ABSTRACT

Provided are α-olefin copolymer useful as a high-viscosity lubricant oil excellent in viscosity characteristics, low-temperature characteristics and oxidation stability, and a lubricant oil containing the copolymer. The α-olefin copolymer is a 1-octene/1-decene/1-dodecene ternary copolymer produced by the use of a doubly crosslinked metallocene catalyst.
1-OCTENE, 1-DECENE, 1-DODECENE TERNARY COPOLYMER AND LUBRICANT COMPOSITION CONTAINING SAME

TECHNICAL FIELD

[0001] The present invention relates to a 1-octene/1-decene/1-dodecene terpolymer and a lubricant oil composition containing it.

BACKGROUND ART

[0002] As the characteristics heretofore required for the lubricant oil for automobiles and industrial machinery, the lubricant oil is desired to have a relatively high viscosity from the lubrication performance thereof. However, for environmental considerations that have become specifically discussed these days, further advanced fuel efficiency, energy saving and life prolongation are desired. As compared with poly-α-olefins and others heretofore employed in the art, a synthetic lubricant oil having more excellent viscosity characteristics (viscosity index), low-temperature characteristics (low-temperature flowability) and oxidation stability is desired.

[0003] For hydrocarbon-based synthetic lubricant oil, an α-olefin polymer obtained from a relatively short-chain α-olefin has a defect in that its viscosity index is low, while an α-olefin polymer obtained from a relatively long-chain α-olefin has a defect in that its pour point is high; and therefore it is suitable to use 1-decene as the starting material for producing a lubricant oil excellent in point of both the viscosity index and the pour point. However, 1-decene is merely one fraction of an α-olefin produced in an α-olefin producing apparatus, in which many other fractions are produced at the same time, and therefore the quantity of production of 1-decene is limited. Consequently, the demand for 1-decene is high and 1-decene is expensive, and for these reasons, the cost of α-olefin polymer products for lubricant oil is high.

[0004] Consequently, heretofore, various trials have been made for obtaining α-olefin copolymers useful for hydrocarbon-based synthetic lubricant oil. For example, there is mentioned a method of polymerizing 1-decene and 1-dodecene by using aluminium chloride or aluminium bromide as a catalyst (Patent Reference 1). However, the obtained α-olefin polymer was not satisfactory in point of the viscosity index, the pour point and the durability thereof. Some examples are known where ethylene or an α-olefin is copolymerized according to various methods and the obtained polymer is used as a hydrocarbon-based synthetic lubricant oil (for example, Patent Reference 2). An example of using a metalocene catalyst in producing an α-olefin polymer is known in Patent Reference 3, which, however, has some problems in that only a low-molecular-weight polymer could be obtained and the pour point of the obtained polymer is unsatisfactory. A high-viscosity synthetic lubricant oil comprising an α-olefin copolymer and having excellent viscosity characteristics and low-temperature characteristics is unknown.

[0005] On the other hand, as a method for preventing oxidation of poly-α-olefin, for example, Patent Reference 4 discloses a regular "comb-shaped structure"-having polymer produced through polymerization with a metalocene catalyst, in which the monomer repeats 1,2-insertion, saying that the double bond, if remaining in the polymer, would cause a loss of the lubricant oil characteristics through oxidation of the double bond. Patent Reference 1 suggests a correlation between tertiary carbon and oxidation stability, but does not disclose any experimental data to support it. In this, in addition, the 1,2-disubstituted structure of polymer is specifically noted, which, however, is for merely analyzing the regular structure through 1,2-insertion by monomer as in Patent Reference 4, only in a different aspect, or that is, the patent reference does not disclose any method for selective synthesis. Further, Patent Reference 5 has a description indicating that reducing the bromine number could better oxidation stability.

[0006] As described above, the relationship between polymer structure and oxidation stability is not known concretely.

SUMMARY OF THE INVENTION

Technical Problem

[0012] The present invention has been made in consideration of the above-mentioned situation, and is intended to provide relatively inexpensively an α-olefin copolymer useful as a high-viscosity lubricant oil excellent in viscosity characteristics (viscosity index), low-temperature characteristics (low-temperature flowability) and oxidation stability, as well as a lubricant oil containing the copolymer.

Solution to Problem

[0013] The present inventors have assiduously studied and, as a result, have found that, when a small amount of 1-decene and relatively inexpensive 1-octene and 1-dodecene are used as monomers and when a catalyst comprising a doubly crosslinked metalocene compound is used, then the above-mentioned problems can be solved. The present invention has been completed on the basis of these findings.

[0014] Specifically, the present invention provides the following:

[0015] 1. A 1-octene/1-decene/1-dodecene ternary copolymer produced by the use of a doubly crosslinked metalocene catalyst,

[0016] 2. The 1-octene/1-decene/1-dodecene ternary copolymer of the above 1, wherein the proportion of the molecules of which the structure of the polymerization terminal is a 2,1-insertion terminal is 30 mol % or greater,

[0017] 3. The 1-octene/1-decene/1-dodecene ternary copolymer of the above 1 or 2, wherein the ratio by mol of the 1-decene unit to the total of the 1-octene unit and the 1-dodecene unit is from 5/95 to 70/30, and the ratio by mol of the 1-octene unit to the 1-dodecene unit is from 20/80 to 80/20,

[0018] 4. The 1-octene/1-decene/1-dodecene ternary copolymer of any of the above 1 to 3, satisfying the following (a) and (b):

(a) the mesotriad fraction (mm), as measured through 13C-NMR, is from 25 to 50 mol %,
(b) the 100°C kinematic viscosity is from 30 to 1000 mm²/s,

[0019] 5. The 1-octene/1-decene/1-dodecene ternary copolymer of any of the above 1 to 4, of which the number-average molecular weight (Mn), as measured through GPC, is from 1500 to 15000,
6. The 1-octene/1-decene/1-dodecene ternary copolymer of any of the above 1 to 5, of which the weight-average molecular weight (Mw) is from 2100 to 30000,

7. The 1-octene/1-decene/1-dodecene ternary copolymer of any of the above 1 to 6, of which the molecular weight distribution (Mw/Mn) is 3.0 or smaller,

8. The 1-octene/1-decene/1-dodecene ternary copolymer of any of the above 1 to 7, wherein the double bond amount after hydrogenation relative to the total monomer units, as measured through $^{13}$C-NMR, is 0.3 mol % or smaller, and

9. A lubricant oil composition containing the 1-octene/1-decene/1-dodecene ternary copolymer of any of the above 1 to 8, and/or a hydrogenated 1-octene/1-decene/1-dodecene ternary copolymer prepared through hydrogenation of the 1-octene/1-decene/1-dodecene ternary copolymer.

Advantageous Effects of the Invention

According to the present invention, an α-olefin polymer useful as a high-viscosity lubricant oil excellent in viscosity characteristics (viscosity index), low-temperature characteristics (low-temperature flowability) and oxidation stability, as well as a lubricant oil containing the polymer can be provided relatively inexpensively. Specifically, by using a doubly crosslinked metalloocene catalyst to control the balance of 1-octene/1-decene/1-dodecene and by effectively using other fractions than 1-decene, a polymer for lubricant oil having excellent physical properties on the same level as that of 1-decene homopolymer can be provided.

BRIEF DESCRIPTION OF THE DRAWING

FIG. 1 is a view showing the relationship between the viscosity index and the pour point of the copolymers obtained in Examples 1 to 6 and Comparative Examples 1 to 4.

MODE FOR CARRYING OUT THE INVENTION

The 1-octene/1-decene/1-dodecene ternary copolymer of the present invention is characterized in that it is produced by the use of a doubly crosslinked metalloocene catalyst.

Since 1-octene, 1-decene and 1-dodecene are copolymerized by the use of a doubly crosslinked metalloocene catalyst, an α-olefin copolymer excellent in viscosity index and low-temperature flowability can be obtained; and since a doubly crosslinked metalloocene catalyst is used, the polymerization terminal can be readily a 2,1-insertion terminal and a polymer chain with few tertiary carbons can be formed, and therefore the copolymer is excellent in oxidation stability.

Regarding the structure of the polymerization terminal of the 1-octene/1-decene/1-dodecene ternary copolymer of the present invention, the proportion of chain transfer reaction in 2,1-insertion of monomer is preferably large. The proportion of the molecules with 2,1-insertion terminal is preferably 50 mol % or greater, more preferably 50 mol % or greater, even more preferably 60 mol % or greater. When the proportion is 30 mol % or greater, then methyl branching in the molecule after hydrogenation is small and the stability of the copolymer to oxidation and heat is thereby enhanced.

The 1-octene/1-decene/1-dodecene ternary copolymer of the present invention is obtained by using 1-octene, 1-decene and 1-dodecene as monomers. A copolymer obtained by using 1-hexene in place of 1-octene is poor in viscosity characteristics (or that is, the viscosity index thereof is small); and a copolymer obtained by using an α-olefin having a larger carbon number than that of 1-dodecene, in place of 1-dodecene, is poor in flow characteristics.

Preferably, the ratio by mol of the 1-decene unit to the total of the 1-octene unit and the 1-dodecene unit is from 5/9 to 70/30, and the ratio by mol of the 1-octene unit to the 1-dodecene unit is from 20/80 to 80/20. More preferably, the former ratio is from 5/9 to 60/40, and the latter ratio is from 30/70 to 70/30. When the ratio of the 1-octene unit is large, then the viscosity index may be low, but on the other hand, when the ratio of the 1-dodecene unit is large, then the pour point may be high.

Preferably, the 1-octene/1-decene/1-dodecene ternary copolymer of the present invention satisfies the following (a) and (b):

(a) the mesotriad fraction (mm), as measured through $^{13}$C-NMR, is from 25 to 50 mol %,

(b) the 100°C kinematic viscosity is from 30 to 1000 mm²/s.

(a) Preferably, the mesotriad fraction (mm), as measured through $^{13}$C-NMR, is from 25 to 50 mol %, more preferably from 30 to 40 mol %, even more preferably from 31 to 37 mol %. When the mesotriad fraction (mm) is more than 50 mol %, then the copolymer may be poor in low-temperature characteristics (or that is, the pour point thereof may be high); and when less than 25 mol %, the pour point may also be high.

The 100°C kinematic viscosity (b) measured according to JISK2283 is preferably from 30 to 1000 mm²/s, more preferably from 30 to 500 mm²/s, even more preferably from 40 to 200 mm²/s. When the 100°C kinematic viscosity is less than 30 mm²/s, then the durability of the copolymer, when used as a high-viscosity lubricant oil component, may be insufficient; and when the 100°C kinematic viscosity is more than 1000 mm²/s, then the viscosity of the copolymer may be too high to improve fuel efficiency and would be therefore insufficient in point of energy-saving performance.

The number-average molecular weight (Mn), as measured through gel permeation chromatography (GPC), of the 1-octene/1-decene/1-dodecene ternary copolymer of the present invention is preferably from 1500 to 15000 from the viewpoint of equipment life prolongation and energy-saving performance in use in wind power generators or the like, but is more preferably from 1500 to 10000, even more preferably from 2000 to 6000.

For the same reason, the weight-average molecular weight (Mn), as measured through GPC, of the 1-octene/1-decene/1-dodecene ternary copolymer of the present invention is preferably from 2100 to 30000, more preferably from 2800 to 20000, even more preferably from 3500 to 10000.

Preferably, the molecular weight distribution (Mw/Mn) of the 1-octene/1-decene/1-dodecene ternary copolymer of the present invention is 3.0 or smaller, more preferably 2.0 or smaller, even more preferably from 1.3 to 2.0. When the molecular weight distribution (Mw/Mn) is 3.0 or smaller, then the high-molecular weight component may decrease and the shear stability could be thereby bettered, and in addition, the low-molecular weight component may decrease and the volatility could be thereby depressed.

In the 1-octene/1-decene/1-dodecene ternary copolymer of the present invention, the double bond amount after hydrogenation relative to the total monomer units, as measured through $^{13}$C-NMR, is preferably 0.5 mol % or smaller from the viewpoint of oxidation stability since the
unsaturated site could be fully hydrogenated, but is more preferably 0.2 mol % or smaller, even more preferably 0.1 mol % or smaller. Also preferably, the bromine value, as measured according to JIS K 2605, is 0.4 g bromine/100 g or smaller.

[0038] The 1-octene/1-decene/1-dodecene ternary copolymer of the present invention is characterized in that its pour point is low and its viscosity index is high. For example, of the 1-octene/1-decene/1-dodecene ternary copolymer of which the kinematic viscosity at 100°C is about 40 mm²/s, in general, the pour point is not higher than −40°C, and the viscosity index (VI) is 170 or greater. Of the 1-octene/1-decene/1-dodecene ternary copolymer of which the kinematic viscosity at 100°C is about 100 mm²/s, in general, the pour point is not higher than −35°C, and the viscosity index (VI) is 190 or greater.

[0039] The 1-octene/1-decene/1-dodecene ternary copolymer of the present invention can be produced by using the following (A) a doubly crosslinked metallocene compound and (B) (b-1) an organoaluminum compound and/or (b-2) an ionic compound capable of being converted into a cation through reaction with the above-mentioned doubly crosslinked metallocene compound, as a catalyst.

[0040] As the above-mentioned doubly crosslinked metallocene compound (A), usable are those represented by the following general formulae (I) and (II):

\[
\begin{align*}
\text{(I)} & \\
\text{(II)} & 
\end{align*}
\]

(In the formula, n indicates an integer of from 1 to 3, R⁷ and R⁸ each independently represent a hydrogen atom, a halogen atom, a hydrocarbon group having from 1 to 20 carbon atoms, preferably from 1 to 10 carbon atoms, more preferably from 1 to 4 carbon atoms (for example, an alkyl group), or an organic group having from 1 to 20 carbon atoms and containing at least one atom selected from a halogen atom, a silicon atom, an oxygen atom, a sulfur atom, a nitrogen atom and a phosphorus atom. At least one selected from R⁷ to R⁸ is a hydrogen atom, and at least one selected from R⁷ to R⁸ is a hydrogen atom. R⁷ and R⁸ each independently represent a linking group represented by the following general formula (a). X¹ and X² each independently represent a hydrogen atom, a halogen atom, a hydrocarbon group having from 1 to 20 carbon atoms, or an organic group having from 1 to 20 carbon atoms and containing at least one atom selected from a halogen atom, a silicon atom, an oxygen atom, a sulfur atom, a nitrogen atom and a phosphorus atom. M represents a transition metal of Groups 4 to 6 of the Periodic Table.)

\[
\begin{align*}
\text{(a)} & 
\end{align*}
\]

(Preferred examples of R⁹ and R¹⁰ include \(-\text{CR}^\text{R}^{\text{R}^9}\), \(-\text{SiR}^\text{R}^{\text{R}^9}\), \(-\text{CR}^\text{R}^{\text{R}^9}-\text{CR}^\text{R}^{\text{R}^9}\) and \(-\text{SiR}^\text{R}^{\text{R}^9}-\text{SiR}^\text{R}^{\text{R}^9}\).)

(In the formula, R⁹ to R¹⁰ and X¹ and X² each independently represent a hydrogen atom, a halogen atom, a hydrocarbon group having from 1 to 20 carbon atoms, preferably from 1 to 10 carbon atoms, more preferably from 1 to 4 carbon atoms, a halogen-containing hydrocarbon group having from 1 to 20 carbon atoms, a divalent germanium-containing group, a divalent tin-containing group, a divalent tin-containing group, \(-\text{O}-\), \(-\text{CO}-\), \(-\text{S}-\), \(-\text{SO}_2\), \(-\text{NR}^{12}\), \(-\text{PR}^{19}\), \(-\text{PO}^{19}\), \(-\text{BR}^{19}\) or \(-\text{AlR}^{19}\); R¹⁰ represents a hydrogen atom, a halogen atom, a hydrocarbon group having from 1 to 20 carbon atoms, or a halogen-containing hydrocarbon group having from 1 to 20 carbon atoms. M represents a transition metal of Groups 4 to 6 of the Periodic Table.)

[0042] As specific examples of the doubly crosslinked metallocene compound represented by the above-mentioned general formula (I), there may be exemplified dichloride compounds including (1,1'-ethylene)(2,2'-ethylene) biseyclopentadienylzirconium dichloride, (1,1'-ethylene)(2,2'-ethylene)bis(3-methylcyclopentadienyl) zirconium dichloride, (1,1'-ethylene)(2,2'-ethylene)bis(4-methylcyclopentadienyl) zirconium dichloride, (1,1'-ethylene)(2,2'-ethylene)bis(4-methylcyclopentadienyl) zirconium dichloride, (1,1'-ethylene)
ylene)bis(3,4-dimethylcyclopentadienyl)zirconium dichloride, (1,1' -ethyleny)(2,2'-ethyleny)bis(3,5- dimethylcyclopentadienyl)zirconium dichloride, (1,1' -dimethylsilylene)(2,2'-dimethylsilylene)bis(3,4- dimethylcyclopentadienyl)zirconium dichloride, (1,1' -dimethylsilylene)(2,2'-dimethylsilylene)bis(3,5- dimethylcyclopentadienyl)zirconium dichloride, 

(1,1' -dimethylsilylene)(2,2'-dimethylsilylene)bis(4- methylecyclopentadienyl)zirconium dichloride, (1,1' -dimethylsilylene)(2,2'-dimethylsilylene)bis(5,6-benzenyl)zirconium dichloride, (1,1' -dimethylsilylene)(2,2'-dimethylsilylene)bis(4,5-benzindeny)zirconium dichloride, 

(1,1' -dimethylsilylene)(2,2'-dimethylsilylene)bis(5,6-dimethylindenyl)zirconium dichloride, (1,1' -dimethylsilylene)(2,2'-dimethylsilylene)bis(5,6-dimethylindenyl)zirconium dichloride, (1,1' -dimethylsilylene)(2,2'-dimethylsilylene)bis(5,6-dimethylindenyl)zirconium dichloride, (1,1' -dimethylsilylene)(2,2'-dimethylsilylene)bis(5,6-dimethylindenyl)zirconium dichloride, (1,1' -dimethylsilylene)(2,2'-dimethylsilylene)bis(5,6-dimethylindenyl)zirconium dichloride, (1,1' -dimethylsilylene)(2,2'-dimethylsilylene)bis(5,6-dimethylindenyl)zirconium dichloride, (1,1' -dimethylsilylene)(2,2'-dimethylsilylene)bis(5,6-dimethylindenyl)zirconium dichloride, (1,1' -dimethylsilylene)(2,2'-dimethylsilylene)bis(5,6-dimethylindenyl)zirconium dichloride, (1,1' -dimethylsilylene)(2,2'-dimethylsilylene)bis(5,6-dimethylindenyl)zirconium dichloride, (1,1' -dimethylsilylene)(2,2'-dimethylsilylene)bis(5,6-dimethylindenyl)zirconium dichloride, (1,1' -dimethylsilylene)(2,2'-dimethylsilylene)bis(5,6-dimethylindenyl)zirconium dichloride, (1,1' -dimethylsilylene)(2,2'-dimethylsilylene)bis(5,6-dimethylindenyl)zirconium dichloride, (1,1' -dimethylsilylene)(2,2'-dimethylsilylene)bis(5,6-dimethylindenyl)zirconium dichloride, (1,1' -dimethylsilylene)(2,2'-dimethylsilylene)bis(5,6-dimethylindenyl)zirconium dichloride, (1,1' -dimethylsilylene)(2,2'-dimethylsilylene)bis(5,6-dimethylindenyl)zirconium dichloride.

Sep. 11, 2014

As the component (A), one alone or two or more different types of the doubly crosslinked metalocene compounds may be used here, either singly or as combined.  

As the component (B) for the catalyst for use in the present invention, (b-1) an organoaluminoxane compound and/or (b-2) an ionic compound capable of being converted into a cation through reaction with the above-mentioned doubly crosslinked metalocene compound may be used.

As the organoaluminoxane compound (b-1), there may be mentioned linear aluminoxanes represented by the following general formula (III), and cyclic aluminoxanes represented by the following general formula (IV).

In the general formulae (III) and (IV), R²⁰ to R²⁵ each independently represent a hydrocarbon group having from 1 to 20
carbon atoms, preferably from 1 to 12 carbon atoms, or a halogen atom. The hydrocarbon group includes an alkyl group, an alkyl group, an aryl group, an aryl group, etc. n indicates a degree of polymerization and is generally an integer of from 2 to 30, preferably from 2 to 20. R<sup>28</sup> to R<sup>28</sup> may be the same or different from each other.

[0047] Specific examples of the above-mentioned aluminoxanes include methylaluminoxane, ethylaluminoxane, isobutylaluminoxane, etc.

[0048] As the production method for the aluminoxanes, there may be mentioned a method of contacting an alumininium with a condensing agent such as water or the like, for which, however, the means is not specifically defined, and the reaction may be attained according to known methods. For example, there may be mentioned a method of dissolving an organoaluminum compound in an organic solvent and contacting it with water; a method of initially adding an organoaluminum compound during polymerization and then adding water thereto later; a method of reacting crystal water contained in a metal salt of the like or adsorbed water to an inorganic substance or an organic substance with an organoaluminum compound; a method of reacting a tetraalkylaluminoxane with a trialkylaluminoxane followed by further reacting it with water; etc. The aluminoxanes may be toluene-insoluble ones. One or more different types of such aluminoxanes may be used here either singly or as combined.

[0049] On the other hand, as the component (b-2), any ionic compound capable of being converted into a cation through reaction with the doubly crosslinked metalloocene compound of the above-mentioned component (A) is usable here, but preferred is use of those represented by the following general formulae (V) and (VI).

\[
\left(\text{L}^1\cdot\text{R}^{26}\text{H}^{\cdot}\right)_n
\]

(V)

\[
\left(\text{L}^1\cdot\text{R}^{26}\text{H}^{\cdot}\right)_n
\]

(VI)

[0050] In the general formula (V), L<sup>1</sup> represents a Lewis base; R<sup>26</sup> represents a hydrogen atom, an alkyl group having from 1 to 20 carbon atoms, or a hydrocarbon group having from 6 to 20 carbon atoms and selected from an aryl group, an alkylaryl group and an arylalkyl group.

[0051] Specific examples of L<sup>1</sup> include amines such as ammonia, methylamine, aniline, dimethylamine, diethylamine, N-methylpiperidine, diphenylamine, N,N-dimethylamine, trimethylamine, triethylamine, tri-n-butylamine, methylidiphenylamine, pyridine, p-bromonitroaniline, N,N-dimethylbenzylamine, p-nitro-N,N-dimethylamine, etc.; phosphines such as triethylphosphine, triphenylphosphate, diphenylphosphine, etc.; thioethers such as tetrahydrothiophene, etc.; esters such as ethyl benzote, etc.; nitriles such as acetonitrile, benzonitrile, etc.; specific examples of R<sup>26</sup> include a hydrogen atom, a methyl group, an ethyl group, an benzyl group, a propenyl group, etc.

[0052] In the general formula (VI), L<sup>2</sup> represents M<sup>1</sup>, R<sup>27</sup>R<sup>28</sup>M<sup>2</sup>, R<sup>27</sup>C or R<sup>30</sup>M<sup>2</sup>. R<sup>27</sup> and R<sup>28</sup> each independently represent a cyclopentadienyl group, a substituted cyclopentadienyl group, an indenyl group or a fluorenyl group; R<sup>29</sup> represents an alkyl group having from 1 to 20 carbon atoms, or a hydrocarbon group having from 6 to 20 carbon atoms and selected from an aryl group, an alkylaryl group and an arylalkyl group. R<sup>30</sup> represents a macrocyclic ligand such as tetraphenylporphyrin, phthalocyanine, etc.

[0053] M<sup>1</sup> includes elements of Groups 1 to 3, 11 to 13 and 17 of the Periodic Table; and M<sup>2</sup> represents an element of Groups 7 to 12 of the Periodic Table.

[0054] Specific examples of R<sup>27</sup> and R<sup>28</sup> include a cyclopentadienyl group, a methylcyclopentadienyl group, an ethylcyclopentadienyl group, a pentamethylcyclopentadienyl group, etc. Specific examples of R<sup>29</sup> include a phenyl group, a p-tolyl group, a p-methoxyphenyl group, etc.; and specific examples of R<sup>30</sup> include tetraphenylporphyrin, phthalocyanine, etc. Specific examples of M<sup>1</sup> include L<sup>1</sup>, Na, K, Ag, Cu, Br, I, I<sub>2</sub>, etc.; and specific examples of M<sup>2</sup> include Mn, Fe, Co, Ni, Zn, etc.

[0055] In the general formulae (V) and (VI), k is the ionic valence of [L<sup>1</sup>-R<sup>26</sup>]<sup>3-</sup> or [L<sup>1</sup>-R<sup>26</sup>]<sup>3-</sup>, indicating an integer of from 1 to 3; and a indicates an integer of 1 or more; and b = (kca).

[0056] [Z]<sup>1</sup> represents a non-coordinating anion [Z]<sup>1</sup> or [Z]<sup>1</sup>.

[0057] [Z]<sup>1</sup> means an anion with multiple groups bonding to an element, namely representing [M<sup>4</sup>G<sup>2</sup>G<sup>3</sup>...G<sup>s</sup>]<sup>1</sup>. M<sup>4</sup> represents an element of Groups 5 to 15 of the Periodic Table, preferably an element of Groups 13 to 15 of the Periodic Table. G<sup>1</sup> to G<sup>1</sup> each represent a hydrogen atom, a halogen atom, an alkyl group having from 1 to 20 carbon atoms, a dialkylamino group having from 2 to 40 carbon atoms, an aryl group having from 1 to 20 carbon atoms, an alkoxyl group having from 1 to 20 carbon atoms, an alkylaryl group having from 2 to 40 carbon atoms, an arylalkyl group having from 2 to 40 carbon atoms, a halogen-substituted hydrocarbon group having from 1 to 20 carbon atoms, an aryloxy group having from 1 to 20 carbon atoms, an organometallic group, or a hetero atom-containing hydrocarbon group having from 2 to 20 carbon atoms. Two or more of G<sup>1</sup> to G<sup>s</sup> may form a ring, f indicates an integer of [(atomic valence of the center metal M<sup>4</sup>)+1].

[0058] [Z]<sup>1</sup> represents a conjugated base of a Bronsted acid alone of which the logarithmic number of the reciprocal of the acid dissociation constant (pKa) is >10 or smaller, or a combination of such a Bronsted acid and a Lewis acid, or represents a conjugated base of an acid generally defined as a superacid. This may be coordinated with a Lewis base.

[0059] In [Z]<sup>1</sup>, or that is, in [M<sup>4</sup>G<sup>2</sup>G<sup>3</sup>...G<sup>s</sup>]<sup>1</sup>, specific examples of M<sup>4</sup> include B, Al, Si, P, As, Sb, etc., preferably B and Al. As specific examples of G<sup>1</sup> and G<sup>s</sup> to G<sup>s</sup>, the dialkylamino group includes a dimethylamino group, a diethylamino group, etc.; the alkoxy group or the aryloxy group includes a methoxy group, an ethoxy group, an n-propoxy group, a phenoxy group, etc.; the hydrocarboxyl group includes a methyl group, an ethyl group, an n-propyl group, an isopropyl group, an n-butyl group, an isobutyl group, an n-octyl group, an n-ecosyl group, a phenyl group, a p-tolyl group, a benzyl group, a 4-t-butylphenyl group, a 3,5-dimethylphenyl group, etc.; the halogen atom includes fluorine, chlorine, bromine, iodine; the hetero atom-containing hydrocarbon group includes a p-fluorophenyl group, a 3,5-difluorophenyl group, a pentachlorophenyl group, a 3,4,5-trifluorophenyl group, a pentachlorophenyl group, a 3,5-bis(trifluoromethyl) phenyl group, a bis(trimethylsilyl) methyl group, etc.; the organometallic group includes a pentamethyltiamoxime group, a trimethylstil group, a trimethylgermyl group, a diphenylarsenine group, a diecyclohexylamine group, a diphenylboron group, etc.

[0060] Specific examples of the non-coordinating anion, or that is, the conjugated base [Z]<sup>1</sup> of a Bronsted acid alone having a pKa of >10 or smaller, or a combination of such a Bronsted acid and a Lewis acid include a trifluoromethanesulfonate anion (CF<sub>3</sub>SO<sub>2</sub>)<sup>-</sup>, a bis(trifluoromethanesulfonyl)
methyl anion, a bis(trifluoromethanesulfonyl)benzyl anion, a bis(trifluoromethanesulfonyl)amide, a perchlorate anion (ClO$_4^-$), a trifluoroacetate anion (CF$_3$COO$^-$), a hexafluoroantimonio anion (SbF$_6^-$), a fluorosulfonate anion (FSO$_3^-$), a chlorosulfonate anion (ClSO$_3^-$), a fluorosulfonate anion/5-fluoroantimonio (FSO$_3$/SbF$_6^-$), a fluorosulfonate anion/5-fluoroarsenic (FSO$_3$/AsF$_5^-$), a trifluoromethanesulfonate/5-fluoroantimonio (CF$_3$SO$_3$/SbF$_6^-$), etc.

Specific examples of the compound of the component (b-2) include triethylammonium tetrabutylandinate, tri-n-butylammonium tetrabutylandinate, trimethylammonium tetrabutylandinate, tetraethylammonium tetrabutylandinate, methyl(tri-n-butyl)ammonium tetrahexylamide, benzyl(tri-n-butyl)ammonium tetrahexylamide, dimethylphenylammonium tetraethylamide, triphenyl(methyl)ammonium tetrahexylamide, methylpyridinium tetrabutylandinate, 2-cyanopyridinium tetrabutylandinate, triethylammonium tetrakis(pentafluorophenyl)borate, tri-n-butylammonium tetrakis(pentafluorophenyl)borate, tetraethylammonium tetrakis(pentafluorophenyl)borate, tetra-n-butylammonium tetrakis(pentafluorophenyl)borate, tetraethylammonium tetrakis(pentafluorophenyl)borate, benzyl(tri-n-butyl)ammonium tetrakis(pentafluorophenyl)borate, methyltrimethylammonium tetakis(pentafluorophenyl)borate, triphenyl(methyl)ammonium tetakis(pentafluorophenyl)borate, methylpyridinium tetrakis(pentafluorophenyl)borate, 2-cyanopyridinium tetrakis(pentafluorophenyl)borate, benzyl(2-cyanopyridinium) tetakis(pentafluorophenyl)borate, dimethylphenylammonium tetakis(pentafluorophenyl)borate, triphenylmethylammonium tetakis(pentafluorophenyl)borate, trimethylammonium tetakis(pentafluorophenyl)borate, methylpyridinium tetakis(pentafluorophenyl)borate, benzylpyridinium tetakis(pentafluorophenyl)borate, methyl(2-cyanopyridinium) tetrais(pentafluorophenyl)borate, benzyl(2-cyanopyridinium) tetrais(pentafluorophenyl)borate, methyl(4-cyanopyridinium) tetrais(pentafluorophenyl)borate, trimethylammonium tetrais(3,5-ditrifluoromethyl)phenyl)borate, ferrocenium tetraphenylborate, silver tetraphenyloborate, trityl tetrabutylandinate, tetrabutylandinate, porphyrin-manganese tetrabutylandinate, ferrocenium tetrais(pentafluorophenyl)borate, (1,1'-dimethylferrocenium) tetrais(pentafluorophenyl)borate, decamethylferrocenium tetrais(pentafluorophenyl)borate, silver tetrais(pentafluorophenyl)borate, trityl tetrakis(pentafluorophenyl)borate, lithium tetrais(pentafluorophenyl)borate, sodium tetrais(pentafluorophenyl)borate, tetrabutylandinate, porphyrin-manganese tetrais(pentafluorophenyl)borate, silver tetrais(pentafluorophenyl)borate, silver hexafluorocacetate, silver perchlorate, silver trifluoroacetate, silver trifluoromethanesulfonate, etc.

One alone or two or more different types of the components (b-2) may be used here either singly or as combined. The proportion of the component (A) and the component (B) to be used in the present invention is described. In the case where the component (b-1) is used as the component (B), the ratio by mol of the two components is preferably from 1/1 to 1/10,000, more preferably from 1/10 to 1/100,000, and in the case where the component (b-2) is used, the ratio by mol is preferably from 1/10 to 1/100, more preferably from 2/1 to 1/10. As the component (B), one alone or two or more different types of (b-1) and (b-2) may be used either singly or as combined.

The catalyst for use in the present invention may be one containing the above-mentioned component (A) and component (B) as the main components thereof, or may contain the component (A), the component (B) and the organoaluminium compound (C) as the main components thereof. In this case, the organoaluminium compound as the component (C), usable is a compound represented by the following general formula (VII):

$$\text{(R}^1\text{)}_3\text{AlQ}_3$$

In the formula, $\text{R}^1$ represents an alkyl group having from 1 to 10 carbon atoms; Q represents a hydrogen atom, an alkxy group having from 1 to 20 carbon atoms, an aryl group having from 6 to 20 carbon atoms, or a halogen atom; v indicates an integer of from 1 to 3.)

Specific examples of the compound represented by the above-mentioned general formula (VII) include trimethylaluminium, triethylaluminium, triisopropylaluminium, triisobutylaluminium, dimethylaluminium chloride, diethylaluminium chloride, methylaluminium dichloride, ethylaluminium dichloride, dimethylaluminium fluoride, disobutylaluminium hydride, diethylaluminium hydride, ethylaluminium sesqui-chloride, etc. One alone or two or more different types of these organoaluminium compounds may be used here either singly or as combined. The proportion of the above-mentioned component (A) and component (C) to be used here is, in terms of the ratio by mol of the two, preferably from 1/1 to 1/10,000, more preferably from 1/5 to 1/2,000, even more preferably from 1/10 to 1/1000. Using the component (C) enhances the activity per the transition metal; however, if used too much, the organoaluminium compound would go to waste and may remain much in the c-c olefin polymer, and using too much the component is unfavorable.

For use in the present invention, at least one catalyst component may be held by a suitable carrier. The type of the carrier is not specifically defined. Usable here is an inorganic oxide carrier and any other inorganic carrier and organic carrier, but especially from the viewpoint of morphology control, preferred is use of an inorganic oxide carrier or any other inorganic carrier.

The inorganic oxide carrier concretely includes SiO$_2$, Al$_2$O$_3$, MgO, ZrO$_2$, TiO$_2$, Fe$_2$O$_3$, B$_2$O$_3$, CaO, ZnO, BaO, ThO$_2$, and their mixtures, for example, silica-alumina, zeolite, ferrite, glass fiber, etc. Of those, especially preferred are SiO$_2$ and Al$_2$O$_3$. The inorganic oxide carrier may contain a small amount of a carbonate, a nitrate, a sulfate or the like. On the other hand, the other carrier than the above includes magnesium compounds to be represented by a general formula Mg$(\text{R}^{25}_1\text{)}\text{X}_n$, such as typically magnesium compounds of MgCl$_2$, Mg(OCC$_6$H$_4$)$_2$, and others, as well as their complexes. $\text{R}^{25}_1$ represents an alkyl group having from 1 to 20 carbon atoms, an alkxy group having from 1 to 20 carbon atoms, or an aryl group having from 6 to 20 carbon atoms; X represents a halogen atom or an alkyl group having from 1 to 20 carbon atoms; a indicates from 0 to 2; b indicates from 0 to 2; and $a+b=2$. $\text{R}^{25}_1$s and X's each may be the same or different.

The organic carrier includes polymers such as polypropylene, styrene-divinylbenzene copolymer, polyethylene, polypolypropylene, substituted polystyrene, polyarylate, etc., as well as starch, carbon, etc. As the carrier for use in the present invention, preferred are MgCl$_2$, MgCl(OCC$_6$H$_4$)$_2$, Mg(OCC$_6$H$_4$)$_2$-SiO$_2$, Al$_2$O$_3$, etc. The property of the carrier may differ depending on the type and the production method, but in general, the mean particle size of the carrier is from 1 to 300
μm, preferably from 10 to 200 μm, more preferably from 20 to 100 μm. When the particle size is small, then the fine powder in the 1-octene/1-decene/1-dodecene ternary copolymer may increase; but when the particle size is large, then the coarse particles in the 1-octene/1-decene/1-dodecene ternary copolymer may increase, therefore causing bulk density reduction and hopper clogging. The specific surface area of the carrier is generally from 1 to 1,000 m²/g, preferably from 50 to 500 m²/g and the pore volume thereof is generally from 0.15 to 5 cm³/g, preferably from 0.3 to 3 cm³/g. When any of the specific surface area and the pore volume exceeds the above range, then the catalytic activity may lower. The specific surface area and the pore volume can be determined, for example, from the volume of the adsorbed nitrogen gas according to a BET method (see "J. Am. Chem. Soc., 60, 309 (1938)"). Further, it is desirable that the carrier is used after dried generally at from 150 to 1,000°C, but preferably at from 200 to 800°C.

[0068] In case where at least one catalyst component is held by the above-mentioned carrier, at least one of the component (A) and the component (B) but preferably both the component (A) and the component (B) are held. The method for mixing at least one of the component (A) and the component (B) held by the carrier is not specifically defined. For example, there may be employed a method of mixing at least one of the component (A) and the component (B) with the carrier; a method of first processing the carrier with an organoaluminim compound or a halogen-containing silicon compound and then mixing with it at least one of the component (A) and the component (B) in an inert solvent; a method of reacting the carrier with the component (A) and/or the component (B) and an organoaluminium compound or a halogen-containing silicon compound; a method of making the component (A) or the component (B) held by the carrier and then mixing it with the component (B) or the component (A); a method of mixing a contact reaction product of the component (A) and the component (B) with the carrier; a method of making the carrier co-existing in the system of contact reaction of the component (A) and the component (B); etc. In the above reaction, an organoaluminium compound of the component (C) may also be added to the system.

[0069] The catalyst thus obtained in the manner as above may be used for polymerization after once processed for solvent removal through distillation and taken out as a solid, or may be directly used for polymerization. In the present invention, the operation of processing at least one of the component (A) and the component (B) to be held by the carrier may be attained in the polymerization system to prepare the catalyst. For example, there may be employed a method where at least one of the component (A) and the component (B), and the carrier and optionally an organoaluminium compound of the component (C) are put into a reactor, then an olefin such as ethylene or the like is added thereto under normal pressure to 2 MPa, and pre-polymerized at from −20 to 200°C for from 1 minute to 2 hours or so thereby forming catalyst particles.

[0070] In the present invention, the ratio by mass of the component (b-1) to the carrier to be used is preferably from 1/0.5 to 1/1,000, more preferably from 1/1 to 1/50, and the ratio by mass of the component (b-2) to the carrier to be used is preferably from 1/5 to 1/10,000, more preferably from 1/10 to 1/500. In case where two or more different components are used as the catalyst component (B), preferably, the ratio by mass of each component (B) to the carrier to be used falls within the above range. The ratio by mass of the component (A) to the carrier to be used is preferably from 1/5 to 1/10,000, more preferably from 1/10 to 1/500. The catalyst for use in the present invention may contain the above-mentioned component (A) and component (B) and the above-mentioned component (C) as the main components thereof. Preferably, the ratio by mass of the component (B) to the carrier to be used, and the ratio by mass of the component (A) to the carrier to be used each fall within the above-mentioned range. In this case, the amount of the component (C) is preferably in a ratio by mol to the component (A) as described above, of from 1/1 to 1/10,000, more preferably from 1/5 to 1/2,000, further preferably from 1/10 to 1/1,000. When the ratio of the component (B) (the component (b-1) or the component (b-2)) to the carrier to be used, or the ratio of the component (A) to the carrier to be used, as well as the ratio by mass of the component (C) to the component (A) to be used each falls outside the above-mentioned range, then the activity may lower. The mean particle size of the catalyst for the present invention, thus prepared in the manner as above, is generally from 2 to 200 μm, preferably from 10 to 150 μm, more preferably from 20 to 100 μm; and the specific surface area thereof is generally from 20 to 1,000 m²/g, preferably from 50 to 500 m²/g. When the mean particle size is less than 2 μm, then the fine powder in the polymer may increase; but when more than 200 μm, then the coarse particles in the polymer may increase. When the specific surface area is less than 20 m²/g, then the activity may lower; but when more than 1,000 m²/g, then the bulk density of the polymer may lower. In the catalyst for the present invention, the transition metal amount in 100 g of the carrier is generally from 0.05 to 10 g, preferably from 0.1 to 2 g. When the transition metal amount is outside the above range, then the activity may lower. Thus held by a carrier, the catalyst can provide an industrially advantageous production method.

[0071] In the present invention, the polymerization mode is not specifically defined, and herein employable is any of a bulk polymerization method, a solution polymerization method, a suspension polymerization method, a slurry polymerization method, a vapor-phase polymerization method, etc. Regarding the polymerization condition, the polymerization temperature is generally from 0 to 200°C, preferably from 30 to 150°C, more preferably from 40 to 120°C. Regarding the ratio of the starting monomer to the catalyst to be used, the ratio of starting monomer/component (A) is preferably from 1 to 10³, more preferably from 100 to 10³. Further, the polymerization time is generally from 5 minutes to 20 hours, the reaction pressure is preferably from normal pressure to 0.2 MPaG, more preferably from normal pressure to 0.1 MPaG.

[0072] Preferably, the production method in the present invention is carried out in the absence of a solvent from the viewpoint of productivity, in which, however, a solvent may be used. In the latter case, for example, usable are aromatic hydrocarbons such as benzene, toluene, xylene, ethylbenzene, etc.; alicyclic hydrocarbons such as cyclopentane, cyclohexane, methylecyclohexane, etc.; aliphatic hydrocarbons such as pentane, hexane, heptane, octane, etc.; halogenohydrocarbons such as chloroform, dichloromethane, etc. One alone or two or more different types of these solvents may be used alone either singly or as combined. The monomer such as 1-hexene may serve as the solvent.

[0073] In the production method for the 1-octene/1-decene/1-dodecene ternary copolymer of the present invention, add-
In the present invention, the polymerization catalyst may be used for prepolymerization. The prepolymerization may be attained, for example, by contacting the catalyst component with a small amount of an olefin, but the method is not specifically defined, and any known method is employable. The olefin to be used for the prepolymerization is not specifically defined, and for example, there may be mentioned ethylene, α-olefins having from 3 to 20 carbon atoms, or their mixtures, etc. It is advantageous to use the same olefin as the monomer for the polymerization. The prepolymerization temperature is generally from −20 to 200°C, preferably from −10 to 130°C, more preferably from 0 to 80°C. In the prepolymerization, inert hydrocarbons, aliphatic hydrocarbons, aromatic hydrocarbons, monomers and others can be used as the solvent. Of those, especially preferred are aliphatic hydrocarbons and aromatic hydrocarbons. The prepolymerization may be attained in the absence of a solvent. Preferably, the prepolymerization condition is so controlled that the amount of the prepolymerization product per 1 mmol of the transition metal component in the catalyst could be from 1 to 10,000 g, more preferably from 1 to 1,000 g.

For controlling the molecular weight of the polymer in the production method of the present invention, there may be employed a method of selecting the type and the amount of each catalyst component to be used and the polymerization temperature; a method of adding hydrogen; or a method of adding an inert gas such as nitrogen or the like.

In case where the α-olefin polymer is used as a lubricant oil, preferably, the monomers (1-olecne, 1-decene, 1-dodecene and their oligomers) are removed after the above-mentioned polymerization process. For the removal, for example, there may be mentioned a method of distillation under reduced pressure.

Also preferably, the 1-olecne/1-decene/1-dodecene ternary copolymer is hydrogenated to produce a hydrogenated 1-olecne/1-decene/1-dodecene ternary copolymer from the viewpoint of enhancing the stability of the copolymer. The hydrogenation method is not specifically defined, for which any known method is employable.

According to the production method of the present invention, a 1-olecne/1-decene/1-dodecene ternary copolymer, which is useful as a high-viscosity lubricant oil excellent in viscosity characteristics (viscosity index), low-temperature characteristics (low-temperature flowability) and oxidation stability, can be produced industrially with ease. Further, by controlling the reaction condition, for example, by controlling the reaction temperature, the properties of the product can be changed broadly.

The above-mentioned “produce industrially with ease” means, for example, that the amount of hydrogen to be used and the pressure level may be small, the reaction temperature is relatively mild and is easy to control, and the process does not require a step of diluting with an inert solvent.

[Lubricant Oil Composition]

The lubricant oil composition of the present invention contains the above-mentioned 1-olecne/1-decene/1-dodecene ternary copolymer and/or the above-mentioned hydrogenated 1-olecne/1-decene/1-dodecene ternary copolymer, and contains the polymer generally in an amount of from 0.01 to 100% by mass based on the total amount of the composition.

In the lubricant oil composition of the present invention, the type in use of the 1-olecne/1-decene/1-dodecene ternary copolymer and the hydrogenated 1-olecne/1-decene/1-dodecene ternary copolymer is not specifically defined. In the composition, the copolymer may be used as a base oil or may also be used as an additive. When used as a base oil, the copolymer may be widely used, covering from a low-molecular weight one to a high-molecular weight one. When used as a base oil, the copolymer may be used alone, or may be used as combined with any other base oil. The blend ratio is not specifically defined. In general, the copolymer accounts for from 1 to 100% by mass based on the total amount of the composition. When used as an additive, for example, the copolymer may be used as a viscosity index improver. In this case, preferred is use of the 1-olecne/1-decene/1-dodecene ternary copolymer having a relatively high molecular weight. For example, as the 1-olecne/1-decene/1-dodecene ternary copolymer having a high-molecular weight, there may be mentioned those having a number-average molecular weight of more than 5000. The amount of the copolymer to be added may be generally from 0.01 to 33% by mass based on the total amount of the composition.

Various known additives may be suitably added to the lubricant oil composition of the present invention within a range not detracting from the object of the present invention. For example, there may be mentioned phosphorus-containing extreme pressure agents such as phosphates, phosphites, etc.; oily agents such as oleic acid, stearic acid, dimer acid and the like carboxylic acids and their esters, etc.; antioxidant additives such as zinc dithiophosphate (ZnDTP, excepting aryl-type), zinc dithiocarbamate (ZnDTC), oxymelobdenum sulfide dithiocarbamate (MoDTC), nickel dithiophosphate (NiDTP), nickel dithiocarbamate (NiDTC), etc.; amine-type or phenol-type antioxidants; metal inactivators such as thiadiazole, benzotriazole, etc.; sludge dispersants such as alkylaryl succinic acids or their esters or imides, etc.; corrosion inhibitors such as sorbitan esters, neutral alkaline earth metal sulfonates, phenates, sulicylates, etc.; deoiling agents such as dimethyl polysiloxane, polyacrylate, etc.

Use of the lubricant oil composition of the present invention is not specifically defined. The composition can be used for internal combustion oils such as gasoline engine oil (2-cycle, 4-cycle), diesel engine oil, etc.; drive system oils such as gear oil, ATF (automatic transmission fluid), PSF (power steering fluid), buffer oil, etc.; facility oils such as chassis oil, turbine oil, operating oil, working machine oil, refrigeration oil, etc.; working oils such as rolling oil, cutting oil, heat treatment oil, etc.; greases, etc.

EXAMPLES

Next, the present invention is described in more detail with reference to Examples; however, the present invention is not whatsoever limited by these Examples.

The physical properties of α-olefin polymers were evaluated according to the following methods.
Pour Point: Measured according to JIS K 2269.

Kinematic Viscosity and Viscosity Index: The kinematic viscosity was measured according to JIS K 2283. The viscosity index was calculated from the kinematic viscosity according to JIS K 2283.

Number-Average Molecular Weight and Molecular Weight Distribution (Mw/Mn): Using an apparatus of JASCO’s GPC-900 (columns: Tosoh TSK-GEL MULTIPORTE HXL-M (2 columns)+Shodex KF801 (one column)) with a solvent of tetrahydrofuran at a temperature of 40°C, these were determined in terms of polystyrene-equivalent data.

Mesotriad Fraction (mm): According to the method described in "Macromolecules 24, 3334 (1991); Polymer, 30, 1350 (1989)", this was determined through 13C-NMR.

Double Bond Amount, Terminal Structure: Using an NMR apparatus of JEOL’s BURUKER 500 MHz, the sample was dissolved in a solvent of heavy chloroform and analyzed through 1H-NMR.

In 1H-NMR, when the intensity calculated by subtracting the peaks caused by the methyl branch from the peaks caused by the methyl group is represented by A. The value calculated by dividing A by the hydrogen atom number 3, A/3 indicates the total amount of the monomer units in the copolymer. The double bond is in four structures of vinyl, vinylidene, disubstituted internal olefin and trisubstituted internal olefin. Vinyl is detected at around 4.95 ppm and around 5.8 ppm; vinylidene is at around 4.7 ppm; disubstituted one is at around 5.4 ppm; and trisubstituted one is at 5.15 ppm. The intensity of each peak at around 4.95 ppm, at around 5.8 ppm, at around 4.7 ppm, at around 5.4 ppm and at 5.15 ppm is represented by B, C, D, E and F, respectively. The value to be calculated by dividing the peak intensity by the number of the hydrogen atoms bonding to the double bond carbon, (B+C)/3, D/2, E/2 and F each indicate the amount of each double bond. The amount of double bonds G (mol%) remaining in the copolymer is calculated by dividing the total amount of all double bonds by the total amount of the monomer units, as follows:

\[ G = \frac{(B+C)/3 + D/2 + E/2 + F)}{} \times 100 \]

The proportion H (%) of the 2,1-insertion terminal structure can be calculated from the double bond amount in the disubstituted internal olefin and the trisubstituted internal olefin, as follows:

\[ H = \frac{(E/2 + F)}{(B+C)/3 + D/2 + E/2 + F)} \times 100 \]

Number of Double Bond Amount in One Molecule: A mean degree of polymerization P is calculated from the number-average molecular weight Mw and the mean molecular weight I of the monomer units constituting the copolymer, as measured through GPC, as follows:

\[ P = \frac{(Mw)}{I} \]

In this, the mean molecular weight of the monomer units I is obtained from the copolymerization composition. Concretely, the content of 1-octene is represented by X mol% and the content of 1-decene is by Y mol%, and I is calculated as follows:

\[ I = 112X + 140X + 100X + 168X + 100(Y - X) \times 100 \]

The number N of the double bond amount contained in one molecule is calculated by multiplying the molar fraction of double bond, G/100 by the mean degree of polymerization P, as follows:

\[ N = \frac{P \times G}{100} \]

Oxidation Stability Test: Carried out according to the rotating bomb oxidation test (RBOT test) of JIS K 2514.

Production Example 1

Production of (1,1'-dimethylsilylene)(2,2'-dimethylsilylene)-bis(cyclopentadienyl)zirconium dichloride

About 13.8 g (600 mmol) of metal Na and 400 ml of dry THF (tetrahydrofuran) were put into a nitrogen-purged 1000-ml three-neck flask, and stirred therein at 0°C. After 5 minutes, from 1 to 2 ml of cyclopentadiene was dropwise added thereto, and when the hydrogen generation was stopped, from 1 to 2 ml of cyclopentadiene was newly added thereto. This was repeated so that 50 ml (600 mmol) in total of cyclopentadiene was added. The reaction solution changed from colorless transparent to pale pink. After removal of THF through distillation under reduced pressure, the crystal was washed twice with hexane and dried into solid under reduced pressure to give cyclopentadienyl sodium as a pink powder.

457 ml of THF was added to 43.0 g (480 mmol) of cyclopentadienyl sodium and stirred at 0°C. This was cooled to -78°C, and 29.2 ml (480 mmol) of dichlorodimethylsilane was gradually and dropwise added thereto. The solution changed from yellow to milky. After this was stirred overnight at room temperature, THF was distilled out to give a yellow powder [compound (1)].

The compound (1) was extracted with 150 ml of hexane, and the supernatant was transferred into a nitrogen-purged, 1000-ml three-neck flask. After this was cooled to -78°C, 175.8 ml (480 mmol) of n-butyllithium (2.73 mol/l) was dropwise added thereto. The reaction solution changed from yellow to milky. After this was stirred overnight at room temperature, the supernatant was removed through filtration. The obtained white solid was washed with 100 ml of hexane. This was dried under reduced pressure to give a diliathium salt [compound (2)] as a white powder.

50 ml of diethyl ether and 100 ml of hexane were added to 27.4 g (137 mmol) of the compound (2). After this was cooled to -78°C, 16.7 ml (137 mmol) of dichlorodimethylsilane was gradually and dropwise added thereto. This was stirred at room temperature for 5 hours, then the precipitate was removed through filtration, and the filtrate was concentrated. This was recrystallized from hexane to give 405 g (yield 12%) of a compound (3) as a needle-like transparent crystal.

4.05 g (16.6 mmol) of the compound (3) was dissolved in 60 ml of hexane in a nitrogen-purged, 200 ml Schlenk tube. After this was cooled to -78°C, 12.1 ml (33.1 mmol) of n-butyllithium (2.73 mol/l) was dropwise added
thereto, and stirred overnight at room temperature. The solvent of the milky solution was distilled out under reduced pressure, and the precipitate was washed with 20 ml of hexane. This was dried under reduced pressure to give a dilithium salt [compound (4)] as a white powder.

**[0102]** 34 ml of toluene was added to the compound (4). To this suspension, dropwise added at −20°C was a toluene (51 ml) suspension of 3.9 g (16.6 mmol) of zirconium tetrachloride. After this was stirred overnight at room temperature, the solvent was distilled out under reduced pressure to give the intended product [compound (5)]. The compound (5) was extracted with 30 ml of dichloromethane, and the filtrate was concentrated. This was washed with 10 ml of hexane, and dried under reduced pressure to give 500 mg (yield 7.4% of (5). Its ¹H-NMR gave the following data.

**[0103]** ¹H-NMR (500 MHz, CDCl₃): δ: 0.49 [6H, s, (CH₃)₂Si], 0.87 [6H, s, (CH₃)₂Si], 6.40 (2H, t, —CH—), 6.89 (4H, d, —CH—)

Example 1-1

**[0104]** A stainless autoclave having an inner capacity of 1 liter was fully dried and purged with nitrogen, and thereafter 146 ml of 1-dodecene, 183 ml of 1-decene, 71 ml of 1-octene, and next 0.2 mmol of trisobutylaluminium were put into it, and heated up to 105°C. One ml of a catalyst mixture prepared separately (this was prepared as follows: 0.1 mmol of trisobutylaluminium (2 mmol/ml toluene solution; 0.05 ml), 10 of (1,1’-dimethylsilylene)2,2’-dimethylsilylene)-bis(cyclopentadienyl)zirconium dichloride prepared in Production Example 1 (10 mmol/ml toluene solution; 1 ml) and 0.012 mmol (11.5 mg) of powdery N,N-dimethylanilinium tetrakis (pentfluorophenyl)borate were put into a 10-ml glass-made Schlenk bottle in a nitrogen atmosphere, and stirred for 1 minute or so, and then 0.5 ml of 1-octene was added thereto and further stirred at room temperature for 1 hour) was put into the autoclave, and 0.05 MPaG hydrogen was introduced thereto into start polymerization. After 60 minutes at 105°C, 1 ml of the remaining catalyst mixture was added, then further after 60 minutes, 1 ml of the still remaining catalyst mixture was added, and further after 60 minutes, 1 ml of the still remaining catalyst mixture was added, and thereafter 10 ml of methanol was added to stop the polymerization. The content was taken out, put into 200 ml of an aqueous 1 mass NaOH solution, and stirred. The solution was transferred into a separating funnel, the organic layer was taken out, the organic layer was washed with water, and the organic layer was filtered through Toyo Roshi’s Filter Paper 2C to remove the solid. The resulting solution was processed with a rotary evaporator (in an oil bath at 100°C under reduced pressure of about 1×10⁻⁶ MPa) to remove toluene, the starting material, methanol and others, thereby giving 269 g of a colorless transparent liquid. Further, using a thin-film distillation apparatus (Shibata Scientific Technology’s molecule distillation apparatus MS-300 Special Model, high-vacuum degassing apparatus DS-212Z), this was distilled under reduced pressure of 5×10⁻⁶ MPa at 180°C to give 234 g of a polymer from which the components having 24 or smaller carbon atoms had been removed. The obtained polymer was analyzed according to the above-mentioned methods, and the results are shown in Table 1. Next, the polymer after distillation was put into a stainless autoclave having an inner capacity of 1 liter, and a stabilized nickel catalyst (Sakai Chemical Industry’s SN750) was added thereto in a ratio by weight of 1% by mass, and reacted under 2 MPa hydrogen at 130°C for 6 hours. After the reaction, this was cooled to around 80°C, then the content was taken out, and the catalyst component was separated through filtration through a 1-µm filter at 70°C. to give 234 g of a hydrogenated product. This was analyzed according to the above-mentioned methods, and the results are shown in Table 1.

**Example 1-2**

**[0105]** In the same manner as in Example 1-1 except that the polymerization temperature was 90°C, a colorless transparent polymer from which the components having 24 or smaller carbon atoms had been removed, and its hydrogenated product were obtained in an amount of 235 g each. These were analyzed according to the above-mentioned methods, and the results are shown in Table 1.

**Example 1-3**

**[0106]** In the same manner as in Example 1-1 except that 1-dodecene was 118 ml, 1-decene was 148 ml and 1-octene was 134 ml, a colorless transparent polymer from which the components having 24 or smaller carbon atoms had been removed, and its hydrogenated product were obtained in an amount of 238 g each. These were analyzed according to the above-mentioned methods, and the results are shown in Table 1.

**Example 1-4**

**[0107]** In the same manner as in Example 1-1 except that 1-dodecene was 107 ml, 1-decene was 135 ml and 1-octene was 158 ml, a colorless transparent polymer from which the components having 24 or smaller carbon atoms had been removed, and its hydrogenated product were obtained in an amount of 233 g each. These were analyzed according to the above-mentioned methods, and the results are shown in Table 1.

**Example 1-5**

**[0108]** In the same manner as in Example 1-1 except that 1-dodecene was 247 ml, 1-decene was 35 ml and 1-octene was 117 ml, a colorless transparent polymer from which the components having 24 or smaller carbon atoms had been removed, and its hydrogenated product were obtained in an amount of 235 g each. These were analyzed according to the above-mentioned methods, and the results are shown in Table 1.

**Example 1-6**

**[0109]** In the same manner as in Example 1-1 except that 1-dodecene was 183 ml, 1-decene was 130 ml and 1-octene was 87 ml, a colorless transparent polymer from which the components having 24 or smaller carbon atoms had been removed, and its hydrogenated product were obtained in an amount of 236 g each. These were analyzed according to the above-mentioned methods, and the results are shown in Table 1.

**Comparative Example 1-1**

**[0110]** In the same manner as in Example 1-1 except that 160 ml of 1-tetradecene and 240 ml of 1-hexene were used as the monomers, a colorless transparent polymer from which the components having 24 or smaller carbon atoms had been removed, and its hydrogenated product were obtained in an
amount of 236 g each. These were analyzed according to the above-mentioned methods, and the results are shown in Table 2.

Comparative Example 1-2

In the same manner as in Example 1-1 except that 267 ml of 1-dodecene and 133 ml of 1-hexene were used as the monomers, a colorless transparent polymer from which the components having 24 or smaller carbon atoms had been removed, and its hydrogenated product were obtained in an amount of 215 g each. These were analyzed according to the above-mentioned methods, and the results are shown in Table 2.

Comparative Example 1-3

In the same manner as in Example 1-1 except that 300 ml of 1-dodecene and 100 ml of 1-hexene were used as the monomers and the polymerization temperature was 80° C., a colorless transparent polymer from which the components having 24 or smaller carbon atoms had been removed, and its hydrogenated product were obtained in an amount of 230 g each. These were analyzed according to the above-mentioned methods, and the results are shown in Table 2.

Comparative Example 1-4

In the same manner as in Example 1-1 except that the catalyst was bis(tert-butylcyclopentadienyl)zirconium dichloride, a colorless transparent polymer from which the components having 24 or smaller carbon atoms had been removed, and its hydrogenated product were obtained in an amount of 183 g each. These were analyzed according to the above-mentioned methods, and the results are shown in Table 2.

FIG. 1 shows the relationship between the viscosity index and the pour point of the copolymers obtained in Examples 1-1 to 1-6 and Comparative Examples 1-1 to 1-4. It is known that the 1-octene/1-decene/1-dodecene ternary copolymer of the present invention is excellent in the balance between viscosity characteristics and low-temperature characteristics as compared with the copolymer obtained by the use of any other monomers or any other metalocene catalyst.

**Example 2-1**

One ml of water and 30 mg of copper powder serving as a catalyst were added to 5 g of a composition composed of 99% by mass of the hydrogenated product of Example 1-1, and 0.5% by mass of Irganox L-107 and 0.5% by mass of Irganox L-57 both serving as an antioxidant, and put into the space of a chamber. The oxidation stability of the sample was determined according to the rotating bomb oxidation test (RBOT test) of JIS K 2514. The results are shown in Table 3.

**Comparative Example 2-1**

147 g of a hydrogenated product was prepared in the same manner as in Example 1-1 except that 300 ml of 1-octene and 100 ml of 1-dodecene were used as the monomers, that bis (indenyl) zirconium dichloride was used as the catalyst and that the reaction temperature was 50°C. Thus obtained, the hydrogenated product was tested according to the same oxidation stability test as in Example 2-1, and the results are shown in Table 3. The proportion of 2,1-insertion polymerization terminal was determined according to gas chromatography (GC) (Column: Ultra-2, 25 m×0.2 mm×0.33 maximum temperature: 325°C). This is because, owing to chain transfer to hydrogen and to chain transfer to aluminum, the terminal of the polymer was saturated and therefore it was difficult to determine the terminal structure of the polymer through NMR. The polymerization terminal does not change irrespective of the carbon composition, and therefore the polymer can be analyzed from the C32 terminal structure. The GC chart showed the 1,2-intersial terminal at around 20.9 minutes and the 2,1-insertion terminal at around 20.5 minutes. The intensity of each peak is represented by Q and R, and the proportion of the 2,1-insertion terminal S is calculated as S (%)=Q/(Q+R)×100.

**Comparative Example 2-2**

A commercial poly-alpha-olefin, Durasyn® by lonness was tested for oxidation stability in the same manner as in Example 2-1, and the results are shown in Table 3.

**INDUSTRIAL APPLICABILITY**

According to the present invention, a 1-octene/1-decene/1-dodecene ternary copolymer useful as a high-viscosity lubricant oil excellent in viscosity characteristics (viscosity index), low-temperature characteristics (low-temperature fluidity) and oxidation stability can be produced industrially with ease, and the present invention contributes toward advanced fuel efficiency, energy saving and life prolongation required for lubricant oil.

1. A ternary copolymer, comprising:
   a 1-octene unit,
   a 1-decene unit, and
   a 1-dodecene unit,
   wherein the ternary copolymer is produced in the presence of a doubly crosslinked metalocene catalyst.

2. The ternary copolymer according to claim 1, wherein a proportion of molecules whose polymerization terminal is a 2,1-insertion terminal is 30 mol % or greater.

3. The ternary copolymer according to claim 1, wherein a molar ratio of the 1-decene unit to a total of the 1-octene unit and the 1-dodecene unit is from 5/95 to 70/30, and a molar ratio of the 1-octene unit to the 1-dodecene unit is from 20/80 to 80/20.

4. The ternary copolymer according to claim 1, wherein the ternary copolymer has:
   a mesotriol fraction mm, as measured through 13C-NMR, of from 25 to 50 mol %, and
   a kinematic viscosity at 100°C of from 30 to 1000 mm²/s.

5. The ternary copolymer according to claim 1, wherein the ternary copolymer has a number-average molecular weight, as measured through GPC, of from 1500 to 15000.
6. The ternary copolymer according to claim 1, wherein the ternary copolymer has a weight-average molecular weight Mw of from 2100 to 30000.

7. The ternary copolymer according to claim 1, wherein the ternary copolymer has a molecular weight distribution Mw/Mn of 3.0 or smaller.

8. The ternary copolymer according to claim 1, wherein an amount of double bonds after hydrogenation relative to a total amount of monomer units, as measured through 1H-NMR, is 0.3 mol % or smaller.

9. A lubricant oil composition comprising:
   the ternary copolymer according to claim 1,
   a hydrogenated 1-octene/1-decene/1-dodecene ternary copolymer prepared through hydrogenation of the ternary copolymer, or both.
