

(57) Abstract: A patient interface includes a seal-forming structure constructed and arranged to form a seal with a region of the patient's face surrounding an entrance to the patient's airways. The seal-forming structure comprises a first section and a second section. The first section is constructed from a first material. The first section is configured to sealingly engage against a first region of the patient's face. The second section is constructed from a second material that is different than the first material. The second section is configured to sealingly engage against a second region of the patient's face. The second material is foam. The patient interface also includes a positioning and stabilising structure to provide a force to hold a seal-forming structure in a therapeutically effective position on a patient's head.

SEAL-FORMING STRUCTURE OF PATIENT INTERFACE WITH MULTIPLE SEALING MATERIALS

1 CROSS-REFERENCE TO RELATED APPLICATION

[0001] This application claims the benefit of Australian Provisional Patent Application No. 2020902681, filed July 30, 2020, which is incorporated herein by reference in its entirety.

2 BACKGROUND OF THE TECHNOLOGY

2.1 FIELD OF THE TECHNOLOGY

[0002] The present technology relates to one or more of the screening, diagnosis, monitoring, treatment, prevention and amelioration of respiratory-related disorders. The present technology also relates to medical devices or apparatus, and their use.

2.2 DESCRIPTION OF THE RELATED ART

2.2.1 Human Respiratory System and its Disorders

[0003] The respiratory system of the body facilitates gas exchange. The nose and mouth form the entrance to the airways of a patient.

[0004] The airways include a series of branching tubes, which become narrower, shorter and more numerous as they penetrate deeper into the lung. The prime function of the lung is gas exchange, allowing oxygen to move from the inhaled air into the venous blood and carbon dioxide to move in the opposite direction. The trachea divides into right and left main bronchi, which further divide eventually into terminal bronchioles. The bronchi make up the conducting airways, and do not take part in gas exchange. Further divisions of the airways lead to the respiratory bronchioles, and eventually to the alveoli. The alveolated region of the lung is where the gas exchange takes place, and is referred to as the respiratory zone. See “*Respiratory Physiology*”, by John B. West, Lippincott Williams & Wilkins, 9th edition published 2012.

[0005] A range of respiratory disorders exist. Certain disorders may be characterised by particular events, e.g. apneas, hypopneas, and hyperpneas.

[0006] Examples of respiratory disorders include Obstructive Sleep Apnea (OSA), Cheyne-Stokes Respiration (CSR), respiratory insufficiency, Obesity Hyperventilation Syndrome (OHS), Chronic Obstructive Pulmonary Disease (COPD), Neuromuscular Disease (NMD) and Chest wall disorders.

[0007] Obstructive Sleep Apnea (OSA), a form of Sleep Disordered Breathing (SDB), is characterised by events including occlusion or obstruction of the upper air passage during sleep. It results from a combination of an abnormally small upper airway and the normal loss of muscle tone in the region of the tongue, soft palate and posterior oropharyngeal wall during sleep. The condition causes the affected patient to stop breathing for periods typically of 30 to 120 seconds in duration, sometimes 200 to 300 times per night. It often causes excessive daytime somnolence, and it may cause cardiovascular disease and brain damage. The syndrome is a common disorder, particularly in middle aged overweight males, although a person affected may have no awareness of the problem. See US Patent No. 4,944,310 (Sullivan).

[0008] Cheyne-Stokes Respiration (CSR) is another form of sleep disordered breathing. CSR is a disorder of a patient's respiratory controller in which there are rhythmic alternating periods of waxing and waning ventilation known as CSR cycles. CSR is characterised by repetitive de-oxygenation and re-oxygenation of the arterial blood. It is possible that CSR is harmful because of the repetitive hypoxia. In some patients CSR is associated with repetitive arousal from sleep, which causes severe sleep disruption, increased sympathetic activity, and increased afterload. See US Patent No. 6,532,959 (Berthon-Jones).

[0009] Respiratory failure is an umbrella term for respiratory disorders in which the lungs are unable to inspire sufficient oxygen or exhale sufficient CO₂ to meet the patient's needs. Respiratory failure may encompass some or all of the following disorders.

[0010] A patient with respiratory insufficiency (a form of respiratory failure) may experience abnormal shortness of breath on exercise.

[0011] Obesity Hyperventilation Syndrome (OHS) is defined as the combination of severe obesity and awake chronic hypercapnia, in the absence of other known

causes for hypoventilation. Symptoms include dyspnea, morning headache and excessive daytime sleepiness.

[0012] Chronic Obstructive Pulmonary Disease (COPD) encompasses any of a group of lower airway diseases that have certain characteristics in common. These include increased resistance to air movement, extended expiratory phase of respiration, and loss of the normal elasticity of the lung. Examples of COPD are emphysema and chronic bronchitis. COPD is caused by chronic tobacco smoking (primary risk factor), occupational exposures, air pollution and genetic factors. Symptoms include: dyspnea on exertion, chronic cough and sputum production.

[0013] Neuromuscular Disease (NMD) is a broad term that encompasses many diseases and ailments that impair the functioning of the muscles either directly via intrinsic muscle pathology, or indirectly via nerve pathology. Some NMD patients are characterised by progressive muscular impairment leading to loss of ambulation, being wheelchair-bound, swallowing difficulties, respiratory muscle weakness and, eventually, death from respiratory failure. Neuromuscular disorders can be divided into rapidly progressive and slowly progressive: (i) Rapidly progressive disorders: Characterised by muscle impairment that worsens over months and results in death within a few years (e.g. Amyotrophic lateral sclerosis (ALS) and Duchenne muscular dystrophy (DMD) in teenagers); (ii) Variable or slowly progressive disorders: Characterised by muscle impairment that worsens over years and only mildly reduces life expectancy (e.g. Limb girdle, Facioscapulohumeral and Myotonic muscular dystrophy). Symptoms of respiratory failure in NMD include: increasing generalised weakness, dysphagia, dyspnea on exertion and at rest, fatigue, sleepiness, morning headache, and difficulties with concentration and mood changes.

[0014] Chest wall disorders are a group of thoracic deformities that result in inefficient coupling between the respiratory muscles and the thoracic cage. The disorders are usually characterised by a restrictive defect and share the potential of long term hypercapnic respiratory failure. Scoliosis and/or kyphoscoliosis may cause severe respiratory failure. Symptoms of respiratory failure include: dyspnea on exertion, peripheral oedema, orthopnea, repeated chest infections, morning headaches, fatigue, poor sleep quality and loss of appetite.

[0015] A range of therapies have been used to treat or ameliorate such conditions. Furthermore, otherwise healthy individuals may take advantage of such therapies to prevent respiratory disorders from arising. However, these have a number of shortcomings.

2.2.2 Therapies

[0016] Various respiratory therapies, such as Continuous Positive Airway Pressure (CPAP) therapy, Non-invasive ventilation (NIV), Invasive ventilation (IV), and High Flow Therapy (HFT) have been used to treat one or more of the above respiratory disorders.

2.2.2.1 Respiratory pressure therapies

[0017] Respiratory pressure therapy is the application of a supply of air to an entrance to the airways at a controlled target pressure that is nominally positive with respect to atmosphere throughout the patient's breathing cycle (in contrast to negative pressure therapies such as the tank ventilator or cuirass).

[0018] Continuous Positive Airway Pressure (CPAP) therapy has been used to treat Obstructive Sleep Apnea (OSA). The mechanism of action is that continuous positive airway pressure acts as a pneumatic splint and may prevent upper airway occlusion, such as by pushing the soft palate and tongue forward and away from the posterior oropharyngeal wall. Treatment of OSA by CPAP therapy may be voluntary, and hence patients may elect not to comply with therapy if they find devices used to provide such therapy one or more of: uncomfortable, difficult to use, expensive and aesthetically unappealing.

[0019] Non-invasive ventilation (NIV) provides ventilatory support to a patient through the upper airways to assist the patient breathing and/or maintain adequate oxygen levels in the body by doing some or all of the work of breathing. The ventilatory support is provided via a non-invasive patient interface. NIV has been used to treat CSR and respiratory failure, in forms such as OHS, COPD, NMD and Chest Wall disorders. In some forms, the comfort and effectiveness of these therapies may be improved.

[0020] Invasive ventilation (IV) provides ventilatory support to patients that are no longer able to effectively breathe themselves and may be provided using a tracheostomy tube. In some forms, the comfort and effectiveness of these therapies may be improved.

2.2.2.2 Flow therapies

[0021] Not all respiratory therapies aim to deliver a prescribed therapeutic pressure. Some respiratory therapies aim to deliver a prescribed respiratory volume, by delivering an inspiratory flow rate profile over a targeted duration, possibly superimposed on a positive baseline pressure. In other cases, the interface to the patient's airways is 'open' (unsealed) and the respiratory therapy may only supplement the patient's own spontaneous breathing with a flow of conditioned or enriched gas. In one example, High Flow therapy (HFT) is the provision of a continuous, heated, humidified flow of air to an entrance to the airway through an unsealed or open patient interface at a "treatment flow rate" that is held approximately constant throughout the respiratory cycle. The treatment flow rate is nominally set to exceed the patient's peak inspiratory flow rate. HFT has been used to treat OSA, CSR, respiratory failure, COPD, and other respiratory disorders. One mechanism of action is that the high flow rate of air at the airway entrance improves ventilation efficiency by flushing, or washing out, expired CO₂ from the patient's anatomical deadspace. Hence, HFT is thus sometimes referred to as a deadspace therapy (DST). Other benefits may include the elevated warmth and humidification (possibly of benefit in secretion management) and the potential for modest elevation of airway pressures. As an alternative to constant flow rate, the treatment flow rate may follow a profile that varies over the respiratory cycle.

[0022] Another form of flow therapy is long-term oxygen therapy (LTOT) or supplemental oxygen therapy. Doctors may prescribe a continuous flow of oxygen enriched gas at a specified oxygen concentration (from 21%, the oxygen fraction in ambient air, to 100%) at a specified flow rate (e.g., 1 litre per minute (LPM), 2 LPM, 3 LPM, etc.) to be delivered to the patient's airway.

2.2.2.3 Supplementary oxygen

[0023] For certain patients, oxygen therapy may be combined with a respiratory pressure therapy or HFT by adding supplementary oxygen to the pressurised flow of

air. When oxygen is added to respiratory pressure therapy, this is referred to as RPT with supplementary oxygen. When oxygen is added to HFT, the resulting therapy is referred to as HFT with supplementary oxygen.

2.2.3 Respiratory therapy Systems

[0024] These respiratory therapies may be provided by a respiratory therapy system or device. Such systems and devices may also be used to screen, diagnose, or monitor a condition without treating it.

[0025] A respiratory therapy system may comprise a Respiratory Pressure Therapy Device (RPT device), an air circuit, a humidifier, a patient interface, an oxygen source, and data management.

[0026] Another form of therapy system is a mandibular repositioning device.

2.2.3.1 Patient Interface

[0027] A patient interface may be used to interface respiratory equipment to its wearer, for example by providing a flow of air to an entrance to the airways. The flow of air may be provided via a mask to the nose and/or mouth, a tube to the mouth or a tracheostomy tube to the trachea of a patient. Depending upon the therapy to be applied, the patient interface may form a seal, e.g., with a region of the patient's face, to facilitate the delivery of gas at a pressure at sufficient variance with ambient pressure to effect therapy, e.g., at a positive pressure of about 10 cmH₂O relative to ambient pressure. For other forms of therapy, such as the delivery of oxygen, the patient interface may not include a seal sufficient to facilitate delivery to the airways of a supply of gas at a positive pressure of about 10 cmH₂O. For flow therapies such as nasal HFT, the patient interface is configured to insufflate the nares but specifically to avoid a complete seal. One example of such a patient interface is a nasal cannula.

[0028] Certain other mask systems may be functionally unsuitable for the present field. For example, purely ornamental masks may be unable to maintain a suitable pressure. Mask systems used for underwater swimming or diving may be configured to guard against ingress of water from an external higher pressure, but not to maintain air internally at a higher pressure than ambient.

[0029] Certain masks may be clinically unfavourable for the present technology e.g. if they block airflow via the nose and only allow it via the mouth.

[0030] Certain masks may be uncomfortable or impractical for the present technology if they require a patient to insert a portion of a mask structure in their mouth to create and maintain a seal via their lips.

[0031] Certain masks may be impractical for use while sleeping, e.g. for sleeping while lying on one's side in bed with a head on a pillow.

[0032] The design of a patient interface presents a number of challenges. The face has a complex three-dimensional shape. The size and shape of noses and heads varies considerably between individuals. Since the head includes bone, cartilage and soft tissue, different regions of the face respond differently to mechanical forces. The jaw or mandible may move relative to other bones of the skull. The whole head may move during the course of a period of respiratory therapy.

[0033] As a consequence of these challenges, some masks suffer from being one or more of obtrusive, aesthetically undesirable, costly, poorly fitting, difficult to use, and uncomfortable especially when worn for long periods of time or when a patient is unfamiliar with a system. Wrongly sized masks can give rise to reduced compliance, reduced comfort and poorer patient outcomes. Masks designed solely for aviators, masks designed as part of personal protection equipment (e.g. filter masks), SCUBA masks, or for the administration of anaesthetics may be tolerable for their original application, but nevertheless such masks may be undesirably uncomfortable to be worn for extended periods of time, e.g., several hours. This discomfort may lead to a reduction in patient compliance with therapy. This is even more so if the mask is to be worn during sleep.

[0034] CPAP therapy is highly effective to treat certain respiratory disorders, provided patients comply with therapy. If a mask is uncomfortable, or difficult to use a patient may not comply with therapy. Since it is often recommended that a patient regularly wash their mask, if a mask is difficult to clean (e.g., difficult to assemble or disassemble), patients may not clean their mask and this may impact on patient compliance.

[0035] While a mask for other applications (e.g. aviators) may not be suitable for use in treating sleep disordered breathing, a mask designed for use in treating sleep disordered breathing may be suitable for other applications.

[0036] For these reasons, patient interfaces for delivery of CPAP during sleep form a distinct field.

2.2.3.1.1 Seal-forming structure

[0037] Patient interfaces may include a seal-forming structure. Since it is in direct contact with the patient's face, the shape and configuration of the seal-forming structure can have a direct impact the effectiveness and comfort of the patient interface.

[0038] A patient interface may be partly characterised according to the design intent of where the seal-forming structure is to engage with the face in use. In one form of patient interface, a seal-forming structure may comprise a first sub-portion to form a seal around the left naris and a second sub-portion to form a seal around the right naris. In one form of patient interface, a seal-forming structure may comprise a single element that surrounds both nares in use. Such single element may be designed to for example overlay an upper lip region and a nasal bridge region of a face. In one form of patient interface a seal-forming structure may comprise an element that surrounds a mouth region in use, e.g. by forming a seal on a lower lip region of a face. In one form of patient interface, a seal-forming structure may comprise a single element that surrounds both nares and a mouth region in use. These different types of patient interfaces may be known by a variety of names by their manufacturer including nasal masks, full-face masks, nasal pillows, nasal puffs and oro-nasal masks.

[0039] A seal-forming structure that may be effective in one region of a patient's face may be inappropriate in another region, e.g. because of the different shape, structure, variability and sensitivity regions of the patient's face. For example, a seal on swimming goggles that overlays a patient's forehead may not be appropriate to use on a patient's nose.

[0040] Certain seal-forming structures may be designed for mass manufacture such that one design fit and be comfortable and effective for a wide range of different

face shapes and sizes. To the extent to which there is a mismatch between the shape of the patient's face, and the seal-forming structure of the mass-manufactured patient interface, one or both must adapt in order for a seal to form.

[0041] One type of seal-forming structure extends around the periphery of the patient interface, and is intended to seal against the patient's face when force is applied to the patient interface with the seal-forming structure in confronting engagement with the patient's face. The seal-forming structure may include an air or fluid filled cushion, or a moulded or formed surface of a resilient seal element made of an elastomer such as a rubber. With this type of seal-forming structure, if the fit is not adequate, there will be gaps between the seal-forming structure and the face, and additional force will be required to force the patient interface against the face in order to achieve a seal.

[0042] Another type of seal-forming structure incorporates a flap seal of thin material positioned about the periphery of the mask so as to provide a self-sealing action against the face of the patient when positive pressure is applied within the mask. Like the previous style of seal forming portion, if the match between the face and the mask is not good, additional force may be required to achieve a seal, or the mask may leak. Furthermore, if the shape of the seal-forming structure does not match that of the patient, it may crease or buckle in use, giving rise to leaks.

[0043] Another type of seal-forming structure may comprise a friction-fit element, e.g. for insertion into a naris, however some patients find these uncomfortable.

[0044] Another form of seal-forming structure may use adhesive to achieve a seal. Some patients may find it inconvenient to constantly apply and remove an adhesive to their face.

[0045] A range of patient interface seal-forming structure technologies are disclosed in the following patent applications, assigned to ResMed Limited: WO 1998/004,310; WO 2006/074,513; WO 2010/135,785.

[0046] One form of nasal pillow is found in the Adam Circuit manufactured by Puritan Bennett. Another nasal pillow, or nasal puff is the subject of US Patent 4,782,832 (Trimble *et al.*), assigned to Puritan-Bennett Corporation.

[0047] ResMed Limited has manufactured the following products that incorporate nasal pillows: SWIFT™ nasal pillows mask, SWIFT™ II nasal pillows mask, SWIFT™ LT nasal pillows mask, SWIFT™ FX nasal pillows mask and MIRAGE LIBERTY™ full-face mask. The following patent applications, assigned to ResMed Limited, describe examples of nasal pillows masks: International Patent Application WO2004/073,778 (describing amongst other things aspects of the ResMed Limited SWIFT™ nasal pillows), US Patent Application 2009/0044808 (describing amongst other things aspects of the ResMed Limited SWIFT™ LT nasal pillows); International Patent Applications WO 2005/063,328 and WO 2006/130,903 (describing amongst other things aspects of the ResMed Limited MIRAGE LIBERTY™ full-face mask); International Patent Application WO 2009/052,560 (describing amongst other things aspects of the ResMed Limited SWIFT™ FX nasal pillows).

2.2.3.1.2 Positioning and stabilising

[0048] A seal-forming structure of a patient interface used for positive air pressure therapy is subject to the corresponding force of the air pressure to disrupt a seal. Thus a variety of techniques have been used to position the seal-forming structure, and to maintain it in sealing relation with the appropriate portion of the face.

[0049] One technique is the use of adhesives. See for example US Patent Application Publication No. US 2010/0000534. However, the use of adhesives may be uncomfortable for some.

[0050] Another technique is the use of one or more straps and/or stabilising harnesses. Many such harnesses suffer from being one or more of ill-fitting, bulky, uncomfortable and awkward to use.

2.2.3.2 Respiratory Pressure Therapy (RPT) Device

[0051] A respiratory pressure therapy (RPT) device may be used individually or as part of a system to deliver one or more of a number of therapies described above,

such as by operating the device to generate a flow of air for delivery to an interface to the airways. The flow of air may be pressure-controlled (for respiratory pressure therapies) or flow-controlled (for flow therapies such as HFT). Thus RPT devices may also act as flow therapy devices. Examples of RPT devices include a CPAP device and a ventilator.

2.2.3.3 Air circuit

[0052] An air circuit is a conduit or a tube constructed and arranged to allow, in use, a flow of air to travel between two components of a respiratory therapy system such as the RPT device and the patient interface. In some cases, there may be separate limbs of the air circuit for inhalation and exhalation. In other cases, a single limb air circuit is used for both inhalation and exhalation.

2.2.3.4 Humidifier

[0053] Delivery of a flow of air without humidification may cause drying of airways. The use of a humidifier with an RPT device and the patient interface produces humidified gas that minimizes drying of the nasal mucosa and increases patient airway comfort. In addition in cooler climates, warm air applied generally to the face area in and about the patient interface is more comfortable than cold air. Humidifiers therefore often have the capacity to heat the flow of air as well as humidifying it.

2.2.3.5 Oxygen source

[0054] Experts in this field have recognized that exercise for respiratory failure patients provides long term benefits that slow the progression of the disease, improve quality of life and extend patient longevity. Most stationary forms of exercise like tread mills and stationary bicycles, however, are too strenuous for these patients. As a result, the need for mobility has long been recognized. Until recently, this mobility has been facilitated by the use of small compressed oxygen tanks or cylinders mounted on a cart with dolly wheels. The disadvantage of these tanks is that they contain a finite amount of oxygen and are heavy, weighing about 50 pounds when mounted.

[0055] Oxygen concentrators have been in use for about 50 years to supply oxygen for respiratory therapy. Traditional oxygen concentrators have been bulky

and heavy making ordinary ambulatory activities with them difficult and impractical. Recently, companies that manufacture large stationary oxygen concentrators began developing portable oxygen concentrators (POCs). The advantage of POCs is that they can produce a theoretically endless supply of oxygen. In order to make these devices small for mobility, the various systems necessary for the production of oxygen enriched gas are condensed. POCs seek to utilize their produced oxygen as efficiently as possible, in order to minimise weight, size, and power consumption. This may be achieved by delivering the oxygen as series of pulses or “boli”, each bolus timed to coincide with the start of inspiration. This therapy mode is known as pulsed or demand (oxygen) delivery (POD), in contrast with traditional continuous flow delivery more suited to stationary oxygen concentrators.

2.2.3.6 Data Management

[0056] There may be clinical reasons to obtain data to determine whether the patient prescribed with respiratory therapy has been “compliant”, e.g. that the patient has used their RPT device according to one or more “compliance rules”. One example of a compliance rule for CPAP therapy is that a patient, in order to be deemed compliant, is required to use the RPT device for at least four hours a night for at least 21 of 30 consecutive days. In order to determine a patient's compliance, a provider of the RPT device, such as a health care provider, may manually obtain data describing the patient's therapy using the RPT device, calculate the usage over a predetermined time period, and compare with the compliance rule. Once the health care provider has determined that the patient has used their RPT device according to the compliance rule, the health care provider may notify a third party that the patient is compliant.

[0057] There may be other aspects of a patient's therapy that would benefit from communication of therapy data to a third party or external system.

[0058] Existing processes to communicate and manage such data can be one or more of costly, time-consuming, and error-prone.

2.2.3.7 Mandibular repositioning

[0059] A mandibular repositioning device (MRD) or mandibular advancement device (MAD) is one of the treatment options for sleep apnea and snoring. It is an adjustable oral appliance available from a dentist or other supplier that holds the

lower jaw (mandible) in a forward position during sleep. The MRD is a removable device that a patient inserts into their mouth prior to going to sleep and removes following sleep. Thus, the MRD is not designed to be worn all of the time. The MRD may be custom made or produced in a standard form and includes a bite impression portion designed to allow fitting to a patient's teeth. This mechanical protrusion of the lower jaw expands the space behind the tongue, puts tension on the pharyngeal walls to reduce collapse of the airway and diminishes palate vibration.

[0060] In certain examples a mandibular advancement device may comprise an upper splint that is intended to engage with or fit over teeth on the upper jaw or maxilla and a lower splint that is intended to engage with or fit over teeth on the upper jaw or mandible. The upper and lower splints are connected together laterally via a pair of connecting rods. The pair of connecting rods are fixed symmetrically on the upper splint and on the lower splint.

[0061] In such a design the length of the connecting rods is selected such that when the MRD is placed in a patient's mouth the mandible is held in an advanced position. The length of the connecting rods may be adjusted to change the level of protrusion of the mandible. A dentist may determine a level of protrusion for the mandible that will determine the length of the connecting rods.

[0062] Some MRDs are structured to push the mandible forward relative to the maxilla while other MADs, such as the ResMed Narval CC™ MRD are designed to retain the mandible in a forward position. This device also reduces or minimises dental and temporo-mandibular joint (TMJ) side effects. Thus, it is configured to minimise or prevent any movement of one or more of the teeth.

2.2.3.8 Vent technologies

[0063] Some forms of treatment systems may include a vent to allow the washout of exhaled carbon dioxide. The vent may allow a flow of gas from an interior space of a patient interface, e.g., the plenum chamber, to an exterior of the patient interface, e.g., to ambient.

[0064] The vent may comprise an orifice and gas may flow through the orifice in use of the mask. Many such vents are noisy. Others may become blocked in use and

thus provide insufficient washout. Some vents may be disruptive of the sleep of a bed partner 1100 of the patient 1000, e.g. through noise or focussed airflow.

[0065] ResMed Limited has developed a number of improved mask vent technologies. See International Patent Application Publication No. WO 1998/034,665; International Patent Application Publication No. WO 2000/078,381; US Patent No. 6,581,594; US Patent Application Publication No. US 2009/0050156; US Patent Application Publication No. 2009/0044808.

2.2.4 Screening, Diagnosis, and Monitoring Systems

[0069] Polysomnography (PSG) is a conventional system for diagnosis and monitoring of cardio-pulmonary disorders, and typically involves expert clinical staff to apply the system. PSG typically involves the placement of 15 to 20 contact sensors on a patient in order to record various bodily signals such as electroencephalography (EEG), electrocardiography (ECG), electrooculography (EOG), electromyography (EMG), etc. PSG for sleep disordered breathing has involved two nights of observation of a patient in a clinic, one night of pure diagnosis and a second night of titration of treatment parameters by a clinician. PSG is therefore expensive and inconvenient. In particular it is unsuitable for home screening / diagnosis / monitoring of sleep disordered breathing.

[0070] Screening and diagnosis generally describe the identification of a condition from its signs and symptoms. Screening typically gives a true / false result indicating whether or not a patient's SDB is severe enough to warrant further

investigation, while diagnosis may result in clinically actionable information. Screening and diagnosis tend to be one-off processes, whereas monitoring the progress of a condition can continue indefinitely. Some screening / diagnosis systems are suitable only for screening / diagnosis, whereas some may also be used for monitoring.

[0071] Clinical experts may be able to screen, diagnose, or monitor patients adequately based on visual observation of PSG signals. However, there are circumstances where a clinical expert may not be available, or a clinical expert may not be affordable. Different clinical experts may disagree on a patient's condition. In addition, a given clinical expert may apply a different standard at different times.

3 BRIEF SUMMARY OF THE TECHNOLOGY

[0072] The present technology is directed towards providing medical devices used in the screening, diagnosis, monitoring, amelioration, treatment, or prevention of respiratory disorders having one or more of improved comfort, cost, efficacy, ease of use and manufacturability.

[0073] A first aspect of the present technology relates to apparatus used in the screening, diagnosis, monitoring, amelioration, treatment or prevention of a respiratory disorder.

[0074] Another aspect of the present technology relates to methods used in the screening, diagnosis, monitoring, amelioration, treatment or prevention of a respiratory disorder.

[0075] An aspect of certain forms of the present technology is to provide methods and/or apparatus that improve the compliance of patients with respiratory therapy.

[0076] One form of the present technology comprises a patient interface comprising:

a plenum chamber pressurisable to a therapeutic pressure of at least 6 cmH₂O above ambient air pressure, said plenum chamber including a plenum chamber inlet port sized and structured to receive a flow of air at the therapeutic pressure for breathing by a patient;

a first seal-forming structure constructed and arranged to form a seal with a region of the patient's face surrounding an entrance to the patient's mouth such that the flow of air at said therapeutic pressure is delivered to the mouth, the first seal-forming structure constructed and arranged to maintain said therapeutic pressure in the plenum chamber throughout the patient's respiratory cycle in use;

a second seal-forming structure constructed and arranged to form a seal with a region of the patient's face surrounding an entrance to the patient's nose such that the flow of air at said therapeutic pressure is delivered to the nose, the second seal-forming structure constructed and arranged to maintain said therapeutic pressure in the plenum chamber throughout the patient's respiratory cycle in use; and

a vent structure to allow a continuous flow of gases exhaled by the patient from an interior of the plenum chamber to vent to ambient, said vent structure being sized and shaped to maintain the therapeutic pressure in the plenum chamber in use;

the patent interface further comprising:

a pair of support portions provided on opposite sides of the interface between the second seal forming structure and an anterior wall of the plenum chamber, wherein the support portions are configured to oppose compression in the anterior-posterior direction.

[0077] In embodiments:

[0078] a) the support portions are connected to portions of the second seal forming structure which seal, in use, against the patient's lip superior;

[0079] b) the support portions are connected to portions of the second seal forming structure which, in use, seal to the patient's lip superior, directly inferior to the lower corners of the patient's nose;

[0080] c) the support portions are curved when viewed in cross-section parallel to a sagittal plane;

[0081] d) the support portions are curved when viewed in cross-section parallel to a frontal plane;

- [0082] e) the plenum chamber comprises an oral portion and a nasal portion;
- [0083] f) each support portion is connected to the oral portion of the plenum chamber adjacent a boundary of a lateral side wall portion of the oral portion and a lateral side wall portion of the nasal portion;
- [0084] g) each support portion is connected to the oral portion of the shell adjacent a boundary of an anterior wall portion of the oral portion and an anterior wall portion of the nasal portion;
- [0085] h) the lateral side wall portions of the plenum chamber curve inwardly adjacent the boundary with the nasal portion, wherein each support portion is substantially contiguous with an adjacent lateral side wall portion;
- [0086] i) the second seal-forming structure comprises at least one nasal aperture configured to deliver a flow of air at said therapeutic pressure to an entrance to the patient's nares, wherein, in use no part of either support portion is directly inferior to the or each nasal aperture;
- [0087] j) the interface further comprises a positioning and stabilising structure configured to generate a force to hold the seal-forming structure in a therapeutically effective position on the patient's head; and/or
- [0088] k) the plenum chamber is at least partially formed by a shell and the vent structure is provided to the shell.
- [0089] Another form of the technology comprises a patient interface comprising:
- a plenum chamber pressurisable to a therapeutic pressure of at least 6 cmH₂O above ambient air pressure, said plenum chamber including a plenum chamber inlet port sized and structured to receive a flow of air at the therapeutic pressure for breathing by a patient;
 - a first seal-forming structure connected to an oral portion of the plenum chamber, the first seal-forming structure constructed and arranged to form a seal with a region of the patient's face surrounding an entrance to the patient's mouth such that the flow of air at said therapeutic pressure is delivered to the mouth, the first seal-

forming structure constructed and arranged to maintain said therapeutic pressure in the plenum chamber throughout the patient's respiratory cycle in use;

a second seal-forming structure connected to a nasal portion of the plenum chamber, the second seal-forming structure constructed and arranged to form a seal with a region of the patient's face surrounding an entrance to the patient's nose such that the flow of air at said therapeutic pressure is delivered to the nose, the second seal-forming structure constructed and arranged to maintain said therapeutic pressure in the plenum chamber throughout the patient's respiratory cycle in use; and

a vent structure to allow a continuous flow of gases exhaled by the patient from an interior of the plenum chamber to vent to ambient, said vent structure being sized and shaped to maintain the therapeutic pressure in the plenum chamber in use;

wherein

a first anterior wall portion of the nasal portion of the plenum chamber, adjacent a boundary with the oral portion of the plenum chamber, is more flexible than an immediately adjacent region of the oral portion of the plenum chamber, and a second anterior wall portion of the nasal portion of the plenum chamber, which is immediately adjacent the first anterior wall portion and is on an opposite side of the first anterior wall portion to the boundary with the oral portion of the plenum chamber, is less flexible than the immediately adjacent portions of the anterior wall.

[0090] In examples:

[0091] a) the first anterior wall portion is thinner than the immediately adjacent portions of the plenum chamber wall;

[0092] b) the second anterior wall portion is thicker than the immediately adjacent portions of the plenum chamber wall;

[0093] c) the first and second anterior wall portions are made from the same material;

[0094] d) the first anterior wall portion extends across substantially an entire width of the nasal portion of the plenum chamber;

[0095] e) the second anterior wall portion extends across at least a majority of a width of the nasal portion of the plenum chamber;

[0096] f) the first anterior wall portion extends in a superior direction around at least one lateral edge of the second anterior wall portion;

[0097] g) the second anterior wall portion extends across substantially an entire width of the nasal portion of the plenum chamber;

[0098] h) a central portion of the first anterior wall portion extends further in the superior direction than lateral portions of the first anterior wall portion;

[0099] i) an upper boundary of the first anterior wall portion is curved;

[0100] j) a lower boundary of the first anterior wall portion is curved; and/or

[0101] k) the plenum chamber is at least partially formed by a shell and the vent structure is provided to the shell.

[0102] Another form of the technology comprises a patient interface comprising:

a plenum chamber pressurisable to a therapeutic pressure of at least 6 cmH₂O above ambient air pressure, said plenum chamber including a plenum chamber inlet port sized and structured to receive a flow of air at the therapeutic pressure for breathing by a patient;

a first seal-forming structure connected to an oral portion of the plenum chamber, the first seal-forming structure constructed and arranged to form a seal with a region of the patient's face surrounding an entrance to the patient's mouth such that the flow of air at said therapeutic pressure is delivered to the mouth, the first seal-forming structure constructed and arranged to maintain said therapeutic pressure in the plenum chamber throughout the patient's respiratory cycle in use;

a second seal-forming structure connected to a nasal portion of the plenum chamber, the second seal-forming structure constructed and arranged to form a seal with a region of the patient's face surrounding an entrance to the patient's nose such that the flow of air at said therapeutic pressure is delivered to the nose, the second

seal-forming structure constructed and arranged to maintain said therapeutic pressure in the plenum chamber throughout the patient's respiratory cycle in use; and

a vent structure to allow a continuous flow of gases exhaled by the patient from an interior of the plenum chamber to vent to ambient, said vent structure being sized and shaped to maintain the therapeutic pressure in the plenum chamber in use;

wherein

posterior surfaces of the lateral portions of the second seal forming structure slope in a superior-anterior direction from a boundary of the first and second seal forming structures.

[0103] In examples:

[0104] a) the slope of each lateral portion forms an angle of between 20 degrees and 90 degrees with a mid-contact plane of the mask;

[0105] b) no part of the patent interface contacts the patient's alar crest point, in use;

[0106] c) the interface is configured to prevent occlusion of the patient's nares, or to at least reduce occlusion relative to the interfaces of the prior art; and/or

[0107] d) the plenum chamber is at least partially formed by a shell and the vent structure is provided to the shell.

[0108] Another form of the technology comprises a patient interface comprising:

a plenum chamber pressurisable to a therapeutic pressure of at least 6 cmH₂O above ambient air pressure, said plenum chamber including a plenum chamber inlet port sized and structured to receive a flow of air at the therapeutic pressure for breathing by a patient;

a first seal-forming structure connected to an oral portion of the plenum chamber, the first seal-forming structure constructed and arranged to form a seal with a region of the patient's face surrounding an entrance to the patient's mouth such that the flow of air at said therapeutic pressure is delivered to the mouth, the first seal-

forming structure constructed and arranged to maintain said therapeutic pressure in the plenum chamber throughout the patient's respiratory cycle in use;

a second seal-forming structure connected to a nasal portion of the plenum chamber, the second seal-forming structure constructed and arranged to form a seal with a region of the patient's face surrounding an entrance to the patient's nose such that the flow of air at said therapeutic pressure is delivered to the nose, the second seal-forming structure constructed and arranged to maintain said therapeutic pressure in the plenum chamber throughout the patient's respiratory cycle in use; and

a vent structure to allow a continuous flow of gases exhaled by the patient from an interior of the plenum chamber to vent to ambient, said vent structure being sized and shaped to maintain the therapeutic pressure in the plenum chamber in use;

wherein

a boundary between the first seal-forming structure and the second seal-forming structure comprises a ridge.

[0109] In examples:

[0110] a) the ridge has a radius of curvature of less than 2mm;

[0111] b) the ridge extends across substantially an entire boundary between the first seal forming structure and the second seal forming structure;

[0112] c) in use, the ridge engages a patient's face proximate the entrances to the nares where the ala meets the face above the lip superior;

[0113] d) the ridge resists creases forming in the first and/or second seal forming structure adjacent the ridge; and/or

[0114] e) in use the plenum chamber is at least partially formed by a shell and the vent structure is provided to the shell.

[0115] Another form of the technology comprises a patient interface comprising:

a plenum chamber pressurisable to a therapeutic pressure of at least 6 cmH₂O above ambient air pressure, said plenum chamber including a plenum

chamber inlet port sized and structured to receive a flow of air at the therapeutic pressure for breathing by a patient;

a first seal-forming structure connected to an oral portion of the plenum chamber, the first seal-forming structure constructed and arranged to form a seal with a region of the patient's face surrounding an entrance to the patient's mouth such that the flow of air at said therapeutic pressure is delivered to the mouth, the first seal-forming structure constructed and arranged to maintain said therapeutic pressure in the plenum chamber throughout the patient's respiratory cycle in use;

a second seal-forming structure connected to a nasal portion of the plenum chamber, the second seal-forming structure constructed and arranged to form a seal with a region of the patient's face surrounding an entrance to the patient's nose such that the flow of air at said therapeutic pressure is delivered to the nose, the second seal-forming structure constructed and arranged to maintain said therapeutic pressure in the plenum chamber throughout the patient's respiratory cycle in use; and

a vent structure to allow a continuous flow of gases exhaled by the patient from an interior of the plenum chamber to vent to ambient, said vent structure being sized and shaped to maintain the therapeutic pressure in the plenum chamber in use;

wherein,

at least a portion of the oral portion of plenum chamber comprises a flexible shell, wherein the flexible shell is formed from a material having a Young's modulus of less than 0.4GPa.

[0116] In examples:

[0117] a) the flexible shell is formed from a material having a Young's modulus less than 0.1GPa, preferably between 0.3-0.7MPa.

[0118] b) at least one component is connected to the flexible shell, wherein the at least one component is stiffer than a portion of the flexible shell adjacent the component;

[0119] c) the at least one component comprises one or more of: a vent module; a headgear connector; a headgear connector connected to a rigidizing arm; a rigidizing member; a less flexible shell portion;

[0120] d) the at least one component is releasably connectable to the flexible shell;

[0121] e) the at least one component is permanently connected to the flexible shell;

[0122] f) the at least one component is overmoulded to the flexible shell;

[0123] g) the flexible shell comprises stiffening portions having greater thickness than immediately adjacent portions of the flexible shell;

[0124] h) the at least one component is configured as stiffening ribs or bands;

[0125] i) a central portion of the oral portion of the plenum chamber has a greater stiffness than the remainder of the plenum chamber; and/or

[0126] j) the plenum chamber is at least partially formed by a shell and the vent structure is provided to the shell.

[0127] Another form of the present technology comprises a patient interface comprising:

a plenum chamber pressurisable to a therapeutic pressure of at least 6 cmH₂O above ambient air pressure, the plenum chamber including a plenum chamber inlet port sized and structured to receive a flow of air at the therapeutic pressure for breathing by a patient;

a seal-forming structure constructed and arranged to form a seal with a region of the patient's face surrounding an entrance to the patient's airways for sealed delivery of a flow of pressurized air at the therapeutic pressure of at least 6 cmH₂O above ambient air pressure throughout the patient's respiratory cycle in use, the seal-forming structure comprises:

a first section constructed from a first material, the first section configured to sealingly engage against a first region of the patient's face, and

a second section constructed from a second material different than the first material, the second section configured to sealingly engage against a second region of the patient's face, wherein the second material is foam, and

a positioning and stabilising structure to provide a force to hold a seal-forming structure in a therapeutically effective position on a patient's head.

[0128] In examples:

[0129] a) the first material is silicone;

[0130] b) the first section is flush with the second section at the transition;

[0131] c) the plenum chamber includes a mounting surface, the second section of the seal-forming structure coupled to the mounting surface;

[0132] d) the mounting surface is substantially flat and substantially perpendicular to an anterior-posterior direction of the patient's head, in use;

[0133] e) the mounting surface is constructed from the first material;

[0134] f) the first section extends beyond the mounting surface, and forms an overhang relative to the mounting surface;

[0135] g) the overhang is configured to contact the patient proximate each nasal ala;

[0136] h) the plenum chamber inlet port is formed anterior to the mounting surface, in use, and wherein the second material does not contact the plenum chamber inlet port;

[0137] i) the mounting surface is substantially U-shaped or C-shaped and includes a first free end and a second free end, and wherein, in use, the first free end is configured to be spaced apart from the second free end along the patient's lip superior so as to leave the patient's philtrum uncovered by the mounting surface;

[0138] j) the first section and the plenum chamber are integrally formed as a one-piece construction during a molding process;

[0139] k) the plenum chamber is at least partially constructed from the first material;

[0140] l) the second section is coupled to the plenum chamber with an adhesive;

[0141] m) the second section includes a varying thickness;

[0142] n) the second section includes a first thickness and a second thickness greater than the first thickness, wherein the first thickness is adjacent to the second thickness;

[0143] o) the seal-forming structure is configured to form a seal against the patient's face, wherein first section and the second section each combine to form a portion of the seal;

[0144] p) the seal-forming structure is a nasal cushion or a nasal cradle;

[0145] q) the second section is configured to a nasal alar region of the patient, in use;

[0146] r) the seal-forming structure is an oronasal cushion, an ultra-compact full face mask, or a full-face mask;

[0147] s) the first section is configured to contact the patient's nose, in use, between at least the patient's pronasale and the patient's subnasale, and between at least each of the patient's nasal ala;

[0148] t) the second section is configured to contact around the patient's mouth, in use, between at least the patient's lip superior and the patient's lip inferior, and outside of the patient's mouth width adjacent at least each of the patient's nasal ala;

[0149] u) a bridge portion of the second section is configured to contact the patient's lip superior in use;

[0150] v) at least a portion of the bridge portion is unbacked, and is configured to move into the plenum chamber when contacted by the patient's lip superior;

- [0151] w) the transition is between the bridge portion and the first section;
- [0152] x) the seal-forming structure is configured to not seal against the patient's philtrum;
- [0153] y) a portion of the second section is configured to seal against a region inferior to the patient's nares and proximate to the patient's nasal ala;
- [0154] z) the first section is thinner than the second section;
- [0155] aa) when viewed in cross-section, the second section has a substantially rectangular profile;
- [0156] bb) the second section includes a substantially squared edge configured to contact the patient in use;
- [0157] cc) the substantially squared edge is configured to contact the proximate the nasal ala at a juncture of the patient's corner of nose region and the patient's lip superior; and/or
- [0158] dd) the first section is configured to receive a first component of the force and the second section is configured to receive a second component of the force, wherein the first section and the second section are configured to apply the same sealing force to the patient when the first component is less than the second component.
- [0159] Another aspect of the present technology comprises a patient interface comprising:

a plenum chamber formed from a first material and pressurisable to a therapeutic pressure of at least 6 cmH₂O above ambient air pressure, the plenum chamber including a plenum chamber inlet port sized and structured to receive a flow of air at the therapeutic pressure for breathing by a patient, the plenum chamber including a mounting surface;

a seal-forming structure constructed and arranged to form a seal with a region of the patient's face surrounding an entrance to the patient's airways for sealed delivery of a flow of pressurized air at the therapeutic pressure of at least 6 cmH₂O

above ambient air pressure throughout the patient's respiratory cycle in use, the seal-forming structure comprises:

a first section constructed from the first material, the first section configured to sealingly engage against a first region of the patient's face, and

a second section constructed from a second material different than the first material, the second section connected to the mounting surface, the second section configured to sealingly engage against a second region of the patient's face, and

a positioning and stabilising structure to provide a force to hold a seal-forming structure in a therapeutically effective position on a patient's head;

wherein the mounting surface is recessed relative to the first section by a first distance; and

wherein the second section includes a thickness substantially equal to the first distance so that the first section and the second section are substantially flush with one another.

[0160] In examples:

[0161] a) the second material is foam;

[0162] b) the first material is silicone;

[0163] c) the seal-forming structure is an oronasal cushion, an ultra-compact full face mask, or a full-face mask;

[0164] d) the mounting surface is substantially flat and substantially perpendicular to an anterior-posterior direction of the patient's head, in use;

[0165] e) the first section extends beyond the mounting surface, and forms an overhang relative to the mounting surface;

[0166] f) the overhang is configured to contact the patient proximate each nasal ala; and/or

[0167] g) the mounting surface is substantially U-shaped or C-shaped and includes a first free end and a second free end, and wherein, in use, the first free end is configured to be spaced apart from the second free end along the patient's lip superior so as to leave the patient's philtrum uncovered by the mounting surface.

[0168] Another aspect of the present technology comprises a patient interface comprising:

a plenum chamber pressurisable to a therapeutic pressure of at least 6 cmH₂O above ambient air pressure, the plenum chamber including:

a plenum chamber inlet port sized and structured to receive a flow of air at the therapeutic pressure for breathing by a patient, the plenum chamber inlet port having at least one substantially straight side,

a mounting surface being inclined relative to the substantially straight surface;

a seal-forming structure constructed and arranged to form a seal with a region of the patient's face surrounding an entrance to the patient's airways for sealed delivery of a flow of pressurized air at the therapeutic pressure of at least 6 cmH₂O above ambient air pressure throughout the patient's respiratory cycle in use, the seal-forming structure comprises:

a first section constructed from the first material, the first section configured to sealingly engage against a first region of the patient's face, and

a second section constructed from a second material different than the first material, the second section connected to the mounting surface, the second section configured to sealingly engage against a second region of the patient's face, and

a positioning and stabilising structure to provide a force to hold a seal-forming structure in a therapeutically effective position on a patient's head;

wherein the straight surface is configured to be positioned substantially parallel to the patient's sagittal plane in use; and

wherein the positioning and stabilising structure is configured to provide a greater force to the second section as a result of the position of the straight surface in use.

[0169] In examples:

[0170] a) the second material is foam;

[0171] b) the first material is silicone;

[0172] c) the plenum chamber inlet port is a first plenum chamber inlet port, wherein the plenum chamber further includes a second plenum chamber inlet port;

[0173] d) the first section extends beyond the mounting surface, and forms an overhang relative to the mounting surface;

[0174] e) the overhang is configured to contact the patient proximate each nasal ala;

[0175] f) the mounting surface is substantially U-shaped or C-shaped and includes a first free end and a second free end, and wherein, in use, the first free end is configured to be spaced apart from the second free end along the patient's lip superior so as to leave the patient's philtrum uncovered by the mounting surface;

[0176] g) the second section is permanently connected to the mounting surface;

[0177] h) the second section is removably connected to the mounting surface;

[0178] i) the second section is configured to contact the second region at the patient's lip superior; and/or

[0179] j) the first section is configured to contact the first region at the patient's alar rim.

[0180] Another aspect of the present technology comprises a seal-forming structure constructed and arranged to form a seal with a region of the patient's face surrounding an entrance to the patient's airways for sealed delivery of a flow of pressurized air at the therapeutic pressure of at least 6 cmH₂O above ambient air

pressure throughout the patient's respiratory cycle in use, the seal-forming structure comprises:

a first section constructed from a first material, the first section configured to sealingly engage against a first region of the patient's face; and

a second section constructed from a second material different than the first material, the second section configured to sealingly engage against a second region of the patient's face, wherein the second material is foam.

[0181] Another aspect of the present technology comprises a patient interface comprising:

a plenum chamber pressurisable to a therapeutic pressure of at least 6 cmH₂O above ambient air pressure, the plenum chamber including a plenum chamber inlet port sized and structured to receive a flow of air at the therapeutic pressure for breathing by a patient;

a seal-forming structure constructed and arranged to form a seal with a region of the patient's face surrounding an entrance to the patient's airways for sealed delivery of a flow of pressurized air at the therapeutic pressure of at least 6 cmH₂O above ambient air pressure throughout the patient's respiratory cycle in use; and

a positioning and stabilising structure to provide a force to hold a seal-forming structure in a therapeutically effective position on a patient's head.

[0182] In some forms, a) a first section is constructed from a first material and a second section is constructed from a second material different than the first material; b) the first material is configured to contact the patient's face; c) the second material is configured to contact the patient's face; d) the first material is silicone; and/or e) the second material is foam.

[0183] Another aspect of one form of the present technology is an oro-nasal patient interface that is more compact and less obtrusive to the patient.

[0184] Another aspect of one form of the present technology is an oro-nasal patient interface that has a nasal cushion portion that provides an improved fit to the lower corners of the nose.

[0185] Another aspect of one form of the present technology is an oro-nasal patient interface that reduces occlusive contact on the nose.

[0186] Another aspect of one form of the present technology is an oro-nasal patient interface that can self adjust to accommodate patients with a wide variety of nasolabial angles.

[0187] Another aspect of one form of the present technology is an oro-nasal patient interface that has a relatively flexible shell.

[0188] Another aspect of one form of the present technology is a patient interface that is moulded or otherwise constructed with a perimeter shape which is complementary to that of an intended wearer.

[0189] An aspect of one form of the present technology is a method of manufacturing apparatus.

[0190] An aspect of certain forms of the present technology is a medical device that is easy to use, e.g. by a person who does not have medical training, by a person who has limited dexterity, vision or by a person with limited experience in using this type of medical device.

[0191] An aspect of one form of the present technology is a portable RPT device that may be carried by a person, e.g., around the home of the person.

[0192] An aspect of one form of the present technology is a patient interface that may be washed in a home of a patient, e.g., in soapy water, without requiring specialised cleaning equipment. An aspect of one form of the present technology is a humidifier tank that may be washed in a home of a patient, e.g., in soapy water, without requiring specialised cleaning equipment.

[0193] The methods, systems, devices and apparatus described may be implemented so as to improve the functionality of a processor, such as a processor of

a specific purpose computer, respiratory monitor and/or a respiratory therapy apparatus. Moreover, the described methods, systems, devices and apparatus can provide improvements in the technological field of automated management, monitoring and/or treatment of respiratory conditions, including, for example, sleep disordered breathing.

[0194] Of course, portions of the aspects may form sub-aspects of the present technology. Also, various ones of the sub-aspects and/or aspects may be combined in various manners and also constitute additional aspects or sub-aspects of the present technology.

[0195] Other features of the technology will be apparent from consideration of the information contained in the following detailed description, abstract, drawings and claims.

4 BRIEF DESCRIPTION OF THE DRAWINGS

[0196] The present technology is illustrated by way of example, and not by way of limitation, in the figures of the accompanying drawings, in which like reference numerals refer to similar elements including:

4.1 RESPIRATORY THERAPY SYSTEMS

[0197] Fig. 1A shows a system including a patient 1000 wearing a patient interface 3000, in the form of nasal pillows, receiving a supply of air at positive pressure from an RPT device 4000. Air from the RPT device 4000 is conditioned in a humidifier 5000, and passes along an air circuit 4170 to the patient 1000. A bed partner 1100 is also shown. The patient is sleeping in a supine sleeping position.

[0198] Fig. 1B shows a system including a patient 1000 wearing a patient interface 3000, in the form of a nasal mask, receiving a supply of air at positive pressure from an RPT device 4000. Air from the RPT device is humidified in a humidifier 5000, and passes along an air circuit 4170 to the patient 1000.

[0199] Fig. 1C shows a system including a patient 1000 wearing a patient interface 3000, in the form of a full-face mask, receiving a supply of air at positive pressure from an RPT device 4000. Air from the RPT device is humidified in a

humidifier 5000, and passes along an air circuit 4170 to the patient 1000. The patient is sleeping in a side sleeping position.

4.2 RESPIRATORY SYSTEM AND FACIAL ANATOMY

[0200] Fig. 2A shows an overview of a human respiratory system including the nasal and oral cavities, the larynx, vocal folds, oesophagus, trachea, bronchus, lung, alveolar sacs, heart and diaphragm.

[0201] Fig. 2B shows a view of a human upper airway including the nasal cavity, nasal bone, lateral nasal cartilage, greater alar cartilage, nostril, lip superior, lip inferior, larynx, hard palate, soft palate, oropharynx, tongue, epiglottis, vocal folds, oesophagus and trachea.

[0202] Fig. 2C is a front view of a face with several features of surface anatomy identified including the lip superior, upper vermilion, lower vermilion, lip inferior, mouth width, endocanthion, a nasal ala, nasolabial sulcus and cheilion. Also indicated are the directions superior, inferior, radially inward and radially outward.

[0203] Fig. 2D is a side view of a head with several features of surface anatomy identified including glabella, sellion, pronasale, subnasale, lip superior, lip inferior, supramenton, nasal ridge, alar crest point, otobasion superior and otobasion inferior. Also indicated are the directions superior & inferior, and anterior & posterior.

[0204] Fig. 2E is a further side view of a head. The approximate locations of the Frankfort horizontal and nasolabial angle are indicated. The coronal plane is also indicated.

[0205] Fig. 2F shows a base view of a nose with several features identified including naso-labial sulcus, lip inferior, upper Vermilion, naris, subnasale, columella, pronasale, the major axis of a naris and the midsagittal plane.

[0206] Fig. 2G shows a side view of the superficial features of a nose.

[0207] Fig. 2H shows subcutaneous structures of the nose, including lateral cartilage, septum cartilage, greater alar cartilage, lesser alar cartilage, sesamoid cartilage, nasal bone, epidermis, adipose tissue, frontal process of the maxilla and fibrofatty tissue.

[0208] Fig. 2I shows a medial dissection of a nose, approximately several millimeters from the midsagittal plane, amongst other things showing the septum cartilage and medial crus of greater alar cartilage.

[0209] Fig. 2J shows a front view of the bones of a skull including the frontal, nasal and zygomatic bones. Nasal concha are indicated, as are the maxilla, and mandible.

[0210] Fig. 2K shows a lateral view of a skull with the outline of the surface of a head, as well as several muscles. The following bones are shown: frontal, sphenoid, nasal, zygomatic, maxilla, mandible, parietal, temporal and occipital. The mental protuberance is indicated. The following muscles are shown: digastricus, masseter, sternocleidomastoid and trapezius.

[0211] Fig. 2L shows an anterolateral view of a nose.

4.3 PATIENT INTERFACE

[0212] Fig. 3A shows a patient interface in the form of a nasal mask in accordance with one form of the present technology.

[0213] Fig. 3B shows a schematic of a cross-section through a structure at a point. An outward normal at the point is indicated. The curvature at the point has a positive sign, and a relatively large magnitude when compared to the magnitude of the curvature shown in Fig. 3C.

[0214] Fig. 3C shows a schematic of a cross-section through a structure at a point. An outward normal at the point is indicated. The curvature at the point has a positive sign, and a relatively small magnitude when compared to the magnitude of the curvature shown in Fig. 3B.

[0215] Fig. 3D shows a schematic of a cross-section through a structure at a point. An outward normal at the point is indicated. The curvature at the point has a value of zero.

[0216] Fig. 3E shows a schematic of a cross-section through a structure at a point. An outward normal at the point is indicated. The curvature at the point has a

negative sign, and a relatively small magnitude when compared to the magnitude of the curvature shown in Fig. 3F.

[0217] Fig. 3F shows a schematic of a cross-section through a structure at a point. An outward normal at the point is indicated. The curvature at the point has a negative sign, and a relatively large magnitude when compared to the magnitude of the curvature shown in Fig. 3E.

[0218] Fig. 3G shows a cushion for a mask that includes two pillows. An exterior surface of the cushion is indicated. An edge of the surface is indicated. Dome and saddle regions are indicated.

[0219] Fig. 3H shows a cushion for a mask. An exterior surface of the cushion is indicated. An edge of the surface is indicated. A path on the surface between points A and B is indicated. A straight line distance between A and B is indicated. Two saddle regions and a dome region are indicated.

[0220] Fig. 3I shows the surface of a structure, with a one dimensional hole in the surface. The illustrated plane curve forms the boundary of a one dimensional hole.

[0221] Fig. 3J shows a cross-section through the structure of Fig. 3I. The illustrated surface bounds a two dimensional hole in the structure of Fig. 3I.

[0222] Fig. 3K shows a perspective view of the structure of Fig. 3I, including the two dimensional hole and the one dimensional hole. Also shown is the surface that bounds a two dimensional hole in the structure of Fig. 3I.

[0223] Fig. 3L shows a mask having an inflatable bladder as a cushion.

[0224] Fig. 3M shows a cross-section through the mask of Fig. 3L, and shows the interior surface of the bladder. The interior surface bounds the two dimensional hole in the mask.

[0225] Fig. 3N shows a further cross-section through the mask of Fig. 3L. The interior surface is also indicated.

[0226] Fig. 3O illustrates a left-hand rule.

[0227] Fig. 3P illustrates a right-hand rule.

[0228] Fig. 3Q shows a left ear, including the left ear helix.

[0229] Fig. 3R shows a right ear, including the right ear helix.

[0230] Fig. 3S shows a right-hand helix.

[0231] Fig. 3T shows a view of a mask, including the sign of the torsion of the space curve defined by the edge of the sealing membrane in different regions of the mask.

[0232] Fig. 3U shows a view of a plenum chamber 3200 showing a sagittal plane and a mid-contact plane.

[0233] Fig. 3V shows a view of a posterior of the plenum chamber of Fig. 3U. The direction of the view is normal to the mid-contact plane. The sagittal plane in Fig. 3V bisects the plenum chamber into left-hand and right-hand sides.

[0234] Fig. 3W shows a cross-section through the plenum chamber of Fig. 3V, the cross-section being taken at the sagittal plane shown in Fig. 3V. A 'mid-contact' plane is shown. The mid-contact plane is perpendicular to the sagittal plane. The orientation of the mid-contact plane corresponds to the orientation of a chord 3210 which lies on the sagittal plane and just touches the cushion of the plenum chamber at two points on the sagittal plane: a superior point 3220 and an inferior point 3230. Depending on the geometry of the cushion in this region, the mid-contact plane may be a tangent at both the superior and inferior points. For oro-nasal interfaces configured with plenum chambers having separate oral and nasal portions, for example Ultra Compact Full Face (UCFF) masks, the superior point and inferior points are on the seal forming structure of the oral portion of the mask.

[0235] Fig. 3X shows the plenum chamber 3200 of Fig. 3U in position for use on a face. The sagittal plane of the plenum chamber 3200 generally coincides with the midsagittal plane of the face when the plenum chamber is in position for use. The mid-contact plane corresponds generally to the 'plane of the face' when the plenum chamber is in position for use. In Fig. 3X the plenum chamber 3200 is that of a nasal

mask, and the superior point 3220 sits approximately on the sellion, while the inferior point 3230 sits on the lip superior.

4.4 RPT DEVICE

[0236] Fig. 4A shows an RPT device in accordance with one form of the present technology.

[0237] Fig. 4B is a schematic diagram of the pneumatic path of an RPT device in accordance with one form of the present technology. The directions of upstream and downstream are indicated with reference to the blower and the patient interface. The blower is defined to be upstream of the patient interface and the patient interface is defined to be downstream of the blower, regardless of the actual flow direction at any particular moment. Items which are located within the pneumatic path between the blower and the patient interface are downstream of the blower and upstream of the patient interface.

4.5 HUMIDIFIER

[0238] Fig. 5A shows an isometric view of a humidifier in accordance with one form of the present technology.

[0239] Fig. 5B shows an isometric view of a humidifier in accordance with one form of the present technology, showing a humidifier reservoir 5110 removed from the humidifier reservoir dock 5130.

4.6 BREATHING WAVEFORMS

[0240] Fig. 6 shows a model typical breath waveform of a person while sleeping.

5 DETAILED DESCRIPTION OF EXAMPLES OF THE TECHNOLOGY

[0280] Before the present technology is described in further detail, it is to be understood that the technology is not limited to the particular examples described herein, which may vary. It is also to be understood that the terminology used in this disclosure is for the purpose of describing only the particular examples discussed herein, and is not intended to be limiting.

[0281] The following description is provided in relation to various examples which may share one or more common characteristics and/or features. It is to be understood that one or more features of any one example may be combinable with one or more features of another example or other examples. In addition, any single feature or combination of features in any of the examples may constitute a further example.

[0282] Where anatomical directional terms are used in describing aspects and examples of the present technology, such as "anterior", "posterior", "superior" and the like, the directions are to be read in the context of the present technology during use by the patient. For example, an anterior side of a patient interface refers to the side of the patient interface which is anterior with respect to the patient when the patient has donned the interface in the intended manner.

[0283] Where surfaces or portions are described as facing a direction, e.g. "superior facing", "anterior facing" and the like, unless the context clearly requires otherwise, the surfaces or portions are to be understood as at least partially facing in the particular direction. A portion may be "superior facing" if the portion generally faces a superior direction, even if it also partially faces another direction.

5.1 THERAPY

[0284] In one form, the present technology comprises a method for treating a respiratory disorder comprising applying positive pressure to the entrance of the airways of a patient 1000.

[0285] In certain examples of the present technology, a supply of air at positive pressure is provided to the nasal passages of the patient via one or both nares.

[0286] In certain examples of the present technology, mouth breathing is limited, restricted or prevented.

5.2 RESPIRATORY THERAPY SYSTEMS

[0287] In one form, the present technology comprises a respiratory therapy system for treating a respiratory disorder. The respiratory therapy system may comprise an RPT device 4000 for supplying a flow of air to the patient 1000 via an air circuit 4170 and a patient interface 3000.

5.3 PATIENT INTERFACE

[0288] A non-invasive patient interface 3000 in accordance with one aspect of the present technology comprises the following functional aspects: a seal-forming structure 3100, a plenum chamber 3200, a positioning and stabilising structure 3300, a vent 3400, one form of connection port 3600 for connection to air circuit 4170, and a forehead support 3700. In some forms a functional aspect may be provided by one or more physical components. In some forms, one physical component may provide one or more functional aspects. In use the seal-forming structure 3100 is arranged to surround an entrance to the airways of the patient so as to maintain positive pressure at the entrance(s) to the airways of the patient 1000. The sealed patient interface 3000 is therefore suitable for delivery of positive pressure therapy.

[0289] In some examples of the present technology, the plenum chamber is at least partially formed by a shell 3250. In examples the shell 3250 or a portion of the shell 3250 may be somewhat flexible, as is discussed further below.

[0290] The patient interface in some examples of the technology is an oro-nasal patient interface, that is, the patient interface is configured to seal around both the patient's nasal airways and oral airway. In some examples the patient interface comprises separate seals around the each of the nasal airways and the oral airway.

[0291] In the examples shown in Figs 7-22 the seal forming structure at the nasal portion does not lie over a nose bridge region or nose ridge region of the patient's face and instead seals against inferior surfaces of the patient's nose.

[0292] If a patient interface is unable to comfortably deliver a minimum level of positive pressure to the airways, the patient interface may be unsuitable for respiratory pressure therapy.

[0293] The patient interface 3000 in accordance with one form of the present technology is constructed and arranged to be able to provide a supply of air at a positive pressure of at least 6 cmH₂O with respect to ambient.

[0294] The patient interface 3000 in accordance with one form of the present technology is constructed and arranged to be able to provide a supply of air at a positive pressure of at least 10 cmH₂O with respect to ambient.

[0295] The patient interface 3000 in accordance with one form of the present technology is constructed and arranged to be able to provide a supply of air at a positive pressure of at least 20 cmH₂O with respect to ambient.

5.3.1 Seal-forming structure

[0296] In one form of the present technology, a seal-forming structure 3100 provides a target seal-forming region, and may additionally provide a cushioning function. The target seal-forming region is a region on the seal-forming structure 3100 where sealing may occur. The region where sealing actually occurs- the actual sealing surface- may change within a given treatment session, from day to day, and from patient to patient, depending on a range of factors including for example, where the

patient interface was placed on the face, tension in the positioning and stabilising structure and the shape of a patient's face.

[0297] As is described in greater detail below, in certain forms of the invention the seal forming structure 3100 comprises a first seal forming structure 3101 connected to an oral portion 3201 of the plenum chamber and constructed and arranged to form seal with a region of the patient's face surrounding an entrance to the patient's mouth, and a second seal-forming structure 3102 connected to a nasal portion 3202 of the plenum chamber 3200 constructed and arranged to form a seal with a region of the patient's face surrounding an entrance to the patient's nose. The phrase "connected to" is used herein to refer to portions or components which are formed as a single piece as well as to portions or components which are formed separately and subsequently joined together. In some cases components may be connected by an intermediate component.

[0298] In certain forms, the first seal forming structure 3101 seals independently against the patient's face than the second seal forming structure 3102.

[0299] In certain forms, the first seal forming structure 3101 and the second seal forming structure 3102 cooperate to form a single common seal against the patient's face.

[0300] In one form the target seal-forming region is located on an outside surface of the seal-forming structure 3100.

[0301] In certain forms of the present technology, the seal-forming structure 3100 is constructed from a biocompatible material, e.g. silicone rubber.

[0302] A seal-forming structure 3100 in accordance with the present technology may be constructed from a soft, flexible, resilient material such as silicone.

[0303] In certain forms of the present technology, a system is provided comprising more than one seal-forming structure 3100, each being configured to correspond to a different size and/or shape range. For example the system may comprise one form of a seal-forming structure 3100 suitable for a large sized head,

but not a small sized head and another suitable for a small sized head, but not a large sized head.

5.3.1.1 Sealing mechanisms

[0304] In one form, the seal-forming structure 3100 includes a sealing flange utilizing a pressure assisted sealing mechanism. In use, the sealing flange can readily respond to a system positive pressure in the interior of the plenum chamber 3200 acting on its underside to urge it into tight sealing engagement with the face. The pressure assisted mechanism may act in conjunction with elastic tension in the positioning and stabilising structure.

[0305] In one form, the seal-forming structure 3100 comprises a sealing flange and a support flange. The sealing flange comprises a relatively thin member with a thickness of less than about 1mm, for example about 0.25mm to about 0.45mm, which extends around the perimeter of the plenum chamber 3200. Support flange may be relatively thicker than the sealing flange. The support flange is disposed between the sealing flange and the marginal edge of the plenum chamber 3200, and extends at least part of the way around the perimeter. The support flange is or includes a spring-like element and functions to support the sealing flange from buckling in use. Limiting the occurrences of buckling may limit creases from forming in the seal-forming structure 3100, which may lead to leaks and loss of the therapeutic pressure.

[0306] In one form, the seal-forming structure 3100 may comprise a compression sealing portion or a gasket sealing portion. In use the compression sealing portion, or the gasket sealing portion is constructed and arranged to be in compression, e.g. as a result of elastic tension in the positioning and stabilising structure.

[0307] In one form, the seal-forming structure 3100 comprises a tension portion. In use, the tension portion is held in tension, e.g. by adjacent regions of the sealing flange.

[0308] In one form, the seal-forming structure 3100 comprises a region having a tacky or adhesive surface.

[0309] In certain forms of the present technology, a seal-forming structure 3100 may comprise one or more of a pressure-assisted sealing flange, a compression

sealing portion, a gasket sealing portion, a tension portion, and a portion having a tacky or adhesive surface.

5.3.1.2 Nasal region

[0310] Referring next to Figs. 7 to 18, in certain forms of the present technology, the second seal forming structure 3102 comprises a central portion 3110 configured to seal to surfaces of the patient's nose in use. The central portion may seal to an inferior periphery of the patient's nose (e.g. surrounding the patient's nares) and to the patient's lip superior. In examples a portion of the seal forming structure may engage the patient's septum. The second seal forming structure 3102 may further comprise lateral portions 3111 on lateral sides of the central portion 3110. In examples, the seal forming structure 3102 may be configured to contact the patient's face below the bridge of the nose or below the pronasale.

[0311] As best seen in Figs. 10 and 16 – 19, posterior surfaces 3112 of the lateral portions 3111 slope forward in a superior/anterior direction from the boundary 3103 of the first and second seal forming structures 3101, 3102 such that in profile the posterior side of the nasal part of the mask slopes forward.

[0312] In embodiments provided with a ridge 3120 (as described further below), the posterior surfaces 3112 of the lateral portions 3111 may slope forward from the ridge 3120.

[0313] In some forms of the technology the posterior surfaces 3112 of the lateral portions 3111 form an angle with a mid-contact plane of the mask of between 20° and 90°. The mid-contact plane may be perpendicular to the sagittal plane, and may extend substantially along a length of the ridge 3120 and the chord 3210.

[0314] As shown in Fig. 19, in some embodiments the lateral portions 3111 are configured such that no part of the patient interface 3000 contacts the patient's alar crest point 1020 when in use.

[0315] Configuring the lateral portions 3111 to slope in this way results in a smaller portion of the nasal part of the interface 3000 extending over the sides of the ala than some similar interfaces of the prior art. In some forms of the technology this results in the portion of the ala which is in contact with the seal-forming structure

3100 being reduced relative to interfaces with lateral portions which slope backward, toward the patient's face, thereby reducing the proportion of the ala which can be deformed and occluded by the seal-forming structure 3100, for example when the patient sleeps on their side with the interface in contact with a pillow.

5.3.1.3 Boundary of oral and nasal regions

[0316] With particular reference to Figs. 7, 8 and 16-18, in one form of the technology the boundary between the first sealing forming structure 3101 and the second seal forming structure 3102 forms or comprises a corner or ridge 3120. In use, the corner or ridge 3120 may engage the patient's face above the lip superior and immediately below the nose.

[0317] In embodiments the corner or ridge 3120 forms a sharper angle than the equivalent portion or area of some oro-nasal masks of the prior art, for example those described in PCT application No. PCT/AU2019/050278.

[0318] The sharper angle reduces the likelihood of creases forming in the first and/or second seal forming structures 3101, 3102 on or adjacent the corner or ridge 3120 when the mask is donned and therapy is applied. Some oro-nasal patient interfaces which do not use such a structure may require a very thin, rounded formation in this area which may be less resistant to creasing. By contrast, the corner or ridge 3120 may be stiffer, and may hold its shape better, than such interfaces and may therefore seal better against the concavities and creases present around the patient's nose. This effect may be enhanced in embodiments which are provided with support portions, for example support portions 3260 as described herein, which resist or oppose compression of this region.

[0319] In some forms of the technology the radius of the corner or ridge 3120 may be less than 2mm, for example around 1.75mm. In one form of the technology the radius may vary from approximately 1.75mm in the centre of the ridge to approximately 0.75mm at the lateral portions.

[0320] The angle formed by the first and second sealing structures may be between 20 degrees and 90 degrees, for example 36 degrees.

[0321] In some forms of the technology, the corner or ridge 3120 may extend across substantially an entire boundary 3103 between the first seal forming structure 3101 and the second seal forming structure 3102. In embodiments the corner or ridge 3120 may engage the patient's face at least approximate the entrances to the nares, for example where the ala meets the face above the lip superior, as indicated by areas 1010 in Fig 20.

5.3.1.4 Oral region

[0322] As is described above, in one form the non-invasive patient interface 3000 comprises a first seal-forming structure 3101 that forms a seal in use around the patient's mouth. The first seal forming structure 3101 may form a seal on a chin-region of the patient's face.

[0323] In one form, the seal-forming structure includes a saddle-shaped region constructed to form a seal in use on a chin-region of the patient's face.

[0324] The seal forming structure 3100 comprises a lip inferior portion 3130 which forms a seal against the chin region of the patient and/or the lip inferior and/or supramenton of the patient. The lip inferior portion 3130 may be connected to (e.g. contiguous with) a lip superior portion 3131 via an oral hole peripheral portion 3132, as shown in Fig. 16.

[0325] The seal forming structure 3100 comprises a relatively low wall thickness (compared to other portions of the interface), for example less than 0.7mm, at the oral hole peripheral portion 3132, the lip inferior portion 3130 of the seal forming structure which lies against the chin region, and at least the centre of the lip inferior portion 3130. The low wall thickness in these locations assists in achieving an effective, comfortable seal. The seal forming structure in these regions is able to readily conform to any complex geometry.

[0326] In some forms of the technology the oral hole 3133 is substantially trapezoidal rather than oval or elliptical, in order to more accurately correspond to a shape of the patient's nose. This shape of oral hole may allow the interface 3000 to be particularly compact, and not be substantially wider than a width of the patient's nares.

5.3.1.5 Nasal pillows

[0327] In one form the seal-forming structure of the non-invasive patient interface 3000 comprises a pair of nasal puffs, or nasal pillows, each nasal puff or nasal pillow being constructed and arranged to form a seal with a respective naris of the nose of a patient.

[0328] Nasal pillows in accordance with an aspect of the present technology include: a frusto-cone, at least a portion of which forms a seal on an underside of the patient's nose, a stalk, a flexible region on the underside of the frusto-cone and connecting the frusto-cone to the stalk. In addition, the structure to which the nasal pillow of the present technology is connected includes a flexible region adjacent the base of the stalk. The flexible regions can act in concert to facilitate a universal joint structure that is accommodating of relative movement both displacement and angular of the frusto-cone and the structure to which the nasal pillow is connected. For example, the frusto-cone may be axially displaced towards the structure to which the stalk is connected.

5.3.1.6 Foam Sealing Portion

[0329] As shown in Figs. 29-40, some forms of the patient interface 3000 are constructed from multiple materials that together form a cavity 3272, which receives the flow of pressurized air, and air exhaled by the patient.

[0330] In some forms, the seal-forming structure 3100 is constructed from a first material 3150 and a second material 3152, which includes at least one material property that is different than in the first material 3150. The first and second materials 3150, 3152 cooperate in order to form a seal. Each of the first and second materials 3150, 3152 are able to seal against the patient's face and limit leaking of the pressurized air from the cavity 3272.

[0331] In some forms, the seal-forming structure 3100 is constructed entirely from the second material 3152, and a plenum chamber 3200 (described below) is constructed from the first material 3150. The first material 3150 may not contact the patient.

[0332] In some forms, the seal-forming structure 3100 may include a separate seal for sealing around the patient's nares, and for sealing around the patient's mouth. Each separate seal may be constructed from a different material (e.g., one is constructed from the first material 3150, and the other is constructed from the second material 3152).

[0333] In some forms, the seal-forming structure 3100 may be constructed from both the first material 3150 and the second material 3152 throughout the seal-forming structure 3100. For example, in an oral-nasal mask (i.e., a patient interface as illustrated in Figs. 7-23 that seals around both the nares and the mouth), the first material 3150 and the second material 3152 may be included on portions that seal around the patient's nose and on portions that seal around the patient's mouth. Although they may be, both the first and second materials 3150, 3152 do not need to be used in equal amounts when forming the seal-forming structure 3100. The first and second materials 3150, 3152 may be used at specific locations in order to improve patient comfort and/or enhance sealing.

[0334] In some forms, the first material 3150 is silicone, or other similarly flexible material. The silicone 3150 may be biocompatible so that patient does not experience discomfort while using the patient interface 3000. Additionally, the silicone 3150 may be compliant and capable of sealing with a variety of patients' facial structures.

[0335] In some forms, the second material 3152 is foam, although it may also be a textile or other similar material. Like the silicone of the first material 3150, the foam 3152 may be biocompatible, and not irritate the patient when in contact with the patient's skin. The foam 3152 may be softer, lighter, and/or provide additional comfort as compared to the first material 3150.

[0336] In some forms, the foam 3152 may be constructed in portions of the seal-forming structure 3100 that contact regions of the patient's face where movement may occur. For example, these may include regions with a variety of contours, ridges, and/or creases (e.g., the nasal alar region, the nasolabial sulcus, etc.), where the foam 3152 may be required to deform in order to effectively seal against the patient's face. The nasolabial sulcus, for example, is a region with skin may fold and/or crease as a

result of the patient moving their mouth. The foam 3152 may be effective at deforming with the patient's face in order to fill the creases (e.g., as the patient's mouth opens), and relax in order to contact a flatter surface of the patient's skin (e.g., as the patient's mouth closes and the creases flatten). This property allows the foam 3152 to dynamically adjust to changing facial contours, and maintain an effective seal (e.g., by substantially eliminating leaks).

[0337] In some forms, the foam 3152 is permanently coupled to the silicone 3150. In other words, the foam 3152 may not be removed without damaging the patient interface 3000. The foam 3152 may be coupled to the silicone 3150 using an adhesive and/or a mechanical fastener. Alternatively or in addition, the silicone 3150 may be molded to the foam 3152.

[0338] In some forms, the foam 3152 is removably coupled to the silicone 3150, and may be removed by the patient. The patient may remove the foam 3152 and replace with a separate piece of foam 3152 after a certain time (e.g., to provide a clean foam 3152). The patient may also interchange one type of foam 3152 for another type of foam 3152 depending on patient preference and/or comfort.

[0339] As shown in Fig. 29, the patient interface 3000 includes a full face mask (e.g., an ultra-compact full face mask), that seals around the patient's nares and around the patient's mouth (e.g., independently, or using a single seal).

[0340] In some forms, the second seal forming structure 3102 may be constructed from silicone 3150. In other words, the portion of the seal-forming structure 3100 that at least partially seals around the patient's nares is constructed from the first material 3150. The first material 3150 may contact at least a portion of the patient's subnasale and/or the patient's nasal ala. Additionally, the nasal apertures 3135 may be formed through the first material 3150.

[0341] In some forms, the first seal forming structure 3101 may be constructed from foam 3152. In other words, the portion of the seal-forming structure 3100 that at least partially seals around the patient's mouth is constructed from the second material 3152. The second material 3152 may contact the patient's lip inferior, and a lateral area outside of the patient's mouth width.

[0342] In certain forms, the foam of the second material 3152 may be structured so that it is substantially impermeable in order to limit air leaking through the second material.

[0343] In certain forms, the foam of the second material 3152 may be permeable but may be coated with an impermeable material (e.g., a silicone layer). The coating may be applied to an inner surface of the second material 3152 (e.g., a surface within the cavity 3272) so that the patient contacts the second material 3152 and not the coating. In other forms, the coating may be applied to the outer surface in addition or instead of the inner surface.

[0344] In certain forms, a lip superior portion 3131 extends between lateral sides of the seal-forming structure 3100, and may separate the first seal forming structure 3101 from the second seal forming structure 3102. The lip superior portion 3131 contacts the patient's lip superior in use, and may be constructed from foam 3152.

[0345] In one form, the lip superior portion 3131 does not apply any sealing force on the patient's lip superior while in use. Only the outer perimeter of the seal-forming structure 3100 forms a seal with the patient's face. Thus, the first and second sealing structures 3101, 3102 may cooperate to form the seal around the patient's nares and mouth.

[0346] In one form, the lip superior portion 3131 does apply a sealing force to the patient's lip superior while in use. The position of the lip superior portion 3131 between the first and second sealing structures 3101, 3102 may allow it to assist in forming a seal around both the nares and the mouth. Even when a seal is separately formed around each orifice, both the patient's nares and the patient's mouth may be in fluid communication with the cavity 3272 of the plenum chamber 3200.

[0347] As shown in Figs. 30 to 31A, the first and second seal forming structures 3101, 3102 may be flush with one another. In other words, there may be a substantially smooth transition between the first seal forming structure 3101 and the second seal forming structure 3102. The smooth transition may be comfortable for the patient, and therefore improve patient compliance, because there is no substantially sharp, or otherwise uncomfortable, transition between the two materials.

[0348] As illustrated in Fig. 30A, the second material 3152 may be thicker than the first material 3150. This may be to improve impermeability of the second material 3152 and/or to improve patient comfort. Because the first material 3150 may be thinner than the second material 3152, the first material 3150 may not be flush with the second material 3152 across the entire width of the second material 3152. Instead, the first material 3150 may be flush at the corner or ridge region 3120. This region 3120 may be angled as described above in order to improve sealing without causing substantial discomfort. Alternatively, the ridge region 3120 may be entirely smooth so that there is a constant radius of curvature on either side of the ridge region 3120. The first material 3150 may only be flush with the second material 3152 at the patient contacting side, and may not be flush with the second material 3152 within the cavity 3272.

[0349] In some forms, the transition may be at the boundary 3103 between the second seal forming structure 3102 and the lip superior portion 3131. With specific reference to Fig. 31, the lip superior portion 3131 includes a curvature that substantially corresponds to the curvature of the second seal forming structure 3102, and to the remainder of the first seal forming structure 3101. A smooth, continuous surface may extend between the first and second sealing structures 3101, 3102 (e.g., there are no jagged and/or discontinuous portions).

[0350] As shown in Fig. 32, the first seal forming structure 3101, including the lip superior portion 3131, may be constructed from a single piece of foam 3152. In other words, the entire first seal forming structure 3101 is one piece, and may be moved together. This may assist in assembling the seal-forming structure 3100, because constructing the first seal forming structure 3101 as a single piece reduces the number of components limits the possibility that components are incorrectly positioned relative to one another.

5.3.1.6.1 Shape of Foam

[0351] In some forms, the foam 3152 of the first seal forming structure 3101 may include an annular shape, in order to provide an opening to receive the patient's mouth. As described above, the foam 3152 contacts the area around the patient's mouth in order to seal around the orifice. The patient may desire a minimal width of the first seal forming structure 3101 (e.g., the distance between an inner and outer

diameter), because less material in contact with the patient's face may improve patient comfort and compliance.

[0352] In some forms, the sealing perimeter of the first seal forming structure 3101 is minimized in order to maximize patient comfort and compliance. Reducing the sealing perimeter (e.g., as close to the mouth width, and/or upper and/or lower vermillion as possible while still maintaining a seal around the patient's mouth) may reduce the feeling in the patient of wearing a medical device.

[0353] Reducing the sealing perimeter may also reduce the volume of the cavity 3272. This may improve the efficiency of the system because less airflow is needed to reach the desired pressure in the cavity 3272.

[0354] Accordingly, if the outer diameter is already at its minimum (e.g., to establish a minimum sealing perimeter), then the inner diameter may be adjusted to reduce the total contact area between the patient and the first seal forming structure 3101.

[0355] As shown in Fig. 32, increasing the inner diameter (i.e., in order to decrease the width) of the foam 3152, the oral hole 3133 that receives the patient's mouth is larger (e.g., as compared to Fig. 29). A larger oral hole 3133 may improve patient comfort because they may have added room between their mouth and the foam 3152. This may provide the patient the ability to move their lips without experiencing substantial contact with the foam 3152.

[0356] The foam 3152 in the first seal forming structure 3101 may include an average width. The width may be substantially the same along the entire perimeter of the first seal forming structure 3101, so that the width in a given location is substantially the same as the average width. In some forms, the average width may be between approximately 1 mm and approximately 20 mm. In some forms, the average width may be between approximately 5 mm and approximately 15 mm. In some forms, the average width may be approximately 10 mm. This may be less than the average width of the first seal forming structure 3101 in Fig. 29, which may be at least 15 mm.

[0357] In some forms, the width may vary along the perimeter of the first seal forming structure 3101, although the average width may still be between approximately 1 mm and approximately 20 mm. A variable width may allow the first seal forming structure 3101 to be tailored to individual regions of a patient's face, and provide increased sealing and/or cushioning at some locations and less in others.

[0358] In some forms, the first seal forming structure 3101 may form a substantially polygonal shape. In some examples, the first seal forming structure 3101 may form a substantially trapezoidal shape. The lip superior portion 3131 may be the shorter substantially parallel side of the substantially trapezoidal shape.

[0359] In some forms, the first seal forming structure 3101 may include varying thicknesses. For example, the foam 3152 at the lip superior portion 3131 may be thinner than the adjacent foam 3152.

[0360] In certain forms, corners 3153 of the first seal forming structure 3101 may be substantially squared. This may assist in reducing the feeling in the patient that the foam 3152 is crowding their nose and/or mouth.

[0361] In certain forms, the lip superior portion 3131 may have a curvature. For example, the lip superior portion 3131 may have a positive curvature relative to the patient's subnasale. The minimum point of the lip superior portion 3131 may be proximate to the center of the lip superior portion 3131. The curvature may also move the lip superior portion 3131 away from the nostrils and reduce the likelihood of blocking or otherwise obstructing the nostrils.

[0362] In one form, only a portion of the lip superior portion 3131 may be curved. For example, a portion of the lip superior portion 3131 may be straight, and a portion of the lip superior portion 3131 may be curved. In other words, only the central portion of the lip superior portion 3131 may have the curvature.

[0363] In some forms, a transition 3154 between the straight section and the curved section of the lip superior portion 3131 may be sharp. In other words, the transition 3154 may be substantially angled and not smooth. This may allow the foam 3152 of the lip superior portion 3131 to more readily enter small crevices of the patient's face (e.g., proximate to the patient's nasal alae). This may improve sealing,

since air may be limited from escaping through those regions. Since the foam 3152 is compliant, the angled shape of the transition 3154 may not cause the patient discomfort. The sharp edge of the foam 3152 may reduce the feeling of occlusion, and therefore increase patient compliance.

[0364] However, as described above, this surface may alternatively be smooth, like the example illustrated in Fig. 31.

[0365] As shown in Fig. 33, the foam 3152 may have a substantially rectangular shape when viewed from a side (e.g., the left or right side) or in cross-section. The rectangular profile may have sharp or angled edges, which may provide the benefit of allowing the foam 3152 to more readily fit into small crevices of the patient's face (e.g., between the patient's nasolabial sulcus and nasal ala). In other words, the edges of the rectangular profile assist with the dynamic sealing, so that the foam 3152 may more effectively deform into the creases on the patient's skin as they form, and return to the relaxed position as they flatten so minimal air leaks to the ambient from the plenum chamber 3200. The sharp edges may not cause the patient discomfort because of the compliant nature of the foam 3152.

[0366] In some forms, the rectangular profile may have rounded edges, specifically in regions of the foam 3152 configured to contact the patient's face. The rounded edge may not extend entirely around the perimeter of the first seal forming structure 3101, and a portion of the foam 3152 may have a sharp edge. The rounded portion may be proximate inferior portion of the first seal forming structure 3101, and may be configured to sit proximate to the patient's mouth. The sharp portion may be proximate superior portion of the first seal forming structure 3101, and may be configured to sit proximate to the patient's nose.

5.3.2 Plenum chamber

[0367] In some forms, the plenum chamber 3200 (or at least a portion of the plenum chamber 3200) and the seal-forming structure 3100 are formed from a single homogeneous piece of material (e.g., molded silicone). A combination of the seal-forming structure 3100 and the plenum chamber 3200 may be considered a cushion.

5.3.2.1 Angle of nasal portion is adjustable

[0368] With particular reference to Figs. 9, 10 and 16 to 18-2, in one form of the technology a first anterior wall portion 3240 of the nasal portion 3202 of the plenum chamber 3200 is more flexible than an immediately adjacent region of the oral portion 3201. The first anterior wall portion 3240 may be provided adjacent a boundary 3241 of the nasal and oral portions of the plenum chamber 3200. In embodiments the first anterior wall portion 3240 may be symmetrical about the mid-sagittal plane and may extend across at least 50% of the width of the nasal portion 3202 of the plenum chamber, for instance at least 80%. In some embodiments the first anterior wall portion 3240 may extend across substantially the entire width of the nasal portion 3202 of the plenum chamber.

[0369] In some forms of the technology a second anterior wall portion 3242 is less flexible than the immediately adjacent portions of the anterior wall. In some embodiments the second anterior wall portion 3242 is immediately adjacent the first anterior wall portion 3240 on an opposite side to the boundary 3241 of the nasal and oral portions of the plenum chamber. In embodiments the second anterior wall portion 3242 may be symmetrical about the mid-sagittal plane and may extend across at least 50% of the width of the nasal portion 3202 of the plenum chamber, for instance at least 80%. In some embodiments the second anterior wall portion 3242 may extend across substantially the entire width of the nasal portion 3202 of the plenum chamber.

[0370] The flexible first anterior wall portion 3240 may allow the patient contacting portions 3110 of the second seal forming structure 3102 to pivot or hinge about a region on the posterior side of the interface 3000. This may assist in allowing the interface to accommodate patients with a variety of angles between the bottom of the nose and the top lip (i.e. nasolabial angles).

[0371] In embodiments featuring a corner or ridge 3120 between the first and second seal forming structures 3101, 3102, such as have been described above, the patient contacting portions 3110 may pivot or hinge about an area at or adjacent the corner or ridge 3120. In embodiments provided with one or more support portions 3260 (described further below), the hinging or pivoting region may be immediately superior to the support portions 3260.

[0372] As shown in Fig. 9, the first anterior wall portion 3240 may have a superior boundary 3243 and an inferior boundary 3244. One or both of the superior and inferior boundaries 3243, 3244 may be curved, for example such that a central portion of the boundary is inferior to the lateral portions, as shown. The first anterior wall portion 3240 may be substantially the same height across its width (i.e., the superior and inferior boundaries may be substantially parallel) or the height may vary across the width, for example such that the height of a central portion of the first anterior wall portion 3240 is greater than the height of the lateral portions, as shown in the embodiment in Fig. 9. Varying the curvature of one or both of the boundaries 3243, 3244 and/or the height of the first anterior wall portion 3240 may change the stiffness of the first anterior wall portion 3240, that is, its resistance to collapsing or folding in response to forces on the patient-contacting portions 3110 of the second seal forming structure 3102.

[0373] Similarly, the second anterior wall portion 3242 may have a superior boundary 3247 and an inferior boundary 3248. In some forms of the technology the inferior boundary 3248 of the second anterior wall portion 3242 is the same as the superior boundary 3243 of the first anterior wall portion 3240. Both the superior and inferior boundaries 3247, 3248 of the second anterior wall portion 3242 may be curved, for example such that a central portion of the boundary is inferior to the lateral portions. The second anterior wall portion 3242 may be substantially the same height across its width (i.e., the superior and inferior boundaries may be substantially parallel) or the height may vary across the width, for example such that the height of a central portion of the second anterior wall portion 3242 is less than the height of the lateral portions.

[0374] In some forms of the technology other ways of configuring the first anterior wall portion 3240 to have a required stiffness may be used, in addition to or alternatively to curved boundaries. For example, the thickness of the first anterior wall portion 3240 may be selected to provide a required stiffness. In examples the first anterior wall portion 3240 may be thinner than the immediately adjacent portions of the plenum chamber wall. Additionally and/or alternatively, the first anterior wall portion 3240 may extend in a superior direction around a lateral edge of the second anterior wall portion 3242, as shown in Fig. 21, thereby providing a reduced

stiffness/resistance to compression or collapse compared to embodiments in which the first anterior wall portion 3240 is not shaped this way.

[0375] The second anterior wall portion 3242 (e.g., the band 3270) may assist in preventing collapse of the nasal portion 3202, and may provide support for the patient-contacting portions 3110 of the second seal forming structure 3102, which are typically relatively thin. Insufficiently supported patient contacting portions may suffer from blowout of the sealing engagement with the patient's face. In one form the second anterior wall portion 3242 is thicker than the immediately adjacent portions of the plenum chamber wall. In certain forms the second anterior wall portion 3242 is provided as a thickened band of material 3270, as shown in Figs 16-19. The first and second anterior wall portions 3240, 3242 may be made from the same material, for example as part of an integrally moulded shell 3250.

[0376] In some forms, the first and second anterior wall portions 3240, 3242 may include different thicknesses. For example, the thickness of the second anterior wall portion 3242 may be greater than the thickness of the first anterior wall portion 3240, which may provide the increased stiffness in the second anterior wall portion 3242 (e.g., as compared to the first anterior wall portion 3240). Specifically, the second anterior wall portion 3242 may be a band 3270 that may extend into the cavity 3272 of the plenum chamber 3200. For example, the band 3270 may extend past the first anterior wall portion 3240, and extend toward a patient wearing the patient interface 3000. An exterior surface of the nasal portion 3202 may be substantially smooth, while an interior surface of the nasal portion (e.g., within the cavity 3272) may be stepped (or otherwise include a discontinuity).

[0377] As shown in Figs. 16-1 and 16-2, the first anterior wall portion 3240 may act as a hinge and allow the nasal portion 3202 to bend. The first anterior wall portion 3240 may be the thinnest region of the nasal portion 3202, and therefore may be the most susceptible to a bending moment. The increased thickness of the band 3270 directs the bending moment away from the second anterior wall portion 3242, and toward the thinner first anterior wall portion 3240. A larger height of the band 3270 (i.e., a larger distance between the superior and inferior boundaries 3247, 3248) may also make the nasal portion 3202 stiffer and less capable of bending about the first

anterior wall portion 3240. The first and second anterior wall portions 3240, 3242 may move in the anterior direction (e.g., away from the patient) as bending occurs.

[0378] As shown in Figs. 18-1 and 18-2, the superior boundary 3243 of the first anterior wall portion 3240 is not the same as the inferior boundary 3248 of the second anterior wall portion 3242. Instead, the superior boundary 3243 is at least partially more superior than the inferior boundary 3248, and may be at least partially aligned with the superior boundary 3247 of the second anterior wall portion 3242. This allows the first anterior wall portion 3240 to be disposed at least partially alongside of the band 3270 (e.g., and surround the band 3270 on two or more sides). In other words, the first anterior wall portion 3240 may be disposed on at least one of the ends of the band 3270. This may provide the first anterior wall portion 3240 with greater flexibility so that the nasal portion 3202 is able to bend further (e.g., in the anterior direction).

[0379] As shown in Fig. 21-1, the nasal portion 3202 may also be formed without a hinge. In other words, a band may not be formed on the second anterior wall portion 3242, so that the first and second anterior wall portions 3240, 3242 have substantially uniform thicknesses. The nasal portion 3202 may still be able to bend even without band because it may be constructed from silicone, which permits some compliance in the nasal portion 3202 to accommodate different nasolabial angles.

5.3.2.2 Flexible shell

[0380] In some forms of the technology the shell 3250 may be made from a rigid material such as polycarbonate. However, in other forms of the technology the shell 3250, or portions of the shell 3250, may be somewhat flexible. For example, in examples the shell 3250 may be formed from a material which has a Young's modulus of 0.4 GPa or lower, for example foam. In some forms of the technology the shell 3250 may be made from a material having Young's modulus of 0.1 GPa or lower, for example rubber. In other forms of the technology the shell 3250 may be made from a material having a Young's modulus of 0.7 MPa or less, for example between 0.7 MPa and 0.3 MPa. An example of such a material is silicone.

[0381] In examples, the shell 3250 and one or both of the first and second seal forming structures 3101, 3102 may be formed from the same material (e.g., silicone, textile, etc.).

[0382] In some forms of the technology (see e.g., Figs. 23 to 28), the shell 3250 may be constructed substantially entirely from a flexible material, which may provide the shell 3250 with the greatest freedom of movement (i.e., substantially no rigid and/or thickened portions that limit bending). The shell 3250 may be sufficiently flexible that one or more components are added to provide a required stiffness in one or more areas or regions of the shell 3250 (e.g., a region that contacts the area 1010). For example, one or more of a vent module; a connection port; a headgear connector; a headgear connector connected to a rigidising arm and a rigidising member may be connected to the shell 3250 in such a way as to increase the stiffness of the plenum chamber 3200 in the area adjacent the component, for example as described further below. In some forms of the technology such components may be releasably connectable to the flexible shell 3250. Additionally or alternatively one more components may be permanently connected to the shell 3250, for example by bonding and/or overmoulding. The rigidising member may also serve to increase the stiffness and/or support the shape of the seal forming structure 3100.

[0383] In some forms of the technology the shell 3250 may be generally flexible but may comprise stiffening portions having greater thickness than immediately adjacent portions of the shell 3250. Such stiffening portions may be configured as ribs or bands, for example extending laterally across the shell and/or extending in a superior-inferior direction, although many other configurations are possible. In some forms the shell may comprise a substantially rigid portion, for example manufactured from polycarbonate, as well as a somewhat flexible portion.

[0384] In some forms of the technology it may be preferable for a central portion 3251 of the anterior side of the oral portion 3201 of the plenum chamber to have a greater stiffness than the remainder of the plenum chamber 3200. In some forms of the technology the area of increased stiffness may be immediately inferior to the nasal portion 3202, as shown in Fig. 21 and described further below, and/or immediately superior to the oral portion 3201. In one form of the technology, a portion of, or the entirety of, the first anterior wall portion 3240 may be an area of increased stiffness,

rather than an area of increased flexibility. Providing increased stiffness in one or more of these areas may provide shape stability and may limit the extent to which the shell 3250 deforms as a result of headgear forces. Excessive deformation may result in the second seal forming structure 3102 occluding the nares. Avoiding such deformation may be particularly advantageous to patients with relatively wide noses, and may be less important, or in some cases undesirable, for patients with narrow noses. In addition, the areas of increased stiffness described may assist in reducing torsional deformation of the interface which may otherwise result in one side of the second seal forming structure 3102 losing contact with the patient's nose, thereby creating a leak path.

[0385] As shown in Figs. 21 and 21-1, in one form of the technology the shell 3250 may be provided with a rigid portion 3263, or at least a portion which is more rigid than the remainder of the shell, to which one or more connection ports 3600 are provided, e.g. moulded. In one form of the technology a rigid portion 3263 may be made from polycarbonate. This may provide more rigidity than a shell made exclusively of silicone. In one form the technology holes forming a vent 3400 are moulded into the rigid portion 3263. In some forms of the technology connectors 3310 for a positioning and stabilising structure are mounted on arms 3320 which provide some rigidity to the shell.

[0386] In one form of the technology the rigid portion 3263 extends laterally across the anterior of the plenum chamber near a superior boundary of the first anterior wall portion 3240, for example immediately below the second anterior wall portion 3242. The rigid portion 3263 may extend continuously between the connection ports 3600, and may provide an airflow path for the flow of pressurized air entering the plenum chamber 3200 through the connection ports 3600.

[0387] In some forms of the technology the connection ports 3600 may have a substantially elliptical shape in cross-section. The connection ports 3600 may be orientated such that a centreline of each port is substantially parallel to an exterior surface of the plenum chamber adjacent the port.

[0388] In some forms of the technology the rigid portion 3263 may protrude in an anterior direction relative to an adjacent face of the first anterior wall portion 3240, and may be shaped to increase resistance to bending.

[0389] In some forms of the technology (see e.g., Fig. 21), the connectors 3310 and arms 3320 are provided inferior of the connection ports 3600, toward the lateral edges of the plenum chamber 3200. The connectors 3310 may be provided at lateral ends of the arms 3320. The connectors 3310 may provide additional rigidity to the plenum chamber 3200 and/or the seal forming structure 3100.

[0390] In some forms of the technology (see e.g., Fig. 21-1), the connectors 3310 do not include arms 3320, and are instead connected directly to the plenum chamber 3200. This may make the plenum chamber 3200 more flexible than the plenum chamber 3200 of Fig. 21.

[0391] Fig. 22 shows a plenum chamber 3200 with a vent mounting aperture 3410 into which a suitable vent portion or module may be inserted. The vent portion may be made from a relatively stiff material to increase the stiffness of the plenum chamber. In some forms of the technology the vent mounting aperture 3410 may be substantially elliptical in shape, with the minor axis of the ellipse being substantially parallel to a sagittal plane.

[0392] In the embodiment shown in Figure 22 the vent mounting aperture is provided toward a superior border of the oral portion 3201 of the plenum chamber 3200.

[0393] The embodiment shown in Fig. 22 is provided with connectors 3310 for a positioning and stabilising structure. The connectors 3310 may be mounted in relatively thicker regions of the shell 3250. In the embodiment shown the connectors 3310 are inferior of the vent mounting aperture 3410 and toward the lateral sides of the plenum chamber 3200. In some forms of the technology the connectors 3310 are substantially circular magnetic headgear connectors.

[0394] While inlet or connections ports are not shown in the drawings of the plenum chamber shown in Figs. 7-19, those skilled in the art will appreciate that in practice one or more inlet ports will be provided, for example inlet ports 3600 as

shown in Figs. 21-22. The inlet ports 3600 allow connection of the interface to an air circuit 4170, as described further herein. In some forms of the technology one or more components of the air circuit 4170 may also act as components of a positioning and stabilising structure.

[0395] In certain forms of the present technology, the plenum chamber 3200 is constructed from a transparent material, e.g. a transparent polycarbonate. The use of a transparent material can reduce the obtrusiveness of the patient interface, and help improve compliance with therapy. The use of a transparent material can aid a clinician to observe how the patient interface is located and functioning.

[0396] In certain forms of the present technology, the plenum chamber 3200 is constructed from a translucent material, e.g. translucent silicone. The use of a translucent material can reduce the obtrusiveness of the patient interface, and help improve compliance with therapy.

[0397] In certain forms of the present technology, dedicated stiffening members or rigidising members (e.g., with no other function) may be included on the plenum chamber 3200. These members may be formed from a material more rigid than the plenum chamber 3200 (e.g., than the silicone). The dedicated stiffening members may be overmolded to the plenum chamber 3200 to provide more stiffness than the rigid portion 3263 of the shell 3250 or the arms 3320.

5.3.2.3 Mounting Flange

[0398] As shown in Figs. 34 and 35, some forms of the plenum chamber 3200 include a mounting flange or support surface 3290. The mounting flange 3290 may be a substantially flat surface. The mounting flange 3290 may be perpendicular to the anterior-posterior direction (e.g., a direction parallel to the patient's sagittal plane) when worn by the patient.

[0399] In some forms, the mounting flange 3290 includes a first free end 3291 and a second free end 3292 spaced apart from the first free end 3291. Thus, the mounting flange 3290 may not form a continuous annular shape. A space or gap 3293 between the first and second free ends 3291, 3292 may be proximate the patient's lip superior when the plenum chamber 3200 is in use.

[0400] In certain forms, the mounting flange 3290 may have a substantially C-shape, where a portion of the mounting flange 3290 extends toward the patient's philtrum in use.

[0401] In certain forms, the mounting flange 3290 may have a substantially U-shape, where the mounting flange 3290 does not extend toward the patient's philtrum in use.

[0402] In some forms, the plenum chamber 3200, with the mounting flange 3290, is constructed together with the second seal forming structure 3102. For example, the plenum chamber 3200 and the second seal forming structure 3102 may be constructed from the same material (e.g., silicone), and may be molded together. Although in other forms, the plenum chamber 3200 may be constructed at least partially from a different material (e.g., hard plastic) than the second seal forming structure 3102. In still other forms, the mounting flange 3290 and the second seal forming structure may be constructed from the same material, but the mounting flange 3290 may be thicker or otherwise stiffer.

[0403] In some forms, the second seal forming structure 3102 may extend beyond the mounting flange 3290 in the posterior direction. In other words, the second seal forming structure may form an overhang 3294 with respect to the mounting flange 3290.

[0404] In some forms, the second seal forming structure 3102 includes two overhangs 3294, which may be positioned on either lateral side of the patient's nose, when the patient interface 3000 is worn by the patient. The overhangs 3294 of the second seal forming structure 3102 may not extend across the gap 3293. Rather, the overhangs 3294 may extend up to the respective first and second free ends 3291, 3292, so that a width of the gap 3293 may not be obstructed by the overhangs 3294.

[0405] In certain forms, the width of the gap 3293 is substantially the width of a patient's nose. In use, the patient's nose may fit into the gap 3293 so that the overhangs 3294 may be disposed on either side of the patient's nose. An inner surface of each overhang 3294 may contact the patient proximate their respective nasal ala.

[0406] As shown in Fig. 35, a lower surface 3295 of each overhang 3294 may be substantially flat, and may be formed perpendicularly with the support flange 3290. An upper surface 3296 of each overhang 3294 may be inclined and/or curved so that the thickness of each overhang 3294 may decrease in the posterior direction. Thus, the thickness of each overhang 3294 may be greater proximate to the mounting flange 3290, and less distal to the mounting flange 3290.

[0407] In some forms, connection ports 3600 (described below) may be molded with the plenum chamber 3200 and the second seal forming structure 3102. In other words, the connection ports 3600 may be formed as one piece with the plenum chamber 3200, and may not be removable from the plenum chamber 3200.

[0408] As shown in Fig. 31, some forms of the patient interface 3000 include connection ports 3600 that are spaced apart from the support flange 3290. For example, the connection ports 3600 may be more anterior than the support flange 3290 while the patient interface 3000 is in use. In this way, the support flange 3290 may be unobstructed by the connection ports 3600 or the air circuit 4170 (described below).

[0409] As shown in Fig. 33, certain forms of the patient interface 3000 may include connection ports 3600 that are oriented offset from the superior-inferior direction (e.g., as opposed to being positioned generally along the superior-inferior direction of Fig. 31). During assembly for example, a superior end of the connection port 3600 may be rotated toward the patient and an inferior end of the connection port 3600 may be rotated away from the patient (i.e., in a clockwise direction as shown in Fig. 33).

[0410] In some forms, the connection ports may have a substantially straight surface 3604 that may be inclined relative to the mounting flange 3290.

[0411] In certain forms, the connection ports 3600 may be substantially D-shaped, and the straight surface 3604 may be proximate to the mounting flange 3290.

[0412] Rotating the connector ports 3600 may cause the patient interface 3000 to be worn in a rotated position. For example, when in use, the connector ports 3600 may be aligned with the superior-inferior direction. Since the connector ports 3600

were rotated (e.g., during assembly), the plenum chamber 3200 must be rotated (e.g., when donning) in the opposite direction (e.g., counter clockwise as viewed in Fig. 33) in order to orient the connector ports 3600 as described above. This causes the plenum chamber 3200 to be rotated in a direction away from the patient's nose and toward the patient's mouth. Rotating away from the patient's nose may reduce the load experienced by a patient proximate their pronasale (e.g., around an alar perimeter), or in similar areas where excessive loading may be uncomfortable for a patient. It may also give the patient's nose more room within the cavity 3272 so that the patient's nose does not contact or "bottom out" against a surface of the plenum chamber before a seal has been sufficiently established.

[0413] For example, as illustrated in Fig. 33, the mounting flange 3290 is oriented generally along the superior-inferior axis of the page. The straight surface 3604 is inclined relative to the superior-inferior direction. In use, the patient interface 3000 may rotate (e.g., in the counter clockwise direction of Fig. 33) from the position illustrated in Fig. 33 toward the position illustrated in Fig. 19 so that the straight surface of Fig. 3604 is more closely aligned with the superior-inferior direction of the page (and may also be substantially parallel to the patient's sagittal plane).

[0414] In this position, the tensile force provided by the conduits connected to the connection port 3600 (or from straps of the positioning and stabilizing structure 3000) may pull the first seal forming structure 3101 into the patient's face with more force than the second seal forming structure 3102, which may be more comfortable for the patient.

5.3.2.3.1 Connection with the First Seal Forming Structure

[0415] In some forms, the first seal forming structure 3101 may be coupled to the plenum chamber 3200, after the plenum chamber 3200 has been constructed (e.g., after the plenum chamber 320 and the second seal forming structure 3102 are molded together).

[0416] In some forms, the mounting flange 3290 provides a mounting surface for the first seal forming structure 3101. The first seal forming structure 3101 may be coupled to the mounting flange 3290 so that it is positioned to contact the patient's face in use. The first seal forming structure 3101 may be coupled to the mounting

flange 3290 using adhesives (e.g., glue), mechanical fasteners (e.g., snaps, clasps, etc.), magnets, hook and loop material, or any other similar connection means. Additionally, a combination of two or more connection means may be used.

[0417] As shown in Figs. 32 and 33, the foam 3152 that forms the first seal forming structure 3101 may be constructed from a single piece of material. When coupled to the mounting flange 3290, a portion of the foam 3152 extends across the gap 3293 between the first and second free ends 3291, 3292, so that unlike the mounting flange 3290, the foam may extend around an entire perimeter of the patient's mouth.

[0418] In certain forms, the foam 3152 spanning the gap 3293 is unbacked. In other words, the foam 3152 spanning the gap 3293 is unsupported, and may move into and/or out of the cavity 3272 of the plenum chamber 3200. The remainder of the foam 3152 is supported by the mounting flange 3290 and is not free to move, although it may compress as a result of contact with a patient's face. For example, as illustrated in Fig. 31A, the foam 3152 configured to contact the patient's lip superior is unbacked, and may therefore be movable relative to the remainder of the foam 3152 (e.g., which contacts the mounting flange 3290).

[0419] In use, at least part of the lip superior portion 3131 of the first seal forming structure 3101 spans the gap 3293 and is unsupported by the mounting flange 3290. Thus, the patient's lip superior (e.g., the patient's philtrum) may contact the unsupported section of the foam 3152. As the patient dons the patient interface 3000, the lip superior portion 3131 may move at least partially into the cavity 3272 (e.g., as a result of a force applied by the patient's lip superior). When the patient doffs the patient interface, the lip superior portion 3131 may move in the opposite direction to return to its substantially initial position.

[0420] In certain forms, the movement of the lip superior portion 3131 may provide additional comfort for the patient wearing the patient interface. For example, the lip superior portion 3131 may be under some tension prior to contact with the patient's lip superior. As the patient contacts the lip superior portion 3131, the tension increases and provides a support surface for the patient's lip superior. Patients with a

variety of sized lip superiors may experience substantially similar support (i.e., via the tension in the lip superior portion 3131).

[0421] With continued reference to Fig. 33, the foam 3152 of the first seal forming structure 3101 may be substantially flush with the second seal forming structure 3102. This may form a substantially continuous surface without discontinuities in order to limit discomfort for a patient donning the patient interface 3000.

[0422] In some forms, the foam 3152 may contact the lower surface 3295 after being coupled to the support flange 3290. The foam 3152 may be pressed against the lower surface 3295 so that there is no gap between the first seal forming structure 3101 and the second seal forming structure 3102 along either overhang 3294.

[0423] In some forms, the foam 3152 and the overhangs 3294 may extend to the same position in the posterior direction. In other words, the overhangs 3294 and the foam 3152 may extend up to a common plane (e.g., a plane substantially parallel to the coronal plane of the patient). This may limit the patient from unevenly contacting the seal-forming structure 3100, which may reduce patient comfort (e.g., because the seal forming structure 3101, 3102 that extends further in the posterior direction may dig into the patient and cause irritation as the patient continues to push the seal-forming structure 3100 against their face in order to properly orient the seal-forming structure 3100). The compliant nature of the materials (e.g., foam and silicone) that comprise the first and second seal forming structures 3101, 3102 allow both to compress so that they maintain a substantially constant surface while the patient interface 3000 is worn. Additionally, since the first and second seal forming structures 3101, 3102 are coupled together (e.g., via an adhesive), they generally move together when compressed, although one material (e.g., the foam 3152) may be more compliant than the other material (e.g., so the compressed surface may be slanted and/or curved).

[0424] In use, the foam 3152 of the first seal forming structure 3101 may provide the patient with comfort from using a soft, compliant material. The low density and weight of foam (e.g., as compared to silicone, plastic, etc.) may provide additional comfort for the patient (e.g., because the patient interface 3000 is lighter and more

comfortable in contact with the patient's skin). Additionally, the foam 3152 may be effective at sealing against the patient's face proximate to the commissure (i.e., the corner of the mouth) and/or the nasal alar region (i.e., corner of nose), where there are numerous crevices that may disrupt sealing. The foam 3152 may deform into these crevices as a result of contact with the patient's face, in order to limit air from escaping from the plenum chamber 3200.

[0425] When worn by the patient, the silicone 3150 contacts, and at least partially seals around, the patient's nares, and the foam 3152 contacts, and at least partially seals around, the patient's mouth. As described above, the foam 3152 is positioned around the mouth in order to seal with the complex facial topography that exists around the mouth. However, sealing with foam 3152 may require a greater force than with another material, like silicone 3150. Thus, the patient may experience a greater force around their mouth in order to create the therapeutically effective seal. The area around the patient's mouth may be adapted to handle greater forces, and thus the forces necessary to seal using foam 3152 may not cause the patient discomfort.

[0426] However, the patient's nose and nasal region may be more sensitive, and the forces used to seal the foam 3152 against the patient's face may be comfortable if experienced around the patient's nose. Thus, silicone 3150 is used to seal around the patient's nares, because a lower sealing force is required in order to achieve a therapeutically effective seal. Therefore, patient comfort around the nose may be balanced with seal effectiveness around the mouth, so that a material is selected that may optimize sealing based on facial topography and/or sensitivity. Different forces may be achieved by separately adjusting upper and lower straps of the positioning and stabilizing structure 3300, so that different components of the overall force provided by the positioning and stabilizing structure 3300 are provided to each material 3150, 3152.

[0427] In some forms, the foam 3152 may not be air impermeable, but is capable of maintaining therapeutic pressure within the plenum chamber 3200 because of the mounting flange 3290. In other words, since the mounting flange 3290 may be formed from an air impermeable material (e.g., silicone), air may be unable to reach the foam 3152 and pass through. The deformation of the foam 3152 simply allows for a tighter

(and more individualized) fit, so that the mounting flange 3290 or the second seal forming structure 3102 are tight against the patient's face.

[0428] In some forms, since the lip superior portion 3131 is not backed by the mounting flange 3290 (or an air impermeable material like a silicone membrane), air is able to pass through the lip superior portion 3131. In other words, the seal-forming structure 3100 may not seal against the entire lip superior of the patient. Specifically, the lip superior portion 3131 may not seal against the patient's philtrum. This may provide additional comfort to a patient, since less surface area of their face is subject to a seal. Since the lip superior portion 3131 (and specifically the portion which contacts the patient's philtrum) is within the outermost perimeter of the seal-forming structure 3100, pressurized air may not leak from the plenum chamber 3200 through the lip superior portion 3131.

[0429] In certain forms, the unbacked lip superior portion 3131 may be thinner than the adjacent foam 3152 that contacts the mounting flange 3290. The thinner lip superior portion 3131 may allow for easier movement into the plenum chamber 3200.

[0430] In some forms, the foam 3152 is air impermeable or is backed with an air impermeable membrane. The impermeability of the foam 3152 may work in conjunction with the mounting flange 3290 in order to seal at least partially around the patient's mouth.

[0431] For example, inner sides of the foam 3152 may be backed with an impermeable material as described above. These sides of the foam 3152 form the opening to the oral hole 3133 and are within the pressurized volume when the patient interface is in use, but are not in contact with the mounting flange 3290. The impermeable membrane may be applied in order to limit pressurized air from escaping the cavity. However, these surfaces are not in contact with the patient's skin, and so the patient's skin may still contact the foam 3152 and not the membrane.

[0432] In other forms, at least a portion of the foam 3152 may not be backed with an impermeable membrane. For example, the lip superior portion 3131 that is unsupported by the mounting flange 3290 may be unbacked. When the seal-forming structure 3100 is in contact with the patient's face, the unsupported section of the lip superior portion 3131 is within the sealing perimeter, and sealing is not necessary

(e.g., airflow leaking through the unsupported section of the lip superior portion 3131 remains within the sealing perimeter). Additionally, as described previously, sealing against the patient's lip superior may be uncomfortable. Not including a backing membrane on the unsupported section of the lip superior portion 3131 may allow airflow to leak through the foam 3152 and contact the patient's lip. This flow of air may assist in cooling the patient's skin so that the patient interface 3000 may be more comfortable.

[0433] As shown in Figs. 36-38, the foam 3152 may also comprise the seal-forming structure 3100 of a nasal only mask. The foam 3152 may be similarly assembly to the plenum chamber 3200 (e.g., by using an adhesive on a mounting flange 3290) as in the full face mask described above. Additionally, many of the benefits of including a foam surface may also apply to the patient interface 3000 of Figs. 36-38. At least some of the similarities and differences are described below.

[0434] Since a nasal only mask does not seal around the patient's mouth (i.e., the patient's upper and lower vermillion are not positioned within the plenum chamber 3200), the first material and the second material (e.g., foam and silicone) make up the first seal-forming structure 3101.

[0435] In some forms, the foam 3152 is inferior to the silicone of the seal-forming structure 3100. The foam 3152 may contact the patient's lip superior. The foam 3152 may seal against the patient's philtrum since the outer perimeter of the seal-forming structure 3100 contacts the patient's lip superior.

[0436] In the illustrated example, the foam 3152 may not be positioned around the nasal apertures 3135. In other forms, the foam 3152 may not form a perimeter of the nasal apertures 3135. As shown in Fig. 37, the first material 3150 may form the perimeter of the nasal apertures 3135, and there may be a length of the first material 3150 between the edge of a nasal aperture 3135 and the foam 3152. Additionally, the foam 3152 may contact the mounting flange 3290 and the overhang 3294 so that the foam 3152 does not form a surface of the cavity of the plenum chamber 3200. The foam 3152 may not need to be backed with an impermeable membrane as a result.

5.3.3 Support portions

[0437] As best seen in Figs. 12 and 14 - 18, in one form of the technology support portions 3260 are provided on opposite sides of the interface 3000 between the second seal forming structure 3102 and an anterior wall of the plenum chamber 3200. As shown in Fig. 12, in an example each support portion 3260 extends to a lateral edge of the interface.

[0438] The support portions 3260 do not act as undercushions and are instead configured to resist or hinder compression in the anterior-posterior direction. The support portions 3260 thereby support and/or stiffen portions of the second seal forming structure 3102 which engages the patient's lip superior. In particular, the support portions 3260 may support and/or stiffen regions of the second seal forming structure 3102 that may contact an area 1010 of the patient's face proximate the entrances to the nares where the ala meets the area above the lip superior, as shown in Fig. 20. In other words, the area 1010 may be directly inferior to each of the lower corners of the patient's nose.

[0439] The support portions 3260 assist in ensuring that creases do not form in the seal forming structure 3100. Creases in a seal forming structure may form as a result of a very flexible seal forming structure, with a large radius of curvature, conforming to a patient's face. The seal forming structure may fold over itself, or crease, as a result of being too flexible, and lead to leaks in the seal forming structure. Creasing may be particularly of concern where the seal forming structure seals against the area 1010 of the patient's face. The support portions 3260 may be particularly advantageous when the seal forming structure is configured to create a corner and/or ridge 3120 as described herein. The corner and/or ridge 3120 may be a sharper curve (e.g., a curve with a lower radius of curvature) as compared to seal forming structures without the support portions 3260. The support and/or stiffness added by the support portions 3260 decreases the ability of the second seal forming structure 3102 from conforming to the patient's face. In order to retain comfort for the patient, the corner and/or ridge 3120 is selected and/or sized to substantially match the geometry (e.g., contours) of the patient's face. For example, the seal forming structure 3100 for a particular patient may be selected from a variety of sizes in order to substantially conform to the nasal alar region (i.e., proximate to the area 1010). The sharper

curvature permits the second seal forming structure 3102 to seal against the various crevices around the patient's nose with reduced likelihood that creases will form.

[0440] As seen in Figs. 14 -16 in particular, in one form of the technology the support portions 3260 are connected to the anterior side of the oral portion 3201 of the plenum chamber adjacent the boundary 3241 of the oral portion 3201 and the nasal portion 3202. In some embodiments the support portion 3260 may be curved when viewed in cross-section parallel to a sagittal plane (as shown in Figs. 16-18) and/or when viewed in cross-section parallel to a frontal plane (as shown in Figs. 14 and 15). The curvature may be positive or negative. In the illustrated example, the curvature may be negative (e.g., with respect to the patient's nose). In some examples, a lateral side wall portion 3245 of the plenum chamber 3200 may curve inwardly adjacent the boundary 3241 with the nasal portion 3202, and the support portion 3260 may be substantially contiguous with an adjacent lateral side wall portion 3245. As shown in Fig. 18, when viewed in cross-section parallel to a sagittal plane, at least a portion of the support portion 3260 may reduce in thickness between a first end 3261 adjacent the anterior wall of the plenum chamber 3200 and a second end 3262 adjacent the seal forming structure 3100. For example, the support portion 3260 may be thicker proximate to the first end 3261, which may assist in providing increased support and/or stiffness to the second seal forming structure 3102. In some examples, the support portion 3260 may vary between a thickness of 0.1 mm (e.g., proximate to the second end 3262), and a thickness of 3.5 mm (e.g., proximate to the first end 3261). In some examples, the support portion 3260 may vary between a thickness of 0.3 mm (e.g., proximate to the second end 3262), and a thickness of 3 mm (e.g., proximate to the first end 3261). In some examples, the support portion 3260 may vary between a thickness of 1.3 mm (e.g., proximate to the second end 3262), and a thickness of 2.5 mm (e.g., proximate to the first end 3261).

[0441] Support portions 3260 with different geometries may be used for different patients. For example, patient's that require more support and/or stiffness in the second seal forming structure 3102 may use a seal forming structure 3100 with a thicker (e.g., proximate to the first end 3261 and/or at any location along the length) and/or more curved (e.g., lower radius of curvature) support portion 3260. For example, patients that want a more flexible second seal forming structure 3102 may

use a seal forming structure 3100 with a thinner (e.g., proximate to the first end 3261 and/or at any location along the length) and/or less curved (e.g., greater radius of curvature) support portion 3260.

[0442] As seen in particular in Figs. 14 and 15, in one form of the technology the support portion 3260 is connected to the oral portion 3201 of the plenum chamber adjacent a boundary of a lateral side wall portion 3245 of the oral portion 3201 and a lateral side wall portion 3246 of the nasal portion 3202.

[0443] In some forms of the technology, the support portions 3260 are shaped to provide a substantially clear flow path from the oral portion 3201 of the plenum chamber to the nasal aperture(s) 3135 during inspiration. In some forms of the technology no part of either support portion 3260 is directly inferior to the nasal aperture(s) 3135.

5.3.4 Positioning and stabilising structure

[0444] The seal-forming structure 3100 of the patient interface 3000 of the present technology may be held in sealing position in use by the positioning and stabilising structure 3300.

[0445] In one form the positioning and stabilising structure 3300 provides a retention force at least sufficient to overcome the effect of the positive pressure in the plenum chamber 3200 to lift off the face.

[0446] In one form the positioning and stabilising structure 3300 provides a retention force to overcome the effect of the gravitational force on the patient interface 3000.

[0447] In one form the positioning and stabilising structure 3300 provides a retention force as a safety margin to overcome the potential effect of disrupting forces on the patient interface 3000, such as from tube drag, or accidental interference with the patient interface.

[0448] In one form of the present technology, a positioning and stabilising structure 3300 is provided that is configured in a manner consistent with being worn by a patient while sleeping. In one example the positioning and stabilising structure

3300 has a low profile, or cross-sectional thickness, to reduce the perceived or actual bulk of the apparatus. In one example, the positioning and stabilising structure 3300 comprises at least one strap having a rectangular cross-section. In one example the positioning and stabilising structure 3300 comprises at least one flat strap.

[0449] In one form of the present technology, a positioning and stabilising structure 3300 is provided that is configured so as not to be too large and bulky to prevent the patient from lying in a supine sleeping position with a back region of the patient's head on a pillow.

[0450] In one form of the present technology, a positioning and stabilising structure 3300 is provided that is configured so as not to be too large and bulky to prevent the patient from lying in a side sleeping position with a side region of the patient's head on a pillow.

[0451] In one form of the present technology, a positioning and stabilising structure 3300 is provided with a decoupling portion located between an anterior portion of the positioning and stabilising structure 3300, and a posterior portion of the positioning and stabilising structure 3300. The decoupling portion does not resist compression and may be, e.g. a flexible or floppy strap. The decoupling portion is constructed and arranged so that when the patient lies with their head on a pillow, the presence of the decoupling portion prevents a force on the posterior portion from being transmitted along the positioning and stabilising structure 3300 and disrupting the seal.

[0452] In one form of the present technology, a positioning and stabilising structure 3300 comprises a strap constructed from a laminate of a fabric patient-contacting layer, a foam inner layer and a fabric outer layer. In one form, the foam is porous to allow moisture, (e.g., sweat), to pass through the strap. In one form, the fabric outer layer comprises loop material to engage with a hook material portion.

[0453] In certain forms of the present technology, a positioning and stabilising structure 3300 comprises a strap that is extensible, e.g. resiliently extensible. For example the strap may be configured in use to be in tension, and to direct a force to draw a seal-forming structure into sealing contact with a portion of a patient's face. In an example the strap may be configured as a tie.

[0454] In one form of the present technology, the positioning and stabilising structure comprises a first tie, the first tie being constructed and arranged so that in use at least a portion of an inferior edge thereof passes superior to an otobasion superior of the patient's head and overlays a portion of a parietal bone without overlaying the occipital bone.

[0455] In one form of the present technology suitable for a nasal-only mask or for a full-face mask, the positioning and stabilising structure includes a second tie, the second tie being constructed and arranged so that in use at least a portion of a superior edge thereof passes inferior to an otobasion inferior of the patient's head and overlays or lies inferior to the occipital bone of the patient's head.

[0456] In one form of the present technology suitable for a nasal-only mask or for a full-face mask, the positioning and stabilising structure includes a third tie that is constructed and arranged to interconnect the first tie and the second tie to reduce a tendency of the first tie and the second tie to move apart from one another.

[0457] In certain forms of the present technology, a positioning and stabilising structure 3300 comprises a strap that is bendable and e.g. non-rigid. An advantage of this aspect is that the strap is more comfortable for a patient to lie upon while the patient is sleeping.

[0458] In certain forms of the present technology, a positioning and stabilising structure 3300 comprises a strap constructed to be breathable to allow moisture vapour to be transmitted through the strap,

[0459] In certain forms of the present technology, a system is provided comprising more than one positioning and stabilizing structure 3300, each being configured to provide a retaining force to correspond to a different size and/or shape range. For example the system may comprise one form of positioning and stabilizing structure 3300 suitable for a large sized head, but not a small sized head, and another suitable for a small sized head, but not a large sized head.

[0460] Figs. 21 and 22 show embodiments which are provided with connectors 3310, e.g. magnetic connectors, for connection to a positioning and stabilising structure.

5.3.4.1 Frame

[0461] As shown in Figs. 23 to 28, a frame 3350 is coupled to the plenum chamber 3200 (e.g., as shown in Figs. 7-19) and assists in maintaining the therapeutically effective position of the seal-forming structure 3100.

[0462] In some forms, the frame 3350 is constructed from a rigid or semi-rigid material, and provides support to the seal-forming structure 3100 and/or the plenum chamber 3200. For example, the frame 3350 may assist in maintaining the shape of the seal-forming structure 3100 and/or the plenum chamber 3200 in order to reduce leaks of pressurized air as a result of folding and/or creasing as the seal-forming structure 3100 engages the patient's face.

[0463] In some forms, the frame 3350 provides at least one connection point 3352, which may assist in indirectly connecting the headgear straps 3354 to the plenum chamber 3200 and/or seal-forming structure 3100. The connection point 3352 may be a loop (e.g., with a fully formed perimeter) that receives a portion of the headgear straps 3354. For example, a length of a left superior headgear strap 3356 may be threaded through a first loop 3352a, and pulled away from the plenum chamber 3200 in order to apply tension through the left superior headgear strap 3356. The left superior headgear strap 3356 may be folded against itself and retained in the selected length (e.g., using Velcro, magnets, adhesives, etc.) in order to maintain the applied tension. Similar steps may be performed regarding adjusting the tension in the right superior headgear strap 3358 in a second loop 3352b.

[0464] In some forms, each loop 3352a, 3352b may be oriented so that a force vector applied by the respective superior headgear strap 3356, 3358 is substantially perpendicular to a loop inner surface 3351, against which the superior headgear straps 3356, 3358 contact. As shown in Fig. 23, the right superior headgear strap 3358 engages the loop 3352b in substantially the center of the loop inner surface 3351. When the right superior headgear strap 3358 is tightened, the force vector is applied in a substantially straight direction, and not oblique relative to the loop inner surface 3351. This may improve the sealing of the seal-forming structure 3100, as the forces are directed along the arms 3362, and not oblique relative to the arms 3362, which may require the superior headgear straps 3356, 3358 to be further tightened to receive the same sealing effects (e.g., at the detriment to patient comfort), and/or may prevent

the seal-forming structure 3100 from properly engaging the patient's face (e.g., leading to leaks).

[0465] In one form, at least one of the loops 3352a, 3352b may not be completely formed around an outer perimeter. In other words, the loops 3352a, 3352b may be C-shaped and/or U-shaped. The left and/or right superior headgear straps 3356, 3358 may be individually folded against themselves, and then inserted through into the respective loop 3352a, 3352b. This may allow the patient to maintain the same length adjustment in the respective superior headgear strap 3356, 3358, when the seal-forming structure 3100 is being removed from the therapeutically effective position.

[0466] In some forms, the frame 3350 includes a central portion 3360 that is coupled to the plenum chamber 3200. The central portion 3360 may have an annular shape, and may have a profile that corresponds to the shape of the plenum chamber 3200 (e.g., approximating a positive domed curvature).

[0467] In one form, a single size of the central portion 3360 may be used with a variety of sizes of plenum chambers 3200 and/or seal-forming structures 3100. For example, the seal-forming structure 3100 may come in multiple sizes (e.g., small, medium, large, etc.) and/or shapes (e.g., narrow, wide, etc.) in order to better seal against patients with a variety of facial shapes. An engagement region of the central portion 3360 may remain substantially the same regardless of the size of the plenum chamber 3200 and/or seal-forming structure 3100. Thus, the central portion 3360 may be coupled to a variety of shaped and/or sized cushions, and provide substantially the same support.

[0468] In one form, the central portion 3360 may be removable coupled to the plenum chamber 3200. A patient may use the same frame 3350 with multiple plenum chambers 3200. This may be useful when the patient is first beginning the therapy, and is trying different sized plenum chambers 3200, in order to find an appropriate fit. Removing the frame 3350 may also be helpful when cleaning the patient interface 3000, as the different elements of the patient interface 3000 may be cleaned separately, to help ensure a more thorough clean.

[0469] In some forms, the frame 3350 includes arms 3362 that extend away from the central portion 3360. The loops 3352a, 3352b are formed at ends of the arms

3362. In use, the arms 3362 may extend at least partially in the posterior direction, which may position the loops 3352a, 3352b more posterior than the plenum chamber 3200 and/or the seal-forming structure 3100. The arms 3362 may also extend in the lateral direction (e.g., left or right respectively) so as to generally extend along contours of the patient's face.

[0470] In some forms, the arms 3362 engage a portion of the patient's face while the patient interface 3000 is worn by the patient. For example, the arms 3362 may contact the patient's cheeks. The arms 3362 may be shaped in order to correspond to the curvatures of a patient's face (e.g., extend in posterior and lateral directions).

[0471] In some forms, the arms 3362 may not substantially stretch as a result of the tension applied by the respective headgear strap 3356, 3358 via the respective loop 3352a, 3352b (e.g., the arms 3362 may be rigidizers and/or may be inextensible). Tension may be transferred along the arm 3362 to the plenum chamber 3200 and/or seal-forming structure 3100 in order to maintain the therapeutically effective pressure and limit leaks from occurring.

[0472] In one form, the arms 3362 are constructed from a material that is more flexible than the material used to construct the central portion 3360. The two materials may be molded together so that the frame 3350 is constructed in an integral, one-piece construction. The arms 3362 may have some rigidity in order to assist in maintaining their shape. However, the arms 3362 may be bendable so that a patient may adjust the shape in order to correspond to their facial structure. Allowing a patient to adjust the shape of the arms 3362 may increase the comfort experienced by the patient, which may increase patient compliance with the therapy. In this way, the arms 3362 may bend or flex relative to the central portion 3360 (e.g., because of a cantilevered configuration), but may be unable to stretch further in the posterior direction (e.g., because of its inextensibility). Additionally, the relatively flexible material used to construct each of the arms 3362 may assist in reducing facial markings, and increase patient comfort.

[0473] In one form, the arms 3362 and the central portion 3360 are constructed from the same material. This material provides enough flexibility in order to permit shape adjustment, and also provides enough rigidity in order to maintain the adjusted

shape. The central portion 3360 may be more rigid than the arms 3362 as a result of being coupled to the plenum chamber 3200. In addition or instead of, the central portion 3360 may be thicker than the arms 3362, which may also cause an increased rigidity of the central portion 3360. Each arm 3362 is formed as a cantilevered shape, so that the ends proximate to the respective loop 3352a, 3352b are unsupported. Additionally, the thickness of the frame 3350 may decrease along the length of each arm 3362 in the direction of the respective loop 3352a, 3352b. This may provide each arm 3362 with the flexibility necessary to be bent and/or shaped in order to substantially correspond to a shape of the patient's face (e.g., cheek). Decreasing the width of each arm 3362 may also reduce cheek contact between the respective arm 3362 and the patient's cheek, which may improve patient comfort. Decreasing the width along the length of each arm 3362 may also allow for greater flexibility proximate each respective loop 3352a, 3352b.

[0474] In some forms, the fixed end of each arm 3362 may have a thickness of between approximately 2 mm and approximately 7 mm. In some forms, the fixed end of each arm 3362 may have a thickness of between approximately 2.5 mm and approximately 6 mm. In some forms, the fixed end of each arm 3362 may have a thickness of between approximately 3 mm and approximately 5 mm. In some forms, the fixed end of each arm 3362 may have a thickness of approximately 4 mm.

[0475] In some forms, the free end of each arm 3362 may have a thickness of between approximately 0 mm and approximately 4 mm. In some forms, the fixed end of each arm 3362 may have a thickness of between approximately 0.5 mm and approximately 3 mm. In some forms, the fixed end of each arm 3362 may have a thickness of between approximately 1 mm and approximately 2.5 mm. In some forms, the fixed end of each arm 3362 may have a thickness of approximately 2 mm.

[0476] In some forms, the frame 3350 further includes at least one secondary connection point 3364 that is spaced apart from the loops 3352a, 3352b. The secondary connection point(s) 3364 provides an additional connection location, which may further assist in indirectly connecting the headgear straps 3354 to the plenum chamber 3200 and/or seal-forming structure 3100.

[0477] In certain forms, the frame 3350 includes two secondary connection points 3364 (e.g., a left secondary connection point 3364a, and a right secondary connection point 3364b). The secondary connection points 3364a, 3364b may be inferior to the loops 3352a, 3352b while the patient interface 3000 is worn by the patient. The headgear straps 3354 may further include a left inferior headgear straps 3366 and a right inferior headgear strap 3368, each configured to couple to the respective secondary connection point 3364a, 3364b. The headgear 3354 as a whole may then be able to provide a force to the superior and inferior regions of the seal-forming structure 3100 and/or the plenum chamber 3200.

[0478] In certain forms, the secondary connection points 3364a, 3364b are formed directly on the central portion 3360. The secondary connection points 3364a, 3364b may be more anterior than the loops 3352a, 3352b while the patient interface 3000 is worn by the patient.

[0479] In certain forms, the secondary connection points 3364a, 3364b may be constructed from a single component, which may assist in reducing tooling and/or manufacturing costs.

[0480] In certain forms, the left and/or right inferior headgear straps 3366, 3368 are removably coupled to the respective secondary connection point 3364a, 3364b. The secondary connection points 3364a, 3364b may be magnetic, and a left and/or right inferior headgear straps 3366, 3368 may be threaded through a magnet 3370 with an opposite polarity as the secondary connection points 3364a, 3364b. The length of the left and/or right inferior headgear straps 3366, 3368 may be adjusted by folding the respective strap 3366, 3368 on itself (e.g., as done with the left and/or right superior headgear straps 3356, 3358). Each magnet 3370 may be removed from the respective secondary connection point 3364a, 3364b, without changing the length adjustment of the left and/or right inferior headgear straps 3366, 3368. A patient may be able to don and/or doff the patient interface 3000 while only removing the magnets 3370 from the respective secondary connection points 3364a, 3364b (e.g., without having to remove the left and/or right superior headgear straps 3356, 3358 from the respective loops 3352a, 3352b).

[0481] As shown in Fig. 24, the engagement region of the plenum chamber 3200 may include a groove 3280. In the illustrated example, the groove 3280 may be included on the oral portion 3201 of the plenum chamber 3200, and may be radially outside of the central portion 3251. The central portion 3360 of the frame 3350 may be positioned within the groove 3280. The shape of the central portion 3360 may substantially correspond to the shape of the groove 3280, which may assist the patient in properly orienting the frame 3350 with respect to the plenum chamber 3200 (e.g., in examples where the frame 3350 is removably coupled to the plenum chamber 3200).

[0482] In some forms, the groove 3280 may have a completely formed perimeter with a substantially annular shape. The perimeter may have substantially the same length in any sized cushion.

[0483] In some forms, the groove 3280 is recessed relative to a remainder of the outer surface of the plenum chamber 3200. The recessed groove 3280 may not extend substantially into the plenum chamber 3200 and obstruct the patient's face. The groove 3280 may have substantially the same depth throughout its perimeter.

[0484] In some forms, a width of the groove 3280 may be less than a width of central portion 3360 of the frame 3350. The compliant nature of the cushion may allow the wider central portion 3360 to be received within the groove 3280. This may allow the central portion 3360 to couple to the groove 3280 via a press fit, friction fit, and/or snap-fit. The engagement between the groove 3280 and the central portion 3360 may assist in providing rigidity to the plenum chamber 3200 and/or the seal-forming structure 3100, because the rigidity of the frame 3350 (e.g., as compared to the plenum chamber 3200) may limit some flexibility of the plenum chamber 3200 alone.

[0485] In some forms, the cushion may be molded to the frame 3350 so that the groove 3280 may be created during a molding process. The material of the plenum chamber 3200 (e.g., silicone) may be molded at least partially around the central portion 3360 of the frame 3350, and may limit the central portion 3360 from being removed from the groove 3280.

[0486] As shown in Fig. 25, the frame 3350 may be constructed from multiple pieces (e.g., each constructed from a different material). For example, the central portion may be constructed from a first material (e.g., hard plastic). The arms 3362 may be coupled to the central portion 3360 (e.g., via glue, molding, etc.), and may be constructed from a second material (e.g., flexible plastic, foam, etc.) that is more flexible than the first material. A third material may be a magnetic material, and may be coupled to the central portion 3360 (e.g., via an adhesive). Once coupled together, the arms 3362 may be able to similarly move as in the integral, one-piece constructions described above.

[0487] As shown in Figs. 26 and 27, the frame 3350 may be constructed from a single piece of material. For example, the frame 3350 may be constructed from a TPE material, like Hytrel. As described above, the material used in constructing the frame 3350 may provide both rigidity and flexibility to the frame 3350. The magnets 3370 may be overmolded (or otherwise coupled to) the central portion 3360.

[0488] In some forms, the central portion 3360 includes openings or slots 3372, which may be formed on either lateral side of the central portion 3360. The slots 3372 may have a generally elongated shape (e.g., rectangular, elliptical, etc.), and may be completely formed within the boundary of the central portion 3360.

[0489] As shown in Fig. 27, some forms of the central portion 3360 may include a tapered slot 3372. Specifically, an opening to the slot 3372 may be wider proximate a posterior surface of the central portion 3360 (e.g., the surface in contact with the plenum chamber 3200). The opening to the slot 3372 may decrease uniformly toward the anterior surface of the central portion 3360.

[0490] Fig. 27 also illustrates that some forms of the arm 3362a (or arm 3362b) may include an indent or scallop 3373. The scallop 3373 may be formed on an inner surface of the arm 3362a, and may be positioned proximate to the patient's skin when the positioning and stabilizing structure 3300 is worn by the patient. The scallop 3373 reduces the thickness along a portion of the arm 3362a, and may decrease the likelihood of developing sink marks in the arm 3362a during a manufacturing (e.g., injection molding) process. The scallop 3373 may also result in less material being

used to manufacture the arm 3362a, which may lead to lower manufacturing times and/or lower manufacturing costs.

[0491] Returning to Fig. 26, the plenum chamber 3200 may include projections 3284 on the oral portion 3201. The projections may be elongated, and may have a similar shape to the slots 3372 (e.g., tapered). The projections 3284 may be disposed within the groove 3280 so that they cooperate with the frame 3350 during assembly. When the frame 3350 is being assembled to the plenum chamber 3200 (e.g., via a press fit, friction fit, snap-fit, etc.), the patient may align the projections 3284 with the slots 3372, so that the projections 3284 are received within the slots 3372 in use. The wider openings of the slots 3372 proximate to the posterior surface may assist the patient in aligning each projection 3284 within the respective slot 3372. The projections 3284 may be slightly wider than the anterior opening of each slot 3372, but are able to be received within the slot because of the flexible properties of the plenum chamber 3200 (e.g., being constructed from a resilient material like silicone). The projections 3284 may slightly deform as they enter the respective slot 3372 (e.g., as a result of the slot 3372 narrowing). Once the projections 3284 are through the slot 3372, the projections 3284 may substantially return to their original shape. Specifically, ends of the projections 3284 may become wider than the anterior opening of the respective slot 3372. Thus, the frame 3350 may not be easily removed from the plenum chamber 3200. The patient may have to apply a force to the frame 3350 in order to remove it from the groove 3280. In other forms, the plenum chamber 3200 may be molded to the frame 3350, and the projections 3284 may result from the molding process in order to permanently retain the position of the frame 3350 relative to the plenum chamber 3200.

[0492] As shown in Fig. 28, the frame 3350 may be shaped similarly to the frame in Figs. 26 and 27. In other words, the frame 3350 may be constructed from a single material (e.g., with semi-rigid properties). The frame 3350 may be thicker proximate the central portion 3360, and thinner toward each respective loop 3352a, 3352b.

[0493] In some forms, the central portion 3360 of the frame 3350 may be substantially solid throughout, and may not include slots 3372, and the plenum chamber 3200 may not include projections 3284 within the groove 3280. Instead, the plenum chamber 3200 may include protrusions 3288 disposed radially inside of the

groove 3280. The protrusions 3288 may be raised from the rest of the anterior surface of the plenum chamber 3200. The protrusions 3288 may also extend at least partially in a radially outward direction. In other words, the protrusions 3288 may extend at least partially over the groove 3280 (e.g., the protrusions 3388 are spaced apart from the groove 3380).

[0494] While assembling a removable frame 3350 to the plenum chamber 3200, a patient may be required to position the frame 3350 so that it extends into the groove 3280, and underneath of the protrusions 3288. Once the central portion 3260 is positioned, the protrusions 3288 may assist in retaining the central portion 3360 in place. To decouple the frame 3350 from the plenum chamber 3200, the patient may push on at least one of the protrusions 3288 (e.g., in a lateral direction toward the other protrusion 3288) so that the protrusion no longer extends over the groove 3280. In other forms, the plenum chamber 3200 may be molded to the frame 3350, the protrusions 3288 may prevent the central portion 3360 from being removed.

[0495] In some forms, the frame 3350 of any of the examples described above may be substantially flush with the outer surface of the plenum chamber 3200 when positioned within the groove 3280. The depth of the groove 3280 substantially corresponds to a thickness of the central portion 3360. Similarly, the shape of the central portion may substantially approximate the shape of the cushion as described above. The resulting assembly may have a substantially uniform surface. This assists in maintaining a low profile look of the patient interface 3000, because the frame 3350 is not projecting in front of the cushion where it may obstruct the patient's line of sight.

5.3.5 Vent

[0496] In one form, the patient interface 3000 includes a vent 3400 constructed and arranged to allow for the washout of exhaled gases, e.g. carbon dioxide.

[0497] In certain forms the vent 3400 is configured to allow a continuous vent flow from an interior of the plenum chamber 3200 to ambient whilst the pressure within the plenum chamber is positive with respect to ambient. The vent 3400 is configured such that the vent flow rate has a magnitude sufficient to reduce

rebreathing of exhaled CO₂ by the patient while maintaining the therapeutic pressure in the plenum chamber in use.

[0498] One form of vent 3400 in accordance with the present technology comprises a plurality of holes, for example, about 20 to about 80 holes, or about 40 to about 60 holes, or about 45 to about 55 holes.

[0499] The vent 3400 may be located in the plenum chamber 3200. Alternatively, the vent 3400 is located in a decoupling structure, e.g., a swivel.

[0500] While no vent structures are shown in Figs. 7-18, embodiments of the technology shown in Figs. 7-18 may be provided with a suitable vent structure, for example in the plenum chamber (one example of which is shown in Fig. 21).

5.3.6 Decoupling structure(s)

[0501] In one form the patient interface 3000 includes at least one decoupling structure 3500, for example, a swivel or a ball and socket. In some examples, the decoupling structure may be an elbow 3500 that is connected (e.g., removably connected, permanently connected, etc.) to the plenum chamber 3200 (e.g., a plenum chamber inlet port).

[0502] As shown in Figs. 23-28, the central portion 3360 of the frame 3350 has an annular shape, so that a central region of the oral portion 3201 of the plenum chamber 3200 is not covered by the frame 3350. In some examples, the oral portion 3201 includes an opening for receiving the elbow 3500. The opening may be significantly wider than the opening for receiving the elbow 3500, so that the frame 3350 is completely spaced apart from the opening. In other words, there is a length between the inner edge of the central portion 3360 and the opening for receiving the elbow 3500. The arms 3362a, 3362b and the secondary connection portions 3342a, 3342b are each spaced apart from the opening and the elbow 3500, so that the headgear straps 3358 do not interfere with movement (e.g., rotation) of the elbow.

[0503] While not explicitly shown in the drawings of the plenum chamber shown in Figs. 7-19, those skilled in the art will appreciate that in practice an elbow 3500 may be provided (e.g., as illustrated in Fig. 23), and allow connection of the interface to an air circuit 4170.

5.3.7 Connection port

[0504] Connection port 3600 allows for connection (e.g., a removable connection via a snap-fit, a permanent connection, etc.) to the air circuit 4170. The patient interface 3000 may include two connection ports 3600, one on either side of the plenum chamber 3200. Conduits may connect to the connection ports 3600 in order to convey pressurized breathable gas to the patient. In some forms, the conduits may be conduit headgear, and may contact the patient's head. The conduits may extend toward the crown of the patient's head, where the decoupling structure 3500 is located.

5.3.8 Forehead support

[0505] In one form, the patient interface 3000 includes a forehead support 3700.

5.3.9 Anti-asphyxia valve

[0506] In one form, the patient interface 3000 includes an anti-asphyxia valve.

5.3.10 Ports

[0507] In one form of the present technology, a patient interface 3000 includes one or more ports that allow access to the volume within the plenum chamber 3200. In one form this allows a clinician to supply supplementary oxygen. In one form, this allows for the direct measurement of a property of gases within the plenum chamber 3200, such as the pressure.

5.4 RPT DEVICE

[0508] An RPT device 4000 in accordance with one aspect of the present technology comprises mechanical, pneumatic, and/or electrical components and is configured to execute one or more algorithms 4300, such as any of the methods, in whole or in part, described herein. The RPT device 4000 may be configured to generate a flow of air for delivery to a patient's airways, such as to treat one or more of the respiratory conditions described elsewhere in the present document.

[0509] In one form, the RPT device 4000 is constructed and arranged to be capable of delivering a flow of air in a range of -20 L/min to +150 L/min while maintaining a positive pressure of at least 6 cmH₂O, or at least 10cmH₂O, or at least 20 cmH₂O.

[0510] The RPT device may have an external housing 4010, formed in two parts, an upper portion 4012 and a lower portion 4014. Furthermore, the external housing 4010 may include one or more panel(s) 4015. The RPT device 4000 comprises a chassis 4016 that supports one or more internal components of the RPT device 4000. The RPT device 4000 may include a handle 4018.

[0511] The pneumatic path of the RPT device 4000 may comprise one or more air path items, e.g., an inlet air filter 4112, an inlet muffler 4122, a pressure generator 4140 capable of supplying air at positive pressure (e.g., a blower 4142), an outlet muffler 4124 and one or more transducers 4270, such as pressure sensors 4272 and flow rate sensors 4274.

[0512] One or more of the air path items may be located within a removable unitary structure which will be referred to as a pneumatic block 4020. The pneumatic block 4020 may be located within the external housing 4010. In one form a pneumatic block 4020 is supported by, or formed as part of the chassis 4016.

[0513] The RPT device 4000 may have an electrical power supply 4210, one or more input devices 4220, a central controller 4230, a therapy device controller 4240, a pressure generator 4140, one or more protection circuits 4250, memory 4260, transducers 4270, data communication interface 4280 and one or more output devices 4290. Electrical components 4200 may be mounted on a single Printed Circuit Board Assembly (PCBA) 4202. In an alternative form, the RPT device 4000 may include more than one PCBA 4202.

5.4.1.1 Air filter(s)

[0514] An RPT device in accordance with one form of the present technology may include an air filter 4110, or a plurality of air filters 4110.

[0515] In one form, an inlet air filter 4112 is located at the beginning of the pneumatic path upstream of a pressure generator 4140.

[0516] In one form, an outlet air filter 4114, for example an antibacterial filter, is located between an outlet of the pneumatic block 4020 and a patient interface 3000 or 3800.

5.4.1.2 Muffler(s)

[0517] An RPT device in accordance with one form of the present technology may include a muffler 4120, or a plurality of mufflers 4120.

[0518] In one form of the present technology, an inlet muffler 4122 is located in the pneumatic path upstream of a pressure generator 4140.

[0519] In one form of the present technology, an outlet muffler 4124 is located in the pneumatic path between the pressure generator 4140 and a patient interface 3000 or 3800.

5.4.1.3 Pressure generator

[0520] In one form of the present technology, a pressure generator 4140 for producing a flow, or a supply, of air at positive pressure is a controllable blower 4142. For example, the blower 4142 may include a brushless DC motor 4144 with one or more impellers. The impellers may be located in a volute. The blower may be capable of delivering a supply of air, for example at a rate of up to about 120 litres/minute, at a positive pressure in a range from about 4 cmH₂O to about 20 cmH₂O, or in other forms up to about 30 cmH₂O when delivering respiratory pressure therapy. The blower may be as described in any one of the following patents or patent applications the contents of which are incorporated herein by reference in their entirety: U.S. Patent No. 7,866,944; U.S. Patent No. 8,638,014; U.S. Patent No. 8,636,479; and PCT Patent Application Publication No. WO 2013/020167.

[0521] The pressure generator 4140 may be under the control of the therapy device controller 4240.

[0522] In other forms, a pressure generator 4140 may be a piston-driven pump, a pressure regulator connected to a high pressure source (e.g. compressed air reservoir), or a bellows.

5.4.1.4 Transducer(s)

[0523] Transducers may be internal of the RPT device, or external of the RPT device. External transducers may be located for example on or form part of the air circuit, e.g., the patient interface. External transducers may be in the form of non-

contact sensors such as a Doppler radar movement sensor that transmit or transfer data to the RPT device.

[0524] In one form of the present technology, one or more transducers 4270 are located upstream and/or downstream of the pressure generator 4140. The one or more transducers 4270 may be constructed and arranged to generate signals representing properties of the flow of air such as a flow rate, a pressure or a temperature at that point in the pneumatic path.

[0525] In one form of the present technology, one or more transducers 4270 may be located proximate to the patient interface 3000 or 3800.

[0526] In one form, a signal from a transducer 4270 may be filtered, such as by low-pass, high-pass or band-pass filtering.

5.4.1.5 Anti-spill back valve

[0527] In one form of the present technology, an anti-spill back valve 4160 is located between the humidifier 5000 and the pneumatic block 4020. The anti-spill back valve is constructed and arranged to reduce the risk that water will flow upstream from the humidifier 5000, for example to the motor 4144.

5.4.2 RPT device electrical components

5.4.2.1 Power supply

[0528] A power supply 4210 may be located internal or external of the external housing 4010 of the RPT device 4000.

[0529] In one form of the present technology, power supply 4210 provides electrical power to the RPT device 4000 only. In another form of the present technology, power supply 4210 provides electrical power to both RPT device 4000 and humidifier 5000.

5.4.3 RPT device algorithms

[0530] As mentioned above, in some forms of the present technology, the central controller 4230 may be configured to implement one or more algorithms 4300 expressed as computer programs stored in a non-transitory computer readable storage

medium, such as memory 4260. The algorithms 4300 are generally grouped into groups referred to as modules.

[0531] In other forms of the present technology, some portion or all of the algorithms 4300 may be implemented by a controller of an external device such as the local external device 4288 or the remote external device 4286. In such forms, data representing the input signals and / or intermediate algorithm outputs necessary for the portion of the algorithms 4300 to be executed at the external device may be communicated to the external device via the local external communication network 4284 or the remote external communication network 4282. In such forms, the portion of the algorithms 4300 to be executed at the external device may be expressed as computer programs stored in a non-transitory computer readable storage medium accessible to the controller of the external device. Such programs configure the controller of the external device to execute the portion of the algorithms 4300.

[0532] In such forms, the therapy parameters generated by the external device via the therapy engine module 4320 (if such forms part of the portion of the algorithms 4300 executed by the external device) may be communicated to the central controller 4230 to be passed to the therapy control module 4330.

5.5 AIR CIRCUIT

[0533] An air circuit 4170 in accordance with an aspect of the present technology is a conduit or a tube constructed and arranged to allow, in use, a flow of air to travel between two components such as RPT device 4000 and the patient interface 3000.

[0534] In particular, the air circuit 4170 may be in fluid connection with the outlet of the pneumatic block 4020 and the patient interface. The air circuit may be referred to as an air delivery tube. In some cases there may be separate limbs of the circuit for inhalation and exhalation. In other cases a single limb is used.

[0535] In some forms, the air circuit 4170 may comprise one or more heating elements configured to heat air in the air circuit, for example to maintain or raise the temperature of the air. The heating element may be in a form of a heated wire circuit, and may comprise one or more transducers, such as temperature sensors. In one form, the heated wire circuit may be helically wound around the axis of the air circuit 4170. The heating element may be in communication with a controller such as a central

controller 4230. One example of an air circuit 4170 comprising a heated wire circuit is described in United States Patent 8,733,349, which is incorporated herewithin in its entirety by reference.

5.5.1 Supplementary gas delivery

[0536] In one form of the present technology, supplementary gas, e.g. oxygen, 4180 is delivered to one or more points in the pneumatic path, such as upstream of the pneumatic block 4020, to the air circuit 4170, and/or to the patient interface 3000.

5.6 HUMIDIFIER

5.6.1 Humidifier overview

[0537] In one form of the present technology there is provided a humidifier 5000 (e.g. as shown in Fig. 5A) to change the absolute humidity of air or gas for delivery to a patient relative to ambient air. Typically, the humidifier 5000 is used to increase the absolute humidity and increase the temperature of the flow of air (relative to ambient air) before delivery to the patient's airways.

[0538] The humidifier 5000 may comprise a humidifier reservoir 5110, a humidifier inlet 5002 to receive a flow of air, and a humidifier outlet 5004 to deliver a humidified flow of *air*. In some forms, as shown in Fig. 5A and Fig. 5B, an inlet and an outlet of the humidifier reservoir 5110 may be the humidifier inlet 5002 and the humidifier outlet 5004 respectively. The humidifier 5000 may further comprise a humidifier base 5006, which may be adapted to receive the humidifier reservoir 5110 and comprise a heating element 5240.

5.6.2 Humidifier components

5.6.2.1 Water reservoir

[0539] According to one arrangement, the humidifier 5000 may comprise a water reservoir 5110 configured to hold, or retain, a volume of liquid (e.g. water) to be evaporated for humidification of the flow of air. The water reservoir 5110 may be configured to hold a predetermined maximum volume of water in order to provide adequate humidification for at least the duration of a respiratory therapy session, such as one evening of sleep. Typically, the reservoir 5110 is configured to hold several

hundred millilitres of water, e.g. 300 millilitres (ml), 325 ml, 350 ml or 400 ml. In other forms, the humidifier 5000 may be configured to receive a supply of water from an external water source such as a building's water supply system.

[0540] According to one aspect, the water reservoir 5110 is configured to add humidity to a flow of air from the RPT device 4000 as the flow of air travels therethrough. In one form, the water reservoir 5110 may be configured to encourage the flow of air to travel in a tortuous path through the reservoir 5110 while in contact with the volume of water therein.

[0541] According to one form, the reservoir 5110 may be removable from the humidifier 5000, for example in a lateral direction as shown in Fig. 5A and Fig. 5B.

[0542] The reservoir 5110 may also be configured to discourage egress of liquid therefrom, such as when the reservoir 5110 is displaced and/or rotated from its normal, working orientation, such as through any apertures and/or in between its sub-components. As the flow of air to be humidified by the humidifier 5000 is typically pressurised, the reservoir 5110 may also be configured to prevent losses in pneumatic pressure through leak and/or flow impedance.

5.6.2.2 Conductive portion

[0543] According to one arrangement, the reservoir 5110 comprises a conductive portion 5120 configured to allow efficient transfer of heat from the heating element 5240 to the volume of liquid in the reservoir 5110. In one form, the conductive portion 5120 may be arranged as a plate, although other shapes may also be suitable. All or a part of the conductive portion 5120 may be made of a thermally conductive material such as aluminium (e.g. approximately 2 mm thick, such as 1 mm, 1.5 mm, 2.5 mm or 3 mm), another heat conducting metal or some plastics. In some cases, suitable heat conductivity may be achieved with less conductive materials of suitable geometry.

5.6.2.3 Humidifier reservoir dock

[0544] In one form, the humidifier 5000 may comprise a humidifier reservoir dock 5130 (as shown in Fig. 5B) configured to receive the humidifier reservoir 5110. In some arrangements, the humidifier reservoir dock 5130 may comprise a locking

feature such as a locking lever 5135 configured to retain the reservoir 5110 in the humidifier reservoir dock 5130.

5.6.2.4 Water level indicator

[0545] The humidifier reservoir 5110 may comprise a water level indicator 5150 as shown in Fig. 5A-5B. In some forms, the water level indicator 5150 may provide one or more indications to a user such as the patient 1000 or a care giver regarding a quantity of the volume of water in the humidifier reservoir 5110. The one or more indications provided by the water level indicator 5150 may include an indication of a maximum, predetermined volume of water, any portions thereof, such as 25%, 50% or 75% or volumes such as 200 ml, 300 ml or 400ml.

5.7 BREATHING WAVEFORMS

[0546] Fig. 6 shows a model typical breath waveform of a person while sleeping. The horizontal axis is time, and the vertical axis is respiratory flow rate. While the parameter values may vary, a typical breath may have the following approximate values: tidal volume V_t 0.5L, inhalation time T_i 1.6s, peak inspiratory flow rate Q_{peak} 0.4 L/s, exhalation time T_e 2.4s, peak expiratory flow rate Q_{peak} -0.5 L/s. The total duration of the breath, T_{tot} , is about 4s. The person typically breathes at a rate of about 15 breaths per minute (BPM), with Ventilation V_{ent} about 7.5 L/min. A typical duty cycle, the ratio of T_i to T_{tot} , is about 40%.

5.8 RESPIRATORY THERAPY MODES

[0547] Various respiratory therapy modes may be implemented by the disclosed respiratory therapy system including CPAP therapy and bi-level therapy.

5.9 GLOSSARY

[0548] For the purposes of the present technology disclosure, in certain forms of the present technology, one or more of the following definitions may apply. In other forms of the present technology, alternative definitions may apply.

5.9.1 General

[0549] *Air*: In certain forms of the present technology, air may be taken to mean atmospheric air, and in other forms of the present technology air may be taken to

mean some other combination of breathable gases, e.g. atmospheric air enriched with oxygen.

[0550] *Ambient*: In certain forms of the present technology, the term ambient will be taken to mean (i) external of the treatment system or patient, and (ii) immediately surrounding the treatment system or patient.

[0551] For example, ambient humidity with respect to a humidifier may be the humidity of air immediately surrounding the humidifier, e.g. the humidity in the room where a patient is sleeping. Such ambient humidity may be different to the humidity outside the room where a patient is sleeping.

[0552] In another example, ambient pressure may be the pressure immediately surrounding or external to the body.

[0553] In certain forms, ambient (e.g., acoustic) noise may be considered to be the background noise level in the room where a patient is located, other than for example, noise generated by an RPT device or emanating from a mask or patient interface. Ambient noise may be generated by sources outside the room.

[0554] *Automatic Positive Airway Pressure (APAP) therapy*: CPAP therapy in which the treatment pressure is automatically adjustable, e.g. from breath to breath, between minimum and maximum limits, depending on the presence or absence of indications of SDB events.

[0555] *Continuous Positive Airway Pressure (CPAP) therapy*: Respiratory pressure therapy in which the treatment pressure is approximately constant through a respiratory cycle of a patient. In some forms, the pressure at the entrance to the airways will be slightly higher during exhalation, and slightly lower during inhalation. In some forms, the pressure will vary between different respiratory cycles of the patient, for example, being increased in response to detection of indications of partial upper airway obstruction, and decreased in the absence of indications of partial upper airway obstruction.

[0556] *Flow rate*: The volume (or mass) of air delivered per unit time. Flow rate may refer to an instantaneous quantity. In some cases, a reference to flow rate will be

a reference to a scalar quantity, namely a quantity having magnitude only. In other cases, a reference to flow rate will be a reference to a vector quantity, namely a quantity having both magnitude and direction. Flow rate may be given the symbol Q . 'Flow rate' is sometimes shortened to simply 'flow' or 'airflow'.

[0557] In the example of patient respiration, a flow rate may be nominally positive for the inspiratory portion of a breathing cycle of a patient, and hence negative for the expiratory portion of the breathing cycle of a patient. Device flow rate, Q_d , is the flow rate of air leaving the RPT device. Total flow rate, Q_t , is the flow rate of air and any supplementary gas reaching the patient interface via the air circuit. Vent flow rate, Q_v , is the flow rate of air leaving a vent to allow washout of exhaled gases. Leak flow rate, Q_l , is the flow rate of leak from a patient interface system or elsewhere. Respiratory flow rate, Q_r , is the flow rate of air that is received into the patient's respiratory system.

[0558] *Flow therapy*: Respiratory therapy comprising the delivery of a flow of air to an entrance to the airways at a controlled flow rate referred to as the treatment flow rate that is typically positive throughout the patient's breathing cycle.

[0559] *Humidifier*: The word humidifier will be taken to mean a humidifying apparatus constructed and arranged, or configured with a physical structure to be capable of providing a therapeutically beneficial amount of water (H_2O) vapour to a flow of air to ameliorate a medical respiratory condition of a patient.

[0560] *Leak*: The word leak will be taken to be an unintended flow of air. In one example, leak may occur as the result of an incomplete seal between a mask and a patient's face. In another example leak may occur in a swivel elbow to the ambient.

[0561] *Noise, conducted (acoustic)*: Conducted noise in the present document refers to noise which is carried to the patient by the pneumatic path, such as the air circuit and the patient interface as well as the air therein. In one form, conducted noise may be quantified by measuring sound pressure levels at the end of an air circuit.

[0562] *Noise, radiated (acoustic)*: Radiated noise in the present document refers to noise which is carried to the patient by the ambient air. In one form, radiated noise

may be quantified by measuring sound power/pressure levels of the object in question according to ISO 3744.

[0563] *Noise, vent (acoustic)*: Vent noise in the present document refers to noise which is generated by the flow of air through any vents such as vent holes of the patient interface.

[0564] *Patient*: A person, whether or not they are suffering from a respiratory condition.

[0565] *Pressure*: Force per unit area. Pressure may be expressed in a range of units, including cmH₂O, g-f/cm² and hectopascal. 1 cmH₂O is equal to 1 g-f/cm² and is approximately 0.98 hectopascal (1 hectopascal = 100 Pa = 100 N/m² = 1 millibar ~ 0.001 atm). In this specification, unless otherwise stated, pressure is given in units of cmH₂O.

[0566] The pressure in the patient interface is given the symbol P_m , while the treatment pressure, which represents a target value to be achieved by the interface pressure P_m at the current instant of time, is given the symbol P_t .

[0567] *Respiratory Pressure Therapy (RPT)*: The application of a supply of air to an entrance to the airways at a treatment pressure that is typically positive with respect to atmosphere.

[0568] *Ventilator*: A mechanical device that provides pressure support to a patient to perform some or all of the work of breathing.

5.9.1.1 Materials

[0569] *Silicone or Silicone Elastomer*: A synthetic rubber. In this specification, a reference to silicone is a reference to liquid silicone rubber (LSR) or a compression moulded silicone rubber (CMSR). One form of commercially available LSR is SILASTIC (included in the range of products sold under this trademark), manufactured by Dow Corning. Another manufacturer of LSR is Wacker. Unless otherwise specified to the contrary, an exemplary form of LSR has a Shore A (or Type A) indentation hardness in the range of about 35 to about 45 as measured using ASTM D2240.

[0570] *Polycarbonate*: a thermoplastic polymer of Bisphenol-A Carbonate.

5.9.1.2 Mechanical properties

[0571] *Resilience*: Ability of a material to absorb energy when deformed elastically and to release the energy upon unloading.

[0572] *Resilient*: Will release substantially all of the energy when unloaded. Includes e.g. certain silicones, and thermoplastic elastomers.

[0573] *Hardness*: The ability of a material *per se* to resist deformation (e.g. described by a Young's Modulus, or an indentation *hardness* scale measured on a standardised sample size).

- 'Soft' materials may include silicone or thermo-plastic elastomer (TPE), and may, e.g. readily deform under finger pressure.
- 'Hard' materials may include polycarbonate, polypropylene, steel or aluminium, and may not e.g. readily deform under finger pressure.

[0574] *Stiffness (or rigidity) of a structure or component*: The ability of the structure or component to resist deformation in response to an applied load. The load may be a force or a moment, e.g. compression, tension, bending or torsion. The structure or component may offer different resistances in different directions. The inverse of stiffness is *flexibility*.

[0575] *Floppy structure or component*: A structure or component that will change shape, e.g. bend, when caused to support its own weight, within a relatively short period of time such as 1 second.

[0576] *Rigid structure or component*: A structure or component that will not substantially change shape when subject to the loads typically encountered in use. An example of such a use may be setting up and maintaining a patient interface in sealing relationship with an entrance to a patient's airways, e.g. at a load of approximately 20 to 30 cmH₂O pressure.

[0577] As an example, an I-beam may comprise a different bending stiffness (resistance to a bending load) in a first direction in comparison to a second,

orthogonal direction. In another example, a structure or component may be floppy in a first direction and rigid in a second direction.

5.9.2 Respiratory cycle

[0578] *Apnea*: According to some definitions, an apnea is said to have occurred when flow falls below a predetermined threshold for a duration, e.g. 10 seconds. An obstructive apnea will be said to have occurred when, despite patient effort, some obstruction of the airway does not allow air to flow. A central apnea will be said to have occurred when an apnea is detected that is due to a reduction in breathing effort, or the absence of breathing effort, despite the airway being patent. A mixed apnea occurs when a reduction or absence of breathing effort coincides with an obstructed airway.

[0579] *Breathing rate*: The rate of spontaneous respiration of a patient, usually measured in breaths per minute.

[0580] *Duty cycle*: The ratio of inhalation time, T_i to total breath time, T_{tot} .

[0581] *Effort (breathing)*: The work done by a spontaneously breathing person attempting to breathe.

[0582] *Expiratory portion of a breathing cycle*: The period from the start of expiratory flow to the start of inspiratory flow.

[0583] *Flow limitation*: Flow limitation will be taken to be the state of affairs in a patient's respiration where an increase in effort by the patient does not give rise to a corresponding increase in flow. Where flow limitation occurs during an inspiratory portion of the breathing cycle it may be described as inspiratory flow limitation. Where flow limitation occurs during an expiratory portion of the breathing cycle it may be described as expiratory flow limitation.

[0584] Types of flow limited inspiratory waveforms:

(i) *Flattened*: Having a rise followed by a relatively flat portion, followed by a fall.

(ii) *M-shaped*: Having two local peaks, one at the leading edge, and one at the trailing edge, and a relatively flat portion between the two peaks.

(iii) *Chair-shaped*: Having a single local peak, the peak being at the leading edge, followed by a relatively flat portion.

(iv) *Reverse-chair shaped*: Having a relatively flat portion followed by single local peak, the peak being at the trailing edge.

[0585] *Hypopnea*: According to some definitions, a hypopnea is taken to be a reduction in flow, but not a cessation of flow. In one form, a hypopnea may be said to have occurred when there is a reduction in flow below a threshold rate for a duration. A central hypopnea will be said to have occurred when a hypopnea is detected that is due to a reduction in breathing effort. In one form in adults, either of the following may be regarded as being hypopneas:

(i) a 30% reduction in patient breathing for at least 10 seconds plus an associated 4% desaturation; or

(ii) a reduction in patient breathing (but less than 50%) for at least 10 seconds, with an associated desaturation of at least 3% or an arousal.

[0586] *Hyperpnea*: An increase in flow to a level higher than normal.

[0587] *Inspiratory portion of a breathing cycle*: The period from the start of inspiratory flow to the start of expiratory flow will be taken to be the inspiratory portion of a breathing cycle.

[0588] *Patency (airway)*: The degree of the airway being open, or the extent to which the airway is open. A *patent* airway is open. Airway patency may be quantified, for example with a value of one (1) being patent, and a value of zero (0), being closed (obstructed).

[0589] *Positive End-Expiratory Pressure (PEEP)*: The pressure above atmosphere in the lungs that exists at the end of expiration.

[0590] *Peak flow rate (Q_{peak})*: The maximum value of flow rate during the inspiratory portion of the respiratory flow waveform.

[0591] *Respiratory flow rate, patient airflow rate, respiratory airflow rate (Q_r):* These terms may be understood to refer to the RPT device's estimate of respiratory flow rate, as opposed to "true respiratory flow rate" or "true respiratory flow rate", which is the actual respiratory flow rate experienced by the patient, usually expressed in litres per minute.

[0592] *Tidal volume (V_t):* The volume of air inhaled or exhaled during normal breathing, when extra effort is not applied. In principle the inspiratory volume V_i (the volume of air inhaled) is equal to the expiratory volume V_e (the volume of air exhaled), and therefore a single tidal volume V_t may be defined as equal to either quantity. In practice the tidal volume V_t is estimated as some combination, e.g. the mean, of the inspiratory volume V_i and the expiratory volume V_e .

[0593] *(inhalation) Time (T_i):* The duration of the inspiratory portion of the respiratory flow rate waveform.

[0594] *(exhalation) Time (T_e):* The duration of the expiratory portion of the respiratory flow rate waveform.

[0595] *(total) Time (T_{tot}):* The total duration between the start of one inspiratory portion of a respiratory flow rate waveform and the start of the following inspiratory portion of the respiratory flow rate waveform.

[0596] *Typical recent ventilation:* The value of ventilation around which recent values of ventilation V_{ent} over some predetermined timescale tend to cluster, that is, a measure of the central tendency of the recent values of ventilation.

[0597] *Upper airway obstruction (UAO):* includes both partial and total upper airway obstruction. This may be associated with a state of flow limitation, in which the flow rate increases only slightly or may even decrease as the pressure difference across the upper airway increases (Starling resistor behaviour).

[0598] *Ventilation (V_{ent}):* A measure of a rate of gas being exchanged by the patient's respiratory system. Measures of ventilation may include one or both of inspiratory and expiratory flow, per unit time. When expressed as a volume per

minute, this quantity is often referred to as “minute ventilation”. Minute ventilation is sometimes given simply as a volume, understood to be the volume per minute.

5.9.3 Ventilation

[0599] *Adaptive Servo-Ventilator (ASV)*: A servo-ventilator that has a changeable, rather than fixed target ventilation. The changeable target ventilation may be learned from some characteristic of the patient, for example, a respiratory characteristic of the patient.

[0600] *Backup rate*: A parameter of a ventilator that establishes the minimum breathing rate (typically in number of breaths per minute) that the ventilator will deliver to the patient, if not triggered by spontaneous respiratory effort.

[0601] *Cycled*: The termination of a ventilator's inspiratory phase. When a ventilator delivers a breath to a spontaneously breathing patient, at the end of the inspiratory portion of the breathing cycle, the ventilator is said to be cycled to stop delivering the breath.

[0602] *Expiratory positive airway pressure (EPAP)*: a base pressure, to which a pressure varying within the breath is added to produce the desired interface pressure which the ventilator will attempt to achieve at a given time.

[0603] *End expiratory pressure (EEP)*: Desired interface pressure which the ventilator will attempt to achieve at the end of the expiratory portion of the breath. If the pressure waveform template $\Pi(\Phi)$ is zero-valued at the end of expiration, i.e. $\Pi(\Phi) = 0$ when $\Phi = 1$, the EEP is equal to the EPAP.

[0604] *Inspiratory positive airway pressure (IPAP)*: Maximum desired interface pressure which the ventilator will attempt to achieve during the inspiratory portion of the breath.

[0605] *Pressure support*: A number that is indicative of the increase in pressure during ventilator inspiration over that during ventilator expiration, and generally means the difference in pressure between the maximum value during inspiration and the base pressure (e.g., $PS = IPAP - EPAP$). In some contexts pressure support

means the difference which the ventilator aims to achieve, rather than what it actually achieves.

[0606] *Servo-ventilator*: A ventilator that measures patient ventilation, has a target ventilation, and which adjusts the level of pressure support to bring the patient ventilation towards the target ventilation.

[0607] *Spontaneous/Timed (S/T)*: A mode of a ventilator or other device that attempts to detect the initiation of a breath of a spontaneously breathing patient. If however, the device is unable to detect a breath within a predetermined period of time, the device will automatically initiate delivery of the breath.

[0608] *Swing*: Equivalent term to pressure support.

[0609] *Triggered*: When a ventilator delivers a breath of *air* to a spontaneously breathing patient, it is said to be triggered to do so at the initiation of the respiratory portion of the breathing cycle by the patient's efforts.

5.9.4 Anatomy

5.9.4.1 Anatomy of the face

[0610] *Ala*: the external outer wall or "wing" of each nostril (plural: alar)

[0611] *Alare*: The most lateral point on the nasal *ala*.

[0612] *Alar curvature (or alar crest) point*: The most posterior point in the curved base line of each *ala*, found in the crease formed by the union of the *ala* with the cheek.

[0613] *Auricle*: The whole external visible part of the ear.

[0614] *(nose) Bony framework*: The bony framework of the nose comprises the nasal bones, the frontal process of the maxillae and the nasal part of the frontal bone.

[0615] *(nose) Cartilaginous framework*: The cartilaginous framework of the nose comprises the septal, lateral, major and minor cartilages.

- [0616] *Columella*: the strip of skin that separates the nares and which runs from the pronasale to the upper lip.
- [0617] *Columella angle*: The angle between the line drawn through the midpoint of the nostril aperture and a line drawn perpendicular to the Frankfort horizontal while intersecting subnasale.
- [0618] *Frankfort horizontal plane*: A line extending from the most inferior point of the orbital margin to the left trignon. The trignon is the deepest point in the notch superior to the tragus of the auricle.
- [0619] *Glabella*: Located on the soft tissue, the most prominent point in the midsagittal plane of the forehead.
- [0620] *Lateral nasal cartilage*: A generally triangular plate of cartilage. Its superior margin is attached to the nasal bone and frontal process of the maxilla, and its inferior margin is connected to the greater alar cartilage.
- [0621] *Lip, lower (labrale inferius)*:
- [0622] *Lip, upper (labrale superius)*:
- [0623] *Greater alar cartilage*: A plate of cartilage lying below the lateral nasal cartilage. It is curved around the anterior part of the naris. Its posterior end is connected to the frontal process of the maxilla by a tough fibrous membrane containing three or four minor cartilages of the *ala*.
- [0624] *Nares (Nostrils)*: Approximately ellipsoidal apertures forming the entrance to the nasal cavity. The singular form of nares is naris (nostril). The nares are separated by the nasal septum.
- [0625] *Naso-labial sulcus or Naso-labial fold*: The skin fold or groove that runs from each side of the nose to the corners of the mouth, separating the cheeks from the upper lip.
- [0626] *Naso-labial angle*: The angle between the columella and the upper lip, while intersecting subnasale.

[0627] *Otobasion inferior*: The lowest point of attachment of the auricle to the skin of the face.

[0628] *Otobasion superior*: The highest point of attachment of the auricle to the skin of the face.

[0629] *Pronasale*: the most protruded point or tip of the nose, which can be identified in lateral view of the rest of the portion of the head.

[0630] *Philtrum*: the midline groove that runs from lower border of the nasal septum to the top of the lip in the upper lip region.

[0631] *Pogonion*: Located on the soft tissue, the most anterior midpoint of the chin.

[0632] *Ridge (nasal)*: The nasal ridge is the midline prominence of the nose, extending from the Sellion to the Pronasale.

[0633] *Sagittal plane*: A vertical plane that passes from anterior (front) to posterior (rear). The midsagittal plane is a sagittal plane that divides the body into right and left halves.

[0634] *Sellion*: Located on the soft tissue, the most concave point overlying the area of the frontonasal suture.

[0635] *Septal cartilage (nasal)*: The nasal septal cartilage forms part of the septum and divides the front part of the nasal cavity.

[0636] *Subalare*: The point at the lower margin of the alar base, where the alar base joins with the skin of the superior (upper) lip.

[0637] *Subnasal point*: Located on the soft tissue, the point at which the columella merges with the upper lip in the midsagittal plane.

[0638] *Supramenton*: The point of greatest concavity in the midline of the lower lip between labrale inferius and soft tissue pogonion

5.9.4.2 Anatomy of the skull

[0639] *Frontal bone*: The frontal bone includes a large vertical portion, the *squama frontalis*, corresponding to the region known as the forehead.

[0640] *Mandible*: The mandible forms the lower jaw. The mental protuberance is the bony protuberance of the jaw that forms the chin.

[0641] *Maxilla*: The maxilla forms the upper jaw and is located above the mandible and below the orbits. The *frontal process of the maxilla* projects upwards by the side of the nose, and forms part of its lateral boundary.

[0642] *Nasal bones*: The nasal bones are two small oblong bones, varying in size and form in different individuals; they are placed side by side at the middle and upper part of the face, and form, by their junction, the "bridge" of the nose.

[0643] *Nasion*: The intersection of the frontal bone and the two nasal bones, a depressed area directly between the eyes and superior to the bridge of the nose.

[0644] *Occipital bone*: The occipital bone is situated at the back and lower part of the cranium. It includes an oval aperture, the *foramen magnum*, through which the cranial cavity communicates with the vertebral canal. The curved plate behind the foramen magnum is the *squama occipitalis*.

[0645] *Orbit*: The bony cavity in the skull to contain the eyeball.

[0646] *Parietal bones*: The parietal bones are the bones that, when joined together, form the roof and sides of the cranium.

[0647] *Temporal bones*: The temporal bones are situated on the bases and sides of the skull, and support that part of the face known as the temple.

[0648] *Zygomatic bones*: The face includes two zygomatic bones, located in the upper and lateral parts of the face and forming the prominence of the cheek.

5.9.4.3 Anatomy of the respiratory system

[0649] *Diaphragm*: A sheet of muscle that extends across the bottom of the rib cage. The diaphragm separates the thoracic cavity, containing the heart, lungs and

ribs, from the abdominal cavity. As the diaphragm contracts the volume of the thoracic cavity increases and air is drawn into the lungs.

[0650] *Larynx*: The larynx, or voice box houses the vocal folds and connects the inferior part of the pharynx (hypopharynx) with the trachea.

[0651] *Lungs*: The organs of respiration in humans. The conducting zone of the lungs contains the trachea, the bronchi, the bronchioles, and the terminal bronchioles. The respiratory zone contains the respiratory bronchioles, the alveolar ducts, and the alveoli.

[0652] *Nasal cavity*: The nasal cavity (or nasal fossa) is a large air filled space above and behind the nose in the middle of the face. The nasal cavity is divided in two by a vertical fin called the nasal septum. On the sides of the nasal cavity are three horizontal outgrowths called nasal conchae (singular "concha") or turbinates. To the front of the nasal cavity is the nose, while the back blends, via the choanae, into the nasopharynx.

[0653] *Pharynx*: The part of the throat situated immediately inferior to (below) the nasal cavity, and superior to the oesophagus and larynx. The pharynx is conventionally divided into three sections: the nasopharynx (epipharynx) (the nasal part of the pharynx), the oropharynx (mesopharynx) (the oral part of the pharynx), and the laryngopharynx (hypopharynx).

5.9.5 Patient interface

[0654] *Anti-asphyxia valve (AAV)*: The component or sub-assembly of a mask system that, by opening to atmosphere in a failsafe manner, reduces the risk of excessive CO₂ rebreathing by a patient.

[0655] *Elbow*: An elbow is an example of a structure that directs an axis of flow of air travelling therethrough to change direction through an angle. In one form, the angle may be approximately 90 degrees. In another form, the angle may be more, or less than 90 degrees. The elbow may have an approximately circular cross-section. In another form the elbow may have an oval or a rectangular cross-section. In certain forms an elbow may be rotatable with respect to a mating component, e.g. about 360 degrees. In certain forms an elbow may be removable from a mating component, e.g.

via a snap connection. In certain forms, an elbow may be assembled to a mating component via a one-time snap during manufacture, but not removable by a patient.

[0656] *Frame*: Frame will be taken to mean a mask structure that bears the load of tension between two or more points of connection with a headgear. A mask frame may be a non-airtight load bearing structure in the mask. However, some forms of mask frame may also be air-tight.

[0657] *Headgear*: Headgear will be taken to mean a form of positioning and stabilizing structure designed for use on a head. For example the headgear may comprise a collection of one or more struts, ties and stiffeners configured to locate and retain a patient interface in position on a patient's face for delivery of respiratory therapy. Some ties are formed of a soft, flexible, elastic material such as a laminated composite of foam and fabric.

[0658] *Membrane*: Membrane will be taken to mean a typically thin element that has, preferably, substantially no resistance to bending, but has resistance to being stretched.

[0659] *Plenum chamber*: a mask plenum chamber will be taken to mean a portion of a patient interface having walls at least partially enclosing a volume of space, the volume having air therein pressurised above atmospheric pressure in use. A shell may form part of the walls of a mask plenum chamber.

[0660] *Seal*: May be a noun form ("a seal") which refers to a structure, or a verb form ("to seal") which refers to the effect. Two elements may be constructed and/or arranged to 'seal' or to effect 'sealing' therebetween without requiring a separate 'seal' element *per se*.

[0661] *Shell*: A shell will be taken to mean a curved, relatively thin structure having some bending, tensile and compressive stiffness. For example, a curved structural wall of a mask may be a shell. In some forms a shell or portions of a shell, may not be rigid. In some forms, a shell may be faceted. In some forms a shell may be airtight. In some forms a shell may not be airtight.

[0662] *Stiffener*: A stiffener will be taken to mean a structural component designed to increase the bending resistance of another component in at least one direction.

[0663] *Strut*: A strut will be taken to be a structural component designed to increase the compression resistance of another component in at least one direction.

[0664] *Swivel* (noun): A subassembly of components configured to rotate about a common axis, preferably independently, preferably under low torque. In one form, the swivel may be constructed to rotate through an angle of at least 360 degrees. In another form, the swivel may be constructed to rotate through an angle less than 360 degrees. When used in the context of an air delivery conduit, the sub-assembly of components preferably comprises a matched pair of cylindrical conduits. There may be little or no leak flow of air from the swivel in use.

[0665] *Tie* (noun): A structure designed to resist tension.

[0666] *Vent*: (noun): A structure that allows a flow of *air* from an interior of the mask, or conduit, to ambient air for clinically effective washout of exhaled gases. For example, a clinically effective washout may involve a flow rate of about 10 litres per minute to about 100 litres per minute, depending on the mask design and treatment pressure.

5.9.6 Shape of structures

[0667] Products in accordance with the present technology may comprise one or more three-dimensional mechanical structures, for example a mask cushion or an impeller. The three-dimensional structures may be bounded by two-dimensional surfaces. These surfaces may be distinguished using a label to describe an associated surface orientation, location, function, or some other characteristic. For example a structure may comprise one or more of an anterior surface, a posterior surface, an interior surface and an exterior surface. In another example, a seal-forming structure may comprise a face-contacting (e.g. outer) surface, and a separate non-face-contacting (e.g. underside or inner) surface. In another example, a structure may comprise a first surface and a second surface.

[0668] To facilitate describing the shape of the three-dimensional structures and the surfaces, we first consider a cross-section through a surface of the structure at a point, p . See Fig. 3B to Fig. 3F, which illustrate examples of cross-sections at point p on a surface, and the resulting plane curves. Figs. 3B to 3F also illustrate an outward normal vector at p . The outward normal vector at p points away from the surface. In some examples we describe the surface from the point of view of an imaginary small person standing upright on the surface.

5.9.6.1 Curvature in one dimension

[0669] The curvature of a plane curve at p may be described as having a sign (e.g. positive, negative) and a magnitude (e.g. $1/\text{radius}$ of a circle that just touches the curve at p).

[0670] *Positive curvature:* If the curve at p turns towards the outward normal, the curvature at that point will be taken to be positive (if the imaginary small person leaves the point p they must walk uphill). See Fig. 3B (relatively large positive curvature compared to Fig. 3C) and Fig. 3C (relatively small positive curvature compared to Fig. 3B). Such curves are often referred to as concave.

[0671] *Zero curvature:* If the curve at p is a straight line, the curvature will be taken to be zero (if the imaginary small person leaves the point p , they can walk on a level, neither up nor down). See Fig. 3D.

[0672] *Negative curvature:* If the curve at p turns away from the outward normal, the curvature in that direction at that point will be taken to be negative (if the imaginary small person leaves the point p they must walk downhill). See Fig. 3E (relatively small negative curvature compared to Fig. 3F) and Fig. 3F (relatively large negative curvature compared to Fig. 3E). Such curves are often referred to as convex.

5.9.6.2 Curvature of two dimensional surfaces

[0673] A description of the shape at a given point on a two-dimensional surface in accordance with the present technology may include multiple normal cross-sections. The multiple cross-sections may cut the surface in a plane that includes the outward normal (a “normal plane”), and each cross-section may be taken in a different direction. Each cross-section results in a plane curve with a corresponding curvature.

The different curvatures at that point may have the same sign, or a different sign. Each of the curvatures at that point has a magnitude, e.g. relatively small. The plane curves in Figs. 3B to 3F could be examples of such multiple cross-sections at a particular point.

[0674] *Principal curvatures and directions:* The directions of the normal planes where the curvature of the curve takes its maximum and minimum values are called the principal directions. In the examples of Fig. 3B to Fig. 3F, the maximum curvature occurs in Fig. 3B, and the minimum occurs in Fig. 3F, hence Fig. 3B and Fig. 3F are cross sections in the principal directions. The principal curvatures at p are the curvatures in the principal directions.

[0675] *Region of a surface:* A connected set of points on a surface. The set of points in a region may have similar characteristics, e.g. curvatures or signs.

[0676] *Saddle region:* A region where at each point, the principal curvatures have opposite signs, that is, one is positive, and the other is negative (depending on the direction to which the imaginary person turns, they may walk uphill or downhill).

[0677] *Dome region:* A region where at each point the principal curvatures have the same sign, e.g. both positive (a “concave dome”) or both negative (a “convex dome”).

[0678] *Cylindrical region:* A region where one principal curvature is zero (or, for example, zero within manufacturing tolerances) and the other principal curvature is non-zero.

[0679] *Planar region:* A region of a surface where both of the principal curvatures are zero (or, for example, zero within manufacturing tolerances).

[0680] *Edge of a surface:* A boundary or limit of a surface or region.

[0681] *Path:* In certain forms of the present technology, ‘path’ will be taken to mean a path in the mathematical – topological sense, e.g. a continuous space curve from $f(0)$ to $f(1)$ on a surface. In certain forms of the present technology, a ‘path’ may be described as a route or course, including e.g. a set of points on a surface. (The path

for the imaginary person is where they walk on the surface, and is analogous to a garden path).

[0682] *Path length:* In certain forms of the present technology, ‘path length’ will be taken to mean the distance along the surface from $f(0)$ to $f(1)$, that is, the distance along the path on the surface. There may be more than one path between two points on a surface and such paths may have different path lengths. (The path length for the imaginary person would be the distance they have to walk on the surface along the path).

[0683] *Straight-line distance:* The straight-line distance is the distance between two points on a surface, but without regard to the surface. On planar regions, there would be a path on the surface having the same path length as the straight-line distance between two points on the surface. On non-planar surfaces, there may be no paths having the same path length as the straight-line distance between two points. (For the imaginary person, the straight-line distance would correspond to the distance ‘as the crow flies’.)

5.9.6.3 Space curves

[0684] *Space curves:* Unlike a plane curve, a space curve does not necessarily lie in any particular plane. A space curve may be closed, that is, having no endpoints. A space curve may be considered to be a one-dimensional piece of three-dimensional space. An imaginary person walking on a strand of the DNA helix walks along a space curve. A typical human left ear comprises a helix, which is a left-hand helix, see Fig. 3Q. A typical human right ear comprises a helix, which is a right-hand helix, see Fig. 3R. Fig. 3S shows a right-hand helix. The edge of a structure, e.g. the edge of a membrane or impeller, may follow a space curve. In general, a space curve may be described by a curvature and a torsion at each point on the space curve. Torsion is a measure of how the curve turns out of a plane. Torsion has a sign and a magnitude. The torsion at a point on a space curve may be characterised with reference to the tangent, normal and binormal vectors at that point.

[0685] *Tangent unit vector (or unit tangent vector):* For each point on a curve, a vector at the point specifies a direction from that point, as well as a magnitude. A tangent unit vector is a unit vector pointing in the same direction as the curve at that

point. If an imaginary person were flying along the curve and fell off her vehicle at a particular point, the direction of the tangent vector is the direction she would be travelling.

[0686] *Unit normal vector:* As the imaginary person moves along the curve, this tangent vector itself changes. The unit vector pointing in the same direction that the tangent vector is changing is called the unit principal normal vector. It is perpendicular to the tangent vector.

[0687] *Binormal unit vector:* The binormal unit vector is perpendicular to both the tangent vector and the principal normal vector. Its direction may be determined by a right-hand rule (see e.g. Fig. 3P), or alternatively by a left-hand rule (Fig. 3O).

[0688] *Osculating plane:* The plane containing the unit tangent vector and the unit principal normal vector. See Figures 3O and 3P.

[0689] *Torsion of a space curve:* The torsion at a point of a space curve is the magnitude of the rate of change of the binormal unit vector at that point. It measures how much the curve deviates from the osculating plane. A space curve which lies in a plane has zero torsion. A space curve which deviates a relatively small amount from the osculating plane will have a relatively small magnitude of torsion (e.g. a gently sloping helical path). A space curve which deviates a relatively large amount from the osculating plane will have a relatively large magnitude of torsion (e.g. a steeply sloping helical path). With reference to Fig. 3S, since $T_2 > T_1$, the magnitude of the torsion near the top coils of the helix of Fig. 3S is greater than the magnitude of the torsion of the bottom coils of the helix of Fig. 3S

[0690] With reference to the right-hand rule of Fig. 3P, a space curve turning towards the direction of the right-hand binormal may be considered as having a right-hand positive torsion (e.g. a right-hand helix as shown in Fig. 3S). A space curve turning away from the direction of the right-hand binormal may be considered as having a right-hand negative torsion (e.g. a left-hand helix).

[0691] Equivalently, and with reference to a left-hand rule (see Fig. 3O), a space curve turning towards the direction of the left-hand binormal may be considered as

having a left-hand positive torsion (e.g. a left-hand helix). Hence left-hand positive is equivalent to right-hand negative. See Fig. 3T.

5.9.6.4 Holes

[0692] A surface may have a one-dimensional hole, e.g. a hole bounded by a plane curve or by a space curve. Thin structures (e.g. a membrane) with a hole, may be described as having a one-dimensional hole. See for example the one dimensional hole in the surface of structure shown in Fig. 3I, bounded by a plane curve.

[0693] A structure may have a two-dimensional hole, e.g. a hole bounded by a surface. For example, an inflatable tyre has a two dimensional hole bounded by the interior surface of the tyre. In another example, a bladder with a cavity for air or gel could have a two-dimensional hole. See for example the cushion of Fig. 3L and the example cross-sections therethrough in Fig. 3M and Fig. 3N, with the interior surface bounding a two dimensional hole indicated. In a yet another example, a conduit may comprise a one-dimension hole (e.g. at its entrance or at its exit), and a two-dimension hole bounded by the inside surface of the conduit. See also the two dimensional hole through the structure shown in Fig. 3K, bounded by a surface as shown.

5.10 OTHER REMARKS

[0694] A portion of the disclosure of this patent document contains material which is subject to copyright protection. The copyright owner has no objection to the facsimile reproduction by anyone of the patent document or the patent disclosure, as it appears in Patent Office patent files or records, but otherwise reserves all copyright rights whatsoever.

[0695] Unless the context clearly dictates otherwise and where a range of values is provided, it is understood that each intervening value, to the tenth of the unit of the lower limit, between the upper and lower limit of that range, and any other stated or intervening value in that stated range is encompassed within the technology. The upper and lower limits of these intervening ranges, which may be independently included in the intervening ranges, are also encompassed within the technology, subject to any specifically excluded limit in the stated range. Where the stated range includes one or both of the limits, ranges excluding either or both of those included limits are also included in the technology.

[0696] Furthermore, where a value or values are stated herein as being implemented as part of the technology, it is understood that such values may be approximated, unless otherwise stated, and such values may be utilized to any suitable significant digit to the extent that a practical technical implementation may permit or require it.

[0697] Furthermore, “approximately”, “substantially”, “about”, or any similar term as used herein means +/- 5-10% of the recited value.

[0698] Unless defined otherwise, all technical and scientific terms used herein have the same meaning as commonly understood by one of ordinary skill in the art to which this technology belongs. Although any methods and materials similar or equivalent to those described herein can also be used in the practice or testing of the present technology, a limited number of the exemplary methods and materials are described herein.

[0699] When a particular material is identified as being used to construct a component, obvious alternative materials with similar properties may be used as a substitute. Furthermore, unless specified to the contrary, any and all components herein described are understood to be capable of being manufactured and, as such, may be manufactured together or separately.

[0700] It must be noted that as used herein and in the appended claims, the singular forms "a", "an", and "the" include their plural equivalents, unless the context clearly dictates otherwise.

[0701] All publications mentioned herein are incorporated herein by reference in their entirety to disclose and describe the methods and/or materials which are the subject of those publications. The publications discussed herein are provided solely for their disclosure prior to the filing date of the present application. Nothing herein is to be construed as an admission that the present technology is not entitled to antedate such publication by virtue of prior invention. Further, the dates of publication provided may be different from the actual publication dates, which may need to be independently confirmed.

[0702] The terms "comprises" and "comprising" should be interpreted as referring to elements, components, or steps in a non-exclusive manner, indicating that the referenced elements, components, or steps may be present, or utilized, or combined with other elements, components, or steps that are not expressly referenced.

[0703] The subject headings used in the detailed description are included only for the ease of reference of the reader and should not be used to limit the subject matter found throughout the disclosure or the claims. The subject headings should not be used in construing the scope of the claims or the claim limitations.

[0704] Although the technology herein has been described with reference to particular examples, it is to be understood that these examples are merely illustrative of the principles and applications of the technology. In some instances, the terminology and symbols may imply specific details that are not required to practice the technology. For example, although the terms "first" and "second" may be used, unless otherwise specified, they are not intended to indicate any order but may be utilised to distinguish between distinct elements. Furthermore, although process steps in the methodologies may be described or illustrated in an order, such an ordering is not required. Those skilled in the art will recognize that such ordering may be modified and/or aspects thereof may be conducted concurrently or even synchronously.

[0705] It is therefore to be understood that numerous modifications may be made to the illustrative examples and that other arrangements may be devised without departing from the spirit and scope of the technology.

6 CLAIMS

1. A patient interface comprising:

a plenum chamber pressurisable to a therapeutic pressure of at least 6 cmH₂O above ambient air pressure, the plenum chamber including a plenum chamber inlet port sized and structured to receive a flow of air at the therapeutic pressure for breathing by a patient;

a seal-forming structure constructed and arranged to form a seal with a region of the patient's face surrounding an entrance to the patient's airways for sealed delivery of a flow of pressurized air at the therapeutic pressure of at least 6 cmH₂O above ambient air pressure throughout the patient's respiratory cycle in use, the seal-forming structure comprises:

a first section constructed from a first material, the first section configured to sealingly engage against a first region of the patient's face, and

a second section constructed from a second material different than the first material, the second section configured to sealingly engage against a second region of the patient's face, wherein the second material is foam, and

a positioning and stabilising structure to provide a force to hold a seal-forming structure in a therapeutically effective position on a patient's head.

2. The patient interface of claim 1, wherein the first material is silicone.

3. The patient interface of any one of claims 1 to 2, wherein the first section is flush with the second section at a transition between the first section and the second section.

4. The patient interface of any one of claims 1 to 3, wherein the plenum chamber includes a mounting surface, the second section of the seal-forming structure coupled to the mounting surface.

5. The patient interface of claim 4, wherein the mounting surface is substantially flat and substantially perpendicular to an anterior-posterior direction of the patient's head, in use.

6. The patient interface of any one of claims 4 to 5, wherein the mounting surface is constructed from the first material.
7. The patient interface of any one of claims 4 to 6, wherein the first section extends beyond the mounting surface, and forms an overhang relative to the mounting surface.
8. The patient interface of any one of claims 4 to 7, wherein the overhang is configured to contact the patient proximate each nasal ala.
9. The patient interface of any one of claims 4 to 8, wherein the plenum chamber inlet port is formed anterior to the mounting surface, in use, and wherein the second material does not contact the plenum chamber inlet port.
10. The patient interface of any one of claims 4 to 9, wherein the mounting surface is substantially U-shaped or C-shaped and includes a first free end and a second free end, and wherein, in use, the first free end is configured to be spaced apart from the second free end along the patient's lip superior so as to leave the patient's philtrum uncovered by the mounting surface.
11. The patient interface of any one of claims 1 to 10, wherein the first section and the plenum chamber are integrally formed as a one-piece construction during a molding process.
12. The patient interface of any one of claims 1 to 11, wherein the plenum chamber is at least partially constructed from the first material.
13. The patient interface of any one of claims 1 to 12, wherein the second section is coupled to the plenum chamber with an adhesive.
14. The patient interface of any one of claims 1 to 13, wherein the second section includes a varying thickness.
15. The patient interface of claim 14, wherein the second section includes a first thickness and a second thickness greater than the first thickness, wherein the first thickness is adjacent to the second thickness.

16. The patient interface of any one of claims 1 to 15, wherein the seal-forming structure is configured to form a seal against the patient's face, wherein first section and the second section each combine to form a portion of the seal.
17. The patient interface of any one of claims 1 to 16, wherein the seal-forming structure is a nasal cushion or a nasal cradle.
18. The patient interface of claim 17, wherein the second section is configured to contact a nasal alar region of the patient, in use.
19. The patient interface of any one of claims 1 to 16, wherein the seal-forming structure is an oronasal cushion, an ultra-compact full face mask, or a full-face mask.
20. The patient interface of claim 19, wherein the first section is configured to contact the patient's nose, in use, between at least the patient's pronasale and the patient's subnasale, and between at least each of the patient's nasal ala.
21. The patient interface of any one of claims 19 to 20, wherein the second section is configured to contact around the patient's mouth, in use, between at least the patient's lip superior and the patient's lip inferior, and outside of the patient's mouth width adjacent at least each of the patient's nasal ala.
22. The patient interface of any one of claims 19 to 21, wherein a bridge portion of the second section is configured to contact the patient's lip superior in use.
23. The patient interface of claim 22, wherein at least a portion of the bridge portion is unbacked, and is configured to move into the plenum chamber when contacted by the patient's lip superior.
24. The patient interface of any one of claims 22 to 23, wherein the transition is between the bridge portion and the first section.
25. The patient interface of any one of claims 19 to 24, wherein the seal-forming structure is configured to not seal against the patient's philtrum.

26. The patient interface of any one of claims 19 to 25, wherein a portion of the second section is configured to seal against a region inferior to the patient's nares and proximate to the patient's nasal ala.
27. The patient interface of any one of claims 19 to 26, wherein the first section is thinner than the second section.
28. The patient interface of any one of claims 19 to 27, wherein, when viewed in cross-section, the second section has a substantially rectangular profile.
29. The patient interface of any one of claims 19 to 28, wherein the second section includes a substantially squared edge configured to contact the patient in use.
30. The patient interface of claim 29, wherein the substantially squared edge is configured to contact the proximate the nasal ala at a juncture of the patient's corner of nose region and the patient's lip superior.
31. The patient interface of any one of claims 1 to 30, wherein the first section is configured to receive a first component of the force and the second section is configured to receive a second component of the force, wherein the first section and the second section are configured to apply the same sealing force to the patient when the first component is less than the second component.
32. A patient interface comprising:
- a plenum chamber formed from a first material and pressurisable to a therapeutic pressure of at least 6 cmH₂O above ambient air pressure, the plenum chamber including a plenum chamber inlet port sized and structured to receive a flow of air at the therapeutic pressure for breathing by a patient, the plenum chamber including a mounting surface;
 - a seal-forming structure constructed and arranged to form a seal with a region of the patient's face surrounding an entrance to the patient's airways for sealed delivery of a flow of pressurized air at the therapeutic pressure of at least 6 cmH₂O above ambient air pressure throughout the patient's respiratory cycle in use, the seal-forming structure comprises:

a first section constructed from the first material, the first section configured to sealingly engage against a first region of the patient's face, and

a second section constructed from a second material different than the first material, the second section connected to the mounting surface, the second section configured to sealingly engage against a second region of the patient's face, and

a positioning and stabilising structure to provide a force to hold a seal-forming structure in a therapeutically effective position on a patient's head;

wherein the mounting surface is recessed relative to the first section by a first distance; and

wherein the second section includes a thickness substantially equal to the first distance so that the first section and the second section are substantially flush with one another.

33. The patient interface of claim 32, wherein the first material is silicone.

34. The patient interface of any one of claims 32 to 33, wherein the second material is foam.

35. The patient interface of any one of claims 32 to 34, the seal-forming structure is an oronasal cushion, an ultra-compact full face mask, or a full-face mask.

36. The patient interface of any one of claims 32 to 35, the mounting surface is substantially flat and substantially perpendicular to an anterior-posterior direction of the patient's head, in use.

37. The patient interface of any one of claims 32 to 36, the first section extends beyond the mounting surface, and forms an overhang relative to the mounting surface.

38. The patient interface of any one of claims 32 to 37, the overhang is configured to contact the patient proximate each nasal ala.

39. The patient interface of any one of claims 32 to 38, the mounting surface is substantially U-shaped or C-shaped and includes a first free end and a second free end, and wherein, in use, the first free end is configured to be spaced apart from the second free end along the patient's lip superior so as to leave the patient's philtrum uncovered by the mounting surface.

40. A patient interface comprising:

a plenum chamber pressurisable to a therapeutic pressure of at least 6 cmH₂O above ambient air pressure, the plenum chamber including:

a plenum chamber inlet port sized and structured to receive a flow of air at the therapeutic pressure for breathing by a patient, the plenum chamber inlet port having at least one substantially straight side,

a mounting surface being inclined relative to the substantially straight surface;

a seal-forming structure constructed and arranged to form a seal with a region of the patient's face surrounding an entrance to the patient's airways for sealed delivery of a flow of pressurized air at the therapeutic pressure of at least 6 cmH₂O above ambient air pressure throughout the patient's respiratory cycle in use, the seal-forming structure comprises:

a first section constructed from the first material, the first section configured to sealingly engage against a first region of the patient's face, and

a second section constructed from a second material different than the first material, the second section connected to the mounting surface, the second section configured to sealingly engage against a second region of the patient's face, and

a positioning and stabilising structure to provide a force to hold a seal-forming structure in a therapeutically effective position on a patient's head;

wherein the straight surface is configured to be positioned substantially parallel to the patient's sagittal plane in use; and

wherein the positioning and stabilising structure is configured to provide a greater force to the second section as a result of the position of the straight surface in use.

41. The patient interface of claim 40, wherein the first material is silicone.

42. The patient interface of any one of claims 40 to 41, wherein the second material is foam.

43. The patient interface of any one of claims 40 to 42, wherein the plenum chamber inlet port is a first plenum chamber inlet port, wherein the plenum chamber further includes a second plenum chamber inlet port.

44. The patient interface of any one of claims 40 to 43, wherein the first section extends beyond the mounting surface, and forms an overhang relative to the mounting surface.

45. The patient interface of any one of claims 40 to 44, wherein the mounting surface is substantially U-shaped or C-shaped and includes a first free end and a second free end, and wherein, in use, the first free end is configured to be spaced apart from the second free end along the patient's lip superior so as to leave the patient's philtrum uncovered by the mounting surface.

46. The patient interface of any one of claims 40 to 45, wherein the second section is permanently connected to the mounting surface.

47. The patient interface of any one of claims 40 to 46, wherein the second section is removably connected to the mounting surface.

48. The patient interface of any one of claims 40 to 47, wherein the second section is configured to contact the second region at the patient's lip superior.

49. The patient interface of any one of claims 40 to 48, wherein the first section is configured to contact the first region at the patient's alar rim.

INTERNATIONAL SEARCH REPORT

International application No.

PCT/AU2021/050826

A. CLASSIFICATION OF SUBJECT MATTER

A61M 16/06 (2006.01)

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

PATENW cluster (EPODOC, WPIAP, TXTE Cluster); CPC/IPC as appropriate: A61M16/0622, A61M16/06, A61M16/0605, A61M2205/02, Classification used in various combinations and with selected keywords: seal, cushion, silicone, foam, polyurethane, open cell, dual, two, second, multi, mouth, face, lip, nasal, mask, interface, material, different, stiff, oronasal, plenum chamber, bridge, flex, shell, philtrum, C-shape, U-shape, mount, frame, recess and similar terms. Applicant and inventor names searched in PATENW and IP Australia internal databases.

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
	Documents are listed in the continuation of Box C	

☒ Further documents are listed in the continuation of Box C☒ See patent family annex

* Special categories of cited documents:	
"A" document defining the general state of the art which is not considered to be of particular relevance	"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
"D" document cited by the applicant in the international application	"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
"E" earlier application or patent but published on or after the international filing date	"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	"&" document member of the same patent family
"O" document referring to an oral disclosure, use, exhibition or other means	
"P" document published prior to the international filing date but later than the priority date claimed	

Date of the actual completion of the international search
26 October 2021

Date of mailing of the international search report
26 October 2021

Box No. II Observations where certain claims were found unsearchable (Continuation of item 2 of first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:
the subject matter listed in Rule 39 on which, under Article 17(2)(a)(i), an international search is not required to be carried out, including
2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a)

Box No. III Observations where unity of invention is lacking (Continuation of item 3 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

See Supplemental Box for Details

1. ☒ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying additional fees, this Authority did not invite payment of additional fees.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest and, where applicable, the payment of a protest fee.
- ☐ The additional search fees were accompanied by the applicant's protest but the applicable protest fee was not paid within the time limit specified in the invitation.
- ☒ No protest accompanied the payment of additional search fees.

Supplemental Box**Continuation of: Box III**

This International Application does not comply with the requirements of unity of invention because it does not relate to one invention or to a group of inventions so linked as to form a single general inventive concept.

This Authority has found that there are different inventions based on the following features that separate the claims into distinct groups:

(1) Claims 1-3, 11-31, (4-10 in part) are directed to a patient interface. Features relating to the properties of the first and second section of the seal-forming structure are specific to this group of claims.

(2) Claims 32-49, (4-10 in part) are directed to a patient interface. The features of a mounting surface for mounting the seal forming structure to the plenum chamber are specific to this group of claims.

PCT Rule 13.2, first sentence, states that unity of invention is only fulfilled when there is a technical relationship among the claimed inventions involving one or more of the same or corresponding special technical features. PCT Rule 13.2, second sentence, defines a special technical feature as a feature which makes a contribution over the prior art.

When there is no special technical feature common to all the claimed inventions there is no unity of invention.

In the above groups of claims, the identified features may have the potential to make a contribution over the prior art but are not common to all the claimed inventions and therefore cannot provide the required technical relationship. The only features common to all of the claimed inventions are: a plenum chamber, a positioning and stabilizing structure and a seal forming structure having a first section formed of first material configured to sealingly engage with a first portion of the face and a second section formed of a second material configured to engage a second region of the face.

However, these common features do not make a contribution over the prior art because they are disclosed in: US 2014/0283842 A1 (FISHER & PAYKEL HEALTHCARE LIMITED) 25 Sep 2014 See: (Figs. 1, 76-78), mask seal (704), nasal seal (740), formed of different materials [0329, 0330].

Therefore, in the light of this document, these common features cannot be a special technical feature. Therefore, there is no special technical feature common to all the claimed inventions and the requirements for unity of invention are consequently not satisfied, *a posteriori*.
