FIELD OF THE INVENTION

The present invention relates to pyrrolopyrimidine derivatives, compositions and medicaments containing the same, as well as processes for the preparation and use of such compounds, compositions and medicaments. Such pyrrolopyrimidine derivatives are useful in the treatment of diseases associated with inappropriate IGF-1R and IR activity.

BACKGROUND OF THE INVENTION

Receptor tyrosine kinases (RTKs) have been implicated in cellular signaling pathways that control various cellular functions, including cell division, growth, metabolism, differentiation, and survival, through reversible phosphorylation of the hydroxyl groups of tyrosine residues in proteins. Extracellular signals are transduced via activation of the cell surface receptors, with amplification and propagation using a complex choreography of cascades of protein phosphorylation, and protein dephosphorylation events to avoid uncontrolled signaling. These signaling pathways are highly regulated, often by complex and intermeshed kinase pathways where each kinase may itself be regulated by one or more other kinases and protein phosphatases. The biological importance of these finely tuned systems is such that a variety of cell proliferative disorders have been linked to defects in one or more of the various cell signaling pathways mediated by tyrosine or serine/threonine kinases.

Receptor tyrosine kinases (RTKs) catalyse phosphorylation of certain tyrosyl amino acid residues in various proteins, including themselves, which govern cell growth, proliferation and differentiation. Insulin-like growth factor-1 receptor (IGF-1 R) is a transmembrane tyrosine kinase ubiquitous among fetal and post-natal cell types.

The IGF signaling axis is made up of multiple ligands (IGF-1, IGF-2 and Insulin), at least six high affinity ligand binding proteins and proteases, multiple receptors (IGF-1 R & IGF-2R, IR and IRR), and many other down stream signaling proteins (Pollak, MN et al., Nature Reviews Cancer (2004) 4(7):505-518). The structure and function of the IGF-1 R has been reviewed by Adams et al., Cell. Mol. Life Sci. (2000) 57:1050-1093 and Benito, M et al., Int J Biochem Cell Biol (1996) 28(5):499-510. The receptor is activated by the ligands IGF-1 and IGF-2, which are mitogenic proteins that signal through the IGF-1 R and IR in an endocrine, paracrine or autocrine manner. Activation of the IGF-1 receptor elicits cellular responses which
include cellular proliferation and protection of cells from apoptosis. (Id.)
Overexpression of IGF-1 R leads to malignant transformation of cultured cells, while
downregulation can reverse the transformed phenotype of tumor cells and potentially
render them susceptible to apoptosis. (Id.)

There are two splice variants of the IR gene, the IR-B isoform which regulates
glucose uptake and is expressed in liver, muscle and adipose tissue, and the exon
11 variant human insulin receptor isoform A (IR-A) binds IGF-2 with high affinity and
promotes proliferation and protection from apoptosis (Sciacca L. Oncogene (2002)
21(54):8240-8250). IR-A is predominantly expressed in fetal tissue and malignancies
and at this receptor, IGF-2 is more potent than insulin in stimulating cancer cell
migration. (Sciacca, Oncogene (2002) supra). Insulin receptor-related receptor
(IRR) has 79% homology with the kinase domain of IR and is expressed only in a few
limited cell types (Dandekar, AA et al., Endocrinology (1998) 139(8):3578-3584).

IGF-1 R is a hetero-tetrameric, transmembrane, cell surface receptor. (Benito,
Int J Biochem Cell Biol (1996)) An IGF-1 binding domain is part of the extracellular
alpha-chain of IGF-1 R, whereas the intracellular beta-chain contains the tyrosine
kinase domain. Three tyrosine residues represent autophosphorylation sites,
specifically Tyr1131, Tyr1135, and Tyr1136, within the activation loop of the IGF-1 R

Phosphorylation of all three is required for full receptor activation, and precedes
phosphorylation of juxtamembrane tyrosines and carboxy terminus serines. The
insulin receptor has three similar autophosphorylation sites on the activation loop and
juxtamembrane region. Activation and autophosphorylation results in the recruitment
of multiple docking proteins and the generation of intracellular signaling (Benito, Int J
Biochem Cell Biol (1996)). Once activated, IGF-1 R and IR can phosphorylate or
interact directly with a number of intracellular protein substrates, including IRS-1,
IRS-2, Grb2, Grb10, Grb14, She, SOC, 14.3.3, FAK, or indirectly with other proteins
2(5):559-569). Focal adhesion kinase (FAK) is of particular interest because of its
role as a regulator of cell survival, proliferation, migration and invasion. FAK is
activated by growth factor receptors such as IGF-1 R, by binding through its N-
terminal domain and autophosphorylation at Tyr397. Activated or over expressed
FAK is common in a wide variety of cancers, and may play a role in human

The role of the IGF/IGF-1 R signaling system in cancer has been thoroughly examined over the last 15 years. In particular, the implication of IGF-1 R in human cancer stems from its roles in stimulating mitogenesis, mobility and metastasis and in protecting against apoptosis. (Kurmasheva, Biochim. Biophys. Acta (2006).) Interest has grown with the understanding that in addition to its antiapoptotic and mitogenic roles, IGF/IGF-1 R signaling seems to be necessary for the establishment and continuation of a transformed phenotype. It has been well established that constitutive activation or over expression, often results in non-adherent cell growth, even under serum depleted conditions in vitro, and is associated with the formation of tumors in nude mice. (Kaleko M et al, Mol Cell Biol. (1990) 10(2): 464-473). Perhaps even more importantly, it has been firmly established that cells, in which the gene encoding for IGF-1 R has been deactivated, are totally resistant to transformation by agents which are normally capable of immortalizing normal cells, such as over expression of PDGFR or EGFR, the T antigen of the SV40 virus, the E5 protein of bovine papilloma virus, and activated ras. (DeAngelis T et al., Cell. Physiol. (1995) 164() :214-221; Coppola D et al., Mol. Cell. Biol. (1994) 14(7) :4588-4595; Morrione AJ, Virol. 1995 695300-5303; Sell C et al., Mol. Cell. Biol. (1994) 14(6):3604-3612; Sell C et al., Proc. Natl. Acad. Sci. USA (1993) 90(23):121 121 1221). Thus, IGF-1 R has been identified as the major survival factor that protects from oncogene induced cell death (Harrington et al., EMBO J. (1994) 13():3286-3295). IGF-1 R is expressed in a large number and variety of tumors and the IGFs amplify the tumor growth through their interaction with the receptor. Evidence supporting the role of IGF-1 R in carcinogenesis can be found in studies using monoclonal antibodies directed towards the receptor which inhibit the proliferation of numerous cell lines in culture and in vivo (Arteaga C et al., Cancer Res. (1989) 49(22):6237-6241; Li et al., Biochem. Biophys.

Thus, in virtually all types of human cancers there is a strong association between dysregulation of IGF signaling and carcinogenesis (Bohula EA et al., Anticancer Drugs (2003) 14(9):669-682). Inhibition of IGF-1R expression or function has been shown to block tumor growth and metastasis and also enhance sensitivity to other anti-neoplastic therapies, including cytotoxic drugs and radiation. (Bohula, Anticancer Drugs (2003)).

Specific examples of compounds of the present invention include those recited in the Examples which follow, and pharmaceutically acceptable salts or solvates thereof.

It will be appreciated by those skilled in the art that the compounds of the present invention may be utilized in the form of a pharmaceutically acceptable salt or solvate. The pharmaceutically acceptable salts of the compounds of formula (I) include conventional salts formed from pharmaceutically acceptable (i.e., non-toxic) inorganic or organic acids or bases as well as quaternary ammonium salts. Representative salts include the following: acetate, benzenesulfonate, benzoate, bicarbonate, bisulfate, bitartrate, borate, bromide, calcium edetate, camyslate, carbonate, chloride, clavulanate, citrate, dihydrochloride, edetate, edisylate, estolate, esylate, fumarate, gluceptate, gluconate, glutamate, glycollylarsanilate, hexylresorcinate, hydrabamine, hydrobromide, hydrochloride, hydroxynaphthoate, iodide, isethionate, lactate, lactobionate, laurate, maleate, maleate, mandelate, mesylate, methylobromide, methylnitrate, methylsulfate, monopotassium maleate, mucate, napsylate, nitrate, N-methylglucamine, oxalate, pamoate (embonate), palmitate, pantothenate, phosphate/diphosphate, polygalacturonate, potassium, salicylate, sodium, stearate, subacetate, succinate, tannate, tartrate, teoclate, tosylate, triethiodide, trimethylammonium and valerate. Other salts, such as oxalic, which are not themselves pharmaceutically acceptable, may be useful in the preparation of salts useful as intermediates in obtaining compounds of this invention and these form a further aspect of the invention.
Processes for preparing pharmaceutically acceptable salts and solvates of compounds such as the compounds of formula (I) are conventional in the art. See, e.g., Burger's Medicinal Chemistry And Drug Discovery 5th Edition, Vol 1: Principles And Practice.

As will be apparent to those skilled in the art, in the processes described below for the preparation of compounds of formula (I) certain intermediates may be in the form of pharmaceutically acceptable salts or solvates of the compound. Those terms as applied to any intermediate employed in the process of preparing compounds of formula (I) have the same meanings as noted above with respect to compounds of formula (I). Processes for preparing pharmaceutically acceptable salts and solvates of intermediates are known in the art and are analogous to the process for preparing pharmaceutically acceptable salts and solvates of compounds such as the compounds of formula (I).

The compounds of this invention may be in crystalline or non-crystalline form, and, if crystalline, may optionally be hydrated or solvated. This invention includes within its scope stoichiometric hydrates as well as compounds containing variable amounts of water.

Certain compounds of formula (I) may exist in stereoisomeric forms (e.g. they may contain one or more asymmetric carbon atoms or may exhibit cis-trans isomerism). The individual stereoisomers (enantiomers and diastereomers) and mixtures of these are included within the scope of the present invention. The present invention also covers the individual isomers of the compounds represented by formula (I) as mixtures with isomers thereof in which one or more chiral centres are inverted. It is understood that compounds of formula (I) may exist in tautomeric forms other than that shown in the formula and these are also included within the scope of the present invention.

Since the compounds of formula (I) are intended for use in pharmaceutical compositions it will readily be understood that they are each preferably provided in substantially pure form, for example at least 60% pure, more suitably at least 75% pure and preferably at least 85%, especially at least 98% pure (% are on a weight for weight basis). Impure preparations of the compounds may be used for preparing the more pure forms used in the pharmaceutical compositions.

The compounds of the present invention are inhibitors of one or more IGFR family receptors. By "IGFR inhibitor" is meant a compound which exhibits a pIC$_{50}$ of greater than 5.5 against at least one IGFR family receptor in the IGFR inhibition
enzyme assay described below (TR-FRET) and/or an IC\textsubscript{50} of below about 1.0 µM potency against IGFR cellular autophosphorylation and/or in cell proliferation of a cell line that is dependent upon IGF signaling (e.g. Colo205, NCI-H929) in at least one of the cellular assay described below. In a more particular embodiment "IGFR inhibitor" refers to a compound which exhibits a pIC\textsubscript{50} of greater than 7.6 against at least one IGFR family receptor in the IGFR inhibition enzyme assay described below. In an alternative particular embodiment "IGFR inhibitor" refers to a compound which exhibits an IC\textsubscript{50} of below about 250 nM potency against IGFR cellular autophosphorylation and/or in cell proliferation of a cell line that is dependent upon IGF signaling (e.g. Colo205, NCI-H929) in at least one of the cellular assay described below.

The present invention is not limited to compounds of formula (I) which are selective for IGFR family receptor kinases; rather, the present invention expressly contemplates compounds of formula (I) which may also possess activity against receptors in addition to the IGFR family receptors. For instance, the compounds of formula (I) are selective for insulin receptor (IR) family kinases. Several compounds of the present invention also possess activity against, for instance, one or more of the Jnk1, Jnk2, and Jnk3, insulin related receptor (IRR), and anaplastic lymphoma kinase (ALK).

With regard to Anaplastic lymphoma kinase, ALK is a receptor tyrosine kinase believed to be involved in the pathogenesis of various cancers, and is named for its involvement in anaplastic large cell lymphoma (ALCL), a sub-type of non-Hodgkins lymphoma (Chiarle et al. (2008) Nature 8, 11-23).

Dysregulated activation of ALK in cancers is believed to occur primarily by fusion of the C-terminal intracellular domain containing the catalytic activity with one of several proteins having an oligomerization domain that drives the dimerization of the receptor (Duyster et al (2001) Oncogene 20, 5623-5637). Dimerization of the ALK fusion proteins results in autophosphorylation and activation of downstream signal transduction cascades, ultimately leading to uncontrolled cell proliferation.

Full-length ALK expression with or without gene amplification has been observed in neuroblastomas, rhabdomyosarcomas, and breast cancer in the absence of gene fusion (Chiarle et al. (2008)).

ALK fusions are found in some cases of inflammatory myofibroblastic tumors and rare cases of diffuse large B-cell lymphomas (DLBCL). In these cases, fusion of the ALK gene may play a role in tumorigenesis (Chiarle et al. (2008)). NPM-ALK has
been found to be a transforming oncogene in in vitro models [Bai et al. (1998) Mol.
Cell Biol. 18, 6951-6961) and in transgenic mice (Chiarle et al. (2003) Blood 101,
1919-1927), where expression of NPM-ALK in bone marrow precursor cells results
in B-and T-cell lymphomas. More recently, fusions of ALK have been observed in
lung cancers (Soda et al. (2007) Nature 448, 561-567; Rikova et al. (2007) Cell, 131,

Previously, a potent selective inhibitor of ALK, NVP-TAE68 (5-chloro-2,4-
diaminophenylpyrimidine), has been shown to be active against ALCL cells in vitro
270-275). The compound inhibited ALK autophosphorylation, resulting in cell cycle
arrest and apoptosis. PF2341066, a dual inhibitor of the Met tyrosine kinase and
ALK has also been shown to inhibit the growth of ALCL cells in experimental systems
in vitro and in vivo (Christensen et al. (2007) Mol. Cancer Ther. 6, 3314-3322). A
series of fused pyrrolocarbazole-derived molecules (Wan et al. (2006) Blood, 107,
1617-1623), pyrazoloisoquinolines((Li and Morris (2007)), and 5-aryl-pyridine-
carboximides (Li et al (2006) J. Med. Chem. 49, 1006-1015) have also been reported
to inhibit ALK activity and the proliferation of ALCL cells in vitro.

The present invention further provides compounds of formula (I) for use in
medical therapy in a mammal, e.g. a human. In particular, the present invention
provides compounds of formula (I) for use in the treatment of a condition mediated by
at least one IGFR family receptor in a mammal, and, advantageously, conditions
mediated by inappropriate activity of one or more IGFR family receptor in a mammal.

The inappropriate IGFR family receptor activity referred to herein is any IGFR
receptor activity that deviates from the normal IGFR family receptor activity expected
in a particular mammalian subject. Inappropriate IGFR family receptor activity may
take the form of, for instance, an abnormal increase in activity, or an aberration in the
timing and/or control of IGFR family receptor activity. Such inappropriate activity may
result then, for example, from overexpression or mutation of the protein kinase or
ligand leading to inappropriate or uncontrolled activation of the receptor.

Furthermore, it is also understood that unwanted IGFR family receptor activity may
reside in an abnormal source, such as a malignancy. That is, the level of IGFR family
activity does not have to be abnormal to be considered inappropriate, rather the
activity derives from an abnormal source.
The compounds of formula (I) and salts and solvates thereof, are believed to have anticancer and antitumor activity as a result of inhibition of one or more IGFR family receptor and its effect on selected cell lines whose growth is dependent on IGFR family activity.

The present invention provides compounds of formula (I) for use in the treatment of a susceptible neoplasm. "Susceptible neoplasm" as used herein refers to neoplasms which are susceptible to treatment with a IGFR inhibitor. Neoplasms which have been associated with inappropriate activity of one or more IGFR family receptors and are therefore susceptible to treatment with a IGFR inhibitor are known in the art, and include both primary and metastatic tumors and cancers. For example, susceptible neoplasms within the scope of the present invention include but are not limited to breast cancer, sarcomas, lung cancer (including non-small cell lung carcinoma), prostate cancer, colorectal cancer, renal cancer, pancreatic cancer, hematologic cancers (including multiple myeloma), neuroblastomas, gliomas, head and neck cancer, thyroid cancer, hepatocarcinoma, ovarian cancer, vulval cancer, cervical cancer, endometrial cancer, testicular cancer, bladder cancer, esophageal cancer, gastric cancer, nasopharangeal cancer, buccal cancer, cancer of the mouth, gastrointestinal stromal tumor, and skin cancer (including melanoma). More particularly, susceptible neoplasms may be selected from breast cancer, sarcoma, lung cancer, non-small cell lung carcinoma, prostate cancer, colorectal cancer, pancreatic cancer, hematologic cancers, multiple myeloma, head and neck cancer, and ovarian cancer.

The present invention provides methods for the treatment of several conditions in a mammal in need thereof, all of which comprise the step of administering a therapeutically effective amount of a compound of formula (I). The mammal in need of treatment with a compound of the present invention is advantageously a human.

As used herein, the term "treatment" refers to alleviating the specified condition, eliminating or reducing the symptoms of the condition, slowing or eliminating the progression of the condition and preventing or delaying the reoccurrence of the condition in a previously afflicted subject.

As used herein, the term "therapeutically effective amount" means an amount of a compound of formula (I) which is sufficient, in the subject to which it is administered, to elicit the biological or medical response of a cell culture, tissue, system, mammal (including human) that is being sought, for instance, by a
researcher or clinician. The term also includes within its scope amounts effective to enhance normal physiological function. For example, a therapeutically effective amount of a compound of formula (I) for the treatment of a condition mediated by at least one IGFR family receptor is an amount sufficient to treat the condition in the subject. Similarly, a therapeutically effective amount of a compound of formula (I) for the treatment of a susceptible neoplasm is an amount sufficient to treat the susceptible neoplasm in the subject. In one embodiment of the present invention, a therapeutically effective amount of a compound of formula (I) is an amount sufficient to regulate, modulate, bind or inhibit at least one IGFR family receptor.

The precise therapeutically effective amount of the compounds of formula (I) will depend on a number of factors including, but not limited to, the age and weight of the subject being treated, the precise condition requiring treatment and its severity, the nature of the formulation, and the route of administration, and will ultimately be at the discretion of the attendant physician or veterinarian. Typically, the compound of formula (I) will be given for treatment in the range of 0.1 to 200 mg/kg body weight of recipient (mammal) per day and more usually in the range of 1 to 100 mg/kg body weight per day. Acceptable daily dosages, may be from about 0.1 to about 200 mg/day, and preferably from about 0.1 to about 100 mg/day. Thus, for a 70kg adult human being treated for a condition mediated by at least one IGFR family receptor, the actual amount per day would usually be from 5 to 700 mg and this amount may be given in a single dose per day or more usually in a number (such as two, three, four, five or six) of sub-doses per day or, alternatively, on an alternative dosing schedule such as weekly or monthly, such that the total daily dose is the same. A therapeutically effective amount of a salt or solvate, may be determined as a proportion of the therapeutically effective amount of the compound of formula (I) per se. It is envisaged that similar dosages would be appropriate for treatment of the other conditions referred to above.

The present invention also provides the use of a compound of formula (I) for the preparation of a medicament for the treatment of condition mediated by at least one IGFR family receptor in a mammal (e.g., a human) in need thereof. The present invention further provides the use of a compound of formula (I) for the preparation of a medicament for the treatment of a susceptible neoplasm in a mammal.

While it is possible that, for use in therapy, a therapeutically effective amount of a compound of formula (I) may be administered as the raw chemical, it is typically presented as the active ingredient of a pharmaceutical composition or formulation.
Accordingly, the invention further provides a pharmaceutical composition comprising a compound of the formula (I). The pharmaceutical composition may further comprise one or more pharmaceutically acceptable carriers, diluents, and/or excipients. The carrier(s), diluent(s) and/or excipient(s) must be acceptable in the sense of being compatible with the other ingredients of the formulation and not deleterious to the recipient thereof. In accordance with another aspect of the invention there is also provided a process for the preparation of a pharmaceutical formulation including admixing a compound of the formula (I) with one or more pharmaceutically acceptable carriers, diluents and/or excipients.

Pharmaceutical formulations may be adapted for administration by any appropriate route, for example by the oral (including buccal or sublingual), rectal, nasal, topical (including buccal, sublingual or transdermal), vaginal or parenteral (including subcutaneous, intramuscular, intravenous or intradermal) route. Such formulations may be prepared by any method known in the art of pharmacy, for example by bringing into association the active ingredient with the carrier(s) or excipient(s).

Pharmaceutical formulations adapted for oral administration may be presented as discrete units such as capsules or tablets; powders or granules; solutions or suspensions in aqueous or non-aqueous liquids; edible foams or whips; or oil-in-water liquid emulsions or water-in-oil liquid emulsions.

For instance, for oral administration in the form of a tablet or capsule, the active drug component can be combined with an oral, non-toxic pharmaceutically acceptable inert carrier such as ethanol, glycerol, water and the like. Powders are prepared by comminuting the compound to a suitable fine size and mixing with a similarly comminuted pharmaceutical carrier such as an edible carbohydrate, as, for example, starch or mannitol. Flavoring, preservative, dispersing and coloring agent can also be present.

Capsules are made by preparing a powder mixture, as described above, and filling formed gelatin sheaths. Glidants and lubricants such as colloidal silica, talc, magnesium stearate, calcium stearate or solid polyethylene glycol can be added to the powder mixture before the filling operation. A disintegrating or solubilizing agent such as agar-agar, calcium carbonate or sodium carbonate can also be added to improve the availability of the medicament when the capsule is ingested.

Moreover, when desired or necessary, suitable binders, lubricants, disintegrating agents and coloring agents can also be incorporated into the mixture.
Suitable binders include starch, gelatin, natural sugars such as glucose or beta-lactose, corn sweeteners, natural and synthetic gums such as acacia, tragacanth or sodium alginate, carboxymethylcellulose, polyethylene glycol, waxes and the like. Lubricants used in these dosage forms include sodium oleate, sodium stearate, magnesium stearate, sodium benzoate, sodium acetate, sodium chloride and the like. Disintegrators include, without limitation, starch, methyl cellulose, agar, bentonite, xanthan gum and the like. Tablets are formulated, for example, by preparing a powder mixture, granulating or slugging, adding a lubricant and disintegrant and pressing into tablets. A powder mixture is prepared by mixing the compound, suitably comminuted, with a diluent or base as described above, and optionally, with a binder such as carboxymethylcellulose, an alginate, gelatin, or polyvinyl pyrrolidone, a solution retardant such as paraffin, a resorption accelerator such as a quaternary salt and/or an absorption agent such as bentonite, kaolin or dicalcium phosphate. The powder mixture can be granulated by wetting with a binder such as syrup, starch paste, acacia mucilage or solutions of cellulosic or polymeric materials and forcing through a screen. As an alternative to granulating, the powder mixture can be run through the tablet machine and the result is imperfectly formed slugs broken into granules. The granules can be lubricated to prevent sticking to the tablet forming dies by means of the addition of stearic acid, a stearate salt, talc or mineral oil. The lubricated mixture is then compressed into tablets. The compounds of the present invention can also be combined with a free flowing inert carrier and compressed into tablets directly without going through the granulating or slugging steps. A clear or opaque protective coating consisting of a sealing coat of shellac, a coating of sugar or polymeric material and a polish coating of wax can be provided. Dyestuffs can be added to these coatings to distinguish different unit dosages.

Oral fluids such as solution, syrups and elixirs can be prepared in dosage unit form so that a given quantity contains a predetermined amount of the compound. Syrups can be prepared by dissolving the compound in a suitably flavored aqueous solution, while elixirs are prepared through the use of a non-toxic alcoholic vehicle. Suspensions can be formulated by dispersing the compound in a non-toxic vehicle. Solubilizers and emulsifiers such as ethoxylated isostearyl alcohols and polyoxyethylene sorbitol ethers, preservatives, flavor additive such as peppermint oil or natural sweeteners or saccharin or other artificial sweeteners, and the like can also be added.
Where appropriate, dosage unit formulations for oral administration can be microencapsulated. The formulation can also be prepared to prolong or sustain the release as for example by coating or embedding particulate material in polymers, wax or the like.

The compounds of formula (I) may be administered by inhalation, such as by metered dose pressurised aerosols, metered dose inhalers, dry powder inhalers, nebulizers or insufflators.

According to one embodiment, the compound is provided in the form of a dry powder composition. As such, the composition is suitable for inhaled administration and may be incorporated into a plurality of sealed dose containers (e.g. containing the dry powder composition) mounted in a strip or ribbon inside a suitable inhalation device. The container is rupturable or peel-openable on demand and the dose of the dry powder composition may be administered by inhalation via a device such as the DISKUS™ device, marketed by GlaxoSmithKline. The DISKUS™ inhalation device is, for example, described in GB2242134A.

According to another embodiment, the compounds of formula (I) may be formulated into spray compositions for inhalation which may, for example, be formulated as aqueous solutions or suspensions or as aerosols delivered from pressurised packs, such as a metered dose inhaler (MDI), with the use of a suitable liquefied propellant. Aerosol compositions suitable for inhalation can be either a suspension or a solution and generally contain a compound of formula (I) or a pharmaceutically acceptable salt or solvate thereof and a suitable propellant such as a fluorocarbon or hydrogen-containing chlorofluorocarbon or mixtures thereof, particularly hydrofluoroalkanes, especially 1,1,1,2-tetrafluoroethane, 1,1,1,2,3,3,3-heptafluoro-n-propane or a mixture thereof. The aerosol composition may optionally contain additional formulation excipients well known in the art such as surfactants e.g. oleic acid, lecithin or an oligolactic acid derivative e.g. as described in WO94/21229 and WO98/34596 and cosolvents e.g. ethanol.

The compounds of formula (I) can also be administered in the form of liposome delivery systems, such as small unilamellar vesicles, large unilamellar vesicles and multilamellar vesicles. Liposomes can be formed from a variety of phospholipids, such as cholesterol, stearylamine or phosphatidylcholines.

The compounds of formula (I) may also be delivered by the use of monoclonal antibodies as individual carriers to which the compound molecules are coupled. The compounds may also be coupled with soluble polymers as targetable
drug carriers. Such polymers can include polyvinylpyrrolidone, pyran copolymer, polyhydroxypropylmethacrylamide-phenol, polyhydroxyethylaspartamidephenol, or polyethyleneoxidepolylysine substituted with palmitoyl residues. Furthermore, the compounds may be coupled to a class of biodegradable polymers useful in achieving controlled release of a drug, for example, poly lactic acid, polylactone, polyhydroxybutyric acid, polyorthoesters, polyacetals, polydihydropyran, polycyanoacrylates and cross-linked or amphipathic block copolymers of hydrogels.

Pharmaceutical formulations adapted for transdermal administration may be presented as discrete patches intended to remain in intimate contact with the epidermis of the recipient for a prolonged period of time. For example, the active ingredient may be delivered from the patch by iontophoresis as generally described in Pharmaceutical Research, 3(6), 318 (1986).

Pharmaceutical formulations adapted for topical administration may be formulated as ointments, creams, suspensions, lotions, powders, solutions, pastes, gels, sprays, aerosols or oils.

For treatments of the eye or other external tissues, for example mouth and skin, the formulations are preferably applied as a topical ointment or cream. When formulated in an ointment, the active ingredient may be employed with either a paraffinic or a water-miscible ointment base. Alternatively, the active ingredient may be formulated in a cream with an oil-in-water cream base or a water-in-oil base.

Pharmaceutical formulations adapted for topical administrations to the eye include eye drops wherein the active ingredient is dissolved or suspended in a suitable carrier, especially an aqueous solvent.

Pharmaceutical formulations adapted for topical administration in the mouth include lozenges, pastilles and mouth washes.

Pharmaceutical formulations adapted for rectal administration may be presented as suppositories or as enemas.

Pharmaceutical formulations adapted for nasal administration wherein the carrier is a solid include a coarse powder having a particle size for example in the range 20 to 500 microns which is administered in the manner in which snuff is taken, i.e. by rapid inhalation through the nasal passage from a container of the powder held close up to the nose. Suitable formulations wherein the carrier is a liquid, for administration as a nasal spray or as nasal drops, include aqueous or oil solutions of the active ingredient.
Pharmaceutical formulations adapted for administration by inhalation include fine particle dusts or mists, which may be generated by means of various types of metered, dose pressurised aerosols, nebulizers or insufflators.

Pharmaceutical formulations adapted for vaginal administration may be presented as pessaries, tampons, creams, gels, pastes, foams or spray formulations. Pharmaceutical formulations adapted for parenteral administration include aqueous and non-aqueous sterile injection solutions which may contain anti-oxidants, buffers, bacteriostats and solutes which render the formulation near isotonic with the blood of the intended recipient; and aqueous and non-aqueous sterile suspensions which may include suspending agents and thickening agents. The formulations may be presented in unit-dose or multi-dose containers, for example sealed ampoules and vials, and may be stored in a freeze-dried (lyophilized) condition requiring only the addition of the sterile liquid carrier, for example water for injections, immediately prior to use. Extemporaneous injection solutions and suspensions may be prepared from sterile powders, granules and tablets.

It should be understood that in addition to the ingredients particularly mentioned above, the formulations may include other agents conventional in the art having regard to the type of formulation in question, for example those suitable for oral administration may include flavouring agents.

In the above-described methods of treatment and uses, a compound of the invention may be employed alone, in combination with one or more other compounds of the invention, or in combination with other therapeutic methods or agents. In particular, in methods of treating a condition improved by inhibition of IGF-1 R and in methods of treating susceptible neoplasms, the compound of the invention may be used alone or in combination with one or more of a chemotherapeutic, a hormonal and/or antibody agent, surgical therapy, and radiotherapy.

The term "chemotherapeutic" as used herein refers to any chemical agent having a therapeutic effect on the subject to which it is administered. "Chemotherapeutic" agents include but are not limited to anti-neoplastic agents, analgesics and anti-emetics. As used herein, "anti-neoplastic agents" include both cytostatic and cytotoxic agents. Anti-emetics include but are not limited to 5HT₃ antagonists such as ondansetron, granisetron, and the like; metaclopramide; dexamethasone and neurokinin-1 antagonists.

As an additional aspect, the present invention provides the methods of treatment and uses as described above, which comprise administering a compound
of the invention together with at least one chemotherapeutic agent. In one particular embodiment, the chemotherapeutic agent is an anti-neoplastic agent. In another embodiment, the present invention provides a pharmaceutical composition as described above further comprising at least one other chemotherapeutic agent, more particularly, the chemotherapeutic agent is an anti-neoplastic agent.

The compounds of the invention and at least one additional anti-neoplastic therapy may be employed in combination concomitantly or sequentially in any therapeutically appropriate combination. The administration of a compound of the invention with one or more other anti-neoplastic agents may be in combination in accordance with the invention by administration concomitantly in (1) a unitary pharmaceutical composition including both or all compounds or (2) separate pharmaceutical compositions each including one of the compounds. The combination may be administered separately in a sequential manner wherein one anti-neoplastic agent is administered first and the other(s) second or vice versa.

Such sequential administration may be close in time or remote in time.

When a compound of the invention is used in combination with a chemotherapeutic agent, the dose of each compound may differ from that when the compound is used alone. Appropriate doses will be readily appreciated by those skilled in the art. The appropriate dose of the compound(s) of the invention and the other therapeutically active agent(s) and the relative timings of administration will be selected in order to achieve the desired combined therapeutic effect, and are within the expertise and discretion of the attendant clinician.

Among the many chemotherapeutic agents, which may be used in combination with a compound of the present invention, are anti-proliferative/anti-neoplastic agents. Anti-neoplastic agents may induce anti-neoplastic effects in a cell-cycle specific manner, i.e., are phase specific and act at a specific phase of the cell cycle, or bind DNA and act in a non cell-cycle specific manner, i.e., are non-cell cycle specific and operate by other mechanisms. Both types of anti-neoplastic agents may be employed in combination with the compounds of the present invention.

Non-receptor kinases and agents, which inhibit non-receptor tyrosine kinase function, are described in Sinha, S. and Corey, SJ., (1999) J. Hematother. Stem Cell Res. 8:465-80; and Bolen, J.B. and Brugge, J.S., (1997) Annu. Rev. of Immunol. 15:371-404.

Examples of Plk inhibitors are described in PCT Publication No. WO04/014899 to GlaxoSmithKline.

Inhibitors of urokinase, also referred to as urokinase-type Plasminogen Activator (uPA), expression may be used in combination with the compounds of the present invention in the compositions and methods described above.

Inhibitors of kinases involved in the IGF signalling axis may also be useful in combination with the compounds of the present invention. Such inhibitors include but are not limited to inhibitors of JNK1/2/3, PI3K, AKT and MEK, and 14.3.3 signalling inhibitors.

Cell cycle signaling inhibitors, including inhibitors of cyclin dependent kinases (CDKs) are also useful in combination with the compounds of the invention in the compositions and methods described above. Examples of cyclin dependent kinases,

Receptor kinase angiogenesis inhibitors may also find use in the present invention. Inhibitors of angiogenesis related to VEGFR and TIE-2 are discussed above in regard to signal transduction inhibitors (both are receptor tyrosine kinases). Other inhibitors may be used in combination with the compounds of the present invention. For example, anti-VEGF antibodies, which do not recognize VEGFR (the receptor tyrosine kinase), but bind to the ligand; small molecule inhibitors of integrin (\(\alpha_v\beta_3\)) that inhibit angiogenesis; endostatin and angiostatin (non-RTK) may also prove useful in combination with the compounds of the invention. Examples of antisense therapies include those directed towards the targets described above such as ISIS 2503 and gene therapy approaches such as those using thymidine kinase or cytosine deaminase.

Agents used in immunotherapeutic regimens may also be useful in combination with the compounds of the invention. Immunotherapeutic regimens include ex-vivo and in-vivo approaches to increasing immunogenicity of patient tumor cells such as transfection with cytokines (IL-2, IL-4, GMCSF and MCFS), approaches to increase T-cell activity, approaches with transfected immune cells and approaches with anti-idiotypic antibodies.

Agents used in proapoptotic regimens (e.g., Bcl-2 antisense oligonucleotides) may also be used in combination with the compounds of the invention. Members of the Bcl-2 family of proteins block apoptosis. Upregulation of Bcl-2 has therefore been linked to chemoresistance. Studies have shown that the epidermal growth factor (EGF) stimulates anti-apoptotic members of the Bcl-2 family (i.e., mcl-1). Therefore, strategies designed to downregulate the expression of Bcl-2 in tumors have demonstrated clinical benefit and are now in Phase II/III trials, namely Genta’s G3139 bcl-2 antisense oligonucleotide. Such proapoptotic strategies using the antisense oligonucleotide strategy for Bcl-2 are discussed in Water, J.S., et al., J.
Compounds of formula (I) may be prepared using the processes described below. In all of the schemes described below, it is understood that protecting groups may be employed where necessary in accordance with general principles known to those of skill in the art, for example, see T. W. Green and P. G. M. Wuts (1991) Protecting Groups in Organic Synthesis, John Wiley & Sons. These groups may be removed at a convenient stage of the compound synthesis using methods known to those of skill in the art. The selection of processes as well as the reaction conditions and order of their execution shall be consistent with the preparation of compounds of formula (I).

The invention also provides a process for preparing the compound of formula (I) and pharmaceutically acceptable derivatives thereof. Specifically, compounds of formula (I) are prepared by reacting the three main components of the compounds, referred to herein as the head, core, and tail of the compounds.

**Synthesis and Schemes**

Each compound of formula (I) may be conveniently prepared by separately preparing three constituents of the compound and subsequently combining those constituents to form the compound (I). For convenience, the three constituents are referred to herein as the head (II), the core (III), and the tail (IV). For convenience, the head, core, and tail nomenclature is used throughout to refer to each constituent when referred to individually, and also to refer to the corresponding moiety when described in the context of head/core, tail/core, and/or head/core/tail combinations.

The head component of the invented compounds is an o-amino carboxamide represented by formula (II):

![Head Component](image)

wherein substituents R^4, R^5, and R^6 are as defined above.

The core component of the invented compounds is pyrrolopyrimidine represented by formula (III):
wherein each of substituents $L_1$ and $L_2$ represent a leaving group, e.g. a halogen, preferably chlorine, or OTF, and $X$ represents a protecting group, e.g. sulfonamide or alcholated alkyl, e.g. allyl, benzyl, or SEM.

The tail component of the invented compounds is a substituted aniline represented by formula (IV):

wherein substituents $R^7$, $R^8$, $R^9$, and $R^{10}$ are as defined above.
The head (II), core (III), and tail (IV) of the compounds may be combined, for instance, with the synthetic route shown in Scheme 1:

As shown, a core of formula (III), for instance where L_1 and L_2 are Cl and X is sulfonyl chloride (CiventiChem, Research Triangle Park, NC), is reacted with a head of formula (II) in the presence of a tertiary amine, e.g. DIPEA, and a polar protic solvent, preferably a hindered alcoholic solvent, e.g. iPrOH, at heat, e.g. 102°C. The result is the compound of formula (V).

Compound of formula (V) is reacted with a tail of formula (IV) under a series of three sequential reaction conditions. First, an acid, e.g. HCl (2 eq.), is used with a catalyst, e.g. an iodine salt such as KI or TBAI, and a polar protic solvent having low nucleophilicity, e.g. TFE, at heat, e.g. 85°C. Second, an amine-containing heteroatom nucleophile, e.g. NH_4OH or R^3NH_2, is added in solvent, e.g. THF or THF/H_2O. Third, a base, e.g. NaOMe, in solvent, e.g. MeOH/THF, is used to remove the protecting group X, resulting in the compound of formula (I).

Removal of the protecting group, e.g. sulfonyl chloride, is preferably accomplished with the base with a mixture of polar protic solvent and ethereal solvent, e.g. MeOH/THF. Alternatively, when substituents R^4 and R^6 are both...
halogen, e.g. F, removal of the protecting group is preferably accomplished with a base, e.g. NaOH, in solvent, e.g. THF, under heat, e.g. 120°C by microwave.

Compound (I) is converted from compound (V) by displacement of leaving group L₂ with the functionalized aniline (IV) according to Scheme 2.

A more particular description of the tail addition is shown in Scheme 2. Displacement of the L₂ group by the functionalized aniline can be carried out using the carboxamide group as a means of internal activation. Treatment of the functionalized pyrrolopyrimidine with an aniline (IV), acid, e.g. HCl, optional iodide source catalyst, e.g. KI, and solvent, e.g. TFE, at heat, e.g. 80°C for a length of typically 1 or 2 days affords the isolable tetracyclic species (VI). Reaction of the tetracyclic species (VI) to an amine-containing heteroatom nucleophile, e.g. NH₄OH or R₃NH₂, added in solvent, e.g. THF or THF/H₂O, affords ring opened, rearomatized products (VII) and (VIII). The alkyl group of the nucleophile is retained in the compounds (VII) and (VIII).
Referring to Scheme 3, the head (II) may be installed on the core (III) at the A-L₁ position by displacement of the 4-L₁ group using either an acid or a base.

Displacement under basic conditions with base, e.g. iPr₂EtN, and polar protic solvent, e.g. iPrOH, at heat, e.g. 85°C (2-5 days), is preferable for most classes of compounds (except for compounds II where the R₄ position is halogenated). Displacement using an acid is preferred for headgroups (II) having a halogen at position R₄. In these cases 4-L₁ displacement can be efficiently carried out using an acid, e.g. trifluoroacetic acid, in a polar protic solvent, e.g. trifluoroethanol, at heat, e.g. 80°C.

A variety of aniline tails (IV) having substituents R⁷, R⁸, R⁹, and R¹⁰ as defined herein, may be prepared in accordance with schemes 4-9.

Scheme 4
As shown in Scheme 4, 4-piperidinyl aniline tails can be prepared from commercially available starting materials, such as 2-methyl-4-chloro-nitrobenzene and 2-methoxy-4-chloro-nitrobenzene (both from Aldrich). Suzuki cross-coupling (Palladium Reagents and Catalysts, Jiro Tsuji, 2004, John Wiley and Sons, Ltd.) using a palladium source and base with either 3- or 4-pyridyl boronic acid gives the corresponding 4-pyridyl nitrobenzenes in high yield. The pyridine is alkylated with any of a variety of primary alkyl halides, e.g. alkyl iodide or allyl bromide, in solvent, e.g. pinacolone. Reduction of the resulting pyridinium with, for example, a reducing agent and solvent, e.g. NaBH₄/THF, gives the corresponding 3- or 4-tetrahydropyridine analogs (XII and XIII, respectively). If an allyl halide is used (see sequence 1-5 for compound XI), then an alkyl substitution may be incorporated by removal of the allyl with a deprotecting agent, e.g. a palladium source such as Pd(PPh₃)₄, optionally in presence of a cation trapping agent, e.g. dimethylbarbituric acid, to provide N-dealkylated tetrahydropyridines. The N-dealkylated tetrahydropyridines may be subsequently alkylated with alkyl iodides or bromides in polar solvent and base. Compounds XII and XIII may be selectively reduced with a reducing agent and hydrogen source, e.g. with Fe(III) and hydrazine (hereinafter referred to as “selective nitro reduction”), to provide 4-piperidinyl aniline tails IVa and
IVd, respectively. Alternatively, compounds XII and XIII may be exhaustively reduced with a palladium source and hydrogen source in solvent, e.g. with Pd/C, H₂, EtOH under pressure, such as 60 psi (hereinafter referred to as "exhaustive reduction") to provide 4-piperidinyl aniline tails IVb and IVe, respectively. For compounds XII where the alkyl substituent is an allyl group, the allyl may be replaced by a substitute alkyl group, including branched alkyls (see discussion with respect to sequence 1-5 for compound XI above). The resultant compound is then subjected to selective nitro reduction to provide compounds IVc with a branching alkyl group on the piperidyl nitrogen.

As shown in Scheme 5, 4-piperazine 2-methoxy nitrobenzene tails can be generated via Buchwald/Hartwig coupling with, for instance, Pd₂(dba)₃, xantphos, dioxane, and CSCO₃, (see Yin, Jingjun & Buchwald, Stephen. J. Am. Chem. Soc. 2002, 124, 6043-6048) of a functionalized piperazine, e.g. PG = Me, iPr, Boc, etc., with an aromatic halide. The tail may be selectively nitro reduced to provide a directly functionalized aniline IVf where the protecting group (PG) remains as a substituent of the tail.
Alternatively, the protecting group (PG) may be removed from the piperazine with an acid and solvent, e.g. TFA/CH$_2$Cl$_2$, to form compound XIII. Compound XIII may be alkylated and then exhaustively nitro reduced to form aniline tail IVg. Alternatively, compound XIII may be acylated with an acylating agent, e.g. Ac$_2$O, base, e.g. Et$_3$N, and solvent, e.g. CH$_2$Cl$_2$, and then exhaustively nitro reduced to form aniline tail IVh.

Scheme 5a

As shown in scheme 5a, 4-homopiperazine 2-methoxy nitrobenzene tails can be generated by coupling an aromatic halide (IVba) with a functionalized homopiperazine, e.g. PG = Boc, under basic conditions, e.g. K$_2$CO$_3$ / DMSO, to form an intermediate which is deprotected with an acid, e.g. TFA/CH$_2$Cl$_2$, reacted with an electrophile, e.g. MeI, iPrI, CISO$_2$Me, under basic conditions, e.g. K$_2$CO$_3$ or DIPEA, and subsequently hydrogenated to form compound IVbb.

2-methoxy-4-alkoxy anilines can be prepared by reaction of aromatic (IVba) with an alcohol, e.g. HO-R" where R" is as shown, under basic conditions, e.g. K$_2$CO$_3$ / DMSO, followed by hydrogenation, e.g. H$_2$ and Pd/C, to provide compounds IVbc and IVbd.
Similarly, reaction of (IVba) with (1-propyl-4-piperidinyl)methanol, followed by subsequent deprotection with acid, e.g. TFA, alkylation, e.g. propyl iodide, and nitro-reduction gave aniline (IVfa).

As shown in scheme 6, 4-piperidinyl 2-methoxy nitrobenzenes can be prepared via direct displacement of 4-fluoro nitrobenzenes (XIV) (commercially available, ex. R⁸=F, R¹⁰=H from Aldrich; or literature compounds, ex. R⁸=R¹⁰=H as shown in Bolton, et al., Nucleophilic displacement in polyhaloaromatic compounds, Journal of the Chemical Society, Perkin Transactions 2: Physical Organic Chemistry (1972-1999) (1978),(2), 141-4; or R⁸=H, R¹⁰=Me as shown in Van Zandt, et al., Design and synthesis of highly potent and selective (2-arylcarbamoyl-phenoxy)-acetic acid inhibitors of aldose reductase for treatment of chronic diabetic complications, Bioorganic & Medicinal Chemistry (2004), 12(21), 5661-5675). The 4-
piperidinyl 2-methoxy nitrobenzene may be subject to SNAR displacement (reaction with an amine nucleophile, base, e.g. K₂CO₃, and polar solvent, e.g. DMSO) to provide aminated intermediate XV and subsequent selective nitro reduction to obtain aniline tails IVj. Alternatively, displacement with 4-piperidinol and oxidation with the Dess-Martin Periodinane (see Tohma, Hirofumi & Kita, Yasuyuki. Adv. Synth. Catal. 2004, 346, 111-124) gives the corresponding functionalized piperidinone, which can be subjected to reductive amination with a proton source, e.g. AcOH, buffer, e.g. Et₃N, solvent, e.g. CICH₂CH₂Cl, acid stable hydride source, e.g. Na(OAc)₃BH, and primary or secondary amine to give bicyclic 4-piperidinyl 2-methoxy anilines IVk, after nitro-reduction, where the amine provides the substituent of the piperidine ring.

Where the amine is a Boc protected piperazine, the piperazine of compound IVk may be alkylated by the steps of Boc deprotection, alkylation, and selective nitro reduction, as described above, to produce aniline tail IVn.

Alternatively, 4-fluoro nitrobenzenes (XIV) may be used to prepare the compounds of (IVm) via SNAR displacement using a Boc protected, followed by Boc deprotection, followed by alkylation with alkylation agent, e.g. ethylene methyl sulfone, a base, e.g. Et₃N, solvent, e.g. CH₂Cl₂, followed by selective nitro reduction.
As shown in Scheme 7, commercially available 3-amino nitrobenzenes (for example $R^7=\text{Me}$ from Alpha Aesar, Ward Hill, MA, $R^7=\text{F}$ from 3B Medical Systems, Libertyville, IL, $R^7=\text{Alrdich}, R^7=\text{OCF}_3$ from Matrix Scientific, Columbia, SC) can be acylated with an acylating agent, e.g. N,N-dimethylglycyl chloride in the presence of a base, e.g. Et$_3$N, catalyst, e.g. DMAP, and solvent, e.g. CH$_2$CL$_2$. Subsequent exhaustive reduction of the nitro gives the corresponding functionalized 3-aminoacyl anilines IVp. If a-bromo-acetyl chloride is used rather than N,N-dimethylglycyl chloride, trapping of the intermediate $\alpha$-bromo-acetyl amine with an appropriate nucleophile (pyrrolidine in the example above) with base, e.g. K$_2$CO$_3$, catalyst KI, and solvent, e.g. MeCN, and subsequent exhaustive reduction affords further functionalized 3-aminoacyl amines IVq. Alternatively, the compound may be subject to electron transfer reduction after trapping with a metal, e.g. SnCL$_2$, and acid, e.g. AcOH.
Alternatively, 2-methoxy-5-acyl anilines IVr may be made directly from commercially available 2-methoxy-5-nitro aniline, Aldrich. The NH₂ of the aniline is first protected with a protecting agent, e.g. BoC₂O, solvent, e.g. THF, and base, e.g. Et₃N, then exhaustively reduced, then acylated with N,N-dimethylglycyl chloride (see acylation of IVp), and then deprotected with acid, e.g. TFA, and solvent, e.g. CH₂Cl₂.

Scheme 8

As shown in scheme 8, 5-piperidinyl 2-methoxy anilines IVs were generated from Suzuki cross-coupling reactions (see scheme 4) with 5-bromo-2-methoxy nitrobenzene (3B Medical Systems, Libertyville, IL), then alkylation with an alkyl halide, e.g. l-propane, with solvent, e.g. pinacolone, then reduction with reducing agent, e.g. Na(CN)BH₃, and acid, e.g. HCl with solvent, e.g. MeOH, then selective nitro reduction or electron transfer reduction (see scheme 7, electron transfer reduction of IVq). 5-Piperazinyl 2-methoxy anilines IVt were generated from Buchwald/Hartwig coupling (see scheme 5) with 5-bromo-2-methoxy nitrobenzene, then selective nitro reduction.
Alternatively, 5-alkoxy 2-methoxy anilines (IVu) may be prepared by direct alkylation of 3-nitro, 4-methoxy phenol (CiventiChem, Research Triangle Park, NC) with an alkylation agent, e.g. (S)-(++)-Glycigyl-3-nitrobenzenesulfonate, and Lewis acid, e.g. LiCl, followed by alkylation with an amine alkylation agent, and solvent, e.g. isopropanol, at heat, e.g. microwave at 140°C. The product is subjected to selective nitro reduction to provide aniline tail IVu. Alternatively, the 3-nitro, 4-methoxy phenol may be alkylated with an alkylation agent, e.g. dimethylaminopropylchloride HCl, iodide source, e.g. TBAI, base, e.g. K₂CO₃, and solvent, e.g. MeCN, followed by selective nitro reduction to provide aniline tail IVw.

As shown in scheme 9, bicyclic indane tails may be prepared using 5-methoxy indole (Aldrich) as a starting material. The 5-methoxy indole is first reduced using a hydride source, e.g. Na(CN)BH₃, and acid, e.g. AcOH, then protected with an acylating agent, e.g. Ac₂O, in solvent, e.g. AcOH, optionally with a base. The protection provides for subsequent selective nitration with nitrating agent, e.g. HNO₃, and acid, e.g. Ac₂O, followed by deprotection with acid, e.g. HCl in solvent, e.g. MeOH to provide intermediate XVI.
Intermediate XVI is subjected to subsequent acylation with an acylating agent, e.g. \(\alpha\)-bromoacetyl chloride, acryloyl chloride, or an amino acid, with coupling reagents, e.g. HATU, DMAP, and base, e.g. PS-DIPEA, and solvent, e.g. THF. The acylating agent may be reacted with an appropriate amine base, e.g. \(\text{Me}_2\text{NH}\) (with solvent, e.g. THF), and the product then reduced (see reduction of IVa, scheme 4) to provide anilino indoline tails IVx.

As shown in scheme 9a, additional indoline tails may be prepared by alternative schemes. Chloro aniline (IVbf) is readily prepared via acylation of 6-nitro indoline with an acylating agent, e.g. \(\alpha\)-bromoacetyl chloride, subsequent displacement with an amine base, and nitro-reduction (hydrogenation). Subsequent reaction with an electrophilic halogen source, e.g. NCS, affords (IVbf).

Similarly, aniline (IVbh) is produced via nitration and deprotection of amide (IVbg) (see International Patent Publication WO 2001023374), acylation, e.g. \(\alpha\)-bromoacetyl chloride, subsequent displacement with an amine base, and nitro-reduction to afford (IVbh). (IVbj) is prepared from (IVbi) in a manner analogous to that of (IVbh) from (IVbg).

Scheme 9b
As shown in scheme 9b, tetrahydroquinoline tails may be prepared as follows.

Intermediate (IVbk), prepared according to Chem. Pharm. Bull. (2001) p. 822, may be alkylated with an alkylating agent and base, e.g. Mel and K₂CO₃, then amide reduced, e.g. borane, treated with an acylating agent, e.g. α-chloro acetyl chloride, an amine base, e.g. dimethyl amine, and nitro-reduced to provide (IVbl).

Intermediate (IVbm), readily available 4-anisidine, may be acylated with 3,3-diemethylacryloyl chloride and base, e.g. K₂CO₃, heated with a Lewis acid, e.g. AlCl₃, and solvent, e.g. methylene chloride, followed by nitrination with an oxidative reagent, e.g. NaNO₂, in acid, e.g. TFA. Subsequent amide reduction, e.g. borane, followed by treatment with an acylating agent, e.g. α-bromoacetyl chloride, displacement with an amine base, e.g. dimethyl amine, and nitro reduction provides (IVbo).

Nitroreduction of amide intermediates shown in scheme 9b affords intermediate (IVbn).

Scheme 9c
As shown in scheme 9c, tetrahydroisoquinoline tails may be prepared as follows.

Intermediate (IVbp) may be acylated with e.g. ethyl chloroformate, heated with acid, e.g. polyphosphoric acid, to afford intermediate (IVbt). Subsequently, (IVbt) may be alkylated, e.g. Mel, NaH, nitrated, e.g. HNO₃ in acid, amide reduced, e.g. borane, followed by nitro-reduction, e.g. H₂, Pd/C, to afford (IVbq). Alternatively, (IVbq) may be provided from (IVbt) via (IVbu) by nitration and amide reduction prior to alkylation and nitro-reduction.

(IVbs) may be prepared from (IVbu) via reductive amination, e.g. ketone and NaCNBH₃, and nitro-reduction, e.g. H₂, Pd/C.

(IVbr) may be prepared from (IVbu) via acylation, e.g. acryloyl chloride, treatment with an amine base, e.g. dimethyl amine, and heat, followed by nitro-reduction, e.g. H₂, Pd/C, and amide reduction, e.g. LiAlH₄.

Scheme 10
As shown in scheme 10, a number of 4-piperazinyl anilines can be prepared using standard chemistries and readily available starting materials. For instance, tails IVaa and IVab may be prepared from 2,5-difluoro-4-bromo nitrobenzene and 2,5-dimethoxy-4-chloro-nitrobenzene (Alpha Aesar, Ward Hill, MA and ABCR GmbH & Co., Germany, respectively) by treatment with sodium methoxide (only for compound IVaa) and Buchwald/Hartwig coupling (see scheme 8) with isopropyl piperazine, followed by selective nitro reduction (see reduction of IVa, scheme 4) to afford tails IVa and IVab. Tail IVc may be prepared from 2-nitro-5-chloro-benzaldehyde (Aldrich) using Buchwald/Hartwig coupling with isopropyl piperazine as with IVaa and IVab, followed by Wittig olefination (see Reactions and Syntheses in the Organic Chemistry Laboratory, Tietze, Lutz-Friedjan and Eicher, Theophil. 1989. University Science Books, Mill Valley, CA.) with a phosphonium salt, e.g. MePPh$_3$Br, and base, e.g. nBuLi, followed by hydrogenation (see hydrogenation of IVb, scheme 4).

Sulfone-containing tails IVd and IVe are readily prepared from 3-methoxy-4-nitro-benzyl alcohol and 3-nitro-4-methoxy benzyl alcohol, respectively (both from Aldrich), via chlorination (with for instance PPh$_3$/NCS) followed by displacement of the derived benzyl chloride with methyl sulfone (with for instance MeSO$_2$Na/EtOH), and nitro-reduction (see reduction of IVb, scheme 4).
The aniline tail (IVaf) was prepared from 2-methyl-5-hydroxy-fluoro-benzene by nitration with a nitrating agent, e.g. HNO₃, catalyst, e.g. TBAI, and solvent, e.g. CICH₂CH₂Cl, followed by phenolic alkylation with an alkylation agent, e.g. Mel, base, e.g. KH₂PO₄, solvent, e.g. DMF, at heat, e.g. 80°C. The intermediate is subjected to SNAR displacement (see scheme 6) using Boc protected piperizine, followed by Boc deprotection (see scheme 6), followed by alkylation with an alkylation agent, e.g. CH₂CHSO₂Me, and solvent, e.g. Et₃N, followed by selective nitro reduction, to provide IVaf.

Additional anilines may be prepared as illustrated in Scheme 10b. Aniline (IVca) can be subjected to reductive amination conditions (e.g. formaldehyde, sodium methoxide, sodium borohydride), followed by acylation with an acylating agent and base (e.g. α-bromo-acetyl-chloride and diisopropylethylamine), followed by exposure to an amine or other nucleophile (e.g. diethyl amine) to afford (IVcb). Nitration of (IVca) with a nitrating agent and acid (e.g. sodium nitrite/TFA) followed by nitro reduction with a reducing agent (e.g. Pd/C and hydrogen gas) affords aniline (IVcc).
Similarly, (IVca) can be protected (e.g. with an acyl group) and subsequently exposed to nitration conditions as described above for (IVcb) to give (IVcd). Subsequent deprotection (e.g. deacylation with acid/alcoholic solvent), reacylation with an acylating agent and base (e.g. a-bromo-acetyl chloride and diisopropylethylamine), treatment with an amine or other nucleophile (for example dimethyl amine) and nitro reduction (e.g. Pd/C and hydrogen gas) affords (IVce). An orthogonally protected diamine (e.g. (IVcf)) can be subjected to reductive amination conditions (e.g. formaldehyde, sodium methoxide, sodium borohydride), followed by acylation with an acylating agent and base (e.g. a-bromo-acetyl chloride and diisopropylethylamine), followed by exposure to an amine or other nucleophile (e.g. diemethyl amine) to afford (IVcg). Removal of the BOC protecting group with acid (i.e. HCl or TFA) affords (IVch).

Exposure of (IVci) (see Arp, Forrest O.; Fu, Gregory C. Kinetic Resolutions of Indolines by a Nonenzymatic Acylation Catalyst. Journal of the American Chemical Society (2006), 128(44), 14264-14265.) to nitration conditions (e.g. sodium nitrate and TFA) followed by deprotection of the acyl group with acid (e.g. HCl) affords (IVcj). Advancement of (IVcj) and (IVci) (see: Achvlediani, R.; Natsvlishvili, M.; Baberkina, E.; Khachidze, M.; Abesadze, I.; Suvorov, N. Synthesis of 1H-pyrrolo[3,2-g]- and 1H-pyrrolo[2,3-g]quinoline. Izvestiya Akademii Nauk Gruzii, Seriya Khimicheskaya (1996), 22(1-4), 43-47.) through a reaction sequence similar to that described above (e.g. acylation with α-bromo acetyl chloride, displacement with an amine or other nucleophile, and nitro reduction) affords anilines (IVck) and (IVcn).

**Scheme 11**

As shown in scheme 11, O-amino carboxamide heads II can be prepared by treatment of the corresponding commercially available o-amino benzoic acids with a diactivated carbonyl, e.g. phosgene, and subsequent opening of the in situ generated isatoic anhydride with an ammonia source, e.g. ammonium hydroxide.
As shown in scheme 12, heads may be prepared from commercially available di-halogenated anilines (for instance 3-choro-5-fluoro-aniline from Apollo Scientific, UK; 3-4-difluoro aniline from ABCR GmbH & Co., Germany). Note, this scheme is applicable for heads wherein substituent R4 is not H. As shown, the amine group is first protected with a carbamate protecting group, e.g. BOC₂O, in solvent, e.g. THF, at heat, e.g. 80°C, and then deprotonating with a strong alkyl lithium base, e.g. tBuLi, in ethereal solvent, e.g. THF, at reduced temperature, e.g. -80°C, with subsequent trapping with an electrophile, e.g. MeCO₂C₁ to provide a methyl ester (XVII). The methyl ester XVII is Boc deprotected with an acid and solvent, e.g. TFA/CH₂CL₂, and hydrolyzed with a hydroxide source, e.g. LiOH, in solvent with water, e.g. THF/H₂O. Conversion of the amide to the acid (Na) is carried out using standard coupling procedure, with for instance NH₃, EDCI, and dioxane.

Thin-layer chromatography (TLC) was performed on silica gel 60 F₂₅⁴₅ precoated plates. Detection was effected by exposure to UV light (254 nm). Flash
and flush column chromatography was performed using Silica Gel 60. Reverse
phase preparative and analytical HPLC were performed using C18 columns and
acetonitrile:water gradients with 0.05% TFA as a modifier.

Compound purity and characterization were determined by $^1$H-NMR, liquid
chromatography-mass spectrometry (LCMS), high resolution mass spectrometry
(HRMS), combustion (elemental) analysis, HPLC, and melting point. Compounds of
general formula I were typically found to have purities of > 90%.

$^1$H NMR spectra were recorded on Varian INOVA-300, Varian INOVA-400,
and Bruker AV400 instruments. Chemical shifts are expressed in parts per million
(ppm, $\delta$ units). Coupling constants are in units of hertz (Hz). Splitting patterns
describe apparent multiplicities and are designated as s (singlet), d (doublet), dd
doublet of doublet), t (triplet), q (quartet), m (multiplet), or br (broad).

Low resolution mass spectra were obtained on Micromass ZQ, Micromass
ZMD, Micromass QuattroMicro, and Micromass GCT instruments from Micromass
Ltd., Altricham, UK, using either Atmospheric Pressure Chemical Ionization (APCI) or
ESI Ionization (ESI).

High resolution mass spectral data (HRMS) were recorded with Micromass
LCT and Micromass GCT instruments.

Combustion analyses were performed by Atlantic Microlab, Inc. (Norcross,
Georgia).

Melting points were recorded in open capillary tubes and are uncorrected.
X-ray diffraction patterns were determined by dusting sample onto a silicon
zero background plate of a PANalytical X’Pert Pro diffractometer using the following
parameters:

General Protocol I: Synthesis of o-amino carboxamides:

To a solution of the 2-amino benzoic acid in THF was slowly added phosgene as a 20% solution in toluene (1.1 equivalents). The resulting suspension was allowed to stir at room temperature until solids had completely dissolved, and then cooled to 0°C. The column fractions containing 1,1-dimethylethyl (3-chloro-5-fluorophenyl)carbamate were concentrated, redissolved in methylene chloride, and stirred with MP-Trisamine resin (35g, Argonaut Technologies) overnight. Filtration and concentration afforded 1,1-dimethylethyl (3-chloro-5-fluorophenyl)carbamate as a clear oil (9.8g, 58% yield) of sufficient purity for use in the next transformation. 1H NMR (400 MHz, CDCl₃) δ ppm 1.52 (s, 9 H), 6.51 (s, 1 H), 6.75 (dt, J=8.43, 2.02 Hz, 1 H), 7.09 - 7.17 (m, 2 H).

Organics were washed with water and saturated brine solution and dried over sodium sulfate. Solvents were removed under reduced pressure to afford a yellow solid. Efforts to dissolve the solid in ethyl acetate resulted in a suspension that was let sit for several hours. Hexanes were added and the solids filtered to afford N-[2-methyl-4-(methyloxy)-5-nitrophenyl]acetamide (1.13g, 5.04 mmol) as yellow fluffy solid. The filtrate was purified via SiO₂ chromatography to afford N-[2-methyl-4-(methyloxy)-5-nitrophenyl]acetamide (1.02g, 4.55 mmol) as a yellow solid. ¹H NMR (400 MHz, DMSO-de) δ ppm 2.00 - 2.11 (m, 3 H) 2.29 (s, 3 H) 3.90 (s, 3 H) 7.24 (s, 1 H) 7.99 (s, 1 H) 9.42 (s, 1 H)

General Protocol III: Synthesis of 2,4-bisanilinopyrrolopyrimidines
Step A: To a suspension of the 2-chloro-4-anilino-7-[(4-methylphenyl)sulfonyl]-7/-/-pyrrolo[2,3-c]pyrimidine (i, Intermediates C1-C19, 300mg-6g) in trifluoroethanol (7-300 mL) was added an aniline (1.25-1.75 equiv., Intermediates B1-B124), hydrochloric acid as a 4.0M solution in dioxane (4 equiv.), and catalytic potassium iodide (<10 mg). The resulting slurry was stirred at -85 °C in a pressure vial until all solids had completely dissolved 12-36 hr.) The resulting solution was cooled to room temperature and diluted with dichloromethane and saturated sodium bicarbonate as to adjust the aqueous layer to pH >10. The organic layer was dried over sodium sulfate, filtered, and the solvents removed under reduced pressure to afford the corresponding 3-[(4-methylphenyl)sulfonyl]-5-(phenylamino)pyrrolo[2',3':4,5]pyrimido[6,1-6]quinazolin-7(3/-/-)-ones (ii).

Step B: Tetracyclic ii was suspended in tetrahydrofuran (12-20 mL) and either 27% aqueous ammonium hydroxide (50 mL) or another primary amine (i.e. 4-fluorobenzylamine, 2-15 equiv.) was added. The resulting solution was warmed to -80 °C in a pressure vessel until all solids had dissolved (1-10 hr.) After cooling to room temperature, the vessel was cautiously opened and the organic layer was dried with solid sodium sulfate, filtered, and concentrated under reduced pressure to afford adequately pure intermediate iii.
Step C: These solids (iii) were dissolved in a 1:1 mixture of tetrahydrofuran and methanol and solid sodium methoxide was added. The resulting suspension was stirred at room temperature (or 80°C in a pressure vessel) until all starting materials were judged consumed by thin layer chromatography. Upon cooling to room temperature saturated sodium bicarbonate (10 ml) and ethyl acetate (20 ml) were added. The organic layer was subsequently washed with 2.0N sodium hydroxide and brine, dried over sodium sulfate, filtered, stripped onto celite, and purified by chromatography on SiO₂ (8Og SiO₂, 0% to 10% MeOH/CH₂CL₂ with 0.2% added NH₃) to afford the final bisanilinopyrrolopyrimidines (6-39% yield, 3 steps, Examples 1-115) as yellow or white solids.

2-fluoro-6-([4-[4-(1-methylethyl)-1-piperazinyl]-2-(methyl oxy)phenyl]amino)-1H-pyrrolo[2,3-c]pyrimidin-4-yl]amino]benzamide

To a solution of 2-[[2-chloro-7-[[4-methylphenyl)sulfonyl]-7H-pyrrolo[2,3-c]pyrimidin-4-yl]amino]-6-fluorobenzamide (5.50g, 11.98 mmol), [4-[[4-(1-methylethyl)-1-piperazinyl]-2-(methyloxy)phenyl]amine (4.5g, 18 mmol, 1.50 equiv.), and potassium iodide (<20 mg) in trifluoroethanol (200 ml) in a 300 ml. sealed tube was added hydrochloric acid as a 4.0M solution in dioxane (12 ml, 48 mmol, 4 equiv.). The vessel was sealed and the resulting suspension was stirred rapidly at 80°C for 12 hours. TLC/LCMS analysis indicates starting material still remains, so additional hydrochloric acid (5 ml. as a 4.0M solution in dioxane) and potassium iodide (<20 mg) were added and heating was continued. Three such reactions were cooled and poured directly in saturated sodium bicarbonate/methylene chloride. The organic layer was collected, concentrated under reduced pressure, and then resuspended in diethylether. Sonication for 10 minutes was followed by filtration to give crude 8-fluoro-5-[[4-[4-(1-methylethyl)-1-piperazinyl]-2-(methyloxy)phenyl]amino]-3-[[4-
methylphenyl)sulfonyl]pyrrolo[2',3':4,5]pyrimido[6,1-6]quinazolin-7(3/-/)-one as an orange solid with sufficient purity for use in the next transformation (23.5 g, ca 99% yield, purity 85-90%). ESIMS (M+H)+ = 655.

The resulting biphasic mixture was rapidly stirred for 24 hours, at which time no starting material was evident by TLC/LCMS. Three such reactions were combined, diluted with EtOAc, and the organic layers washed with saturated sodium chloride, dried over sodium sulfate, and taken to a residue under reduced pressure to give 2-fluoro-6-\{2-[4-[4-(1-methylethyl)-1-piperazinyl]-2-(methyloxy)phenyl]amino\}-7-[4-methylphenyl)sulfonyl]pyrrolo[2,3-c]pyrimidin-4-yl]amino\}benzamide (19.3 g, 28.7 mmol, 80% Yield). \(^1\)H NMR (400 MHz, DMSO-d\(_6\)) \(\delta\) ppm 10.36 (s, 1 H), 8.04 (d, J=8.2 Hz, 1 H), 7.87 - 7.99 (m, 4 H), 7.79 (br. s., 2 H), 7.26 - 7.47 (m, 4 H), 6.87 - 7.06 (m, 1 H), 6.63 (d, J=2.4 Hz, 1 H), 6.47 - 6.58 (m, 2 H), 3.70 - 3.85 (m, 3 H), 3.05 - 3.19 (m, 4 H), 2.66 (quin, J=6.5 Hz, 1 H), 2.54 - 2.63 (m, 4 H), 2.32 (s, 3 H), 1.00 (d, J=6.6 Hz, 6 H). Three separate mixtures of 2-[(2-chloro-1H-pyrrolo[2,3-c]pyrimidin-4-yl)amino]-4,6-difluorobenzamide (3.50 g, 7.32 mmol), 2-(methyloxy)-4-(1-propyl-4-piperidinyl)aniline (2.7 g, 11 mmol), and 2,2,2-trifluoroethanol (150 mL) were taken in three separate sealed tubes and heated at 90 °C for 48 h. After 1 h, the solution turned a clear brown color, at which time about 450 ml of solvent were removed via distillation. The remaining mixture was treated with DIEA (90 ml.) and heated to reflux for 16 hours. A light brown solution of 2-[(2-[[1-(Λ,Λ-dimethylglycyl)-5-(methyloxy)-2,3-dihydro-1 H-indol-6-yl]amino]-7-[(4-methylphenyl)sulfonyl]-7H-pyrrolo[2,3-c]/pyrimidin-4-yl]amino]-6-fluoro-N-methylbenzamide (19.1 kg, 27.8 mol), a method for preparation of which is described in Step C above, was suspended in dioxane (191 L, 10 volumes) and treated with a 15% aqueous KOH solution (76.4 L, 4 volumes). The mixture was heated to reflux (approximately 85 °C). Once the suspension became homogeneous, the reaction mixture was kept at reflux for 2 hours. In-process monitoring after 2h showed completion. The heat was discontinued and the suspension was concentrated to remove approximately 80 L of solvent. Water (141 L) was added and the suspension was stirred at ambient temperature for 1h and filtered through centrifuge. The solid was washed with water till the filtrate ran clear to obtain 2-[(2-[(1-(N,N-dimethylglycyl)-5-(methyloxy)-2,3-dihydro-1 H-indol-6-yl]amino]-1 H-pyrrolo[2,3-c]/pyrimidin-4-yl]amino]-6-fluro-N-methylbenzamide monohydrate as a light brown solid (14.1 kg, 95% yield).

NMR analysis confirmed 2-[(2-[[1-(N,N-dimethylglycyl)-5-(methyloxy)-2,3-dihydro-1 H-indol-6-yl]amino]-1 H-pyrrolo[2,3-c]/pyrimidin-4-yl]amino]-6-fluro-N-methylbenzamide. Powder x-ray diffraction confirmed existence of the monohydrate, characterized by the pattern shown in Figure 1, including the peaks of Table 1.

To a suspension of 2-[[2-chloro-7-[(4-methylphenyl)sulfonyl]-7H-pyrrolo[2,3-c]pyrimidin-4-yl]amino]-4,6-difluorobenzamide (4 g, 8.37 mmol) in 2,2,2-trifluoroethanol (100 ml.) was added 1-[(dimethylamino)acetyl]-5-(methyloxy)-2,3-dihydro-1/-/-indol-6-amine (3.13 g, 12.56 mmol), a solution of 4M HCl in dioxane (16.7 ml, 67 mmol) and a catalytic amount of KI. The resulting slurry was stirred in a pressure vessel at 80°C for 48 h, with an additional 2 ml of 4M HCl in dioxane being added after 24 h.
The reaction mixture was diluted with dichloromethane and a saturated sodium bicarbonate solution (aq) as to adjust the aqueous layer to pH > 10. The organic layer was washed with water and a saturated brine solution and dried over sodium sulfate. Solvents were removed under reduced pressure and the residue was purified via trituration from diethyl ether to afford a yellow solid (5.25g, 7.77 mmol). A portion of the solid (3.1 g) was suspended in THF (100 ml) and 2M methylamine in THF (18.55 ml, 37.1 mmol) was added and the reaction let stir for 1h. Additional 2M methylamine in THF (2 ml) was added and reaction let stir for an additional 1h at which time the reaction mixture was diluted with ethyl acetate and washed with water and a saturated brine solution. The organic layer was dried over sodium sulfate and all volatiles were removed under reduced pressure to afford a yellow solid which was purified via chromatography on SiO2 to afford 2-[(2-[[1-(N,N-dimethylglycyl)-5-(methyloxy)-2,3-dihydro-1 H-indol-6-yl]amino]-7-[(4-methylphenyl)sulfonyl]-7H-pyrrolo[2,3-d]pyrimidin-4-yl]amino)-4,6-difluoro-N-methylbenzamide (1.6 g, 2.27 mmol) (ESIMS (M+H)+ = 705) as a yellow solid. The resulting mixture was stirred in the microwave at 120°C for 9 min. The reaction mixture was diluted with EtOAc and THF and the organic layer was washed with water and a saturated brine solution. Combined organic layers were dried over sodium sulfate and all solvents were removed under reduced pressure and purified via chromatography on SiO2 to afford 2-[(2-[[1-(N,N-dimethylglycyl)-5-(methyloxy)-2,3-dihydro-1 H-indol-6-yl]amino]-1 H-pyrrolo[2,3-c]pyrimidin-4-yl]amino]-4,6-difluoro- N-methylbenzamide (0.532 g, 0.966 mmol) as a beige solid. ASSAYS

Time Resolved Fluorescence Resonance Energy Transfer (TR-FRET) assays were carried out on the exemplified compounds as follows:
The source of substrate peptide

The biotinylated substrate peptide, (sequence - Biotin-aminohexyl-AEEEEY MMMMAKKKK-NH₂) is purchased from QCB, Inc. (Hopkinton, MA). Purity is determined by HPLC. The calculated molecular mass of the peptide is 2216 dalton. Tyrosine phosphorylation by human IGF1 R (hIGF1 R) or human IR (hIR) occurs as indicated (Y*) in the peptide sequence described. Solid peptide sample is dissolved to approximately 1 mM in DMSO, aliquoted, and stored at -20°C until use. True peptide concentration is determined by amino acid analysis.

The source of enzyme:

hIGF1 R: GST-rTEV-IGF-1 R(957-1367) containing amino acid residues 957-1367 of human IGF1 R (as annotated by National Center for Biotechnology Information (NCBI) accession number NP_000866) is purified from a baculovirus expression system in Sf9 cells using Glutathione Sepharose 4FF column chromatography followed by Sephadex-200 size exclusion column chromatography. Enzyme purity of approximately 95% is achieved. Samples, in 25 mM Tris-HCl, 250 mM NaCl, 5% glycerol, 1 mM DTT, pH 7.5, are stored at -80°C until use.

hIR: GST-rTEV-IR(979-1382) containing amino acid residues 979-1382 of human IR (as annotated by NCBI accession number NP_000199) is expressed and purified by the same process as hIGF1 R. Enzyme purity of approximately 92% is achieved. Samples, in 25 mM Tris-HCl, 250 mM NaCl, 5% glycerol, 1 mM DTT, pH 7.5, are stored at -80°C until use.

Activation of hIGF1 R and hIR by autophosphorylation:

hIGF1 R: Activation of GST-rTEV-IGF-1 R(957-1367) is achieved by a 4 minute incubation of hIGF1 R (2.7 µM final) with 2 mM ATP in 50 mM HEPES, 20 mM MgCl₂, 0.1 mg/ml BSA, at room temperature. Autophosphorylation is stopped by addition of EDTA (to 100 mM final). Aliquotted samples are flash frozen in liquid nitrogen and stored at -80°C until use.

hIR: Activation of GST-rTEV-IGF-1 R(957-1367) is achieved by a 5 minute incubation of hIR (2.7 µM final) with 2 mM ATP in 100 mM HEPES, 10 mM MgCl₂, 0.1 mg/ml BSA, at room temperature. Autophosphorylation is stopped by addition of EDTA (to 100 mM final). Aliquotted samples are flash frozen in liquid nitrogen and stored at -80°C until use.
Kinase assay of purified hlGF1 R or hIR:

Assays are performed in 384-well (Greiner, Catalog No. 784076) microtiter plates. Reaction buffer (50 mM HEPES buffer, pH 7.5; 10 mM MgCl₂; 3 mM DTT; 1 mM CHAPS; 0.1 mg/ml BSA) for peptide phosphorylation (10 µl volume) contained, in final concentrations, 500 nM biotinylated peptide substrate; 10 µM ATP; and purified, activated hlGF1 R or hIR (0.5 nM). Compounds, titrated in DMSO, are evaluated at eleven concentrations ranging from 50 µM to 0.2 nM. Final assay concentrations of DMSO do not exceed 10%. No effect on activity relative to controls without DMSO is observed for hlGF1 R or IR at these DMSO amounts. Reactions are incubated for 1 hour at room temperature and are stopped by a 5 µl addition of EDTA (to 33 mM). A further addition of 5 µl detection reagents (for final 7 nM Streptavidin-APC (PerkinElmer #CR130-150), 1 nM Europium-labeled anti-phosphotyrosine monoclonal antibody (PerkinElmer #AD0067), added in reaction buffer without DTT), is required for signal generation. After 30 minutes, signal is read on PerkinElmer Viewlux microplate imager or Wallac Victor fluorometer.

The data for compound concentration responses were plotted as % Inhibition, calculated with the data reduction formula 100*(1-[(U1-C2)/(C1-C2)]), versus concentration of compound, where

\[ U \] is the unknown value,

\[ C1 \] is the average control value obtained for DMSO only, and

\[ C2 \] is the average control value obtained for reactions stopped with EDTA at \( t=0 \).

Data were fitted to the curve described by:

\[ y = \left( \frac{(V_{\text{max}} - x)}{(K + x)} \right) \]

where

\[ V_{\text{max}} \] is the upper asymptote and

\[ K \] is the IC₅₀.

The results for each compound were recorded as pIC₅₀ calculated as follows:

\[ \text{pIC}_{50} = -\log_{10}(K). \]

pIC₅₀ values for the compounds of the examples (if available) were categorized by relative inhibition of IGF-1 R and IR. The results are summarized in the tables below.

ALK Enzyme Assay:

The method measures the ability of the isolated enzyme to catalyse the transfer of the gamma-phosphate from ATP onto the tyrosine residue of a biotinylated synthetic peptide. The extent of tyrosine phosphorylation was measured using an anti-phosphotyrosine antibody, and quantified by homogenous time-resolved fluorescence (HTRF) assay purchased from CisBio (62TK0PEJ).

Reactions were performed in black 384-well polystyrene low volume plates in a final volume of 5 µl. Assays were performed by adding 2.5 µl of each of the following solutions, enzyme mix and substrate: The enzyme mix, final concentration in plate, contained 50 mM MOPS (pH 7.0); 10 nM supplement enzymatic buffer; 0.03 % NaN3; 0.01 % BSA, 0.1 mM orthovanadate, 5 mM MgCl2, 1 mM CHAPS, 1 mM dithiothreitol and 0.25 nM ALK. The Substrate mix, final concentration in plate, contained 50 mM MOPS (pH 7.0); 10 nM supplement enzymatic buffer; 0.03 % NaN3; 0.01 % BSA, 0.1 mM orthovanadate, 5 mM MgCl2, 1 mM CHAPS, 1 mM dithiothreitol, 15.0 µM ATP, and 0.25 µM TK substrate-biotin.

To quantify compound potencies, the enzyme mix was added to the compound plates and the plates were incubated at 20°C for 30 minutes. The reactions were then started by adding the substrate mix. The reactions were allowed to proceed for 120 minutes at 20°C. The reactions were then terminated by the addition of 5 µl HTRF detection mix to each well. The final concentrations of the detection reagents were: 50 mM HEPES (pH7.0); 0.1 % BSA; 0.8 M KF; 20 mM EDTA; 1 mM CHAPS; TK-antibody Europium Cryptate; and 41 nM streptavidin-XL665. Assay plates were left unsealed, stacked and incubated at 20° for 60 minutes. Quantification of activity was achieved by counting in an Envision Counter (PerkinElmer).

Compounds under analysis were dissolved in Me2SO to 1.0 mM and serially diluted 1 to 3 with Me2SO through twelve dilutions. 0.05 µl of each concentration was transferred to the corresponding well of an assay plate. This creates a final compound concentration range from 0.00017 to 10 µM.

The data for dose responses were plotted as % Inhibition calculated with the data reduction formula 100*(1-(U1-C2)/(C1-C2)) versus concentration of compound where U is the unknown value, C1 is the average control value obtained for 1%
DMSO, and C2 is the average control value obtained for 0.1 M EDTA. Data were fitted with a curve described by:

\[ y = A + \frac{B - A}{1 + \frac{x}{D}} \]

where A is the minimum y, B is the maximum y concentration [M], D is the slope factor, and x is the log10 of the compound. The results for each compound were recorded as pIC50s, calculated as follows:

\[ \text{pIC50} = \text{-Log10}(K) \]

pIC50 values for the compounds of the examples (if available) were categorized by relative inhibition of IGF-1 R and IR. The results are summarized in the tables below.

Cell Proliferation Data

A. Inhibition of cell proliferation by IGF-1 R inhibitors

Cell proliferation was measured by either CellTiter-Glo (measures cellular ATP level as a surrogate for total cell number) or by InCell analyzer (counts number of nuclei as a measure of cell number).

For CellTiter-Glo assay, exponentially growing cell lines of different tumor origins, cultured in appropriate media containing 10% fetal bovine serum at 37°C in a 5% CO₂ incubator, were plated at low density (less than 2000 cells/well) in 96-well plates. Twenty-four hours post-plating, cells were treated with different concentrations of test compounds ranging from 30μM to 1.5nM. Several wells were left untreated as a control. Seventy-two hours post-treatment, cell numbers were determined using 50-1000ul per well of CellTiter-Glo (Promega #G7573). Plates were incubated at 37°C for 30 minutes and the chemiluminescent signal was read on the Victor V or Envision 2100 reader. Percent inhibition of cell growth was expressed as percent proliferation relative to 100% proliferation (control). Concentration of test compound that inhibited 50% of cell growth (IC₅₀) was determined by 4 parameter fit of data using XLfit, (value of no cell control was subtracted from all samples for background).

For InCell Analyser assay, various cell lines of different tumor origins were grown to 70-80% confluence in appropriate culture media containing 10% fetal bovine serum at 37°C in a 5% CO₂ incubator. On day -1, cells were seeded at 2 densities in 384-well plates and incubated at 37°C overnight. Stock compound plates were prepared in advance which contained dimethyl sulfoxide (DMSO) alone and a 9-point half-log decreasing dose range of the compound in DMSO. The compound plates were stored at -80°C and each plate was only thawed once and used. On day 0, the main assay plates received compound or DMSO via a sonic delivery system (ECHO). The highest final concentration of compound of the dose range in the culture plates was 10μM. These plates were cultured at 37°C for 3 days. A parallel set of cell line plates, which did not receive compound, were processed and read on day 0 to provide a T=0 (time zero). On day 3, the compound treated plates were stained and fixed to measure proliferation, apoptosis, and mitotic index using an InCell 1000 analyser. A nuclear stain was used to identify cells in the wells. By counting the number of nuclei, the proliferation index of compound treated groups
were calculated as a percentage relative to the DMSO control, which was set to 100%. The IC50 values were calculated using model 205 in ExcelFit.

IC50 (nM) values for compounds of select examples were categorized by relative inhibition of cell proliferation. The results are summarized in the tables below.

B. IGF-1 R and IR Cellular Autophosphorylation
NIH-3T3 cells overexpressing human IGF-1R or IR were plated in 96-well plates (10,000 cells/well) in culture media containing 10% fetal bovine serum and incubated at 37°C in a 5% CO₂ incubator. Twenty four hours post-plating, cells were treated with different concentrations of test compounds ranging from 30uM to 1.5nM.

Two hours after compound addition, cells were stimulated with either human IGF-1 (30 ng/ml) or insulin (3 ug/ml) for 15 minutes. Cell lysates are analyzed for phosphorylated receptors using dissociation enhanced lanthanide fluor-immuno assay (DELFIA) with anti-IGF-1 R (MAB391, R&D Systems, Minneapolis, MN) or anti-IR β (sc-71 1, Santa Cruz Biotechnology, Santa Cruz, CA) capture antibody and europium-labeled anti-pTyr antibody (Eu-NI PT66, Perkin Elmer, Waltham, MA) for detection. The fluorescence signal for cells treated with compounds was expressed as percent relative to 100% stimulation (IGF-1 or insulin stimulated signal).

Concentration of test compound that inhibited 50% of ligand-induced receptor phosphorylation (IC50) was determined by 4 parameter fit of data using XLfit, (value of no cell control was substraction from all samples for background).

IC50 values for the compounds of the examples (if available) were categorized by relative inhibition of IGF-1 R and IR. The results are summarized in the tables below.
