup, the workstation user will, via a given user interface 18, cause a display on a monitor M of devices and subdevices. The user will then select a given subdevice (e.g., DRIVEC in the example of Fig. 4), resulting in the user interface displaying on monitor M names of various files and directories. The user will then select the file name to be backed up (COMMAND.COM in the example) resulting in the submission of a tape backup job for the file server FS in the network 10.

Next, the sequence of GRFS file system command messages and GRFS agent response messages will occur as shown in order in the simplified Fig. 4. The sequence, as illustrated, commences with the GRFS command message ATTACH_DLE(naming "DougCompaq" (dle.id=01) and completes with the final GRFS agent response message DETACH_DLE_STAT() by which DougCompaq (dle.id=01) is detached. Thus, the file COMMAND.COM will be read from DRIVEC and written onto the tape drive TD of the file server FS for network 10.

Fig. 5 shows a sequence of GRFS command/response messages to restore information backed up on the file server FS of the network 10. In this example, it is assumed that a 5000 byte file named CONFIG.SYS has been backed up from a given workstation and is to be restored to DRIVEC of the workstation DougCompag. After the workstation user has selected the file CONFIG.SYS using the user interface to select the file CONFIG.SYS for restore, the sequence of GRFS command/response messages will proceed as shown in Fig. 5. The sequence begins with the GRFS command message ATTACH_DLE(and completes with the GRFS response message DETACH_DLE_STAT(). file CONFIG.SYS will be read from the tape drive TD and restored onto DRIVEC.

As mentioned previously, the command/response messages are structured such that objects such as files and directories may be backed up from a GRFS agent running one operating system, e.g., OS/2, and restored to a GRFS agent running another operating system, e.g., DOS.

This is accomplished by the messages containing a structure GRFS_STREAM_INFO. This structure has the following definition:

```
struct GRFS_STREAM_INFO {
    UNET32 id;
    UNET16 fs_attrib;
    UNET16 tf_attrib;
    UNET64 size;
    }
```

5

10

When the backup application is reading an object, the GRFS_READ_OBJ_STAT response message contains a GRFS_STREAM_INFO structure. The GRFS agent program must set the id field of the first GRFS_READ_OBJ_STAT response message of each individual data stream to the appropriate value for the agent's particular operating system. Succeeding GRFS_READ_OBJ_STAT messages for the stream must have the stream header id field set to 0 (STREAM_INVALID). The data in the stream info structure

5

10

15

is used by the backup application's tape format module and is written to the backup media of tape device TD. A well-known Microsoft Tape Format Version 1.0 Specification describes stream header structures and also contains a list of pre-defined stream header id values. The size field must be set to the number of bytes contained in the succeeding data stream and should only be set in the first stream header structure for a particular data stream, i.e., if the stream header id value is 0, then the size field does not need to be set.

An example is presented below of what a Macintosh GRFS agent would return in the GRFS_READ_OBJ_STAT messages when a file with a 2000 byte resource fork and a 4000 byte data fork is being backed up. This example also assumes that a GRFS data buffer limit is 1000 bytes.

	strm_header.id=STRM_MAC_RESOURCE	(returns 1st 1000 bytes of resource fork)	
20	strm_header.size=2000		
	strm_header.id=STREAM_INVALID	(returns last 1000 bytes of resource fork)	
25	strm_header.size=0		
	strm_header.id=STRM_NORMAL_DATA	(returns 1st 1000 bytes of data fork)	
30	strm_header.size=2000	bytes of data fork)	
30	strm_header.id=STREAM_INVALID	(returns next 1000 bytes of data fork)	
	strm_header.size=0	byces or data fork,	
35	strm_header.id=STREAM_INVALID	(returns next 1000 bytes of data fork)	
	strm_header.size=0	byces of data fork)	
40	strm_header.id=STREAM_INVALID	(returns last 1000 bytes of data fork)	
-0	strm_header.size=0	Dices of data fork)	

5

10

15

20

25

30

35

When the backup application is restoring an object, the GRFS commands (GRFS_WRITE_OBJ, GRFS_VERIFY_OBJ) will also contain a GRFS_STREAM_INFO structure. agent must examine the stream header id value to determine whether the data stream type is supported on the agent's operating system platform. If the data stream type is not supported the GRFS agent should set the response message retcode to FS_DONT_WANT_STREAM. This will cause the backup application to skip to the next data stream or the next object if at the last data stream for a particular object. For instance, if an object was backed up from an OS/2 agent which supports a normal data stream, an extended attribute (EA) data stream, and an access control list (ACL) data stream, then if the object is restored to a DOS agent, the DOS agent will return FS_DONT_WANT_STREAM when it receives GRFS_WRITE_OBJ commands with stream header id values that indicate either EA or ACL data streams are being restored since this data is not supported by DOS. The DOS agent will accept the normal data stream which it does support. Thus, this functionality allows objects to be backed up from an agent running on one operating system and restored to an agent running on another operating system.

As also mentioned above, the message structure is defined as well, such that backup and restore can be supported with respect to most operating systems, including the current major operating systems which are DOS, OS/2, Macintosh, Windows, and UNIX. Each operating system will have its own data structures aligned differently from one another. For example, one operating system may have a 1-byte alignment where a data byte may be placed anywhere, whereas another operating system may have a 2-byte alignment where a data byte may be placed in either an even or odd byte location. Other operating systems, for example, may have what is known as a 4-byte

alignment. The GRFS messages are defined with a "least common denominator" alignment that would apply to the above-noted major operating systems. Thus, for example, a given network 10 which may include workstations running only DOS, OS/2, and Macintosh, may be expanded to include a workstations running UNIX and/or Windows. In other words, the present invention supports a scalable network for backup and restore purposes from a small or departmental local area network (LAN) to a large or enterprise wide area network (WAN).

Furthermore, the message structure enables multiple users working at multiple computers 12 on the network 10 to request simultaneously backup and restore of objects. This structure enables the GRFS file system to create a unique request id for every GRFS command message. Consequently, the GRFS file system can communicate simultaneously with multiple GRFS agents and, therefore, multiple users of the network 10 who at the same time want to have backup and/or restore operations performed. The present invention will manage these requests such that they are placed in a job queue in the file server FS, thereby allowing each user to operate independently from any other user on the network 10 and without waiting access to the backup and restore system.

While each user can independently manage his/her own data on a given workstation, backup and restore of data on the entire network 10 can be centrally managed at a single location by, for example, a network administrator, from a given workstation or file server, or a system console.

The remaining portion of this specification describes in much more detail the structure of the command/response messages, followed by a detailed description of the individual fields of the GRFS common

35

20

25

DBLK structure which may be manipulated by GRFS agent programs.

SPECIFIC DESCRIPTION OF COMMAND/RESPONSE MESSAGES

3.0 Using GRFS Command and Response Messages

This following sections provide the information necessary to implement each of the GRFS command and response messages.

GRFS_ATTACH_DLE_, GRFS_ATTACH_DLE_STAT

After establishing an NRL session with the GRFS agent, the first GRFS command the backup application will send to the GRFS agent is the GRFS_ATTACH_DLE command. The GRFS_ATTACH_DLE command message contains the following parameters:

dle_name:

This field contains the name of the DLE that the backup application desires to attach to. The dle name field is encrypted in conjunction with the encryption done on the password field. The encryption/decryption method used by GRFS is described in the GRFS encryption section of this document.

bec_flags: This field contains a bit-mapped value which defines the configuration options chosen by the backup application program. The values defined for use in this field are as follows:

BEC BACKUP FILES INUSE

0x01

If this flag is set, then the GRFS agent should attempt to open files even if they are already in use by another process.

BEC_EXTENDED DATE SUPPORT

0x02

If this flag is set, then the backup application knows how to handle the ACCESS DATE and ARCHIVE DATE fields in the GRFS DBLK, so if the agent's OS platform supports these time-stamps, they should be provided in DBLKs.

BEC SET ARCHIVE FLAG

0x04

If this flag is set and the agent's OS platform supports an object "ARCHIVED" flag, then the GRFS agent should set an object's ARCHIVED flag after the object is closed during the backup operation.

BEC_RESTORE_SECURITY

0x08

If this flag is set and the agent's OS platform has support for security specific data forks (ie ACL support for LANMAN 0S/2), then security information should be restored during the restore operation.

BEC_GET_HIDDEN_FILES

0x10

This flag controls whether "hidden" objects should be returned while processing GRFS_FIND_FIRST_OBJ and GRFS_FIND_NEXT_OBJ commands.

BEC_GET_SYSTEM_FILES

0x20

This flag controls whether "system" objects should be returned while processing GRFS_FIND_FIRST_OBJ and GRFS_FIND_NEXT_OBJ commands.

BEC_PROC_EMPTY_DIRS

0x40

This flag controls whether directories which are empty should be returned while processing GRFS_FIND_FIRST_OBJ and GRFS_FIND_NEXT_OBJ commands.

special word:

This field is not used.

max obj bsize:

This field contains the size of the buffer that the GRFS file system would like to use when transferring object data to/from the GRFS agent. This buffer size is the size of the object data buffer, not the size of the GRFS message buffer. GRFS message buffers are larger than the object data buffer size because the GRFS message buffer miscellaneous parameters (obj_id, stream_info, etc) used by the GRFS_WRITE_OBJ, GRFS_VERIFY_OBJ, and GRFS_READ_OBJ_CBJ, messages must include the 8-byte common header as well as (obj_id, GRFS_READ_OBJ_STAT messages.

The GRFS object buffer size is a negotiated size, so if the value contained in the max obj bsize is larger than the agent would like, the agent can return a smaller value in the GRFS_ATTACH_DLE_STAT max_obj_bsize field. The GRFS file system will use the value returned by the GRFS agent if it is smaller than the default file system object data buffer size.

dle parent:

This field contains the DLE handle for the parent of the DLE being attached to if a parent DLE exists. If a parent DLE does not exist,

then this field is set to 0.

cmpr_type:

This field is not currently supported.

user_name:

This field contains the user name supplied by the backup application. This field will be filled only if the DLE is defined as requiring a user name.

password:

This field contains the password supplied by backup application if the DLE is defined as requiring a password. Even if the DLE requires no password, this field will appear to have a value until it is decrypted. Please see the section on DLE name/Password decryption for more information.

The proper response message for a GRFS_ATTACH_DLE is the GRFS_ATTACH_DLE_STAT message. The parameters associated with the GRFS DLE ATTACH STAT message are described below.

dle id:

This field must be set to the DLE id which the GRFS agent wishes to use to identify the DLE. The DLE id is a 32-bit value which the backup application will use in future GRFS commands to identify the DLE to be operated upon. Typically, the GRFS agent will create DLE ids as a pointer to a structure of an index into an array. The DLE id can be any value except 0.

max connects:

This field should be set to the maximum number of concurrent GRFS sessions which the agent is capable of.

max_opens_per_connect: This field should be set to the maximum

number of objects which can be opened

simultaneously per GRFS session.

process-ddbs: This field is not currently supported.

max_obj_bsize: This field should be set to the maximum object

data buffer size the agent wishes to use. The maximum GRFS message size is greater than the maximum object data buffer size because of the additional parameters in the GRFS messages which

convey object data.

cmpr_type: This field is not currently supported.

supports_children: This field is a BOOLEAN flag which should

be set to 0 if the DLE does not support children. A non-zero value declares the DLE as supporting children DLEs. A DLE declared as supporting children DLEs CANNOT support file system objects as well. Either a DLE supports children DLEs or file system objects. Never both.

path_len: This field should be set to the length of the

string (including the '/0' terminator) returned in the current_path field. Current GRFS agent implementations will always start in the logical root directory of DLEs when they are attached, so the current_path field should always be set

to ** and the path len field set to 1.

current_path: This field should be set to the current path of

the DLE being attached to. As described above, at DLE attachment time, the current path will be the logical root of the DLE, so the current path

is empty (**).

3.2 GRFS_FIND_FIRST_DLE, GRFS_FIND_NEXT_DLE, GRFS_FIND DLE STAT

The GRFS_FIND_FIRST_DLE and GRFS_FIND_NEXT_DLE commands are used by the backup application program to enumerate children DLEs for DLEs which are declared as supporting children DLEs. The sole parameter associated with these two commands is the dle_id parameter. The backup application will supply the dle_id value which was previously returned by a GRFS_ATTACH_DLE_STAT response message. The GRFS agent should respond with a GRFS_FIND_DLE_STAT message to both the GRFS_FIND_FIRST_DLE and GRFS_FIND_NEXT_DLE command.

It is the responsibility of the GRFS agent to determine the sequence and keep track of the children DLEs as they are being enumerated. The parameter in the GRFS_FIND_DLE_STAT response message are described below.

dle_name: This field should contain the name of DLE which is being enumerated. The value must be a null-terminated string.

passwd_req: This field is a boolean flag and should be set to 0 if no password is required to attach to the DLE. A non-zero value in this field indicates that a password is required.

user_req: This field is a boolean flag and should be set to 0 if no user name is required to attach to the DLE. A non-zero value in this field indicates that a user name is required in order to attach to the DLE.

dle_writable:

This field is a boolean flag used to indicate whether restore operations are permitted on the DLE. Setting this value to 0 will prevent the backup application from attempting restore operations.

last_access_supported:

This field is a boolean flag used to indicate whether the DLE's file system supports the last access date information. This field is used by the Backup application to determine whether file-grooming is supported for this device.

os_id:

os_ver:

fs_type:

cryp_type: This field is not currently used.

cmpr_type: This field is not currently used.

more_flag: This field is a boolean flag and should be used by GRFS agents to indicate that the DLE being returned is the last child DLE available. If the GRFS agent is incapable of knowing ahead of time whether this is the

last DLE, then this field can always be set to a non-zero value (TRUE). This will force the backup application to sent GRFS_FIND_NEXT_DLE commands until the GRFS agent responds with a FS_NO_MORE return code.

- 21/1-

3.3 GRFS_DETACH_DLE, GRFS_DETACH_DLE_STAT

The GRFS_DETACH_DLE command is used by the backup application when it no longer needs to access a DLE. The message has only one command specific parameter, the dle_id of the DLE which the backup application wishes to detach from. DLEs will always be detached in the reverse order to which they were attached. In other words the last DLE which was attached to will be the first to be detached from. When a DLE is detached, the GRFS agent can free any resources associated with the attached DLE. The GRFS_DETACH_DLE_STAT message is the response type for the GRFS_DETACH_DLE command.

3.4
GRFS_FIND_FIRST_OBJ, GRFS_FIND_NEXT_OBJ, and GRFS_FIND_OBJ_STAT

The backup application uses the GRFS_FIND_FIRST_OBJ command to begin scanning for file system objects. GRFS agents must take into account the GRFS find object mask flags which were supplied in the GRFS_ATTACH_DLE command. These flags specify whether HIDDEN and SYSTEM objects should be returned for GRFS_FIND_FIRST_OBJ and GRFS_FIND_NEXT_OBJ commands. The parameters associated with find first command are explained below.

dle_id: This field contains the id of the DLE that the backup application wishes to scan.

find_type: This field contains one of these values:

0x00 -return all object types found 0x01 -return only directory objects found

sname: This field contains the search string qualifier.

Normally this field will contain the string"*.*". The

string "*.*" means that all objects that meet the

find_type criteria should be returned.

3.4.1 GRFS Agent Path Generation

When a GRFS agent is creating the path string used for its file system's "FindFirst" system call, the following components must be included to create the correct path string. The path string must begin with the base directory of the DLE. The DLEs current path is then appended to the path string. Finally the sname parameter is appended to the path string. The GRFS agent must also supply path delimeters wherever required. An example of a "FindFirst" path string created by the OS/2 GRFS agent is presented below:

DLE base path: "C:\DOCS"

DLE current path: "GRFS\DESIGN"

sname: "*.*"

The GRFS agent creates the path string: "C:\DOCS\GRFS\DESIGN*.*"

Agents are responsible for keeping track of when path delimeters must be inserted. For example when OS/2 GRFS agent publishes the root directory of a disk drive, the path string is created as follows:

DLE base path: "C:\"

DLE current path: "DOCS\GRFS\DESIGN"

sname: "*.*"

GRFS agent creates the path string: "C:\DOCS\GRFS\DESIGN*.*"

The GRFS agent does not insert a path delimeter after the DLE base path because the DLE base path already ends with a path delimeter.

3.4.2 GRFS Find Info Area

One of the most important fields in the GRFS DBLK data area is the

Find Info area. Operating systems usually require some data which was returned from a FindFirst operation in order to perform subsequent FindNext operations. GRFS is designed so that the Find Info will reside in the GRFS DBLK, and the Find Info will be available to the GRFS agent whenever the GRFS_FIND_NEXT_OBJ command is issued. This is accomplished by passing the DBLK containing the Find Info back and forth between the backup application and the GRFS agent.

The backup application will never modify the Find Info data area.

The GRFS_FIND_NEXT_OBJ message has only two parameters:

dle_id: This field contains the id

This field contains the id of the DLE that the backup

application wishes to continue scanning.

dblk:

This field is a DBLK which contains the Find Info data required for the agent to perform a FindNext

operation.

The GRFS agent must respond with a GRFS_FIND_OBJ_STAT response message to both the GRFS_FIND_FIRST_OBJ and the GRFS_FIND_NEXT_OBJ commands. The parameters within this response message are described below:

more flag:

This field contains a boolean value that can be used by the GRFS agent to indicate to the GRFS file system whether there are any more objects available after the object currently being returned. If the more flag is set to 0 (FALSE), then the next time the backup application makes a FindNextObject function call, the GRFS file system will immediately return FS NO MORE and will not a transmit GRFS_FIND_NEXT_OBJ command to the GRFS agent. If the agent is unable to know in advance if the object being returned is the last object available, then the agent can always set this field to a non-zero (TRUE) value. This will force the GRFS file system to send a GRFS_FIND_NEXT_OBJ command and the GRFS agent to respond with a FS_NO_MORE return value.

dblk:

This field must be a complete GRFS DBLK. If a directory object is being returned, then the directory name should be a full path relative to the DLEs base path. For example, if the current path of a DLE is "OS2/SYSTEM", and the agent is returning the directory "TRACE", then the path returned in the DBLK data area would be "OS2\SYSTEM\TRACE". The path must be null-terminated, and the null-terminator character must be included in the path length field in the DBLK common structure. Root directory objects are returned with the path name '\0' and the path-leng field set to 1.

File object names are also returned as null-terminated strings, but only the actual file name is returned.

3.5 GRFS_FIND_CLOSE and GRFS_FIND_CLOSE_STAT

The GRFS_FIND_CLOSE command is used by the backup application when it is done scanning a particular directory. When a GRFS agent receives a GRFS_FIND_CLOSE message, the agent is allowed to release any resources associated with the FindFirst/FindNextfunctions. The are two parameters in the GRFS_FIND_CLOSE message and they are described below:

dle_id:

dblk:

The proper response message type for the GRFS_FIND_CLOSE command is the GRFS_FIND_CLOSE_STAT message. There are no parameters associated with the GRFS_FIND_CLOSE message.

3.6 GRFS_GET_OBJ_INFO, GRFS_GET_OBJ_INFO_STAT

The GRFS_GET_OBJ_INFO command is used by the backup application to retrieve a completed DBLK when the backup application has only a partially complete DBLK. The only DBLK fields which are required to contain valid data when the DBLK is passed to the GRFS agent are the blk_type (DIR or FILE) and the object name in the DBLK data area. The proper response message type is GRFS_GET_OBJ_INFO_STAT. The only parameter in the response message is the fully completed DBLK.

There is one slight difference between how a DBLK is created for the GRFS_GET_OBJ_INFO command. All other GRFS commands which create DBLKs return a fully specified path as the object name for directory objects. The GRFS_GET_OBJ_INFO_STAT DBLK returns ONLY the directory name as the path data in the DBLK data area. This is a "truth".

**** If the DBLK sent to the agent contains a Find Info area, then the agent MUST preserve this data within the DBLK which is returned to the backup application.

3.7 GRFS_GET_CURRENT_DDB, GRFS_GET_CURRENT_DDB_STAT

The GRFS_GET_CURRENT_DDB command is used by the backup application to retrieve a DBLK corresponding to the DLEs current directory path. The proper response message type is GRFS_GET_OBJ_INFO_STAT. The directory path string returned in the DBLK must be a fully specified relative to the DLE's base path. An example is presented below:

DLE's base path:

"C:\OS2"

DLE's current path:

"WINOS2\SYSTEM"

The path string returned in the DBLK data area would be "WINOS2\SYSTEM". An example of the DLE's current path being the logical root directory is presented below:

DLE's base path:

"C:\OS2"

DLE's current path:

The path string data returned in the DBLK data area would be a '\0' and the b.d.os_path_leng field would be set to 1.

**** Whenever a GRFS agent returns a logical root directory object DBLK, the DBLK data area path string should be set to '\0' and the b.d.os_path_leng field should be 1.

3.8 GRFS_CREATE_OBJ, GRFS_CREATE_OBJ_STAT

The GRFS_CREATE_OBJ command is used by the backup application during restore operations in order to create a file system object. The parameters associated with this command are the following:

dle_id: This parameter contains the DLE handle of the DLE where the object should be created.

dblk: This parameter is a complete DBLK and contains the type and the name of the object to be created.

Directory object DBLKs will contain fully specified paths, so the DLE's current path is NOT included when creating the full path of the object to be created, GRFS Agents must be capable of creating all levels of a fully specified directory path from a single GRFS_CREATE_OBJ command. For example, the backup application may send the command to create the directory "WIN31\WORD\DOCS\ISPECS". If the any of the directories "DOCS", "WORD", or "WIN31" do not already exist, then the agent must first create the preceding directories within the fully specified path.

File objects are always created in the DLE's current path directory.

The proper response message type is GRFS_CREATE_OBJ_STAT. There are no parameters associated with this response message.

3.9 GRFS_OPEN_OBJ, GRFS_OPEN_OBJ_STAT

The backup application must "open" a file system object before any read, write or verify operations can be performed on the object. The three parameters associated with the GRFS_OPEN_OBJ command are described below:

dle_id: This field contains the DLE handle of the DLE where the object to be opened resides.

mode: This field contains a flag value which is GRFS agent must use to determine the mode which should be used to open the object. This value will be one of the following:

0 READ mode (backup operation) 1 WRITE mode (restore operation) 2 VERIFY mode (compare operation)

dblk: This parameter is a complete DBLK and contains the type and the name of the object to be opened.

When a backup application is backing up a GRFS agent, the backup application may desire to backup files which are already in use on the GRFS agent's machine. The BEC_BACKUP_FILES_INUSE flag in the bec_flags field of the GRFS_ATTACH_DLE command determines whether the GRFS agent should attempt to open objects which have already been opened by a different process. If the DLE is configured to backup files in use and the agent is able to open the object, then the GRFS response message return code should be set to FS_OPENED_INUSE.

When an object is opened successfully, two parameters are returned in the GRFS_OPEN_OBJ_STAT response message. The first parameter is the obj_id. This parameter is a 32-bit value generated by the GRFS agent as an object handle. All succeeding GRFS commands which access the object will reference the obj_id. As with DLE handle ids, GRFS agents can use whatever method desired to generate the object handle ids.

A completed DBLK is also returned to the backup application in the response message. If the GRFS agent's operating system platform has any OS specific object attributes which are accessible only after the object has been successfully opened, they can be saved in the OS specific area within the DBLK's data area. One example of this is OS/2 "longnames" are accessible only after the object is opened.

3.10 GRFS_READ_OBJ, GRFS_READ_OBJ_STAT

The backup application uses the GRFS_READ_OBJ command to read data from previously opened file system objects. The parameters associated with this command are described below:

obj_id: This field contains the object handle id which was

returned by the agent in the GRFS_OPEN_OBJ_STAT

response message.

size: This field contains the size (in \$\)p1230Xbytes) buffer which is available to receive data. The GRFS agent

should endeavor to return as much data as possible for

each GRFS_READ_OBJ command.

offset: This field contains the number of bytes offset into

the object the agent should begin returning data from.

The proper response message type is GRFS_READ_OBJ_STAT. The response message has four fields which are described below:

size: This field should contain the actual number of bytes

of data being returned in the response message.

blk_size: This field should usually be set to 1. This field is used by GRFS agents to request a specific number of

bytes to be read by the next GRFS_READ_OBJ command. This functionality can be used if certain data areas

must be read as "atomic" objects.

As an example, suppose the backup application requests to read 20 bytes. The GRFS agent has 14 bytes available, and then the next 12 bytes must be read a unit. The GRFS would return the 14 bytes, set the size field to 14, and set the blk_size field to 12. This will force the backup application to request 12 bytes in the next GRFS_READ_OBJ command.

The GRFS agent must never set the blk_size field larger than the negotiated GRFS maximum object buffer

size.

strm_info: This field is a STREAM_INFO structure and is discussed

in section 1.3 of this document.

data: This field is the buffer which contains the actual

data. The size of this buffer is limited to the maximum object buffer size as negotiated during the

DLE attach operation.

3.11 GRFS_WRITE_OBJ, GRFS_WRITE_OBJ_STAT

The backup application uses the GRFS_WRITE_OBJ command to restore data to a GRFS agent. The parameters associated with this command are described below:

obj_id: This field contains the object handle id which was returned by the agent in the GRFS_OPEN_OBJ_STAT

response message.

size: This field contains the size (in bytes) of the data

buffer which is to be written.

offset: This field contains the offset in bytes, from the

beginning of the object, that the GRFS agent should

begin writing the data buffer.

strm_info: This field contains a STREAM_INFO structure. As described for the GRFS_READ_OBJ_response message, the

first block of each data stream will have the strm_info.id field set to the stream data type. All succeeding blocks of that data stream type will have the strm_info.id field set to STRM_INVALID. The first block of a particular stream data type will have the strm_info.size field set to the total size (in bytes)

of the stream.

GRFS agents should ignore a data block for a stream type that they do not recognize, and their response message should indicate that the entire block was

successfully written.

data: This field is the buffer which contains the data block

that is to be written.

The proper response message type is GRFS_WRITE_OBJ_STAT. This response message has the following parameters associated with it:

size: This field should be set to the number of bytes

successfully written.

blk_size: This field should normally be set to 1. This field is

used to indicate that the GRFS agent requires a specific number of bytes to be written in the next GRFS_WRITE_OBJ command. Any value other than 1 will force the backup application to attempt to write the requested number of bytes during the next GRFS_WRITE_OBJ operation. The agent should NEVER set this field to greater than the negotiated maximum

object buffer size.

3.12 GRFS_VERIFY_OBJ, GRFS_VERIFY_OBJ_STAT

The backup application uses the GRFS_VERIFY_OBJ command to verify that data contained on the backup media matches the data residing on the GRFS agent. The parameters associated with this command are described below:

obj_id: This field contains the object handle id which was returned by the agent in the GRFS_OPEN_OBJ_STAT

response message.

size: This field contains the size (in bytes) of the data

buffer which is to be compared.

offset: This field contains the offset in bytes, from the

beginning of the object, that the GRFS agent should

begin comparing the data buffer.

strm_info: This field contains a STREAM_INFO structure and is

described in section 1.3 of this document.

data: This field is the buffer which contains the data block

that is to be verified.

The proper response message type is GRFS_VERIFY_OBJ_STAT. This response message has the following parameters associated with it:

size: This field should be set to the number of bytes

successfully verified.

blk_size: This field should normally be set to 1. This field is used to indicate that the GRFS agent requires a

used to indicate that the GRFS agent requires a specific number of bytes to be verified in the next GRFS_VERIFY_OBJ command. Any value other than 1 will force the backup application to attempt to verify the requested number of bytes during the next GRFS_VERIFY-OBJ operation. The agent should NEVER set this field to greater than the negotiated maximum object buffer

size.

3.13 GRFS_SEEK_OBJ, GRFS_SEEK_OBJ_STAT

The backup application uses the GRFS_SEEK_OBJ command to force the GRFS agent to move the previously opened object's file location pointer to a specific offset within the object. This command is typically used by the backup application to seek past sectors which are unreadable in hopes that some of the data may be readable (HaHa). The parameters associated with this command are described below:

obj_id: This field contains the object handle id.which was returned by the agent in the GRFS_OPEN_OBJ_STAT

response message.

offset: This field contains the offset in bytes, from the beginning of the object, that the GRFS agent should

move the file pointer to.

The proper response message type is GRFS_SEEK_OBJ_STAT. This response message contains only one parameter associated with it. The parameter, seek_obj_offset specifies the offset within the object that the agent was able to seek to.

GRFS_CLOSE_OBJ, GRFS_CLOSE_OBJ_STAT

The backup application uses the GRFS_CLOSE_OBJ command to force the GRFS agent to close a previously opened file system object. When an object is closed, the agent is allowed to free any resources associated with the open object. The only parameter in this command message is the obj_id field. This field contains the object handle id which was returned by this agent in the GRFS_OPEN_OBJ_STAT response message.

The proper response message type is GRFS_CLOSE_OBJ_STAT. There are no parameters with this response message.

3.15 GRFS_DELETE_OBJ, GRFS_DELETE_OBJ_STAT

The GRFS_DELETE_OBJ command is used by the backup application during transfer operations in order to remove a file system object. The parameters associated with this command are the following:

dle_id: This parameter contains the DLE handle of the DLE where the object should be removed.

dblk: This parameter is a complete DBLK, and contains the type and the name of the object to be deleted.

*p905Xfully Directory object DBLKs will contain specified paths, so the DLE's current path is NOT included when creating the full path of the object to be deleted. The backup application will first remove file objects from a directory object before removing the directory object.

File objects are always deleted from the DLE's current path directory.

The proper response message type is GRFS_DELETE_OBJ_STAT. There are no parameters associated with this response message.

3.16 GRFS_CHANGE_DIR, GRFS_CHANGE_DIR_STAT

The GRFS_CHANGE_DIR command is used by the backup application to force a GRFS agent to change the "current directory" of a specific DLE. The new path supplied in the message is always a fully specified path relative to the DLE's base path. The GRFS agent MUST verify that the new path is a valid path. This can usually be accomplished by performing a "FindFirst" operation on the new path. As an added bonus, the backup application may send a "null-impreguated" string in the path field. This means that the GRFS agent must replace the internal '\0' path delimeters with the agent's OS specific path delimeter character. No applause necessary.

The proper response message type is GRFS_CHANGE_DIR_STAT. There are no parameters associated with this response message.

3.18 GRFS_SET_OBJ_INFO, GRFS_SET_OBJ_INFO_STAT

The GRFS_SET_OBJ_INFO command is used by the backup application to set the file system attributes of a file system object. The parameters associated with this command are described below:

dle_id: This parameter contains the DLE handle id of the DLE

where the object resides.

dblk: This parameter is complete DBLK and contains the

object type, the object name, and the object attribute data which are to be set.

The GRFS agent must set the following file system object attributes:

ctime (CREATION TIME)

atime (ACCESS TIME) (if possible)

time (MODIFIED TIME) size (object data size)

gen_attr (file system attribute flags)

The proper response message type is GRFS_SET_OBJ_INFO_STAT. There are no parameters associated with this response message.

3.19 GRFS_VERIFY_OBJ_INFO, GRFS_VERIFY_OBJ_INFO_STAT

The GRFS_VERIFY_OBJ_INFO command is used by the backup application to verify that file system object attributes on the GRFS agent match the object attributes contained on the backup media. The parameters associated with this command are described below:

dle_id: This parameter contains the DLE handle of the DLE

where the object resides.

dblk: This parameter is a complete DBLK and contains the object type, the object name, and the object attribute

data which are to be compared.

The GRFS agent must verify that the following input parameter DBLK fields match the actual attributes of the file system object:

cdate (CREATION DATE)
mdate (MODIFIED DATE)
size (object data size)

gen_attr (file system attribute flags)

The proper response message type is GRFS_VERIFY_OBJ_INFO_STAT. There are no parameters associated with this response message.

3.20 GRFS_PREPARE_DBLK, GRFS_PREPARE_DBLK_STAT

The GRFS_PREPARE_DBLK command is used so that during restore operations the GRFS Agent is able to modify ("image") path and directory names into a form which is usable by the target (restore) agent's file systems. For instance, if a backup set is created by a MacIntosh agent, then the file and directory names must be modified in order to restore the backup set onto a DOS agent's FAT file system 8.3 format.

dle_id: This parameter contains the DLE handle of the DLE where the object resides.

dblk: This parameter is a complete DBLK and contains the object type, the object name.

The agent should append the modified name at the end of the DBLK and alter the "os_" name pointers to point to the new name. The agent must also modify the dblk.dblk_actual_size to account for the increased DBLK size. If the input name does not require modification, then the DBLK can be returned unmodified.

Appendix A - GRFS Technical Reference

This section of the GRFS Technical Reference appendix shows the actual definitions of the structures which have been described in this document. All of the structures can be found the GRFS.H include file.

COMMON GRFS MESSAGE PROCESSING

All GRFS messages generated by the backup application include the following common fields: <code>msg_type</code>, <code>retcode</code>, and <code>request_id</code>. The <code>msg_type</code> field must contain a valid GRFS command value. The backup application will set the <code>request_id</code> field to a value which the backup application will use to correlate outgoing GRFS command messages to the corresponding incoming GRFS response messages. The GRFS agent must set the <code>request_id</code> value of the GRFS response message to the <code>request_id</code> value <code>received</code> in the corresponding GRFS command message. The GRFS response message to the <code>request_id</code> value <code>received</code> in the corresponding GRFS command message. The <code>ret_code</code> field is not used for GRFS command messages; it is meaningful only for GRFS response messages.

Several of the message parameter structures contain large fields (DBLKs, full-path names) which are defined statically but contain variable length data, and these data fields will typically fill only a small portion of the allotted space. These large fields are always declared as the last member in the parameter structure. Only the portion of the message parameter field which is actually used must be transmitted across the network. This will allow the GRFS to be more efficient because most non object-data GRFS messages can be transmitted as a single NRL transport packet.

CRITICAL ERROR HANDLING

GRFS agent programs must handle critical error situations without hanging the agent's system. When a GRFS agent detects a critical error while performing an GRFS command, the agent program should "fail" the operation and set the retcode field appropriately (FS_DEVICE_ERROR, etc). The agent can also retry the failed operation before returning a GRFS status message to the backup application. When a fatal FS error code is returned to the backup application, the application user will be given the opportunity to decide whether to retry the failed operation.

FS_COMM_FAILURE	0xFE30
FS_NET_DEV_ERROR	0xFE31
FS_DONT_WANT_STREAM	0xFEB1

The following section provides a list of likely return code values for each of the GRFS response messages. GRFS agents should use the return value listed above which provides the best indication for the cause of an error.

GRFS ATTACH_DLE_STAT

FS_ACCESS_DENIED

FS INVALID DLE

OUT_OF_MEMORY

The user or password field was not

valid.

The dle_name was invalid

GRFS FIND DLE STAT

FS_INVALID_DLE FS NO MORE

dle_id was invalid No more DLEs to enumerate

GRFS_DETACH_DLE_STAT FS_INVALID DLE

dle id was invalid

GRFS FIND OBJ STAT FS_INVALID_DLE FS NO MORE

dle_id was invalid No more file system objects to enumerate

GRFS_FIND_CLOSE_STAT FS INVALID DLE

dle_id was invalid

GRFS_CREATE_OBJ_STAT FS INVALID DLE FS_DEVICE_ERROR

dle id was invalid

"hard" device error, unable to e a t object

FS_ACCESS_DENIED

Agent does not have permission to create object

FS_BAD_DBLK

The DBLK data is invalid

GRFS OPEN OBJ STAT FS OPENED INUSE

FS_IN_USE_ERROR

Object already opened by another process, but not locked, and BEC_CONFIG flag BEC_BACKUP_FILES_IN_USE is set Object already opened by another process and locke BEC_BACKUP_FILES_IN_USE not set and locked, dle id was invalid

FS_INVALID_DLE FS_NOT_FOUND FS_DEVICE_ERROR

Object not found "hard" device error, unable to open object

FS_BAD_DBLK FS_ACCESS_DENIED

The DBLK data was invalid

Agent does not have permission to open object

OUT_OF_MEMORY

GRFS_READ_OBJ_STAT

FS DEVICE ERROR FS_EOF_REACHED FS_ACCESS_DENIED

"hard" device error read FS_OBJECT_NOT_OPENED obj_id parameter was invalid End of File already reached Agent does not have permission to read object

GRFS_WRITE_OBJ_STAT FS_OBJECT_NOT_OPENED FS DEVICE ERROR

obj_id parameter not invalid "hard" device write error

FS_OBJECT_NOT_OPENED obj_id parameter was invalid

- 52/1-

FS_OUT_OF_SPACE Device is full FS_ACCESS_DENIED Agent does not have permission to write object FS DONT WANT STREAM Agent does not want to restore this data stream GRFS_SEEK_OBJ_STAT FS OBJECT NOT OPENED obj_id parameter was invalid FS_EOF_REACHED End of File already reached FS_DEVICE ERROR "hard" device seek error GRFS_VERIFY_OBJ_STAT FS_OBJECT_NOT_OPENED FS_DEVICE_ERROR obj_id parameter was invalid
"hard" error FS EOF REACHED End of File already reached Object's normal data stream does FS_GDATA_DIFFERENT not match FS_SECURITY_DIFFERENT Object's security data stream does not match FS EADATA DIFFERENT Object's extended attribute data stream does not match FS_DONT_WANT_STREAM Agent does not support this data stream type GRFS_CLOSE_OBJ_STAT FS_OBJECT_NOT_OPENED obj_id parameter was invalid FS_DEVICE_ERROR "hard" error GRFS DELETE OBJ STAT FS_INVALID_DLE dle_id was invalid Object not found "hard" device error, unable to FS_NOT_FOUND FS_DEVICE_ERROR delete object FS_BAD_DBLK The DBLK data was invalid FS_ACCESS_DENIED Agent does not have permission to delete object GRFS GET OBJ INFO STAT FS_INVALID_DLE dle id was invalid FS_NO_MORE Object not found FS_DEVICE_ERROR "hard" device error, unable to delete object FS BAD DBLK The DBLK data was invalid GRFS_VERIFY_OBJ_INFO_STAT FS_INVALID DLE dle_id was invalid FS_NOT_FOUND Object not found FS_DEVICE_ERROR "hard" device error, unable to scan device FS BAD DBLK The DBLK data was invalid FS_INFO_DIFFERENT The object's attributes do not match GRFS CHANGE DIR STAT $\texttt{FS_INVALID_DLE}$ dle_id was invalid FS_INVALID_DIR net_path
left too long, or new path does not exist

device

FS_DEVICE_ERROR

"hard" device error, unable to scan

GRFS_GET_CUR_DDB_STAT
FS_INVALID_DLE
FS_DEVICE_ERROR

dle_id was invalid
"hard" device error, unable to scan

device

GRFS_SET_OBJ_INFO_STAT FS_INVALID_DLE

dle_id was invalid

DBLK Fields

The individual fields within the GRFS common DBLK structure which must be manipulated by GRFS agent programs are described below.

These four fields are all defined as type DATE_TIME structures. The DATE_TIME structure has the following format:

struct DATE TIME { /*TRUE or FALSE */ UINT16date_valid; /*year since 1980 */ UINT16year; UINT16month; /* 1 to 12 */ /* 1 to 31 UINT16day; /* 0 to 23 /* 0 to 59 UINT16hour; */ UINT16minute; /* 0 to 59 UINT16second; */ /* 1 to 7 Sun to Sat */ UINT16day_of_week;

ctime = Object CREATION time atime = Object ACCESSED time btime = Object ARCHIVED time time = Object MODIFIED time

If the OS of GRFS Agent being developed does not support one or more of the specific time stamps, then those time stamp fields should be reset to all zeros.

size:

The size field contains the size of the normal data associated with the object. For instance the OS/2 Agent does NOT include the size of EAs and ACLs associated with an object.

gen attr:

This field is a bit-mapped flag which describes the file system attributes of the object. The following flag values can be contained in this field:

 FILE_NORMAL
 0x0000

 FILE_READONLY
 0x0001

 FILE_HIDDEN
 0x0002

 FILE_SYSTEM
 0x0004

 FILE_DIRECTORY
 0x0010

 FILE_ARCHIVED
 0x0020

os_info_complete

This field is a boolean value which must be set to TRUE when the all the DBLK information for an object has been filled in.

min_ddb_info

This field contains a pointer to the information in the DBLK data area which is required to perform either a GRFS_GET_OBJ_INFO or GRFS_FIND_NEXT_OBJ command. The information pointed to by this field must be contiguous within the data area. Typically the DBLK find information and the object name constitute the "MIN_DDB_INFO". The DBLK find information is described in the find_info DBLK field.

min_ddb_size

This field contains the number of bytes of data pointed to by the min_ddb_info field.

os_spec_info

This field contains a pointer to the DBLK data area which contains any OS specific information

> that the GRFS agent would like preserved during backup and restoration operations. For instance the OS/2 agent uses this area to save HPFS "Long Names" when they are present. As another example, a Unix GRFS agent could use this field to save information about special device placeholder files.

os_spec_size

This field contains the number of bytes of data pointed to by the os_spec_info field.

dblk_actual_size

This field contains the size of the entire DBLK. This value is the sum of the size of the GRFS DBLK common structure and the number of bytes of data within the variable length DBLK data area. Remember that the total DBLK must at most 1024 bytes long.

tape attribs

not used

find_info

This field contains a pointer to the information in DBLK data area which can be used by the GRFS agent to perform a GRFS_FIND_NEXT_OBJ command. Examples of this field are the DOS GRFS agent passing a DTA structure and the OS/2 agent passing the DosFindFirstOHDIR value.

find info size

This field contains the number of bytes of data pointed to by the find info field.

obj_type

not used

translate flag

not used

special flag

not used

b.d.os path

This field contains a pointer to the path string contained within the DBLK data area for a directory object. The path string should not begin with a path delimeter character unless it is the root directory of a DLE. The path string must be null-terminated. During backup operations the os_path field and the path field will be identical. During restore operations, the os_path field will represent the "source" path and the path field will represent the

"destination" path.

b.d.os_path_leng This field contains the length of the path pointed to by the os_path field. This value should include the null-termination character.

b.d.path leng

This field contains the length of the path pointed to by the path field. This value should include the null-termination character.

b.d.path

This field contains a pointer to the path string contained within the DBLK data area for a directory object. The path string should not begin with a path delimeter character unless it is the root directory of a DLE. The path string must be null-terminated. During backup operations, the path field will be the same as the os_path field; however during restore operations the path field may be different than the os path field.

b.d.inuse attrib This field contains a flag which is used to mark files which have been opened but the file is currently also opened by another process.

b.f.os_name

This field contains a pointer to the file name string contained within the DBLK data area for a file object. The path string must be null-terminated. The os_name field and the name field will be the same during backup operations. During restore operations the os_name field represents the "source" file name whereas the name field represents the "destination" file

b.f.name

This field contains a pointer to the file name string contained within the DBLK data area for a file object. The path string must be nullterminated.

Whenever a GRFS agent returns a DLE's logical root directory object DBLK, the DBLK data area path string should be set to '\0' and the b.d.os_path_leng field should be 1.

CLAIMS

What is claimed is:

disparate operating systems.

16

A computer network, comprising: 1 1. 2 a plurality of computers running disparate 3 operating systems, respectively; 4 b) a storage device for backing up 5 restoring data processed on the network; and means for performing backup to and restore 6 C) from the storage device, including: 7 i) 8 a GRFS file system running on one of 9 the said computers; ii) 10 a plurality of GRFS agents each 11 running on a respective one of said computers; and 12 iii) wherein said GRFS file system and each of said GRFS agents interface with one another via 13 14 command and response messages, respectively, said command and response messages being structured to support the 15

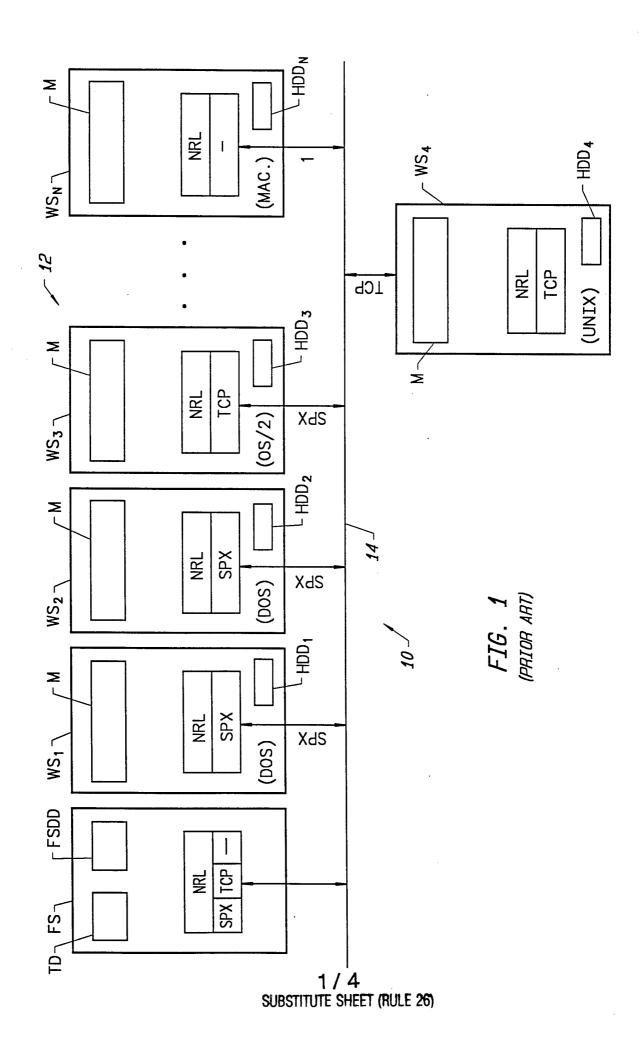

- 2. A computer network, according to claim 1, wherein said disparate operating systems have different data structure alignments, and said command and response messages are structured with a least common denominator alignment for said disparate operating systems.
- 3. A computer network, according to claim 1, wherein said command and response messages are further structured to interchange data between said disparate operating systems.

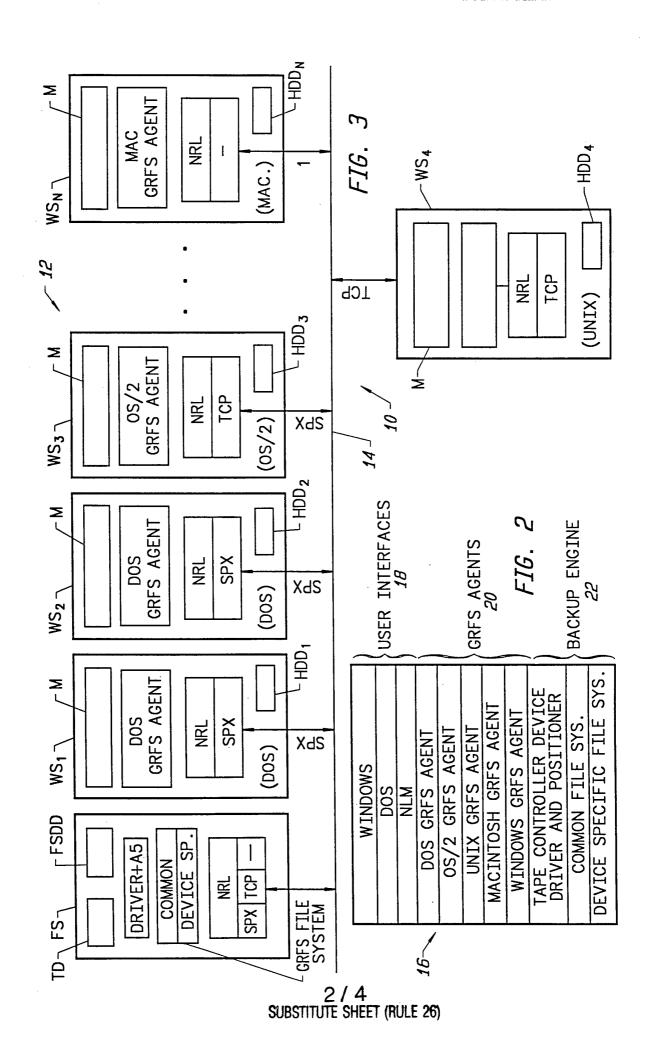

4. A computer network, according to claim 3, wherein said interchange structure of said command and response messages enable data from one of said computers running one of said operating systems to backed up to said storage device and said backed up data to be restored to another of said computers running another of said disparate operating systems.

- 5. A computer network, according to claim 3, wherein said interchange structure of said messages includes a streamer header having an identification value determining whether an associated data stream type is supported by a given one of said disparate operating systems.
- 6. A computer network, according to claim 1, wherein said command and response messages are further structured to enable independent multiple users of said plurality of computers to request simultaneously backup or restore of the data.
- 7. A computer network, according to claim 6, wherein said command and response messages are structured with a request id and wherein said GRFS file system may create a unique request id for every GRFS command message, whereby the GRFS file system can communicate simultaneously with multiple GRFS agents.
- 1 8. A computer network, according to claim 1, 2 wherein said plurality of computers each has a user 3 interface to enable a user to select backup or restore of 4 selected data.

1 9. A computer network, according to claim 1,

- wherein said network may have an additional computer not
- 3 running a GRFS agent.
